Table N.6: Descriptions of Priority flora recorded in the survey area.

Species	Description	Habitat
Indigofera sp. Bungaroo Creek (S. van Leeuwen 4301) P3	Erect shrub or herb, 0.2 m to 2 m high. Pink flowers from May to July (WAHerb 1998-2016).	Drainage lines, creeks in hills or plains (WAHerb 1998-2016).
Triodia sp. Robe River (M.E. Trudgen et al. MET 12367) P3	Hummock grass (WAHerb 1998-2016).	Rocky outcrops, breakaways, hillslopes and crests, and drainage lines (WAHerb 1998-2016).
Rhynchosia bungarensis P4	Compact, prostrate shrub to 0.5 m high. Flowers yellow (WAHerb 1998-2016).	Pebbly, shingle coarse sand amongst boulders. Banks of flow line in the mouth of a gully in a valley wall (WAHerb 1998-2016).

Note: Additional introduced flora species were recorded in proximity to, but outside, the Mesa H survey area boundary.
^Converted to GDA94 from the redundant "AGD84" originally published.

Table N.13: Description of introduced flora recorded in the survey area.

Species	Description	Habitat
**Aerva javanica* (Kapok Bush) 	An erect, much-branched perennial, herb between 0.4 m and 1.6 m high. It has white woolly flowers arranged in spikes between January and October (WAHerb 1998-2016).	Often on sandy soils, along drainage lines (WAHerb 1998-2016).
**Argemone ochroleuca* subsp. *ochroleuca* (Mexican Poppy) 	An erect, prickly, glaucous annual herb between 0.2 m and 1 m in height with white, cream and yellow flowers between February/March and July/November (WAHerb 1998-2016).	Generally along creek edges, riverbanks and roadsides. Occurs in red/white/grey sand and red-brown clay loam (WAHerb 1998-2016).
**Bidens bipinnata* 	An erect annual herb growing to 1 m high. Produces yellow flowers from March to September (WAHerb 1998-2016).	Occurs in a variety of soils including alluvium, clay, loam over sandstone and limestone. Habitat preferences include rivers, creeks, coastal areas and rocky hillsides (WAHerb 1998-2016).
**Cenchrus ciliaris* (Buffel Grass) 	A tufted or sometimes stoloniferous perennial grass between 0.2 m and 1.5 m in height with purple, ciliate flowers between February and October. Seedheads form a dense hairy cylindrical spike to 10 cm long (WAHerb 1998-2016).	**C. ciliaris* favours sand but may also establish in loamy and clayey soils. It is a widespread weed of roadsides, creek lines and river edges (WAHerb 1998-2016).

Species	Description	Habitat
**Cenchrus setiger* (Birdwood Grass) 	An erect, tussock, stoloniferous perennial grass that grows to 0.5 m high. It has cream to purple flowers that occur from April to May (WAHerb 1998-2016).	**C. setiger* favours brown sands, red loam and pindan soils. It is often found on sand dunes, plains, rangelands, stony hillsides and floodplains (WAHerb 1998-2016).
* *Chloris barbata* (Purpletop Chloris) 	Annual or perennial (short-lived), grass, between 0.4 m and 1.1 m high. It has purple flowers in February or between April and October (WAHerb 1998-2016).	Occurs on white or red sand, loam, and black clay, often on sand dunes and river levees (WAHerb 1998-2016).
**Citrullus colocynthis* (Colocynth) 	A trailing perennial, herb or climber with deeply lobed, scabrous leaves. It has greenish yellow flowers between January and October. Fruits are a spherical melon, mottled green and yellow or all yellow with dull yellow-brown seeds (WAHerb 1998-2016).	Commonly occurs on sandy, rocky, stony loam, clay and wet soils; often in floodplains and disturbed areas (WAHerb 1998-2016).
**Cynodon dactylon* (Couch Grass) 	A rhizomatous (or stoloniferous), prostrate perennial grass from 0.05 m to 0.3 m high. Flowers are green or purple June to November (WAHerb 1998-2016).	**C. dactylon* occurs in sand, loam or clay habitats (WAHerb 1998-2016).

Species	Description	Habitat
**Echinochloa colona* (Awnless Barnyard Grass) 	A tufted annual grass between 0.2 m and 0.9 m high. It has a green/purple inflorescence between February and July (WAHerb 1998-2016).	Occurs on black sand and black clay, near watercourses and swamps (WAHerb 1998-2016).
**Euphorbia hirta* (Asthma Plant) 	An erect or prostrate much branched hairy annual herb, growing between 0.1 m and 0.8 m high. Leaves are opposite, narrowly ovate with dark red blotches. Yellow-green-white axillary flowers are produced between January and October (WAHerb 1998-2016).	Occurs on alluvial soils, often along watercourses (WAHerb 1998-2016).
**Flaveria trinervia* (Speedy Weed) 	An erect annual herb, with ovate leaves. It has yellow flowers clustered to form a dense inflorescence (WAHerb 1998-2016).	Occurs in a variety of soils, particularly sandy and clayey sites. Typically occurs in drainage lines (WAHerb 1998-2016).
**Lactuca serriola* (Prickly Lettuce) 	Erect annual or biennial herb 0.4 m to 2 m high. Flowers yellow, October to February (WAHerb 1998-2016).	Roadsides, gardens, cultivated fields, disturbed sites (WAHerb 1998-2016).

Species	Description	Habitat
**Malvastrum americanum* (Spiked Malvastrum) 	An erect, hairy perennial herb or shrub between 0.5 m and 1.3 m in height. Flowers are yellow and orange, between April and July (WAHerb 1998-2016).	**M. americanum* occurs in a variety of sandy and clayey soils, as well as in limestone and calcrete. It typically occurs along stony ridges and hillsides, floodplains and along drainage lines (WAHerb 1998-2016).
**Ocimum basilicum* (Basil) 	Aromatic annual or perennial herb to 0.6 m high. Blue-purple, pink and/or white flowers from February to August (WAHerb 1998-2016).	Sandy soils and disturbed areas (WAHerb 1998-2016).
**Passiflora foetida* var. *hispida* (Stinking Passion Flower) 	A woody climber to 9 m high with an unpleasant smell. It produces cream-white or blue flowers from February to November (WAHerb 1998-2016).	**P. foetida* var. *hispida* is commonly found in coastal areas, rivers and creek banks (WAHerb 1998-2016).
**Phoenix dactylifera* (Date Palm) 	A perennial tree-like monocot (palm) between 0.4 m to 8 m high. It produces flowers from July to September (WAHerb 1998-2016).	It is found on the edges of permanent pools and watercourses (WAHerb 1998-2016).

Species	Description	Habitat
**Rumex vesicarius* (Ruby Dock) 	An erect, fleshy annual herb to 1 m high. Produces red-pink flowers from July to September (WAHerb 1998-2016).	Occurs in a variety of habitats and soils, including sandy alluvial and gravelly ironstone soils. Often occurs along roadsides and other disturbed areas (WAHerb 1998-2016).
**Setaria verticillata* (Whorled Pigeon Grass) 	A loosely tufted annual grass, 0.1 m to 1.3 m high. It flowers from December to June (WAHerb 1998-2016).	**S. verticillata* is found on sand, clay and loam. It is a common weed of disturbed areas and riverine edges (WAHerb 1998-2016).
**Sonchus oleraceus* (Common Sowthistle) 	An erect, fleshy annual herb to 1 m high. Produces red-pink flowers from July to September (WAHerb 1998-2016).	Occurs in a variety of habitats and soils, including sandy alluvial and gravelly ironstone soils. Often occurs along roadsides and other disturbed areas (WAHerb 1998-2016).

Species	Description	Habitat
**Tribulus terrestris* (Caltrop) 	Prostrate, annual herb with yellow flowers less than 1 mm wide from January to December. It has greyish pinnate leaves and produces spiny roughly spherical fruit (Hussey et al. 2007, WAHerb 1998-2016).	Often found in sandy soils and in waste areas (WAHerb 1998-2016).
**Vachellia farnesiana* (Mimosa Bush) 	An erect, sprawling, thicket-forming shrub or tree up to 4 m in height. It has dark grey, rough bark, pinnate leaves and long stiff thorns at right angles to the stems. Branchlets are also covered in rough, light coloured "wart"-like markings. It produces globular yellow flowers from June to August (WAHerb 1998-2016).	**V. farnesiana* favors low lying areas, disturbed areas and river and creeks banks (WAHerb 1998-2016).

Executive Summary

Rio Tinto on behalf of Robe River Mining Co. Pty Ltd is evaluating the potential development of the Mesa H deposit located adjacent to the Mesa J Operation. One aspect of the environmental assessment process for the Mesa H development under consideration is water management, as off-site discharge is likely to result in additional water being directed into the Robe River. In anticipation of potential impacts due to increased stream flow, Astron Environmental Services was commissioned to undertake a Level 2 flora and vegetation assessment and Level 1 vertebrate fauna and aquatic fauna assessment in the riparian community survey area which is 2,128 hectares in size.

Five vegetation associations were described within the survey area, none of which represent a Threatened Ecological Community or Priority Ecological Community. The dominant trees in the upper stratum of three vegetation associations represent potentially Groundwater Dependent Ecosystems. Vegetation condition broadly ranged from 'poor' to 'excellent'. Approximately 17 hectares (less than 1%) of the survey area was 'disturbed', the majority of which represented established tracks and rail infrastructure within the survey area. Other disturbances included small pockets of riparian vegetation being burnt within the past 10 years and grazing on alluvial plains and in drainage lines.

There were 124 plant species from 37 families and 82 genera recorded from sampling sites and opportunistically throughout the survey area. The families and genera recorded are typical of what would be expected in riparian vegetation of major drainage lines in the Pilbara. No Threatened taxa were recorded, however three Priority flora species, *Triodia* sp. Robe River (M.E. Trudgen et al. MET 12367) P3, *Livistona alfredii* P4 and *Rhynchosia bungarensis* P4, were recorded within the Robe River and its tributaries. There were 23 weed species recorded within the sampling sites and opportunistically. None of the weed species recorded is listed as a declared pest for the Shire of Ashburton or a Weed of National Significance.

Two broad fauna habitat types were recorded in the survey area: Riverine and Drainage Line. The Riverine habitat is considered to be of high importance to fauna species providing a range of ecological values to a wide suite of species. Thirteen permanent pools (approximately 16.4 hectares) were recorded within the survey area in the Riverine habitat. These pools are considered a significant fauna habitat due to the refuge they provide to fish, amphibians and water fowl during dry times and the dense vegetation they support. The Drainage Line habitat is a commonly recorded habitat for the wider Pilbara region and considered to be of low to moderate value to a wide spectrum of fauna species. The survey area contains some of the most significant permanent pools in the area (such as Yeera Bluff) that are significant ecological features to the local fauna both up and downstream. The springs and pools of the Robe River that occur in the survey area are considered wetlands of sub-regional significance (Kendrick 2001).

The database searches and literature review results indicate that 318 vertebrate fauna have been previously recorded within 40 kilometres of the survey area, including six amphibian species, 102 reptile species, 160 bird species and 50 mammal species. Thirty-one terrestrial vertebrate fauna species, comprising two reptiles and 29 bird species were recorded within the survey area. This includes one conservation significant species, the Rainbow Bee-eater, which is listed as Migratory under the *Environment Protection and Biodiversity Conservation Act 1999* and Schedule 5 under the *Wildlife Conservation Act 1950*.

A total of 28 species of conservation significance, have been previously recorded in the vicinity of the survey area. Of these, six species were considered to have a 'high' likelihood of occurrence: the Pilbara Olive Python (Vu; S3), Rainbow Bee-eater (Mi; S5), Eastern Great Egret (Mi; S5), Northern Quoll (En; S2), Ghost Bat (Vu; S3) and Pilbara Leaf-nosed Bat (Vu; S3).

Based on the number of previous records of the Matter of National Environmental Significance species (Northern Quoll, Pilbara Olive Python, Ghost Bat and Pilbara Leaf-nosed Bat), the survey area and its surrounds potentially support locally significant populations. These species may be locally common, but their presence is restricted to areas of preferred habitat. Although the fauna habitats of the survey area do not support the caves and den sites these species shelter in, they do provide quality foraging habitat in close proximity to an abundance of suitable shelter. This feature is an important component to supporting the populations and presence of the Matter of National Environmental Significance species in the survey area and its surrounds.

As part of the aquatic ecosystems survey, 12 pools were sampled along the main channel of the Robe River. Sites included six potentially exposed sites adjacent to the predicted groundwater drawdown cone of depression and within the predicted surface extent of dewatering discharge; and six reference sites upstream of the Jimmawurrada Creek confluence. Water quality was highly variable amongst sites, with salinity levels ranging from fresh (592 µS/cm) to brackish (1,700 µS/cm), pH from circum-neutral (6.9) to slightly alkaline (7.9) and dissolved oxygen from hypoxic (14.5%) to supersaturated (134.9%).

Exceedances of the Australian and New Zealand Environment and Conservation Council and Agriculture and Resource Management Council of Australia and New Zealand default trigger values for the protection of 95% of species in slightly-moderately disturbed tropical northern Australian systems were recorded for nitrogen nutrients (N-total, N-NO_x & N-NH_3) at most sites upstream (reference sites) and downstream (impact sites) of the Jimmawurrada-Robe confluence. Elevated background levels of N-NO_3 and N-NH_3 within the survey area are unsurprising, given that the Robe River catchment is already affected by current and historic pastoral practices, with groundwaters also appearing to be enriched.

A total of 81 microinvertebrate taxa were recorded from the survey area, of which 46 were present at potentially exposed sites downstream of the Jimmawurrada-Robe confluence, and 69 were recorded at upstream reference sites. The microinvertebrate fauna was generally typical of that commonly recorded from tropical/sub-tropical freshwater systems, comprising Protista, Rotifera, Copepoda, Cladocera (water fleas) and Ostracoda (seed shrimp), with species from the family Lecanidae dominating within the Rotifera. One microinvertebrate species listed for conservation significance, the copepod *Eodiaptomus lumholtzi* (International Union for Conservation of Nature Vulnerable) was recorded. The conservation listing of this species is considered in need of revision, because it now occurs at numerous locations across the Pilbara region.

A total of 59 taxa were recorded from hyporheic samples, the majority of which were species not specially adapted to groundwater environments (stygoxene). Of these 59 taxa, 8% were considered stygobitic (obligate groundwater inhabitants), 31% occasional hyporheic stygophiles (species that use the hyporheic zone seasonally or during early life history stages), and 2% possible hyporheic taxa. Stygobitic taxa collected included the amphipod *Nedsia* sp., the thermosbaenacean *Halosbaena tulki*, and the ostracods *Candonopsis* cf. *tenuis* and *Vestalenula marmonieri*. Of these, *Nedsia* sp. is considered to be a short range endemic species.

A total of 148 macroinvertebrate taxa were recorded from surface waters (117 from upstream reference sites, and 116 from downstream potentially exposed sites), with composition typical of freshwater systems throughout the world, being dominated by Insecta, in particular Diptera (true flies) and Coleoptera (aquatic beetles). One macroinvertebrate species listed for conservation significance, the Pilbara Pin Damselfly *Eurysticta coolawanyah* (International Union for Conservation of Nature: Near Threatened), was recorded at potentially exposed downstream sites.

A total of 3,515 individual fish, representing 11 species, were recorded in the survey area. True freshwater species included Western Rainbowfish, Spangled Perch, Pilbara Tandan (Eel-tailed Catfish), Fortescue Grunter, Barred Grunter, Terapontidae (Grunter) hybrids and Bony Bream. Estuarine/marine vagrant fish species included Milkfish, Tarpon/Ox-eye Herring, Mullet and Banded Scat/Striped Butterfish. The conservation listed Fortescue Grunter (*Leipotherapon aheneus*; International Union for Conservation of Nature Lower Risk/Near Threatened; P4) was the second most abundant fish species of the survey area.

1 Introduction

1.1 Project Background

Rio Tinto, on behalf of Robe River Mining Co. Pty Ltd (the Proponent), is evaluating the potential development of the Mesa H deposit located adjacent to the Mesa J Operation and approximately 13 km to the south-west of the town of Pannawonica, Western Australia (Figure 1). A key component of the pre-feasibility and feasibility studies being undertaken is the environmental surveys which are required to inform the environmental assessment process for the potential development of the Mesa H deposit.

One aspect of the Mesa H development under consideration is water management involving mine dewatering, off-site discharge and processing/dust suppression water use. Groundwater abstraction has the potential to impact the groundwater levels in the vicinity of the Robe River and off-site discharge is likely to result in additional surplus water being directed into the Robe River. For this reason, biological surveys of the riparian vegetation along the relevant section of the Robe River (and tributaries such as portions of the Jimmawurrada Creek) are required.

Astron Environmental Services (Astron) was commissioned to undertake some of these environmental surveys. This report presents the outcome of a Level 2 vegetation and flora assessment of the Robe River riparian community, and also a Level 1 fauna assessment (Table 1). The survey area is 2,128 ha.

Astron commissioned Wetland Research & Management (WRM) to design and conduct a baseline sampling program encompassing aquatic ecosystems of the Robe River both upstream and downstream of the Mesa H development.

A vegetation and flora survey of previously unsurveyed sections of the Robe River was completed in June 2016. In addition to this, information pertaining to the riparian zone of three separate surveys which overlap the current survey area helped inform the vegetation and flora aspects of this assessment:

- Astron Environmental Services (2016a), '*Middle Robe and East Deepdale Level 2 Vegetation and Flora Assessment'*, unpublished report to Rio Tinto
- Astron Environmental Services (2016b), '*Mesa H Level 2 Vegetation and Flora Assessment'*, report in preparation for Robe River Mining Co. Pty Ltd
- Astron Environmental Services (2016c),'*Mesa H Riparian Vegetation Baseline Monitoring'*, report in preparation for Robe River Mining Co. Pty Ltd.

Table 1: Summary of Astron's Riparian Community Assessment.

Level of survey	Survey area size	Relevant regulatory guidance documents
Level 2 flora and vegetation assessment	2,128 ha	• Environmental Protection Authority (EPA) Position Statement No. 3 (Environmental Protection Authority 2002) • EPA Guidance Statement No. 51 (Environmental Protection Authority 2004a) • EPA & Parks and Wildlife Technical Guide (Environmental Protection Authority and Department of Parks and Wildlife 2015)

Level of survey	Survey area size	Relevant regulatory guidance documents
Level 1 fauna assessment	2,128 ha	• EPA Guidance Statement No. 56 (Environmental Protection Authority 2004b) • EPA and DEC Technical Guide (Environmental Protection Authority and Department of Environment and Conservation 2010)
Baseline Aquatic Survey	12 sites (6 upstream and 6 downstream of the proposed discharge point)	• Australian and New Zealand Guidelines for Fresh and Marine Water Quality (Australian and New Zealand Environment and Conservation Council and Agriculture and Resource Management Council of Australia and New Zealand 2000) • EPA Guidance No. 20, Sampling of Short Range Endemic Invertebrate Fauna for Environmental Impact Assessment in Western Australia (Environmental Protection Authority 2009) • EPA Position Statement No. 3 (Environmental Protection Authority 2002) • EPA Guidance Statement No. 56 (Environmental Protection Authority 2004b)

1.2 Scope and Objectives

The scope of the assessment includes determining the floristic composition and condition of the riparian vegetation, mapping vegetation communities and detailing fauna values along an approximate 28 km section of the Robe River and two of its tributaries. The objectives were to undertake a:

- desktop assessment, including database searches and literature review of available resources.
- vegetation and flora assessment, to include:
  - description of dominant vegetation types (with supporting photographs of each type with location data) including the dominant species and structure
  - the presence or likely presence of Threatened (Declared Rare) and Priority flora, and weeds
  - a list of the vascular plant species recorded within the survey area
- fauna and fauna habitat assessment, to include:
  - habitat assessment and photographs for any significant areas or sites observed that may be suitable for Matters of National Environmental Significance (MNES) species
  - the presence or likely presence of Threatened and Priority fauna
  - opportunistic sightings, species present and their significance
- baseline aquatic assessment, to include:
  - identification of baseline and future riverine monitoring sites, and where possible, inclusion of long-term monitoring sites established previously by Streamtec/the University of Western Australia (UWA)
  - semi-qualitative sampling for aquatic fauna and water quality to allow statistical comparison of any changes overtime
  - qualitative visual assessment of general habitat conditions at all sites

  - identification of all specimens to the lowest taxonomic level practicable
  - assessment of the conservation status of aquatic fauna recorded
  - report water quality data against the Australian and New Zealand Environment and Conservation Council and Agriculture and Resource Management Council of Australia and New Zealand (ANZECC/ARMCANZ) (2000) guidelines for freshwater ecosystems
  - discussion on the potential impacts of the development on aquatic ecosystems
  - preparation of a detailed technical report of all findings
- preparation of a final report which addresses the tasks outlined above, relevant contextual information, methodology, timing and limitations (WRM report displayed in full in Appendix A).

2 Environmental Context

2.1 Physical Environment

2.1.1 Climate

The climate of the Pilbara region of Western Australia is classified as arid tropical with two distinct seasons: a hot, wet summer (October – April) and a mild, dry winter (May – September) (Bureau of Meteorology 2016).

Based on long-term climatic data from the nearest Bureau of Meteorology (BOM) weather station at Pannawonica (Station 5069) (approximately 13 km north-east of the survey area), the mean annual rainfall since 1971 is 404 mm (Bureau of Meteorology 2016). The mean maximum daily temperatures range between 26.7°C and 41°C, and range above 30°C for much of the year (Figure 2) (Bureau of Meteorology 2016).

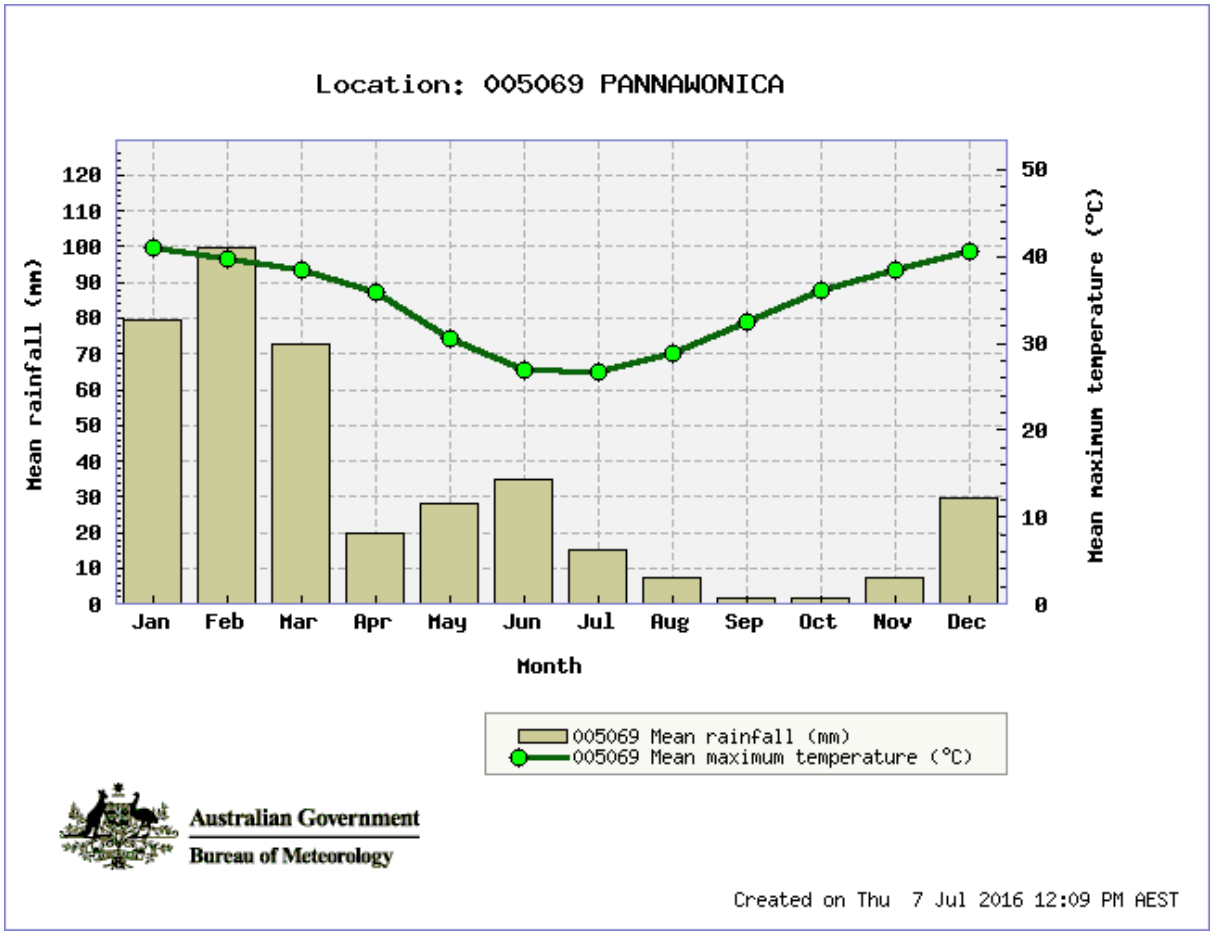

Figure 2: Climate data for Pannawonica (Station 5069). Mean annual rainfall data calculated from 1971-2016 and mean maximum temperature (calculated from 1971-2005) (Bureau of Meteorology 2016).

2.1.2 Geology and Soils

The survey area occurs on the Hamersley Basin which overlies the Archaean Pilbara Craton and comprises of mafic and felsic volcanics, shale, siltstone, sandstone and conglomerate, as well as dolomite and banded iron formation. The basin is extensively deformed from numerous tectonic events, resulting in extensive folding and faulting through the geological formations (van Vreeswyk

et al. 2004). The surface geology of the survey area is comprised of seven units (Stewart et al. 2008) as presented in Table 2. Geological mapping of the survey area and surrounds is presented in Figure B.1 (Appendix B).

Table 2: Geological units of the survey area.

Geological name	Label	Area within survey area (ha)
Marra Mamba Iron Formation: chert, ferruginous chert, jaspilite, banded iron formation, minor shale, siltstone, mudstone	Achm	184.9
Mount McRae Shale and Mount Sylvia Formation: interbedded shale, chert, banded iron-formation	Ashm	1.4
Jeerinah Iron Formation: shale, sandstone, siltstone, mudstone, dolomite, local microbanded chert, jaspilite, conglomerate; fine-grained massive rhyolite; mafic tuff with local accretionary lapilli and agglomerate; thin basalt/dolerite and andesitic basalt flows	Awfj	51.2
Robe Pisolite: pisolitic, oolitic and massive limonite, goethite and hematite deposits containing fossil wood fragments; iron ore	Czlr	107.2
Boolgeeda Iron Formation: fine-grained, finely laminated, dark-grey-brown to black flaggy iron-formation, minor chert, jaspilite, shale	Lchb	3.1
Woongarra Rhyolite: rhyolite, rhyodacite, rhyolitic volcaniclastic breccia and banded iron formation	Lfhw	40.5
Alluvium 38485: channel and flood plain alluvium; gravel, sand, silt, clay, locally calcreted	Qa	1730.3
Colluvium 38491: colluvium, sheetwash, talus; gravel piedmonts and aprons over and around bedrock; clay-silt-sand with sheet and nodular kankar; alluvial and aeolian sand-silt-gravel in depressions and broad valleys in Canning Basin; local calcrete, reworked laterite	Qrc	9.3

The survey area is mapped as soil landscape zone 285 – Hamersley Plateaux in the Fortescue Province (Tille 2006). This soil unit is described as hills and dissected plateaux with some stony plains and hardpan wash plains on volcanic and sedimentary rocks. It is comprised predominately of stony soils with red shallow loams and some red-brown non-cracking clays and red loamy earths (Tille 2006). Some drainage habitats occur and these are characterised by sand, gravel, pebbles and stones (van Vreeswyk et al. 2004).

2.1.3 Surface Water and Hydrology

The Robe River is considered a seasonal watercourse and flows in an east-west orientation. A number of permanent pools in the river were observed within the survey area and have been previously reported in Kendrick (2001) as wetlands of subregional significance. Numerous creeks and smaller drainage lines stem from the main flow line. There are no regionally significant wetlands in proximity. A section of the survey area, represented as the northern extent of Jimmawurrada Creek, is within a Public Drinking Water Source Area, the Bungaroo Water Reserve (Department of Water 2008).

2.2 Biological Environment

2.2.1 Interim Biogeographic Regionalisation of Australia

The Interim Biogeographic Regionalisation for Australia (IBRA version 7) divides the Australian continent into 89 bioregions and 419 subregions (Department of the Environment and Energy 2016a). The IBRA regions represent a landscape-based approach to classifying the land surface, including attributes of climate, geomorphology, landform, lithology, and characteristic flora and fauna. The survey area occurs in the Pilbara Bioregion, of which 5% to 10% is represented in the national reserve system (Department of the Environment and Energy 2016b).

The biodiversity of the 53 subregions recognised in Western Australia was documented as part of a national audit to provide priorities for conservation action (Department of Conservation and Land Management 2002). The survey area occurs in two subregions, the Chichester and Hamersley subregions of the Pilbara region. The subregions are described in the audit as:

- Chichester PIL1 – undulating Archean granite and basalt plains include significant areas of basaltic ranges and plains support shrub steppe characterised by *Acacia inaequilatera* over *Triodia wiseana* hummock grasslands, and ranges comprise of *Eucalyptus leucophloia* tree steppes (Kendrick and McKenzie 2001). This subregion represents approximately 1% of the survey area.
- Hamersley PIL3 – dissected bold plateaux and ranges of flat lying of moderately folded sandstone and quartzite with vegetation described as Mulga low woodland over tussock grasses occurring on fine textured soils in valley floors, with scattered Snappy gum (*Eucalyptus leucophloia*) over *Triodia brizoides* on skeletal soils of the ranges (Kendrick 2001). This subregion represents 99% of the survey area.

2.2.2 Land Systems

Land systems of the Western Australian rangelands have been mapped and described by the Department of Agriculture and Food (DAFWA) outlining the distributions and providing comprehensive descriptions of biophysical resources, including soil and vegetation condition. A total of 102 land systems occur in the Pilbara bioregion covering 181,723 km^2, of which six occur in the survey area (Table 3). The layout of these land systems within the survey area is shown in Figure B.2 (Appendix B).

Table 3: Distribution of land systems within the survey area and Pilbara bioregion (van Vreeswyk et al. 2004).

Land system	Total area within Pilbara bioregion (ha)	Total area within survey area (ha)	Proportion within survey area (%)
Boolgeeda - stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands and mulga shrublands	961,847	0.04	<0.1
McKay - hills, ridges, plateaux remnants and breakaways of meta sedimentary and sedimentary rocks supporting hard spinifex grasslands	425,967	1.79	<0.1
Newman - rugged jaspilite plateaux, ridges and mountains with hard spinifex	1,994,339	38.30	<0.1
River - active flood plains, major rivers and banks supporting grassy eucalypt woodlands, tussock grasslands and soft spinifex grasslands	481,994	1859.92	<0.1
Robe - low limonite mesas and buttes supporting soft spinifex (and occasionally hard spinifex) grasslands	128,680	169.02	<0.1
Urandy - stony plains, alluvial plains and drainage lines supporting shrubby soft spinifex grasslands	132,039	58.82	<0.1
TOTAL	**4,124,866**	**2,127.89**	<0.1

2.2.3 Pre-European Vegetation

Pre-European vegetation was mapped across the Pilbara region at a scale of 1: 1,000,000 (Beard 1975). The survey area is located in the Stuart Hills, Chichester Plateau and Hamersley Plateau physiographic units of the Fortescue Botanical District (Figure B.3, Appendix B). These physiographic units are described as:

Hamersley: a compact unit defined by the outcropping of jaspilite and dolomite, with some shale, siltstone and volcanics. Vegetation is described as:

- ranges – tree steppe of *Eucalyptus brevifolia* (likely to represent *E. leucophloia*) over *Triodia wiseana* hummock grasslands
- valley plains – mulga (*Acacia aneura* complex) low woodlands, or tussock grasslands on cracking clay soils
- basalt hills – mosaic of mulga low woodland and *Acacia pyrifolia* and *Triodia* species shrub steppe.

Chichester Plateau: this very long narrow unit forms a watershed between numerous rivers flowing north to the coast and the Fortescue drainage on the southern side. It is bounded for most of its northern length and at its western end by abrupt escarpments rising from the coastal plains, but the decent to the Fortescue is much less abrupt and more gradual. Vegetation is described as:

- high plains – *Acacia pyrifolia* - *Triodia* shrub steppe on hard alkaline red soils, changing to grass savannah on clay soils in the lower portions.

Stuart Hills: this unit consists mostly of plains, gently undulating pediplains extending out from Breakaways and residuals capped by Robe pisolites, and stony hills and steeply dissected pediments on fine-grained sandstone, shale and dolomite. Vegetation is described as:

- hills and plains – *Triodia wiseana* and *T. basedowii* hummock grasslands with sparse shrubs, particularly *Acacia bivenosa*
- drainage lines – *Corymbia hamersleyana* and *C. candida* occur occasionally, with *Senna* species and ephemerals
- major rivers – *Eucalyptus camaldulensis* and *Acacia citrinoviridis* along river and mulga low woodland on river flats and tributaries.

Six pre-European vegetation units, 82, 173, 603, 605, 609, 620 (Shepherd, Beeston, and Hopkins 2002), are associated with the survey area:

82: 'Hummock grasslands, low tree steppe; snappy gum over *Triodia wiseana*',

173: 'Hummock grasslands, shrub steppe; kanji over soft spinifex and *Triodia wiseana* on basalt',

603: 'Hummock grasslands, sparse shrub steppe; *Acacia bivenosa* over hard spinifex',

605: 'Hummock grasslands, shrub steppe; *Acacia pachycarpa* and waterwood over soft spinifex'

609: 'Mosaic: Hummock grasslands, open low tree steppe; bloodwood with sparse kanji shrubs over soft spinifex/Hummock grasslands, open low tree steppe; snappy gum over *Triodia wiseana* on a lateritic crust'

620: 'Hummock grasslands, shrub steppe; snakewood over soft spinifex'.

Table 4 summarises the current and pre-European extent of these six vegetation units in the Pilbara and the survey area.

Table 4: Extent of pre-European vegetation in the survey area (Government of Western Australia 2014).

Vegetation association	Mapping unit (Beard 1975)	Extent in survey area (ha)	Current extent in Pilbara bioregion (ha)	Pre-European extent (ha)	Proportion of pre-European extent remaining (%)
82	e16Lr t3Hi	402.6	2,550,899.0	2,563,583.2	99.5
173	a2Sr t1, 3Hi	81.4	1,747,677.6	1,752,420.9	99.7
603	a6Sb t3Hi	282.2	55,764.0	56,726.9	98.3
605	a5,11Sr t1Hi	259.3	114,115.9	114,115.9	100.0
609	e24Lr a2Sp t1Hi /e16Lr t3Hi	765.4	72,765.2	74,186.1	98.1
620	a11Sr t1Hi	337.0	15,539.4	15,539.4	100.0

2.3 State and Commonwealth Conservation Categories and Management

Commonwealth and State regulatory authorities maintain databases of the locations and conservation status of significant flora, fauna and ecological communities in Western Australia. The *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) provides a legal framework to protect and manage MNES including listed flora, fauna and ecological communities.

These listed flora, fauna and ecological communities are allocated conservation categories, which are outlined in Tables C.1 and C.2 (Appendix C).

Ecological communities may be subject to processes that threaten to destroy or significantly modify it across much of its range. These communities are identified as Threatened Ecological Communities (TECs) and are listed at both Commonwealth level under the EPBC Act and State level by the Western Australian Minister for Environment (Table C.3, Appendix C). The Department of Parks and Wildlife (Parks and Wildlife) maintains a list of Priority Ecological Communities (PECs), which may also be under threat and are assigned one of four Priority rankings according to the criteria outlined in Table C.4 (Appendix C).

Under Western Australian legislation, all native flora is protected and it is an offence to 'take' protected flora. The *Wildlife Conservation Act 1950* (WC Act) also provides for native plant species to be specially protected when they are under identifiable threat of extinction, are rare, or otherwise in need of special protection (Department of Parks and Wildlife 2015a). Such specially protected flora is considered under the WC Act to be 'declared rare' (Threatened) (Table C.5, Appendix C). In addition, due to the diversity of Western Australia's flora, many species are known from only a few collections or locations, but have not been adequately surveyed. Such flora may be rare or threatened, but cannot be considered for declaration as Threatened flora until adequate surveys have been undertaken. These flora species are included on a supplementary conservation list managed by Parks and Wildlife called the *Priority Flora List*. Priority flora are categorised according to level of threat and other information and the conservation categories are described in Table C.6 (Appendix C).

Groundwater Dependent Ecosystems (GDEs) are often a focus of conditions applied through a Ministerial Statement. GDEs in the Pilbara play an important ecological role by providing essential habitat for species and a haven for biological diversity and productivity in an otherwise harsh, dry climate. Therefore, the vegetation comprised within GDEs may be considered locally significant.

2.4 Introduced Flora (Weeds)

Significant weed species are identified at both the state and national level. The Australian Weeds Strategy (Australian Weeds Committee 2012) identifies Weeds of National Significance (WoNS) which have the potential to impact primary industry and/or environmental and social values. The management of weeds in Western Australia is primarily regulated through the *Biosecurity and Agriculture Management Act 2007* (BAM Act). Species listed under this act are allocated one of three declared pest categories which define the required level of management (Department of Agriculture and Food Western Australia 2016). Declared pest categories and listed weed species' priority ratings are presented in Table C.7 (Appendix C).

2.5 Land Use and Tenure

The survey area is located within the Shire of Ashburton, and is on two pastoral leases; Yalleen Station and Yarraloola Station. The local area is used for pastoralism, mineral exploration and mining activity.

The Millstream-Chichester National Park is the nearest conservation reserve to the survey area, located approximately 79 km to the north-east. The Cane River Conservation Park is located approximately 48 km to the south-west, Murujuga National Park is approximately 120 km north and Karijini National Park is approximately 180 km south-east of the survey area (refer to Figure 1).

3 Methodology

3.1 Desktop Assessment

3.1.1 Database Searches

A search for Environmentally Sensitive Areas (ESAs) in the vicinity of the survey area was conducted using the WA Atlas (Landgate 2016) and Register of the National Estate (RNE) spatial database (Department of the Environment and Energy 2008). Despite all references to the RNE being removed from Commonwealth legislation in 2012, current State regulations (*Environmental Protection (Clearing of Native Vegetation) Regulations 2004*) declare any area registered on the RNE as an ESA (Department of the Environment and Energy 2016c).

In addition, database searches were conducted to identify listed conservation significant ecological communities, and flora and fauna species within, or in close proximity to, the survey area. Search results are presented in Appendix D and details are summarised in Table 5. Conservation categories for ecological communities and flora are presented in Appendix C. Introduced flora species were compared to the DAFWA list to determine if any have been listed as declared pests (Department of Agriculture and Food Western Australia 2016) and the WoNS list (Australian Weeds Committee 2012). Introduced flora categories are also presented in Appendix C.

Table 5: Database searches requested.

Database name	Date search results received	Search focus	Search area
Vegetation & Flora			
Protected Matters Search Tool (Department of the Environment and Energy 2016d)	25/07/2016	Matters of National Environmental Significance flora	50 km radius from the approximate Mesa H Level 2 Vegetation and Flora (Astron Environmental Services 2016b) survey area centre point, defined by the coordinates: 21°44’11 S, 116°11’50 E

3.1.2 Vegetation and Flora

The 30 PECs listed by Parks and Wildlife for the Pilbara region (Department of Parks and Wildlife 2016b) were reviewed to determine if any were analogous with ecological communities recorded in the survey area.

Prior to conducting the field surveys, aerial imagery was interpreted to identify potential habitat types. The conservation significant flora species returned from the database searches were then categorised according to the criteria in Table 6 for potential occurrence within the survey area.

Table 6: Pre-survey criteria used to assess the likely presence of conservation significant flora in the survey area.

Likelihood of occurrence	Pre-survey
Likely	Species previously recorded within the survey area or within 10 km of the survey area and suitable habitat appears to be present in the survey area
Potential	Species previously recorded within 10 km to 20 km of the survey area and/or suitable habitat appears to be present in the survey area
Unlikely	No suitable habitat appears to be present in the survey area

Following the field surveys, the conservation significant flora species identified during the desktop assessment as having the highest potential to occur within the survey area, yet were not recorded during the current survey, were again assessed to determine their likelihood of occurrence within the survey area. Post-field survey likelihood of occurrence was primarily based on validating the presence (and thorough inspection) of suitable habitats within the survey area, combined with life form, habitat and flowering information for each flora species.

3.1.3 Literature Review

3.1.3.1 Vegetation and Flora

Vegetation and flora surveys which have recently been commissioned by Rio Tinto and that are within the vicinity of the survey area are presented in Figure E.1 (Appendix E). The data and results from three reports have also been incorporated into this assessment:

- Middle Robe and East Deepdale Level 2 Vegetation and Flora Assessment (ecologia Environment 2013)
- Mesa H Level 2 Vegetation and Flora Assessment (Astron Environmental Services 2016b)
- Mesa H Riparian Vegetation Baseline Monitoring (Astron Environmental Services 2016c).

A further five surveys previously commissioned by Rio Tinto between 2003 and 2012 provided contextual information appropriate for this riparian survey area, and were supplied to Astron and reviewed as part of the desktop assessment:

- Mesa J Tail Track Extension Vegetation, Flora and Fauna Survey (Astron Environmental Services 2011)
- Mesa J Extension Vegetation, Flora and Fauna Assessment (Biota Environmental Sciences 2003)
- A Vegetation and Flora Survey of the Proposed Mesa A Transport Corridor, Warramboo Deposit and Yarraloola Borefield (Biota Environmental Sciences 2006a)
- Baseline Flora and Vegetation Assessment of Robe Valley Mesas (Mesas B, C, D, E, F, H and I) (Biota Environmental Sciences 2011a)
- Greater Bungaroo Flora and Vegetation Survey (Biota Environmental Sciences 2012).

Ecologia (2013) presents Phase 1 vegetation and flora data for Astron (2016a) and does not contain the final results for that survey, therefore was not considered in this assessment to avoid duplication of information. Additional vegetation and flora surveys have previously been commissioned by Rio

Tinto within the vicinity of the survey area, however did not contain landforms and vegetation analogous to riparian communities, therefore were not used for contextual information.

3.1.3.2 Terrestrial Fauna

Terrestrial fauna surveys have previously been commissioned by Rio Tinto within the vicinity of the survey area and supplied to Astron for the desktop assessment. The reports reviewed as part of the fauna aspects of this assessment include:

- Mesa J Tail Track Extension Vegetation, Flora and Fauna Survey (Astron Environmental Services 2011)
- Mesa H Level 1 Flora, Vegetation and Fauna Assessment (Astron Environmental Services 2014)
- Mesa H Level 2 Fauna Assessment (Astron Environmental Services 2016d)
- Bungaroo Iron Ore Mine and Infrastructure Project, Level 2 Fauna Survey (Astron Environmental Services 2016e)
- Middle Robe and East Deepdale Level 2 Fauna Assessment (Astron Environmental Services 2016f)
- Yarraloola Targeted Fauna Survey (Biologic Environmental Survey 2014)
- Fauna Habitats and Fauna Assemblage of Mesa A and Mesa G (Biota Environmental Sciences 2005)
- Fauna Habitats and Fauna Assemblage of the Mesa A Transport Corridor and Warramboo (Biota Environmental Sciences 2006b)
- Bungaroo Trial Pit and Transport Corridor to Mesa J, near Pannawonica (Biota Environmental Sciences 2007)
- Mesa G Baseline Fauna Survey (Biota Environmental Sciences 2009)
- Greater Bungaroo Seasonal Fauna Survey (Biota Environmental Sciences 2010a)
- Robe Valley Mesas Fauna Survey (Biota Environmental Sciences 2011b)
- Middle Robe and East Deepdale Flora, Vegetation, Vertebrate and Invertebrate Fauna Survey (ecologia Environment 2013).

3.1.3.3 Aquatic Ecosystems

Numerous aquatic ecological surveys have been undertaken within the vicinity of the survey area and were used for the desktop assessment. A more comprehensive description of the aquatic surveys and studies are provided in Appendix A. The reports reviewed as part of the aquatic aspects of this assessment include:

- Streamtec/UWA, annual sampling of Robe River pools (Dobbs and Davies 2009; Streamtec 1996-2014)
- Pilbara Biological Survey: An arid zone awash with diversity: patterns in the distribution of aquatic invertebrates in the Pilbara region of Western Australia (Pinder et al. 2010)
- Fish fauna of the inland waters of the Pilbara (Morgan and Gill 2004)
- API Aquila: Baseline Aquatic Ecosystem Surveys (Wetland Research & Management 2009)

- HD1: Pilbara Regional Aquatic Surveys Wet & Dry 2011 Sampling (Wetland Research & Management 2013)
- HD1: Pilbara Regional Aquatic Surveys Wet & Dry 2015 Sampling (Wetland Research & Management 2016)
- Mesa A/Warramboo Yarraloola Borefield Development: Baseline Stygofauna Assessment (Biota Environmental Sciences 2006c)
- West Pilbara Iron Ore Project Stygofauna Assessment (Biota Environmental Sciences 2010b)
- Bungaroo South: Subterranean Fauna Assessment (Bennelongia Environmental Consultants 2013)
- Exploring the relationship between sampling efficiency and short-range endemism for groundwater fauna in the Pilbara region, Western Australia (Eberhard et al. 2009)
- Pilbara stygofauna: deep groundwater of an arid landscape contains globally significant radiation of biodiversity (Halse et al. 2014).

3.2 Field Survey

The flora field survey was undertaken concurrently with the riparian monitoring survey from 26 May to 7 June 2016 (Astron Environmental Services 2016c). Six other field surveys have also assessed parts of the survey area (Table 7). Applicable data from all seven field surveys has been included to inform the riparian community vegetation and flora assessment. The Level 1 fauna survey was undertaken on 8 May 2016. Habitat assessment data and mapping from the Mesa H fauna survey and Middle Robe and East Deepdale fauna survey (Astron Environmental Services 2016d, 2016f) were used for areas that overlapped with the current survey area. The baseline aquatic ecosystem survey was completed between 28 April and 7 May 2016. The scientists and the dates of the surveys are listed in Table 7.

Table 7: Field survey timing and personnel.

Component	Survey dates	Field personnel
Middle Robe and East Deepdale Level 2 Vegetation and Flora Assessment – Phase 1	15 to 27 June 2015	Janelle Atkinson (Flora permit SL011215; Declared Rare Flora (DRF) 141-1415) Daniel Roocke (Flora permit SL011212; DRF 142-1415) Dr Kellie McMaster (Flora permit SL011404) Linda Vaughan (Flora permit SL011214)
Middle Robe and East Deepdale Level 2 Vegetation and Flora Assessment – Phase 2	21 September to 3 October 2015	Janelle Atkinson (Flora permit SL011215; DRF 141-1415 Daniel Roocke (Flora permit SL011212; DRF 142-1415)
Mesa H Level 2 Vegetation and Flora Assessment – Phase 1	23 to 30 October 2014	Janelle Atkinson (Flora permit SL010911; DRF 107-1516) Daniel Roocke (Flora permit SL010827; DRF 139-1314) Alice Bott (Flora permit SL011640); DRF 140-1314)
	24 September to 4 October 2015	Natalie Cadd (Flora permit SL011621; DRF 170-1415) Dr Kellie McMaster (Flora permit SL011404)
Mesa H Level 2 Vegetation and Flora Assessment – Phase 2	27 April to 14 May 2016	Janelle Atkinson (Flora permit SL011617, DRF 141-1415) Daniel Roocke (Flora permit SL011627, DRF 131-1516) Linda Vaughan (Flora permit SL011631) Dr Kellie McMaster (Flora permit SL011810)

Level 1 Riparian Community Fauna Survey	8 May 2016	Matthew Love John Trainer
Mesa H Baseline Aquatic Ecosystem Survey	28 April to 7 May 2016	Adam Harman Emma Thillainath Fintan Angel

3.2.1 Weather

Daily weather observations recorded from Mesa J were used to describe local rainfall and temperatures preceding the surveys (Figure 3). Rainfall in the second half of 2015 was 28% below average with 45 mm recorded for the 6 month period. Above average rain was recorded in January 2016, although only 30 mm was recorded from February to March compared to the mean of 192 mm for the corresponding period. The months of May, June and July 2016 recorded above average rainfall with a total of 137 mm, which is 60 mm more than the long term mean. The mean maximum temperatures between May 2015 and July 2016 were generally slightly higher than the long-term averages, ranging between 27.0°C and 43.1°C (Figure 3).

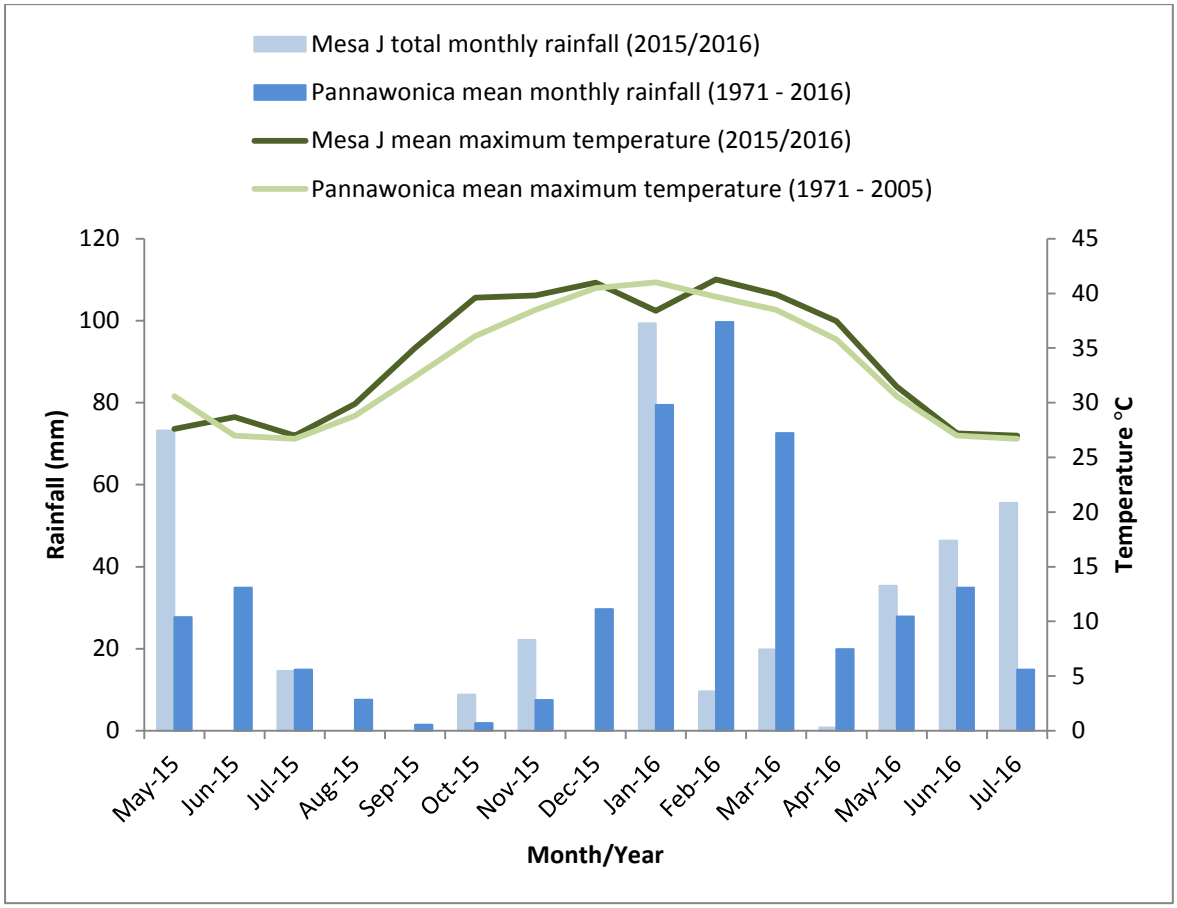

Figure 3: Pannawonica mean monthly rainfall (1971 – 2016) and Mesa J total recorded rainfall (2015 - 2016), and Pannawonica mean monthly maximum temperatures (1971 – 2005) and Mesa J mean monthly maximum temperatures from May 2015 to July 2016. Mesa J data provided by Rio Tinto (2016a). Pannawonica data from Bureau of Meteorology (2016).

3.2.2 Vegetation and Flora Assessment

The vegetation and flora field surveys were undertaken in accordance with the requirements outlined in the Environmental Protection Authority (EPA) (Environmental Protection Authority 2002, 2004a; Environmental Protection Authority and Department of Parks and Wildlife 2015) and Rio Tinto policy and guidance documents.

Information acquired during the desktop assessment assisted in the design of the field surveys. Pre-survey planning involved the examination of 1:10,000 scale aerial photography to identify potential landforms, habitat and vegetation types. It also involved a review of the flora and vegetation assessments previously completed within the Robe River and adjacent to Mesa H for context and to identify data gaps. Proposed quadrat locations were identified prior to the field surveys according to the replicates supporting previous vegetation mapping (Astron Environmental Services 2016a, 2016c).

Data from 28 current and previous sampling sites, representing 27 quadrats and one relevé, was collected (Table 8). Four quadrats were previously sampled as part of the Middle Robe and East Deepdale study (Astron Environmental Services 2016a). Sixteen sampling sites had a single season of survey only. Vegetation associations were aligned with those described in the Mesa H Level 2 Vegetation and Flora Assessment (Astron Environmental Services 2016b).

Table 8: Survey effort for existing and newly installed quadrats and relevés occurring within the survey area.

Author; project; phase of survey	Number of sites	Name of sites
Astron Riparian Community Assessment (current survey) 1 phase	7 quadrats	MH379, MH381, MH384, MH385, MH387, MH388, MH389
Astron Mesa H Level 2 Flora and Vegetation Survey (Astron Environmental Services 2016b) 2 phase	7 quadrats 1 relevé	MH43, MH44, MH203, MH204, MH303, MH321, MH332, MH337r
Astron Mesa H Level 2 Flora and Vegetation Survey (Astron Environmental Services 2016b) 1 phase	9 quadrats	MH354, MH363, MH373, MH392, MH393, MH394, MH397, MH398, MH401
ecologia (2013)and Astron Middle Robe and East Deepdale (2016a) 2 phase	3 quadrats	E07, E09, E20
Astron Middle Robe and East Deepdale (2016a) 1 phase	1 quadrat	AM215

Quadrats were positioned by measuring a square of 50 m by 50 m in suitable terrain, or dimensions measuring 2,500 m^2 where necessary. The four corners of the quadrats were permanently marked with fence droppers and the following information was collected at each quadrat:

- Location – coordinates measured using a handheld GPS (MGA50, GDA94).
- Recorder and date – personnel involved in sampling that location and the survey date.
- Species – representative vascular plant species present. The inventory of associated species was more comprehensive for a quadrat location, with each flora species present recorded; at relevés the species most typical of the vegetation unit and represented at that location were recorded. Species that could not be identified in the field were collected for later identification at the Astron herbarium or Western Australian Herbarium (WAHerb).
- Weeds – the coordinates and density of any introduced flora.
- Foliar cover – the percentage cover was estimated for each flora species.
- Vegetation description – vegetation was described according to the Aplin (1979) modification of the vegetation classification system of Specht (1970) (Table F.1, Appendix F) and the National Vegetation Information System, level 5 (Department of the Environment and Energy 2016e). At this level, vegetation is described to 'association' where up to three dominant genera for each of the upper, middle and ground strata are categorised based on dominant growth form, cover and height.
- Vegetation condition – assessed according to the vegetation condition classification adapted from Trudgen (1988) (Table F.2, Appendix F).
- Habitat – a broad description of the surrounding landscape based on landform, topography and soil.
- Photographs – a representative photograph was taken of each quadrat.
- Disturbances – records of any obvious disturbances such as fire, tracks or grazing.
- Geology – rock type and abundance.
- Soil – including colour and texture.

Quadrat and relevé locations are presented in Figure G.1 (Appendix G).

3.2.3 Vegetation Description and Mapping

Vegetation was described and mapped to be consistent with the descriptions and mapping previously conducted in and adjacent to the survey area (Astron Environmental Services 2016c). Results from the sections of riparian landform within the survey area that had already undergone assessment were incorporated into the data. Vegetation units were described and mapped using the data collected from quadrats, and followed the same convention as that previously used; the vegetation association code is described according to the initials of the dominant flora species defining the community.

3.2.3.1 Vegetation Condition Mapping

Vegetation condition was mapped according to vegetation association boundaries throughout the survey area, using a combination of quadrat data, opportunistic observations and the mean condition rating for each vegetation association. Vegetation condition was rated at each survey site using the five point Trudgen (1988) scale, and then applied to the whole vegetation association polygon in which it was mapped. A mean condition rating was calculated for each vegetation association using the data collected from survey sites and this was applied to any polygons not already attributed with a rating.

3.2.4 Targeted Flora Survey

Previously recorded conservation significant flora records (Astron Environmental Services 2016a, 2016b; Biota Environmental Sciences 2003, 2006a, 2011a; Department of Parks and Wildlife 2015c, 2015d, 2015e) and associated habitat preference information were used to identify vegetation associations and habitat within the survey area that have the potential to support conservation significant flora. The habitats and vegetation associations considered to have the potential to support conservation significant flora were located within the survey area from 1:10,000 colour aerial imagery and on-ground observations.

Population information for conservation significant flora was captured electronically using ArcPad (Esri) on a handheld device. The information recorded included population size, density, landform, soil and reproductive characteristics.

3.2.5 Terrestrial Fauna

3.2.5.1 Habitat Assessment

Data from 10 current and previous fauna habitat assessments located in the survey area were collected. Seven habitat assessments were previously sampled as part of the Mesa H fauna study (Astron Environmental Services 2016d) and one habitat assessment was previously sampled as part of the Middle Robe and East Deepdale fauna study (Astron Environmental Services 2016f) (Table H.1, Appendix H). The locations are shown in Figure H.1 (Appendix H) and the following information was collected at each site:

- Location – coordinates measured using a handheld GPS (GDA94).
- Recorder and date – personnel involved in undertaking the fauna habitat assessment and the survey date.
- Habitat/landform – position in the landscape - major fauna habitat types were described based on the landform and vegetation.
- Vegetation type – a broad description of vegetation type and structure.

- Soils – a brief description of soil type.
- Microhabitat – presence of specific microhabitat features, e.g. leaf litter, logs, burrows, rocky outcrops, rock crevices, hollows, permanent or semi-permanent water.
- Condition – habitat condition was assessed based on the presence of anthropogenic (human-induced) disturbances, and using the condition ratings suggested by Thompson and Thompson (2010) (Table F.3, Appendix F).
- Disturbance – any disturbance such as clearing, fire, weeds, flooding, vehicular, machinery, tracks or grazing.
- Photographs – a representative photograph was taken of each habitat assessment site.

The information derived from the fauna habitat assessments was used to delineate fauna habitats throughout the survey area, which were then mapped accordingly. In sections of the survey area that overlap with other recent fauna surveys the data from fauna habitat assessments and the fauna habitat mapping was used to ensure consistency between projects.

3.2.5.2 Active Foraging

Active searches were undertaken throughout the survey area in microhabitats suitable for ground-dwelling reptiles and mammals. Active searches included the following:

- searching and recording scats, tracks and other traces
- turning over rocks and logs and peeling off bark
- raking soil and leaf litter
- searching around water bodies.

3.2.6 Aquatic Ecosystem

A total of 12 pools were sampled along the main channel of the Robe River. Sites included six potentially exposed sites adjacent to the predicted groundwater drawdown cone of depression and within the predicted surface extent of dewatering discharge; and six reference sites upstream of the Jimmawurrada Creek confluence. Reference sites upstream of Mesa H were selected to serve as the "control" for potentially impacted sites. Surveys conducted in April/May 2016 are part of the benchmark or "before" phase against which to assess any future changes following mine development. A more comprehensive description of aquatic survey methodology is provided in Appendix A.

3.2.6.1 Water Quality

At each site, pH, dissolved oxygen and temperature were measured in situ using hand-held Wissenschaftlich-Technische-Werkstätten field meters. Water depth was measured using a graduated pole. Undisturbed water samples were collected for laboratory analyses of major ions, alkalinity, dissolved metals, nutrients and total suspended solids. Water samples for nitrogen and phosphorus nutrient and dissolved metal analyses were filtered in the field through 0.45 µm nitrocellulose filters. Samples were stored refrigerated or frozen for a maximum of 10 days prior to transport on ice to analytical laboratories at ChemCentre, Bentley, together with chain-of-custody forms.

Water quality data were compared against default ANZECC/ARMCANZ (2000) guidelines (trigger values) for the protection of freshwater ecosystems. Default trigger values (TVs) for 95% aquatic

species protection were considered more appropriate than default TVs for 99% protection, given that the Robe River catchment in the vicinity of current mining developments is already slightly to moderately disturbed by historic mining and pastoral practices (Strategen Environmental Consultants 2006). In accordance with ANZECC/ARMCANZ (2000), the default 99% TVs were applied to bioaccumulating metals such as selenium. For metals and nutrients, dissolved concentrations (0.45 µm filtered samples) were compared to the default TVs. Filtered concentrations were considered a better reflection of the fraction that may be bioavailable. By contrast, comparison of the default TVs to the total metal or total nutrient concentration may overestimate the risk to the environment (Australian and New Zealand Environment and Conservation Council and Agriculture and Resource Management Council of Australia and New Zealand 2000).

3.2.6.2 Microinvertebrates

Microinvertebrate samples were collected from each site by gentle sweeping over an approximate 15 m distance with a 53 µm mesh plankton net. Care was taken not to disturb the benthos (bottom sediments) during sampling. Samples were preserved in 70% ethanol and sent to Dr Russell Shiel at the University of Adelaide, South Australia, for processing. Dr Shiel is a world authority on microfauna, with extensive experience in fauna survey and impact assessment across Australasia, including the Pilbara.

Microinvertebrate samples were processed by identifying the first 200 to 300 individuals encountered in an agitated sample decanted into a 125 mm^2 gridded plastic tray, with the tray then scanned for additional missed taxa also taken to species, and recorded as 'present'. Specimens were identified to the lowest taxon possible, i.e. species or morphotypes. Abundance data were reported as log_{10} scale abundance classes (i.e. 1 = individual, 2 = 2 to 10 individuals, 3 = 11 to 100 individuals, 4 = 101 to 1000 individuals, 5 = >1000 individuals). Where specific names could not be assigned, vouchers were established. These vouchers are held by Dr Shiel at the University of Adelaide, South Australia.

3.2.6.3 Hyporheos

At each site, hyporheic sampling was conducted using the Karaman-Chappuis method (Delamare Deboutteville 1960). This involved digging a hole approximately 20 cm deep and 40 cm diameter in alluvial gravels in dry streambed adjacent to the water's edge, allowing the hole to infiltrate with water, and sweeping the water column with a modified 110 µm mesh plankton net. The water column was swept immediately after the hole had filled, and again after approximately 30 minutes, once other sampling had been conducted.

Samples were preserved in 70% ethanol and returned to the laboratory for processing. Any aquatic fauna present was removed from samples by sorting under a low power dissecting microscope. In-house expertise was used to identify the majority of hyporheic taxa using available published keys and through reference to the established voucher collections held by WRM. External specialist taxonomic expertise was sub-contracted to assist with Chironomidae (Dr Don Edward, UWA) and micro-crustacea (Dr Russell Shiel, University of Adelaide).

3.2.6.4 Macroinvertebrates

Macroinvertebrate sampling was conducted with a 250 µm mesh pond net. All meso-habitats were sampled, including trailing riparian vegetation, woody debris, open water column and benthic sediments with the aim of maximising the number of species recorded. Each sample was washed through a 250 µm sieve to remove fine sediment, while leaf litter and other debris were carefully washed in the sieve and removed by hand. Samples were then preserved in 70% ethanol. In the

laboratory, macroinvertebrates were removed from samples by sorting under a low power dissecting microscope.

Collected specimens were identified to the lowest practicable level (typically genus or species) and enumerated to $\log_{10}$ scale abundance classes (i.e. 1 = individual, 2 = 2 to 10 individuals, 3 = 11 to 100 individuals, 4 = 101 to 1000 individuals, 5 = >1000 individuals). In-house expertise was used to identify invertebrate taxa using available published keys and through reference to the established voucher collections held by WRM. External specialist taxonomic expertise was sub-contracted to assist with Chironomidae (Dr Don Edward, UWA).

3.2.6.5 Fish

A number of fish sampling methods were used at each site in order to collect as many species and individuals as possible. Methods included electrofishing, seine nets and gill nets. Electrofishing is an extremely useful and efficient sampling tool in rivers with clear, low salinity, slow flow water. All meso-habitats within a maximum 40 m reach were shocked with the intention of recovering as many species/individuals as possible. Shocking was not continuous, but targeted areas of optimum habitat, whereby the operator would shock, move to a new habitat before shocking again, and so prevent fish being driven along in front of the electrical field.

Duplicate 30 m multi-panel gill nets were set at each site where there was sufficient depth of water. Each net consisted of six 5 m panels, with panels increasing in size from 1 inch to 6 inch stretched mesh size. At each sampling location, two nets were set for approximately 2.5 hours. Nets were checked frequently to avoid fish deaths. Catch from the duplicate nets were combined to form one replicate sample from each sampling location.

Smaller species and juveniles were sampled by beach seine (10 m net, with a 2 m drop and 6 mm mesh) deployed in shallow areas where there was little vegetation or large woody debris. Typically, two seine hauls were made at each location to maximise the number of individuals caught.

All fish were identified in the field, measured for standard length, and then released alive. Fish nomenclature followed that of Allen *et al.* (2002). Fish measurements provided information on the size structure, breeding and recruitment of fish populations.

3.3 Taxonomy and Nomenclature

Plant specimens that were not identified in the field were later identified in Perth by Astron Botanists Janelle Atkinson, Natalie Cadd and Daniel Roocke. Each of these botanists has worked extensively in the Pilbara and is very familiar with the flora of the region. The assigned nomenclature is consistent with the current listing of scientific names recognised by the WAHerb and was used for the species list and associated species information collected. Where specimens had inadequate descriptive material to allow confident identification, they were assigned a 'sp.' (species) epithet, indicating that identification could not be confirmed beyond genus level. Data from each quadrat was entered into a customised database.

3.4 Limitations

Following completion of the desktop assessment and field survey, a review of any limitations that may affect a complete assessment of the data collected was conducted. The limitations listed in Table 9 are based on those suggested as considerations in Guidance Statement No. 51 (Environmental Protection Authority 2004a) and Guidance Statement No. 56 (Environmental Protection Authority 2004b).

Table 9: Statement of limitations.

Potential limitation	Degree of limitation	Statement regarding potential limitations
(i) Sources of information and availability of contextual information. Is the region well documented?	No limitation	Broad-scale contextual information is available from Van Vreeswyk et al. (2004), IBRA (Kendrick 2001; Kendrick and McKenzie 2001) and Beard (1975) mapping. Numerous consultants' reports have been completed within a 50 km radius of the survey area.
(ii) Scope. The level of survey and detail required to undertake the survey. Was there adequate time to complete the survey to the desired standard?	No limitation	The assessment incorporates data from current and previous vegetation, flora, fauna and aquatic systematic surveys from the survey area. As such, the level of detail and scope of this study is deemed adequate.
(iii) Proportion of biota collected and identified. Was the survey sampling, timing and intensity considered adequate? Was the survey conducted at what was considered an appropriate time of the year for plant identification? Were any taxonomic groups considered to be under-represented?	Minor limitation	The seasonal conditions for field surveys conducted in October 2014 (Astron Environmental Services 2014), September-October 2015 and April-May 2015 (Astron Environmental Services 2016b) were considered dry, with below average rainfall in the months preceding. The seasonal conditions for the July 2015 survey, trip 2 of Phase 2 (Astron Environmental Services 2016b), were considered excellent, following substantial rainfall in the three months preceding. Despite unfavourable seasonal conditions for many surveys, the specimens collected were generally of reasonable quality with flowering and fruiting material available; few specimens were unable to be confidently identified to species level. Most taxonomic groups expected within the survey area were well represented, and floristic richness was considered reasonable given the seasonal conditions. Only opportunistic fauna records were undertaken during the Level 1 fauna assessment; as such many of the reptiles and mammals inhabiting the survey area were not recorded. Due to the recent biological surveys that have been conducted in and around the survey area the faunal assemblage is well known. The aquatic sampling was timed to correspond with recessional flow conditions at the end of the wet (April-May) season. It was considered that the end of the wet season would be a more ecologically important time of year to sample, as biological diversity would be expected to be at its highest. Inherent physical sampling deficiencies are acknowledged as a barrier to sampling aquatic fauna,

Potential limitation	Degree of limitation	Statement regarding potential limitations
		and in particular fish. For example, fish catch rates may have been hindered by the abundance of aquatic vegetation (macrophytes and algae) which physically obstructed seine and gill nets at some sites. This was somewhat compensated for by the use of a back-pack electrofisher, which generates a pulsed direct electrical current to draw fish out from under such habitat.
(iv) Completeness. Is there further work which may be required i.e. was the relevant area fully surveyed?	No limitation	The survey area was considered adequately surveyed to compile a representative list of species, (including conservation significant and introduced species), as well as describe and map vegetation and habitats at a level appropriate for possible future management decisions.
(v) Mapping reliability. Were the aerial photographs, satellite images and site maps available considered adequate to fully understand the area surveyed? Was the mapping generated considered to have a high degree of reliability?	No limitation	Colour aerial photography at a scale of 1:10,000 was used to locate the survey area and to assist in navigation and delineation of vegetation and habitat boundaries. The aerial photography was of good resolution and, in general, accurately represented ground conditions.
(vi) Timing. When was the survey conducted in terms of season, rainfall and severe weather events? Was the survey conducted at an appropriate time for access, observation of the optimal suite of species and for flora the identification of flowering and fruiting species?	Minor limitation	The flora surveys were conducted at what would normally be considered the optimal time for both dry and post-wet season surveys in the Pilbara. During the first post-wet season survey of 2016 (Astron Environmental Services 2016b), quadrat species richness was lower than might be expected. Due to the range of surveys informing this assessment, and the variety of conditions involved, the total floristic diversity was in line with what may be expected. The majority of flora species had adequate identification material present. The rainfall in the three months preceding the fauna survey was well below average. This was evident in the lack of surface water present specifically in the Riverine habitats. This is likely to reduce the number of waterbirds recorded. Due to the range of surveys informing this assessment, and the variety of conditions involved, the total fauna diversity is well known. As stated above, the aquatic sampling was timed to correspond with recessional flow conditions at the end of the wet (April-May) season as this would be a more ecologically important time of year to sample, as biological diversity would be at its highest.
(vii) Disturbance. Had the survey area been impacted by any disturbance which may have limited the survey, i.e. fire, flood,	No limitation	A history of pastoral activity and cattle grazing was evident within the survey area. Uprooted mature *Eucalyptus* and *Melaleuca* trees, and associated debris provided evidence of flood waters flowing

Potential limitation	Degree of limitation	Statement regarding potential limitations
accidental human intervention?		through the river after significant rainfall. Small sections of the survey area had been burnt within five years, although this did not compromise the vegetation mapping for these locations. Two small areas of stressed riparian vegetation were noted within the Robe River, where mature trees had senesced. Vehicle tracks were abundant in open areas of the Robe River where shingle substrate supported very sparse vegetation. None of these disturbances limited the outcomes of this survey.
(viii) Intensity. In retrospect, was the intensity considered to be adequate?	No limitation	The intensity of the survey was considered adequate to compile a representative species list for flora, fauna and aquatic components and to map the vegetation and fauna habitats of the survey area. The vegetation mapping was completed to association level with adequate quadrat replication achieved. The intensity of the survey was adequate to conduct targeted flora searches in potential habitat for likely and potential Priority flora species.
(ix) Resources. Were the appropriate tools and materials available to complete the task effectively?	No limitation	Resources were adequate to complete the survey and all appropriate tools and materials required to complete the task were available.
(x) Access. Were there any factors limiting access to the survey area?	No limitation	Much of the survey area was able to be accessed by vehicle; areas that were unable to be reached by vehicle were accessed and traversed by foot.
(xi) Experience. Were personnel undertaking the field survey and plant identification trained and/or experienced in undertaking the required tasks?	No limitation	The scientists responsible for undertaking the field surveys have considerable experience in conducting biological surveys in the Pilbara. The identification of specimens brought back from the field was conducted by scientists with extensive experience.

4 Results

4.1 Desktop Assessment

4.1.1 Vegetation and Flora

No State or Commonwealth listed TECs are known to occur within or adjacent to the survey area (Department of the Environment and Energy 2016d; Department of Parks and Wildlife 2015b).

Two PECs, '*Triodia sp. Robe River assemblages of mesas of the West Pilbara*' P3 and '*Four plant assemblages of the Wona Land System*' P1, have been previously recorded within 50 km of the Mesa H (Astron Environmental Services 2016b) survey area (Department of Parks and Wildlife 2016b) (Figure I.1, Appendix I). Several mapped occurrences of '*Triodia sp. Robe River assemblages of mesas of the West Pilbara*' are located between approximately 16 km and 19 km south-west of the Mesa H survey area (Astron Environmental Services 2016b). The '*Four plant assemblages of the Wona Land System*' PEC is mapped as occurring approximately 21 km north-east of the Mesa H (Astron Environmental Services 2016b) survey area (Department of Parks and Wildlife 2015b).

The Parks and Wildlife TPFL (Department of Parks and Wildlife 2015c) and WAHerb (Department of Parks and Wildlife 2015e) database searches indicated that no species listed as Threatened have been recorded within 20 km of the Mesa H (Astron Environmental Services 2016b) survey area. The Parks and Wildlife TP List (Department of Parks and Wildlife 2015d), which is searched according to place names rather than coordinates, listed two Threatened species: *Lepidium catapycnon* T and *Thryptomene wittweri* T. Since receiving the TP List database search results, *L. catapycnon* has been removed from the Threatened flora list and is currently listed as P4 (Western Australian Government 2015). A review of recorded specimens of *T. wittweri* T, held by the WAHerb (Western Australian Herbarium 1998-2016), indicates that the closest occurrence of this species to the survey area is approximately 270 km to the south-east. In addition, this species has not been identified during previous surveys conducted within, or in close proximity to, the survey area (Astron Environmental Services 2011, 2016a, 2016b; Biota Environmental Sciences 2003, 2006a, 2011a, 2012).

Fourteen Priority flora species have been previously recorded within 20 km of the Mesa H (Astron Environmental Services 2016b) survey area (Table J.1, Appendix J) (Department of Parks and Wildlife 2015c, 2015d, 2015e, 2015f). Of these, two are P1, four are P2, six are P3 and two are P4 status. The pre-survey desktop assessment indicated that two of the listed Priority flora species were considered likely to occur within the riparian community survey area; a further six were considered to have the potential to occur (Table J.1, Appendix J).

4.1.1.1 Literature Review

Results of the literature review indicate that no TECs have been previously recorded within, or in the vicinity of, the survey area (Astron Environmental Services 2011, 2016a, 2016b; Biota Environmental Sciences 2003, 2006a, 2011a, 2012). Vegetation representing the PEC '*Triodia sp. Robe River assemblages of mesas of the West Pilbara*' was recorded within close proximity to the Robe River and adjacent to the riparian community survey area (Astron Environmental Services 2016a, 2016b) (Table 10). This PEC occurred in association with mesa landforms, where either *Acacia pruinocarpa* or *Acacia citrinoviridis* occurred in conjunction with *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3.

Results of the literature review identified eight currently listed Priority flora species as having been previously recorded within, or within close proximity to, the survey area: *Pentalepis trichodesmoides* subsp. *hispida* P2, *Eragrostis surreyana* P3, *Gymnanthera cunninghamii* P3, *Indigofera* sp. Bungaroo

Creek (S. van Leeuwen 4301) P3, *T.* sp. Robe River (M.E. Trudgen et al. 12367) P3, *Livistona alfredii* P4, *Ptilotus mollis* P4 and *Rhynchosia bungarensis* P4 (Table 10) (Astron Environmental Services 2016a, 2016b, 2016c; Biota Environmental Sciences 2003, 2006a, 2011a, 2012).

Of these species, *R. bungarensis* P4, was recorded in the greatest number of surveys, and species such as *P. trichodesmoides* subsp. *hispida* P2 and *P. mollis* P4 were recorded from non-riparian landforms (Astron Environmental Services 2016a, 2016b, 2016c; Biota Environmental Sciences 2003, 2006a, 2011a, 2012) (Table 10).

4.1.2 Environmentally Sensitive Areas

No ESAs occur within or adjacent to the survey area. The nearest ESA is the Duck Creek Gorge Area, located approximately 78 km south (Landgate 2016). The Millstream-Chichester National Park is the nearest conservation reserve to the survey area, located approximately 79 km to the north-east. The Murujuga National Park is approximately 120 km north and Karijini National Park is approximately 180 km south-east of the survey area.

Springs and pools of the Robe River are listed as 'Wetlands of Subregional Significance' in Kendrick (2001). These springs and pools occur from 40 km east of Pannawonica, downstream to North West Coastal Highway. The significant wetlands are described as 'running spring ecosystems with large deep permanent pools and consist of seasonal and irregular rivers and streams, and freshwater springs, oases and rock pools' (Kendrick 2001).

4.1.3 Terrestrial Fauna

The database searches and literature review results indicate that 318 vertebrate fauna have been previously recorded within 40 km of the survey area, including six amphibian species, 102 reptile species, 160 bird species (including one introduced bird species) and 50 mammal species (including 10 introduced mammal species) (Table K.1-K.4, Appendix K). Of these, 28 species are of conservation significance, including three reptile species, 16 bird species and nine mammal species. Of these, six species were considered to have a 'high' likelihood (inclusive of those previously recorded within the survey area), nine species were considered to have a 'moderate' likelihood and 13 were considered to have a 'low' likelihood of occurrence (Table L.1, Appendix L). This is based on their respective ecology, habitats considered likely to be present and any previous records from historic survey and database records.

4.1.3.1 Literature Review

Previous surveys undertaken for Rio Tinto in the vicinity of the survey area recorded 12 conservation significant vertebrate fauna species: Northern Quoll (*Dasyurus hallucatus),* Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*), Ghost Bat (*Macroderma gigas*), Western Pebble-mound Mouse (*Pseudomys chapmani*), Eastern Great Egret (*Ardea modesta*), Rainbow Bee-eater (*Merops ornatus*), Wood Sandpiper (*Tringa glareola*), Common Sandpiper (*Actitis hypoleucos*), Sharp-tailed Sandpiper (*Calidris acuminata*), Pilbara Olive Python (*Liasis olivaceus barroni*), Blind Snake (*Anilios ganei*) and Lined Soil-crevice Skink (*Notoscincus butleri*) (Table 11).

Table 11: Summary of literature review results from terrestrial fauna surveys conducted within the vicinity of the survey area.

Author (year)	Survey area size (ha)	Survey level	Survey timing	Survey effort	Conservation significant vertebrate fauna recorded
Astron (2011)	Mesa J Mine 78.63 ha	Level 1	June 2011	Desktop survey and site reconnaissance.	*Merops ornatus* (Rainbow Bee-eater)
Astron (2014)	Mesa H 2,582 ha	Level 1	October 2014	Targeted searches of suitable habitat, motion sensor cameras and SM2 acoustic bat call recorders were used to detect the presence of conservation significant fauna species.	*Dasyurus hallucatus* (Northern Quoll) *Rhinonicteris aurantia* (Pilbara Leaf-nosed Bat) *Macroderma gigas* (Ghost Bat) *Pseudomys chapmani* (Western Pebble-mound Mouse) *Ardea modesta* (Eastern Great Egret) *Merops ornatus* (Rainbow Bee-eater)
Astron (2016e)	Bungaroo 9,795 ha	Level 2 (dual phase)	May - June 2015 August 2015	Habitat assessments, eight trapping sites, avifauna censuses at each trapping site, foot traverses, targeted searches for both vertebrates and short range endemic (SRE) invertebrates, and the use of motion sensitive cameras and SM2BAT ultrasonic bat detectors.	*Dasyurus hallucatus* (Northern Quoll) *Liasis olivaceus barroni* (Pilbara Olive Python) *Rhinonicteris aurantia* (Pilbara Leaf-nosed Bat) *Macroderma gigas* (Ghost Bat) *Pseudomys chapmani* (Western Pebble-mound Mouse) *Notoscincus butleri* (Lined Soil-crevice Skink) *Anilios ganei* (Blind Snake) *Merops ornatus* (Rainbow Bee-eater)
Astron (2016f)	Middle Robe and East Deepdale 11,816 ha	Level 2 (dual phase)	June 2015 August 2015	Habitat assessments, 15 trapping sites, avifauna censuses at each trapping site, foot traverses, targeted searches for both vertebrates and SRE invertebrates, and the use of motion sensitive cameras and SM2BAT ultrasonic bat detectors.	*Dasyurus hallucatus* (Northern Quoll) *Liasis olivaceus barroni* (Pilbara Olive Python) *Rhinonicteris aurantia* (Pilbara Leaf-nosed Bat) *Macroderma gigas* (Ghost Bat) *Pseudomys chapmani* (Western Pebble-mound Mouse) *Notoscincus butleri* (Lined Soil-crevice Skink) *Ardea modesta* (Eastern Great Egret) *Merops ornatus* (Rainbow Bee-eater)

Author (year)	Survey area size (ha)	Survey level	Survey timing	Survey effort	Conservation significant vertebrate fauna recorded
Biologic (2014)	Yarraloola Size not stated	Level 1	December 2013	A Level 1 targeted survey for Northern Quolls, Pilbara Olive Pythons and Pilbara Leaf-nosed Bats.	*Dasyurus hallucatus* (Northern Quoll) *Liasis olivaceus barroni* (Pilbara Olive Python) *Pseudomys chapmani* (Western Pebble-mound Mouse) *Rhinonicteris aurantia* (Pilbara Leaf-nosed Bat) *Macroderma gigas* (Ghost Bat) *Merops ornatus* (Rainbow Bee-eater)
Biota (2005)	Mesa A and G, near Pannawonica 1,305 ha	Level 2 (single phase)	May 2004	Ten trapping sites utilising various combinations of pitfall traps (both PVC tubes and 20 L buckets), Elliott traps and/or funnel traps. Avifauna censuses at each trapping site and Anabat echolocation recordings.	*Dasyurus hallucatus* (Northern Quoll) *Macroderma gigas* (Ghost Bat)
Biota (2006b)	Mesa A Transport Corridor and Warramboo 7,045 ha	Level 2 (dual phase)	April - May 2005 July - August 2005	Ten trapping sites, including pits (buckets and PVC tubes), medium sized Elliotts and funnels. Harp traps targeting bat species, avifauna census at each trapping site and targeted searches for both vertebrates and SRE invertebrates.	*Notoscincus butleri* (Lined Soil-crevice Skink) *Macroderma gigas* (Ghost Bat) *Pseudomys chapmani* (Western Pebble-mound Mouse)

4.1.4 Aquatic Fauna

Numerous aquatic ecological surveys have been undertaken within the vicinity of the survey area and were used for the desktop assessment and literature review. A more comprehensive description of the aquatic surveys and studies are provided in Appendix A. A summary of previously recorded species of conservation significance and/or scientific interest are presented in Table 12.

Table 12: Summary of literature review results from aquatic surveys conducted within the vicinity of the survey area.

Species	Common name	Conservation / scientific value	Occurrence within 100 km of survey area	Likelihood of occurrence within the survey area	Occurrence elsewhere
Microinvertebrates					
Lecane noobjupi	Rotifer	WA endemic	Nyeetbury Spring, Red Hill Creek	High, in surface waters	Weeli Wolli Creek, Marillana Creek, Coondiner Creek, Mindy Mindy Creek, Kalgan Creek and Un-named Creek, DeGrey River. Also in south-west Western Australia
Paracyclops sp. 6	Copepod (micro-crustacean)	Pilbara endemic	Chalyarn Pool	High, in surface waters	20+ locations Pilbara-wide
Vestalenula matildae	Ostracod (micro-crustacean)	Pilbara endemic	Chalyarn Pool	High, in surface waters	Various systems of the Ashburton River, DeGrey River, Fortescue River and Sherlock River.
Hyporheos					
Paramelitidae spp.	Stygobitic amphipods	Stygobitic SREs	Yalleen Pool, Red Hill Creek, Mungarathoona Creek.	High in ground-waters and hyporheos	Unknown given family level identification
Melitidae spp.	Stygobitic amphipods	Stygobitic SREs	Bores across the Robe River catchment area	High in ground-waters; Low-moderate in hyporheos	Unknown given family level identification
Haptolana yarraloola	Stygobitic isopod	Stygobitic SRE	Bores in the lower Robe River catchment area – Mesa A/ Warramboo/ Yarraloola	Low	Recently described species; known only from Mesa A/ Warramboo/ Yarraloola bores
Kagalana tonde	Stygobitic isopod	Stygobitic SRE	Bores in the lower Robe River catchment area – Mesa A/ Warramboo/ Yarraloola	Low	Recently described genus and species; elsewhere known from Cane River and Hardey River catchments

Species	Common name	Conservation / scientific value	Occurrence within 100 km of survey area	Likelihood of occurrence within the survey area	Occurrence elsewhere
Pilbarophreatoicus platyarthricus	Stygobitic isopod	Stygobitic SRE	Chalyarn Pool, Nyeetbury Spring, bores in the Robe River catchment area	High in ground-water and hyporheos	Weeli Wolli Creek, Coondiner Creek, Bobswim Pool (Ashburton River)
Pygolabis sp.	Stygobitic isopod	Stygobitic SRE	One undescribed species known from the Robe River catchment	High in ground-water and hyporheos	Uncertain. Members of this genus restricted to either Fortescue, Ashburton or Robe catchment groundwater and hyporheos
Tainisopus sp.	Stygobitic isopod	Stygobitic SRE	Nyeetbury Spring	Low-moderate; only known from Nyeetbury Spring hyporheos	Unknown given genus level identification
Parabathynellidae spp.	Stygobitic syncarids	Stygobitic SREs	Unknown given genus level identification	High in ground-waters; Low-moderate in hyporheos	Unknown given genus level identification
Macroinvertebrates					
Hemicordulia koomina	Pilbara Emerald Dragonfly	IUCN, Near Threatened	Robe River pools, Red Hill Creek	High in surface waters	Fortescue River, Coondiner Creek; now known to be widespread throughout the Pilbara, though infrequently collected
Eurysticta coolawanyah	Pilbara Pin Damselfly	IUCN, Near Threatened	Chalyarn Pool, Robe River pools, Yalleen Pool	High in surface waters	Ashburton River (Bobswim Pool); Kalgan Creek, Coondiner Creek, Fortescue River; now known to be widespread throughout the Pilbara, though infrequently collected
Ictinogomphus dobsoni	Pilbara Tiger Dragonfly	Pilbara endemic; restricted distribution	Chalyarn Pool, Robe River pools, Red Hill Creek	High in surface waters	Fortescue, Ashburton, Yule, DeGrey and Sherlock Rivers
Nannophlebia injibandi	Pilbara Archtail Dragonfly	Pilbara endemic; restricted distribution	Robe River pools, Red Hill Creek	Low-Moderate in surface waters	Fortescue River catchment, but uncommonly collected
Agriocnemis kunjina	Pilbara Wisp Damselfly	Pilbara endemic; restricted distribution	Robe River Pools, Yalleen Pool	Low-Moderate in surface waters	Millstream, Harding River, Tanberry Creek; rarely collected

Species	Common name	Conservation / scientific value	Occurrence within 100 km of survey area	Likelihood of occurrence within the survey area	Occurrence elsewhere
Haliplus halsei	Aquatic beetle	Pilbara endemic; relatively new to science	Chalyarn Pool, Myannore Creek	Low-Moderate in surface waters	Uncommonly collected from ephemeral systems and claypans, e.g. the Fortescue Marsh and Coondiner Pool
Haliplus pilbaraensis	Aquatic beetle	Pilbara endemic; relatively new to science	Red Hill Creek	Low-Moderate in surface waters	Uncommonly collected from ephemeral systems and claypans, e.g. the Fortescue Marsh and Coondiner Pool
Sternopriscus pilbaraensis	Diving beetle	Pilbara endemic; restricted distribution	Red Hill Creek	Moderate in surface waters	A range of systems across the Pilbara, fairly commonly collected
Tiporus tambreyi	Diving beetle	Pilbara endemic; restricted distribution	Chalyarn Pool, Robe River pools, Red Hill Creek	Moderate-High in surface waters	A range of systems across the Pilbara, very commonly collected
Tiporus lachlani	Diving beetle	Pilbara endemic; restricted distribution	Red Hill Creek	Low-Moderate in surface waters	A range of systems across the Pilbara, infrequently collected
Laccobius billi	Aquatic beetle	Pilbara endemic; restricted distribution	Mungarathoona Creek, Red Hill Creek	Low-Moderate in surface waters	Yule River and Fortescue River
Fish					
Leiopotherapon aheneus	Fortescue Grunter	IUCN Near Threatened; P4	Robe River pools, Mungarathoona Creek, Red Hill Creek	High in surface waters	Fortescue River (below Fortescue Marsh); Ashburton River

4.2 Field Survey

4.2.1 Vegetation

There were five vegetation associations described within the survey area, which are summarised in Table 13. Some modifications were made to the vegetation association boundaries and descriptions from Astron (2016b) during this assessment to assist in amalgamating the vegetation associations between the previous and current survey areas. There was 16.9 ha of disturbance within the survey area. Vegetation association mapping is provided in Figure M.1 (Appendix M) and the data collected from each quadrat is presented in Appendix N.

Table 13: Vegetation associations recorded for the survey area.

Vegetation associations and descriptions	Sites	Vegetation condition	Total area (ha)	Representative photograph
Es *Euphorbia schultzii* scattered herbs **Associated species:** *Acacia trachycarpa, Petalostylis labicheoides, Hybanthus aurantiacus, Argemone ochroleuca* subsp. *ochroleuca*	MH388, MH394, MH397, MH398, E09 (Astron Environmental Services 2016a)	Very good - Excellent	114.2	 **Plate 1: Vegetation representing Es – facing south-east from GPS co-ordinate 411162mE and 7594904mN (MGA Zone 50).**

Vegetation associations and descriptions	Sites	Vegetation condition	Total area (ha)	Representative photograph
AtrPl *Acacia trachycarpa*, *Petalostylis labicheoides* tall open scrub **Associated species:** *Acacia ancistrocarpa, A. bivenosa, A. pyrifolia*, *Euphorbia schultzii, Ptilotus astrolasius, Tephrosia rosea* var. Fortescue Creeks (M.I.H Brooker 2186), *Triodia wiseana*, *T. epactia*	MH389, MH203, MH321, MH354 (Astron Environmental Services 2016a)	Very good - Excellent	796.1	 **Plate 2: Vegetation representing AtrPl – facing south-east from GPS co-ordinate 410478mE and 7594630mN (MGA Zone 50).**

4.2.1.1 Vegetation Condition

Vegetation in the survey area ranged from 'poor' to 'excellent' (Trudgen 1988) condition (Table 14; Figure O.1, Appendix O). Indications of multiple disturbances such as pastoral and mining activity, flood waters uprooting mature trees (Plate 6) and extensive vehicle tracks throughout the open shingle landform were evident. Weed proliferation was extensive in areas of deeper soils, and often in conjunction with evidence of cattle grazing and mining activities. Less than 17 ha (1% of the survey area) was mapped as 'disturbed'.

Occasional patches of mature *Melaleuca argentea* and *Eucalyptus camaldulensis* subsp. *refulgens* trees were noted to be in a deteriorating condition. Evidence of fire in the vicinity of a permanent water hole approximately 9 km downstream of Mesa J may be attributed to the stressed vegetation (Plate 7); however, there was no indication of fire in a separate location of unhealthy trees that was 1 km further downstream.

Plate 6: Debris and uprooted trees from flood waters in the main channel.

Plate 7: Stressed trees, exhibiting fire damage within the Robe River.

Table 14: Vegetation condition recorded for the survey area, based on the Trudgen (1988) scale.

Vegetation condition	Total mapped area within the survey area (ha)
Excellent	124.2
Very Good	1,169.5
Good	717.2
Poor	100.1
Disturbed	16.9

4.2.1.2 Conservation Significance of Vegetation

No TECs or PECs were recorded in the survey area.

Vegetation which may be considered indicator species for a GDE was consistently recorded within the survey area. *Melaleuca argentea* and *E. camaldulensis* subsp. *refulgens* are the dominant upper stratum species of MaEcCv and while *E. camaldulensis* subsp. *refulgens* and/or *E. victrix* are the dominant upper stratum species of EcEvAtrApyPlTw and EvAtrTwCspp. *Melaleuca argentea* is considered an obligate phreatophyte and therefore highly dependent on groundwater, while *E. camaldulensis* subsp. *refulgens* and *E. victrix* are facultative phreatophytes and use groundwater

opportunistically during periods of drought or some life stages. Vegetation association MaEcCv is likely to be most reliant on groundwater.

4.2.2 Flora

There were 124 plant species from 37 families and 82 genera recorded in the survey area. The dominant plant family was Fabaceae, with 23 species confirmed, while *Acacia* was the most frequently recorded genus (Table 15). A species list and a site by species matrix for the survey area are presented, respectively, in Tables P.1 and P.3 (Appendix P).

Table 15: Families and genera with the greatest number of taxa in the survey area.

Family	Number of taxa
Fabaceae	23
Poaceae	20
Malvaceae	17
Genus	**Number of taxa**
Acacia	9
Ptilotus	8
Euphorbia	5

4.2.2.1 Conservation Significant Flora

No State or Commonwealth listed Threatened flora were recorded, or are likely to occur, within the survey area.

Targeted searches in potential habitat within the survey area identified three state-listed Priority flora species (Table 16). Detailed location information and abundance data for each recorded occurrence, along with representative photographs of each species, are presented in Tables Q.1-Q.2 (Appendix Q). Conservation significant flora locations, for both this survey and previous surveys, are also mapped in Figure Q.1.A (Appendix Q).

Triodia sp. Robe River (M.E. Trudgen et al. MET 12367) P3 was recorded at three locations within the survey area. Typically, *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 occurs along rocky slopes and crests of hills, occasionally also occurring within rocky drainage gullies. *Triodia* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 has previously been recorded in close proximity to the survey area (Biota Environmental Sciences 2003, 2011a).

One individual of *L. alfredii* P4 (Millstream Fan Palm) was recorded in a broad section of the Robe River, during the Middle Robe and East Deepdale survey (Astron Environmental Services 2016a). *Livistona alfredii* P4 has not been previously recorded within a 20 km radius of the survey area (Astron Environmental Services 2011; Biota Environmental Sciences 2003, 2006a, 2011a, 2012; Department of Parks and Wildlife 2015c, 2015d, 2015e).

Rhynchosia bungarensis P4 was recorded in the survey area, typically occurring in the Robe River. *Rhynchosia bungarensis* P4 was generally recorded from densely shaded vegetation in the river channels, under *E. camaldulensis* subsp. *refulgens* and *M. argentea* woodlands and forests. *Rhynchosia bungarensis* P4 has previously been recorded within the survey area and also adjacent to and in close proximity to the survey area (Biota Environmental Sciences 2003, 2006a, 2011a).

Table 16: Conservation significant flora recorded in the survey area.

Species	Vegetation association/s	Source data		
		Astron 2016a	Astron 2016b	Astron 2016c
Triodia sp. Robe River (M.E. Trudgen et al. MET 12367) P3	MaEcCv, EvAtrTwCspp	✓	✓	
Livistona alfredii P4	EcEvAtrApyPlTw	✓		
Rhynchosia bungarensis P4	MaEcCv, AtrPl, Es, EcEvAtrApyPlTw	✓	✓	✓

4.2.2.2 *Post-survey Likelihood of Occurrence of Conservation Significant Flora*

Following the surveys, and with greater understanding of the soils and habitats of the survey area, four priority flora species, *Euphorbia australis* var. *glabra* P2, *Stylidium weeliwolli* P2, *E. surreyana* P3 and *I.* sp. Bungaroo Creek (S. van Leeuwen 4301) P3 are considered to have potential to occur but were not recorded. These species have been previously recorded in close proximity to the survey area and suitable habitat for all species was identified within the survey area. None of these species would be restricted to the survey area if present, as indicated by the voucher records listed with the WAHerb (Western Australian Herbarium 1998-2016). Survey effort, as shown by tracklog traverses within the survey area, is presented in Figure R.1 (Appendix R).

4.2.2.3 *Introduced Flora*

Weed diversity in the survey area is considered high with 23 weed species recorded. Species and abundance details are summarised in Table 17.

**Argemone ochroleuca* subsp. *ochroleuca* (Mexican Poppy) is listed as a declared pest under the BAM Act, however it is excluded for the Shire of Ashburton (Department of Agriculture and Food Western Australia 2016). The remaining recorded weeds are not listed as declared pests under the BAM Act, or as a WoNS (Australian Weeds Committee 2012). The recorded locations within the survey area and a description of each weed are presented in Tables Q.3 and Q.4 (Appendix Q).

Table 17: Introduced flora species (weeds) recorded in the survey area.

**Sonchus oleraceus* (Common Sowthistle)	Asteraceae	✓	✓	✓
**Vachellia farnesiana* (Mimosa Bush)	Fabaceae	✓	✓	✓

4.2.3 Fauna

4.2.3.1 Fauna Habitats

Two broad fauna habitat types were recorded in the survey area: Riverine and Drainage Line. The habitats are described in Table 18 and mapping is presented in Figure H.1 (Appendix H). Habitat assessments undertaken during the survey are detailed in Table H.1 (Appendix H).

A significant level of disturbance was recorded during the fauna survey; tracks, pastoralism and weed infestation. The majority of Drainage Line and Riverine habitats were generally in 'good' condition due to weed infestation spread through pastoralism; some areas were also heavily impacted from grazing and therefore the introduction and spread of Buffel Grass (Thompson and Thompson 2010).

Riverine habitat is considered to be of high importance to fauna species providing a range of ecological values to a wide suite of species. This habitat type in the survey area was often narrow linear isolated pockets of riparian vegetation which is usually denser, taller and more diverse than the adjacent Drainage Line habitat. The vegetation was complex and diverse and provided a range of micro niches for fauna species to exploit such as shelter and foraging. There were also a significant number of permanent and semi-permanent water bodies providing drinking opportunities to a range of species along with attracting prey for predators. This habitat supports conservation listed fauna species such as the Rainbow Bee-eater and Fortescue Grunter and acts as foraging sites for Ghost Bats and Pilbara Leaf-nosed Bats.

Thirteen permanent pools (approximately 16.4 ha) were recorded within the survey area in the Riverine habitat (Figure H.1, Table H.2, Appendix H). The area of these pools expands during times of inundation and periodically flood with the advent of cyclones. Due to the dry conditions leading up

to the survey, surface water had contracted back to these permanent pools, some of which are groundwater fed (Dobbs and Davies 2009). These pools are considered a significant fauna habitat due to the refuge they provide to fish, amphibians and water fowl during dry times and the dense vegetation they support.

Drainage Line habitat is a commonly recorded habitat for the Pilbara region and considered to be of low to moderate value to a wide spectrum of fauna species. The Drainage Line habitat typically exhibits a moderate diversity of microhabitats, with some tree hollows and woody debris (logs and leaf litter). However, within the survey area this habitat was generally devoid of vegetation when compared to Riverine, with less dense and less complex vegetation associations. There were some locations with water bodies, albeit less significant and less permanent, and would likely be seasonally inundated during large rainfall events only. Conservation listed species including the Rainbow Bee-eater and Lined Soil-crevice Skink may occur in this habitat.

Table 18: Terrestrial fauna habitat types recorded in the survey area.

Habitat type	Extent in survey area (proportion)	Broad habitat description	Vegetation description	Habitat condition	Value (broad faunal assemblage and MNES species)	Representative photos	
Riverine	397.5 ha (18.7%)	Densely vegetated riparian zones of the Robe River often with permanent and semi-permanent water bodies on stony soils	*Eucalyptus camaldulensis* and *Melaleuca argentea* open forest over *Acacia* tall open shrubland over mixed open herbland and open hummock grassland.	Good to High Quality	High value to a wide spectrum of fauna species that are likely to reside in Riverine habitats. Moderate value to target MNES species as they are likely to traverse and forage within this habitat type.		
Drainage Line	1,713.6 ha (80.5%)	Broad open valley floor of the Robe River on stony soils	*Eucalyptus camaldulensis* or *Corymbia hamersleyana* woodland over *Acacia* tall open shrubland over mixed open herbland and *Triodia wiseana* hummock grassland.	Disturbed to Good Quality	Moderate value to a wide spectrum of fauna species that are likely to reside in Drainage habitats. Low value to target MNES species as they do not provide significant refugia or shelter.		

Habitat type	Extent in survey area (proportion)	Broad habitat description	Vegetation description	Habitat condition	Value (broad faunal assemblage and MNES species)	Representative photos	
Disturbed	16.9 ha (0.8%)	Cleared areas from mining and pastoralism activities	N/A	Highly Degraded	Little value as fauna habitat.	No picture available	No picture available

4.2.4 Terrestrial Vertebrate Fauna Species

Thirty-one terrestrial vertebrate fauna species, comprising two reptiles and 29 bird species were recorded within the survey area (Table 19). This includes one conservation significant species; the Rainbow Bee-eater which is listed as Migratory under the EPBC Act and Schedule 5 under the WC Act (Appendix L).

Table 19: Terrestrial fauna species recorded during the survey.

Species name	Common name
Reptiles	
Ctenophorus caudicinctus	Ring-tailed Rock Dragon
Heteronotia binoei	Bynoe's Gecko
Birds	
Anas superciliosa	Pacific Black Duck
Aythya australis	Hardhead
Tachybaptus novaehollandiae	Australasian Grebe
Phaps chalcoptera	Common Bronzewing
Eurostopodus argus	Spotted Nightjar
Phalacrocorax varius	Pied Cormorant
Pelecanus conspicillatus	Australian Pelican
Ardea novaehollandiae	White-faced Heron
Ardea pacifica	White-necked Heron
Haliastur sphenurus	Whistling Kite
Fulica atra	Eurasian Coot
Platycercus zonarius zonarius	Australian Ringneck
Cacatua sanguinea	Little Corella
Chrysococcyx basalis	Horsfield's Bronze Cuckoo
Merops ornatus	Rainbow Bee-eater
Malurus lamberti assimilis	Variegated Fairy-wren
Gerygone fusca	Western Gerygone
Smicrornis brevirostris	Weebill
Ptilotula penicillatus	White-plumed Honeyeater
Lichmera indistincta	Brown Honeyeater
Pomatostomus temporalis	Grey-crowned Babbler
Colluricincla harmonica	Grey Shrike-thrush
Pachycephala rufiventris	Rufous Whistler
Rhipidura albiscapa	Grey Fantail
Rhipidura leucophrys leucophrys	Willie Wagtail
Grallina cyanoleuca	Magpie-lark
Corvus orru	Torresian Crow
Acrocephalus australis	Australian Reed Warbler
Neochmia ruficauda subclarescens	Star Finch (Western)

4.2.5 Conservation Significant Terrestrial Vertebrate Fauna Recorded

Rainbow Bee-eater (*Merops ornatus*)

The Rainbow Bee-eater (Mi; S5) is one of the most common and widespread birds in Australia and was a commonly recorded species during bioregional surveys in the Pilbara (Burbidge, Johnstone, and Pearson 2010). The species winters from the Gascoyne north to Indonesia, moving south mainly in late September and early October and north from February to April (Johnstone and Storr 1998). Rainbow Bee-eaters tend to prefer lightly wooded, preferably sandy country near water (Johnstone and Storr 1998).

The Rainbow Bee-eater was recorded during the field survey at five locations throughout the survey area in both the Riverine and Drainage Line habitats (Figure L.1, Appendix L). Sixteen previous records of this species were made within the survey area (Astron Environmental Services 2014, 2016d, 2016f; Biota Environmental Sciences 2011b; Department of Parks and Wildlife 2015g; ecologia Environment 2013) and numerous records exist in the vicinity of the survey area (Astron Environmental Services 2011, 2016e, 2016f; Biologic Environmental Survey 2014; Biota Environmental Sciences 2010a; ecologia Environment 2013).

4.2.5.1 Conservation Listed Species Potentially Occurring in the Survey Area

Five species, the Pilbara Olive Python (Vu; S3), Eastern Great Egret (Mi; S5), Northern Quoll (En; S2), Ghost Bat (Vu; S3) and Pilbara Leaf-nosed Bat (Vu; S3) have been previously recorded in the survey area and were considered to have a high likelihood of occurring (Table L.1, Appendix L).

Pilbara Olive Python (*Liasis olivaceus barroni*)

The Pilbara Olive Python (VU; S3) prefers escarpments, deep gorges, water holes and rock piles associated with permanent pools in rocky areas in the ranges of the Pilbara region (Pearson 1993; Wilson and Swan 2010). Microhabitat preferences of the Pilbara Olive Python are under rock piles, on top of rocks or under spinifex (Tutt et al. 2004). Individuals spend the cooler winter months within caves and rock crevices away from water sources. In the warmer summer months the pythons are found to move around widely, usually in close proximity to water and rock outcrops (Wilson and Swan 2010). A population is known to exist along the Robe River near Pannawonica (Biota Environmental Sciences 2007). There have been three Pilbara Olive Pythons previously recorded within the survey area in the Riverine habitat (Astron Environmental Services 2016d, 2016f) (Figure L.1, Appendix L). This species occurs within the Riverine habitats particularly in the sites that contain semi-permanent and permanent water. The Pilbara Olive Python has been previously recorded in the vicinity of the survey area (Astron Environmental Services 2016e, 2016f; Biologic Environmental Survey 2014).

Eastern Great Egret (*Ardea modesta*)

The Eastern Great Egret (Mi; S5) is an inland wetland specialist often seen wading in a range of wetlands from lakes, rivers and swamps to estuaries (Johnstone and Storr 1998). Eastern Great Egrets can be seen alone or in small flocks, often with other egret species, and roost at night in small groups. This species has been previously recorded within the survey area in the Riverine habitat (Astron Environmental Services 2014) and in the vicinity of the survey area (Astron Environmental Services 2014, 2016f; ecologia Environment 2013) (Figure L.1, Appendix L). The Eastern Great Egret is likely to be present at permanent pools within the Riverine and Drainage Line habitats of the survey area.

Northern Quoll (*Dasyurus hallucatus*)

The Northern Quoll (EN; S2) occurs in a variety of habitats (Oakwood 2008) but is commonly found in open lowland savannah forest and rocky escarpments. Rocky areas are a particularly important zone for quolls in the Pilbara as these areas retain water and provide a diversity of microhabitats. These areas also tend to have greater floristic diversity and productivity resulting in greater prey density compared to non-rocky areas. These rocky areas also provide refuge from feral cats, fire and livestock (Hill and Ward 2010) and provide breeding potential (Department of the Environment 2013).

The Northern Quoll has previously been recorded for the survey area and within the general vicinity (Astron Environmental Services 2014, 2016d, 2016e, 2016f; Biologic Environmental Survey 2014; Biota Environmental Sciences 2005, 2007, 2011b; ecologia Environment 2013). Within the survey area the Northern Quoll has been recorded at nine locations, in the Riverine habitat type (Astron Environmental Services 2016d, 2016f) (Figure L.1, Appendix L). The Riverine and Drainage Line habitats of the survey area do not contain the rocky habitats this species requires for its den/shelter sites. However, these habitats are likely to be used as foraging sites, in particular when in close proximity to breakaways or gorges.

Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*)

Pilbara Leaf-nosed Bats (VU; S3) are known to require deep caves characterised by high levels of humidity and stable temperatures (Churchill 2008). This is a result of their limited ability to conserve heat and water (Armstrong 2001; Churchill 1991). Caves deep enough to create this environment are relatively uncommon in the Pilbara, with only 20 to 25 roost sites being known (R. Bullen 2014, pers. comm. 20 Oct 2014). Foraging habitat for the Pilbara Leaf-nosed Bat is diverse and includes riparian vegetation, hummock grassland, and sparse tree and shrub savannah (Duncan, Baker, and Montgomery 1999). Pilbara Leaf-nosed Bats have also been recorded flying over small watercourses amongst granite boulder terrain, over pools and low shrubs in ironstone gorges, and above low shrubs and around pools in gravelly watercourses with *Melaleuca leucadendron*, such as in Barlee Range Nature Reserve (Armstrong 2001). In the Pilbara this bat species has been observed in *Triodia* hummock grasslands covering low rolling hills and shallow gullies, with scattered *E. camaldulensis* along the creeks (Armstrong 2001; Churchill 1991).

The Pilbara Leaf-nosed Bat has previously been recorded in the survey area at seven different locations (Astron Environmental Services 2014, 2016f) (Figure L.1, Appendix L) and within the general vicinity (Astron Environmental Services 2014, 2016d, 2016e, 2016f; Biota Environmental Sciences 2009, 2010a; ecologia Environment 2013). The habitats of the survey area lack the caves required as roost sites for this species. The complex vegetation of the Riverine and Drainage Line habitats provide ideal foraging habitat, especially in areas surrounding permanent water sources.

Ghost Bat (*Macroderma gigas*)

The preferred habitat of Ghost Bats (VU; S3) is considered to be rocky gorges and breakaways that support caves and crevices used as maternity roosts. The Ghost Bat uses different natural formations for various purposes and for groups to persist they generally require habitats that provide:

- a selection of roosting opportunities with night roosts or feeding sites, day roosts and at least one deep cave with characteristics of a maternity roost
- nearby gullies and gorges with vegetation of vertical complexity (diverse vegetation heights and density) and presence of water that would attract prey species

- a productive foraging area within a 5 km to 10 km radius, usually including a good quality riparian drainage line.

The Ghost Bat has been previously recorded within the vicinity of the survey area from past fauna surveys (Astron Environmental Services 2014, 2016e, 2016f; Biologic Environmental Survey 2014; Biota Environmental Sciences 2005, 2006b, 2009, 2010a, 2011b). Within the survey area Astron (2014) has previously recorded the presence of Ghost Bats at a single location (Figure L.1, Appendix L). The habitats of the survey area lack the caves required as roost sites for this species, although the complex vegetation of the Riverine and Drainage Line habitats provides ideal foraging habitat, especially in areas surrounding permanent water sources.

Other Potential Conservation Significant Species

Of the potentially occurring conservation significant fauna species, nine species were not found in the survey area but were all considered to have a moderate likelihood of occurrence: Fork-tailed Swift (Mi; S5), Cattle Egret (Mi; S5), Letter-winged Kite (P4), Australian Painted Snipe (EN; S2), Common Sandpiper (Mi; S5), Sharp-tailed Sandpiper (Mi; S5), Wood Sandpiper (Mi; S5), Common Greenshank (Mi; S5) and Oriental Pratincole (Mi; S5) (Table L.1, Appendix L). Suitable habitat is present for these species within the survey area; however, these species are either seasonal migrants and/or only present at certain times of the year or cryptic species such as Australian Painted Snipe and Oriental Pratincole, making individuals difficult to record during fauna surveys.

An additional 13 species not found in the survey area were considered to have a low likelihood of occurrence due to lack of suitable habitats (Table L.1, Appendix L).

4.3 Aquatic Ecosystem

This section contains a summary of results from the aquatic baseline survey completed by WRM. For more detail on this component refer to Appendix A.

4.3.1 Water Quality

Water quality was highly variable amongst sites, with salinity levels ranging from fresh (592 µS/cm) to brackish (1,700 µS/cm), pH from circum-neutral (6.9) to slightly alkaline (7.9) and dissolved oxygen from hypoxic (14.5%) to supersaturated (134.9%). There were no obvious longitudinal gradients in water quality parameters upstream or downstream of the Mesa H development.

Exceedances of ANZECC/ARMCANZ (2000) default TVs for the protection of 95% of species in slightly-moderately disturbed tropical northern Australian systems were recorded for nitrogen nutrients (N-total, N-NO_x and N-NH_3) at most sites upstream and downstream of the Jimmawurrada-Robe confluence. The majority of heavy metal analytes, with the exception of dissolved zinc at RRU5 and RRD3, did not exceed ANZECC/ARMCANZ (2000) default 95% TV s in the survey area.

4.3.2 Microinvertebrates

A total of 81 microinvertebrate taxa were recorded from the survey area, of which 46 were present at potentially exposed sites downstream of the Jimmawurrada-Robe confluence, and 69 were recorded at upstream reference sites. There were no significant differences in total mean microinvertebrate taxa richness between reference and potentially exposed sites, nor was there any significant difference in richness of any of the major microinvertebrate groups (protists, rotifers, micro-crustaceans) between these reaches.

One microinvertebrate species listed for conservation significance, the calanoid copepod *Eodiaptomus lumholtzi* (International Union for Conservation of Nature (IUCN) Vulnerable), was recorded at potentially exposed site RRD6.

4.3.3 Hyporheic Fauna

A total of 59 taxa were recorded from hyporheic samples, the majority of which were species not specially adapted to groundwater environments (stygoxene). Of these 59 taxa, 8% were considered stygobitic (obligate groundwater inhabitants), 31% occasional hyporheic stygophiles (species that use the hyporheic zone seasonally or during early life history stages), and 2% possible hyporheic taxa.

Stygobitic taxa collected included the amphipod *Nedsia* sp., the thermosbaenacean *Halosbaena tulki*, and the ostracods *Candonopsis* cf. *tenuis* and *Vestalenula marmonieri*. Of these, *Nedsia* sp. is considered a SRE species. *Nedsia* sp. was collected from sites potentially exposed to dewatering discharge (RRD1 – 4), as well as upstream reference sites (RRU3, RRU4 & RRU6).

4.3.4 Macroinvertebrates

A total of 148 macroinvertebrate taxa were recorded from surface waters (117 from upstream reference sites, and 116 from downstream potentially exposed sites). One macroinvertebrate species listed for conservation significance, the Pilbara Pin Damselfly *Eurysticta coolawanyah* (IUCN Near Threatened), was recorded at potentially exposed downstream sites RRD3 and RRD4.

4.3.5 Fish

A total of 3,515 individual fish, representing 11 species, were captured, measured and released in the survey area. True freshwater species included Western Rainbowfish, Spangled Perch, Pilbara Tandan (Eel-tailed Catfish), Fortescue Grunter, Barred Grunter, Terapontidae (Grunter) hybrids and Bony Bream. Estuarine/marine vagrant fish species included Milkfish, Tarpon/Ox-eye Herring, Mullet and Banded Scat/Striped Butterfish, the majority of which were recorded at the downstream reach. The conservation listed Fortescue Grunter (*Leiopotherapon aheneus*; IUCN Lower Risk/Near Threatened; P4) was the second most abundant fish species of the survey area, recorded at all sites both upstream and downstream of the proposed Mesa H development.

4.3.6 Aquatic Species of Conservation Significance

During the aquatic survey, four species of conservation significance were recorded in the survey area. These records are summarised in Table 20 and the locations shown in Appendix A.

Table 20: Aquatic fauna species of conservation significance recorded during the survey.

Species	Common name	Conservation Value	Occurrence within the Mesa H survey area	Occurrence elsewhere
Microinvertebrates				
Eodiaptomus lumholtzi	Calanoid copepod	IUCN Vulnerable	RRD6	Koodaderi Spring, Homestead Tributary, Mindy Mindy Creek, Cane River, Northern Territory and Queensland
Stygobitic/SRE invertebrates				
Nedsia spp.	Stygobitic amphipod	Potential short range endemic (data deficient)	RRD1 – 4, RRU3, RRU4 and RRU5	Uncertain, possibly bores within the Yarraloola area
Macroinvertebrates				
Eurysticta coolawanyah	Pilbara Pin Damselfly	IUCN Near Threatened, Pilbara endemic	RRD3 and RRD4	Widespread throughout the Pilbara, though infrequently collected
Fish				
Leiopotherapon aheneus	Fortescue Grunter	IUCN Near Threatened, P4, Pilbara endemic	All sites	Robe River catchment, Fortescue River (below Fortescue Marsh); Ashburton River

5 Discussion

5.1 Overview of Survey Area

The Robe River supports extensive woodlands of *M. argentea* and *E. camaldulensis* subsp. *refulgens* (River Red Gum) over sedges in the main channels, and is surrounded by sparely vegetated shingle beds and tall shrublands of *Acacia trachycarpa* and *Petalostylis labicheoides*. Tributaries of the river exhibited deeper soils supporting higher vegetation density at the shrub and grass stratum. *Eucalyptus camaldulensis* subsp. *refulgens* and *E. victrix* woodlands, mixed *Acacia* shrubs and **C. ciliaris* and **C. setiger* tussock grasses were common to these drainage lines which flow into the Robe River.

5.2 Vegetation

Five vegetation associations were mapped within the survey area. No vegetation community that represent a Commonwealth or State listed TEC or PEC was recorded within the survey area.

The majority of vegetation within the survey area was considered to be in 'very good' condition, but ranged from 'poor to 'excellent'. There was a relatively high diversity and abundance of weeds, although this is typical of drainage systems in the Pilbara bioregion. Vegetation of the Robe River typically occurs on shingle rock and occasionally soft sand where weed species such as **A. ochroleuca* subsp. *ochroleuca* (Mexican Poppy), **Cenchrus* species (spp.) (Buffel and Birdwood Grasses), and **Passiflora foetida* subsp. *hispida* (Stinking Passion Flower) contribute to a decline in vegetation condition.

A number of permanent and semi-permanent pools (Plate 8 and 9) occur in the survey area and are typically fringed by vegetation association EcMaCv dominated by *M. argentea* and *E. camaldulensis* var. *refulgens*. These vegetation associations are consistent with the vegetation that typically occurs along minor and major channels within the River land system. The River land system accounts for 2.3% of the Pilbara, and the river channels constitute 20% of this area (van Vreeswyk et al. 2004). Vegetation association EcMaCv is considered a GDE due to the dominant species being *M. argentea* and *E. camaldulensis* var. *refulgens*. *Melaleuca argentea* and *E. camaldulensis* var. *refulgens*, and therefore the vegetation they occur within, may be sensitive to changes in water depth and availability.

Plate 8: Permanent water fringed by *Melaleuca argentea*.

Plate 9: Permanent water supporting *Typha domingensis*.

5.3 Flora

The suite of flora species recorded was considered typical of what may be expected in the area (Beard 1975; Payne, Mitchell, and Holman 1988). Rainfall in the weeks preceding four of the seven field surveys informing this assessment was below average. It is likely that some annual and herbaceous species would have been more widespread but were not observed during the below average seasonal conditions experienced during some surveys. Despite this, specimens generally had adequate material to allow for confident identification.

Areas considered 'likely' or 'potential' habitat for Threatened or Priority flora were targeted and searched. Three Priority flora species were recorded within the survey area: *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3, *L. alfredii* P4 and *R. bungarensis* P4.

Occasional small clusters of *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 were recorded in the survey area. These were generally the outer extent of a larger population that extended into the riparian zone beyond its favoured habitat of rocky slopes, hillcrests and ledges of mesas. Thirty-eight records of *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 are listed at the WAHerb, with a known range of approximately 175 km (Western Australian Herbarium 1998-2016). Rio Tinto holds 3,443 records consisting of more than 238,000 *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 individuals, with a geographical distribution spanning from Mesa A in the west to Mettawandy, a range of approximately 150 km (Rio Tinto Iron Ore 2016b).

One *L. alfredii* P4 (Millstream Fan Palm) individual was recorded within the Robe River in the Middle Robe and East Deepdale survey area (Astron Environmental Services 2016a). There is no other record of this species in close proximity to the survey area (Astron Environmental Services 2011; Biota Environmental Sciences 2003, 2006a, 2011a, 2012; Department of Parks and Wildlife 2015d, 2016a). There are 13 vouchered specimens for this species at the WAHerb (Western Australian Herbarium 1998-2016), the majority of which are associated with the Fortescue River in the Millstream Chichester National Park, but also extend to Cape Range and Duck Creek near Mount Brockman. Three hundred and fifty-nine individuals of *L. alfredii* P4 are listed on the Rio Tinto database (Rio Tinto Iron Ore 2016b), all of which are approximately 75 km south-east of the survey area.

Rhynchosia bungarensis P4 was recorded throughout the Robe River system, often in sheltered positions under the canopy of *Eucalyptus* and *Melaleuca* woodlands and where mesa landforms were immediately adjacent to the river. *Rhynchosia bungarensis* P4 has previously been recorded from within the survey area (Biota Environmental Sciences 2003, 2006a, 2011a). Seventy records of this species are listed at the WAHerb, with a known range of approximately 545 km (Western Australian Herbarium 1998-2016). The Rio Tinto database lists 10,865 individuals from 1,134 locations, distributed between Mesa A in the west, to Yandi, with a known range of approximately 360 km (Rio Tinto Iron Ore 2016b).

Although some *E. australis* were recorded from the survey area, the specimens observed had hairs on the leaf laminae differentiating them from the priority form. Given the small habit (≤10 cm) and often frequent occurrence of *E. australis*, not all individuals were observed and there is potential that *E. australis* var. *glabra* P2 occurred but was not recorded. *Euphorbia australis* var. *glabra* P2 has previously been recorded from Jimmawurrada Creek, but more typically occurs in the vicinity of Tom Price (Western Australian Herbarium 1998-2016).

Stylidium weeliwolli P2 is a delicate annual species that is difficult to observe when not in flower and may not have been present, should it occur, due to the low rainfall prior to the surveys. *Stylidium*

weeliwolli P2 has previously been recorded in the vicinity of the survey area; however, this location may be erroneous given the unsuitable habitat at the locality.

The small annual tussock grass *E. surreyana* P3 is unlikely to occur during dry conditions and would be difficult to observe post-rainfall if occurring among a grass-dominated lower stratum (such as **Cenchrus* spp. tussock grassland). *Eragrostis surreyana* has previously been recorded in Jimmawurrada Creek (Western Australian Herbarium 1998-2016), which runs through the eastern side of the survey area.

Indigofera sp. Bungaroo Creek (S. van Leeuwen 4301) P3 was recorded within 100 m of the Riparian Community survey area (Astron Environmental Services 2016b). It is possible this species occurs within the survey area, given that suitable habitat is present.

Weed diversity and abundance in the survey area was considered high, with 23 species recorded. **Ocimum basilicum* (Basil) is rarely recorded species in the Pilbara bioregion, with the only record on Florabase being at the junction of the Pannawonica Road and North West Coastal Highway. No other weed species recorded represents a range extension or were atypical to a survey of this scale in the Robe Valley.

5.4 Terrestrial Fauna Habitats

Habitats within the survey area are not restricted at the local, sub-regional or regional scale and no restricted or uncommon geological units or land systems occur within the survey area. The Riverine habitat in the survey area is considered significant for fauna. The deep pools and shallow spring fed pools provide an important permanent water source for drinking and a refuge for amphibians and waterfowl that occur in a wide area up and downstream of the survey area. This habitat contains microhabitats not common in other habitat types such as large tree hollows, hollow logs and moist leaf litter which provide a productive ecosystem attracting and supporting a range of predators and prey. This habitat supports conservation listed fauna species such as the Rainbow Bee-eater and Pilbara Olive Python and acts as foraging sites for Northern Quolls, Ghost Bats and Pilbara Leaf-nosed Bats. The survey area contains some of the most important pools in the area (such as Yeera Bluff) that are significant ecological features to the local fauna both up and downstream. The springs and pools of the Robe River that occur in the survey area are considered wetlands of sub-regional significance (Kendrick 2001).

The Drainage Line habitats within the survey area are mainly the broad valley of the Robe River or minor ephemeral drainage lines that are not likely to provide significant refugia for species. Drainage Line habitats, although not necessarily large in terms of area, are common habitats within the Pilbara region and immediate surrounds, e.g. the Robe River.

5.5 Terrestrial Fauna Species

The fauna species recorded and faunal assemblage expected to occur in the survey area is typical of that from the Hamersley Range subregion as well as a subset of typical fauna assemblages across the Pilbara bioregion. The habitats of the survey area are also considered dispersal habitat for all resident fauna species including conservation significant species. The Riverine and Drainage Line habitats linear shape and complex vegetation form natural corridors that link habitats and provide routes for fauna dispersal.

Based on the number of previous records of the MNES species; Northern Quoll, Pilbara Olive Python, Ghost Bat and Pilbara Leaf-nosed Bat, the survey area and its surrounds potentially supports locally significant populations. These species may be locally common; however, their presence is restricted

to areas of preferred habitat. Although the fauna habitats of the survey area do not support the caves and den sites these species shelter in, they do provide quality foraging habitat in close proximity to an abundance of suitable shelter. This feature is an important component to supporting the populations and presence of the MNES species in the survey area and the surrounding area.

The Rainbow Bee-eater is one of the most widespread bird species in Australia (Barrett et al. 2003) and is commonly recorded in biological surveys. The Riverine and the Drainage Line habitats provide foraging habitat and in areas containing sandy substrate, such as river banks potential breeding habitat. Within the Pilbara this species is classified as a resident, winter visitor and a passage migrant (Johnstone, Burbidge, and Darnell 2013). As such, this species is not reliant upon the habitats found within the survey area.

The Eastern Great Egret occurs across the Pilbara and is considered uncommon to very common throughout that range (Johnstone, Burbidge, and Darnell 2013). This species has been previously recorded within the survey area in the Riverine habitat (Astron Environmental Services 2014) and in the vicinity of the survey area (Astron Environmental Services 2014, 2016f; ecologia Environment 2013).

5.6 Aquatic Ecosystem

5.6.1 Water Quality

Water quality was highly variable amongst sites, with salinity levels ranging from fresh (592 µS/cm) to brackish (1,700 µS/cm), pH from circum-neutral (6.9) to slightly alkaline (7.9) and dissolved oxygen from hypoxic (14.5%) to supersaturated (134.9%). There were no obvious longitudinal gradients upstream or downstream of the Jimmawurrada-Robe confluence.

Exceedance of ANZECC/ARMCANZ default 95% TVs was recorded for nitrogen nutrients (N-total, N-NO_x and N-NH_3) at most sites upstream and downstream of the Jimmawurrada-Robe confluence. Elevated background levels of N-NO_3 and N-NH_3 within the survey area are unsurprising, given that the Robe River catchment is already effected by current and historic pastoral practices, with groundwaters also appearing to be enriched. Cattle, or evidence of high cattle use (e.g. manure, hoof prints and trampled ground), were observed at a number of pools during the current survey. Elevated N-total and N-NO_x downstream of the Jimmawurrada-Robe confluence may also reflect discharge of nitrogen-enriched groundwater from existing mine operations, though the relative contribution of anthropogenic and natural sources to nitrogen enrichment in surface waters of the survey area is unknown. With the exception of dissolved zinc at RRU5 and RRD3, no heavy metal analyte exceeded ANZECC/ARMCANZ default 95% TVs in the survey area.

5.6.2 Aquatic Fauna

Current results indicate little ecological difference between “reference” sites upstream of the proposed Mesa H development, and downstream sites that may be potentially exposed to dewatering discharge operations. As such, these results provide a good starting point to enable the detection of any potential future ecological changes.

5.6.2.1 Microinvertebrates

A total of 81 microinvertebrate taxa were recorded from the survey area, of which 46 were present at potentially exposed sites downstream of the Jimmawurrada-Robe confluence, and 69 were recorded at upstream reference sites. The microinvertebrate fauna was generally typical of that commonly recorded from tropical/sub-tropical freshwater systems, comprising protists, rotifers,

copepods, cladocerans (water fleas) and ostracods (seed shrimp), with Lecanidae dominating within the Rotifera. There were no significant differences in total mean microinvertebrate taxa richness between reference and potentially exposed sites, nor was there any significant difference in richness of any of the major microinvertebrate groups (protists, rotifers, micro-crustaceans) between these reaches.

One microinvertebrate species listed for conservation significance, the calanoid copepod *Eodiaptomus lumholtzi* (IUCN Vulnerable), was recorded at potentially exposed site RRD6. The conservation listing of this species is considered in need of revision because it is now known to occur at numerous locations across the Pilbara region, including sites along the Fortescue River, Coondiner Creek, Kalgan Creek, Weeli Wolli Creek, Mindy Mindy Creek, Koodaideri Springs, Caves Creek, Duck Creek and the Cane River, as well as Papua New Guinea.

5.6.3 Hyporheic Fauna

Hyporheic sampling collected 59 taxa in total, the majority of which were species not specially adapted to groundwater environments (stygoxene). Of these 59 taxa, 8% were considered stygobitic (obligate groundwater inhabitants), 31% occasional hyporheic stygophiles (species that use the hyporheic zone seasonally or during early life history stages), and 2% possible hyporheic taxa. There were no obvious longitudinal gradients or patterns in hyporheic taxa richness between reference and potentially exposed sites, though hyporheic taxa richness was relatively high at RRD1, RRU6, RRD2 and RRU4, suggesting strong connectivity between ground- and surface waters at these sites.

One stygobitic taxa recorded (*Nedsia* sp.) is considered a SRE species. *Nedsia* sp. was collected from sites potentially exposed to dewatering discharge (RRD1 – 4), as well as upstream reference sites (RRU3, RRU4 and RRU6). These amphipods could not be confidently identified to species level due to a current lack of taxonomic resolution within the Melitidae amphipods and would require DNA sequencing.

5.6.4 Macroinvertebrates

A total of 148 macroinvertebrate taxa were recorded from surface waters, with composition typical of freshwater systems throughout the world. There were no clear upstream/downstream gradients in macroinvertebrate richness within the survey area, with no significant difference in mean total taxa richness, and mean richness of most major macroinvertebrate groups, between reference and potentially exposed sites. Similarly, multivariate analysis detected no distinguishable separation of reference or potentially exposed sites based on macroinvertebrate species assemblage structure.

One macroinvertebrate species listed for conservation significance, the Pilbara Pin Damselfly *Eurysticta coolawanyah* (IUCN Near Threatened), was recorded at potentially exposed downstream sites RRD3 and RRD4. It is likely that both RRD3 and RRD4 are important refuge pools for Pilbara Pin Damselfly in the area, as both are persistent waterbodies which support relatively high densities of emergent macrophyte, which are used for perching, mating and oviposition (egg-laying).

5.6.5 Fish

A total of 3,515 individual fish, representing 11 species, were recorded in the survey area. True freshwater species included Western Rainbowfish, Spangled Perch, Pilbara Tandan (Eel-tailed Catfish), Fortescue Grunter, Barred Grunter, Terapontidae (Grunter) hybrids and Bony Bream. Estuarine/marine vagrant fish species included Milkfish, Tarpon/Ox-eye Herring, Mullet and Banded Scat/Striped Butterfish, the majority of which were recorded at the downstream reach. There was no significant difference in mean total abundance of fish between upstream and downstream sites,

nor was there any significant difference in mean abundance of each individual species between the reaches. Healthy (breeding) populations of Western Rainbowfish, the most abundant fish species of the survey area, were recorded from both the upstream and downstream reaches; however, Spangled Perch and Pilbara Tandan recruitment appeared to be low throughout the survey area.

The conservation listed Fortescue Grunter (*Leiopotherapon aheneus*; IUCN Lower Risk/Near Threatened; P4) was recorded at all sites both upstream and downstream of the proposed Mesa H development. This species is endemic to the Pilbara, only known from the Fortescue, Robe and Ashburton River systems. Within this range it is considered to be common and was the second most abundant fish collected during the survey.

Study Team

WRM

Project management: Jess Delaney & Chris Hofmeester
Field work: Adam Harman, Emma Thillainath & Fintan Angel
Macroinvertebrate identification: Bonita Clark, Kim Nguyen & Anton Mittra
Macroinvertebrate QA/QC: Alex Riemer, Anton Mittra & Chris Hofmeester
Report: Chris Hofmeester & Susan Davies
Internal review: Dr Andrew Storey

External Specialist Taxonomists

Dr Don H. Edward, The University of Western Australia (Chironomidae)
Dr Russell Shiel, The University of Adelaide (microinvertebrates)

Recommended Reference Format

WRM (2017) Mesa H Project Baseline Aquatic Ecosystem Surveys - Wet Season Sampling 2016. Unpublished report to Astron Environmental Services Pty Ltd by Wetland Research & Management. Final Report, April 2017.

Acknowledgements

WRM thank Mathew Love for overall management of the project on behalf of Astron Environmental Services Pty Ltd (Astron). Dr Stuart Pearse and John Trainer (Astron) are thanked for comments on the draft report. Laboratory analyses of surface water quality samples collected by WRM were performed by ChemCentre, Bentley WA. Groundwater data were provided courtesy of the Proponent. Adrian Pinder (Parks and Wildlife) is thanked for providing raw data from the Pilbara Biological Survey (PBS), and Streamtec Pty Ltd/UWA are thanked for sharing their unpublished reports on the aquatic fauna of the Robe River. The authors acknowledge, and are very grateful to the Kuruma-Marthudunera Traditional Owners and in particular Brendan Bobby, for sharing their stories, welcoming us to the land and allowing the sampling of the river pools.

SUMMARY LIST OF FIGURES, TABLES AND PLATES

Figure 1. Location of Mesa H Project area and baseline aquatic ecosystem sampling sites. 6
Figure 2. Average monthly rainfall (1971 – 2016) and total monthly rainfall (2016) for Bureau of Meteorology (BOM) Pannawonica Gauging Station (005069). 7
Figure 3. Locations previously sampled for aquatic invertebrates (Streamtec/UWA 1991 - 2014, WRM 2009 - 2016, Pinder *et al.* 2010) and fish (Streamtec 1991 – 2014) within 100 km of the Mesa H project area. 14
Figure 4. Comparison of EC, alkalinity, hardness and concentration of major ions amongst surface water sampling sites upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence. 38
Figure 5. Comparison of N-total, N-NO_X, N-NH_3, pH, DO and TSS amongst surface water sampling sites upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence. 39
Figure 6. Microinvertebrate taxa richness recorded during the current study, upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence, compared with most recent data for nearby Chalyarn Pool (CP; Pinder *et al.* 2010), Yalleen Pool (YP; WRM 2013) and Nyeetbury Spring (NS; WRM 2016). 41
Figure 7. Plot of nMDS ordination on microinvertebrate species assemblages (log_{10} abundance class) upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. 43
Figure 8. Hyporheic taxa richness (combined richness of stygobites, occasional hyporheic stygophiles and possible hyporheic fauna) of sites upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. 44
Figure 9. Macroinvertebrate taxa richness recorded during the current study, upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence, together with most recent data for nearby Chalyarn Pool (CP; Pinder *et al.* 2010), Yalleen Pool (YP; WRM 2013) and Nyeetbury Spring (NS; WRM 2016). 48
Figure 10. Comparison of standardised macroinvertebrate taxa richness recorded during the current study, with that recorded by Streamtec/UWA during long-term monitoring of Robe River pools. 49
Figure 11. Plot of nMDS ordination on macroinvertebrate species assemblages (log_{10} abundance class) upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Ordination based on Bray-Curtis similarity. 50
Figure 12. Abundance of each fish species recorded from upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence. 53
Figure 13. Abundance of western rainbowfish (*Melanotaenia australis*) age-classes recorded from each pool in the Project area. 56
Figure 14. Abundance of spangled perch (*Leipotherapon unicolor*) age-classes recorded from each pool in the Project area. 57
Figure 15. Abundance of Pilbara tandan (*Neosilurus* sp.) age-classes recorded from each pool in the Project area. 58

Table 1. Summary of previous recent aquatic fauna studies (invertebrates and fish) conducted within a 100 km radius of the Mesa H Project area, together with methodologies..... 12
Table 2. Aquatic species (invertebrates and fish) of conservation and/or scientific value known to occur, or likely to occur, within the Project area. 25
Table 3. Aquatic ecosystem sampling sites on the Robe River..... 29
Table 4. Measured and derived water quality and habitat parameters..... 31
Table 5. Summary results from one-way ANOVAs testing for significant (p <0.05) differences in mean concentrations of water quality parameters, upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. 36
Table 6. Summary of higher-order microinvertebrate taxa composition in the Robe River, upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. 41
Table 7. Summary results from one-way ANOVAs testing for significant (p <0.05) differences in taxa richness of major microinvertebrate groups, upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. 41
Table 8. Summary results from ANOSIM testing for significant (p <0.05) differences in microinvertebrate assemblages (Bray-Curtis similarity) upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence..... 43
Table 9. Summary of higher-order microinvertebrate taxa composition in the Robe River, upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. 46
Table 10. Summary results from ANOVAs testing for significant (p <0.05) differences in taxa richness of major macroinvertebrate groups (indicated by *), upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. 47
Table 11. Summary results from ANOSIM testing for significant (p <0.05) differences in macroinvertebrate assemblages (Bray-Curtis similarity) upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence..... 50
Table 12. Summary of freshwater and estuarine/marine vagrant fish species recorded in the Project area, including scientific and common names. 51
Table 13. Age-classes used in length-frequency analysis of Western rainbowfish, spangled perch and Pilbara tandan from the Project area. 55
Table 14. Summary of aquatic species of conservation significance (conservation listed or short range endemic) recorded from the Project area. 60

EXECUTIVE SUMMARY

This report summarises the results of a baseline sampling program for aquatic ecosystems of the Robe River system, both upstream and downstream of the proposed Mesa H iron ore development ("the Project"), managed by Rio Tinto on behalf of the Proponent (Robe River Mining Co. Pty Ltd) in the West Pilbara region of Western Australia. The aim of the sampling program was to document the current ecological condition of the Robe River prior to the implementation of the Mesa H development, which will require dewatering and surplus water discharge, which will result in a surface discharge footprint along the Robe River. The baseline survey included a number of named permanent pools in the Project area known to have ecological and cultural value, such as Gnieraoora (or Dthulurat) at Yeera Bluff. This report also includes a review of previous aquatic fauna surveys of the Robe River, and other nearby systems (*e.g.* Bungaroo Creek, Jimmawurrada Creek and Mungarathoona Creek), including conservation significant species known to occur in the vicinity of the Project area, which provides regional context for the sampling program.

The sampling design included six sites downgradient of the confluence of Jimmawurrada Creek and the Robe River (immediately upstream of the existing Mesa J operation) (RRD1 - 6), which are likely to fall within the zone of dewatering discharge (*i.e*. 'potentially exposed' sites), and six sites (RRU1 - 6) located upstream of the confluence (*i.e.* 'reference' sites). Sites were surveyed during the late wet season (April/May) 2016. The permanency and consistency of flow in the Robe River is already influenced by groundwater abstraction and dewatering discharge from the existing Mesa J mine operation, and so the current sampling program documents "current" ecological condition, more so than "natural" condition. Water quality, microinvertebrates (zooplankton), hyporheic fauna, macroinvertebrates and fish were successfully sampled at each of the 12 sites.

The main findings of the baseline survey were:

- Water quality was highly variable amongst sites, with salinity levels ranging from fresh (592 µS/cm) to brackish (1,700 µS/cm), pH from circum-neutral (6.9) to slightly alkaline (7.9) and dissolved oxygen from hypoxic (14.5%) to supersaturated (134.9%). There were no obvious longitudinal gradients in water quality parameters upstream or downstream. Site RRU6 (~1 km upstream of the Jimmawurrada-Robe confluence) and the downstream sites tended to have higher salinity (as electrical conductivity and total dissolved solids), alkalinity, hardness and concentrations of associated ions, than sites upstream. Some of this variability was attributed to differences in volume of the remnant pools sampled and evapoconcentration effects under recessional flows, however, higher concentrations of some ions downstream of the Jimmawurrada-Robe confluence (most notably magnesium and sulfate) was considered a possible artefact of current mining operations.
- Exceedances of ANZECC/ARMCANZ (2000) default trigger values for the protection of 95% of species in slightly-moderately disturbed tropical northern Australian systems were recorded for nitrogen nutrients (N-total, N-NO_x and N-NH_3) at most sites upstream and downstream of the Jimmawurrada-Robe confluence. Elevated background levels of N-NO_3 and N-NH_3 within the Project area are unsurprising, given that the Robe River catchment is already effected by current and historic pastoral practices, with groundwaters also appearing to be enriched. Elevated N-total and N-NO_x downstream of the Jimmawurrada-Robe confluence may also reflect discharge of nitrogen-enriched groundwater from existing mine operations, though the relative contribution of anthropogenic and natural sources to nitrogen enrichment in surface and groundwater of the Project area is unknown. The majority of heavy metal analytes, with the exception of dissolved zinc at RRU5 and RRD3, did not exceed ANZECC/ARMCANZ (2000) default 95% trigger values in the Project area.
- A total of 81 microinvertebrate taxa were recorded from the Project area, of which 46 were present at potentially exposed sites downstream of the Jimmawurrada-Robe confluence, and 69

were recorded at upstream reference sites. The microinvertebrate fauna was generally typical of that commonly recorded from tropical/sub-tropical freshwater systems, comprising Protista, Rotifera, Copepoda, Cladocera (water fleas) and Ostracoda (seed shrimp), with species from the family Lecanidae dominating within the Rotifera. There were no significant differences in total mean microinvertebrate taxa richness between reference and potentially exposed sites, nor was there any significant difference in richness of any of the major microinvertebrate groups (protists, rotifers, micro-crustaceans) between these sites. One microinvertebrate species listed for conservation significance, the copepod *Eodiaptomus lumholtzi* (IUCN Vulnerable), was recorded at potentially exposed site RRD6. The conservation listing of this species is considered in need of revision because it is known to occur at numerous locations across the Pilbara region, including sites along the Fortescue River, Coondiner Creek, Kalgan Creek, Weeli Wolli Creek, Mindy Mindy Creek, Koodaideri Springs, Caves Creek, Duck Creek and the Cane River, as well as Papua New Guinea.

- A total of 59 taxa were recorded from hyporheic samples, the majority of which were species not specially adapted to groundwater environments (stygoxene). Of these 59 taxa, 8% were considered stygobitic (obligate groundwater inhabitants), 31% occasional hyporheic stygophiles (species that use the hyporheic zone seasonally or during early life history stages), and 2% possible hyporheic taxa. There were no obvious longitudinal gradients or patterns in hyporheic taxa richness between reference and potentially exposed sites, though hyporheic taxa richness was relatively high at RRD1, RRU6, RRD2 and RRU4, suggesting strong connectivity between ground- and surface waters at these sites. Stygobitic taxa collected included the amphipod *Nedsia* sp., the thermosbaenacean *Halosbaena tulki,* and the ostracods *Candonopsis* cf. *tenuis* and *Vestalenula marmonieri.* Of these, *Nedsia* sp. is considered a potential short range endemic (SRE) species. *Nedsia* sp. was collected from sites potentially exposed to dewatering discharge (RRD1 – 4), as well as upstream reference sites (RRU3, RRU4 and RRU6).
- A total of 148 macroinvertebrate taxa were recorded from surface waters (117 from upstream reference sites, and 116 from downstream potentially exposed sites), with composition typical of freshwater systems throughout the world, being dominated by Insecta, in particular Diptera (true flies) and Coleoptera (aquatic beetles). There were no clear upstream/downstream gradients in macroinvertebrate richness within the Project area, with no significant difference in mean total taxa richness, or mean richness of most major macroinvertebrate groups, between reference and potentially exposed sites. Similarly, multivariate analysis detected no distinguishable separation of reference or potentially exposed sites based on macroinvertebrate species assemblage structure. One macroinvertebrate species listed for conservation significance, the Pilbara pin damselfly *Eurysticta coolawanyah* (IUCN Near Threatened), was recorded at potentially exposed downstream sites RRD3 and RRD4.
- A total of 3,515 individual fish, representing 11 species, were recorded in the Project area. True freshwater species included western rainbowfish, spangled perch, Pilbara tandan (eel-tailed catfish), Fortescue grunter, barred grunter, Terapontidae (grunter) hybrids and bony bream. Estuarine/marine vagrant fish species included milkfish, tarpon/ox-eye herring, mullet and banded scat/striped butterfish, the majority of which were recorded at the downstream reach. The conservation listed Fortescue grunter (*Leipotherapon aheneus*; IUCN Lower Risk/Near Threatened; Parks and Wildlife Priority 4) was the second most abundant fish species of the Project area, recorded at all upstream and downstream sites. Similar to other fauna indices, there was no significant difference in mean total abundance of fish between upstream and downstream sites, nor was there any significant difference in mean abundance of each individual species within the Project area. Healthy (breeding) populations of western rainbowfish, the most abundant fish species of the Project area, were recorded from upstream and downstream reaches; however, spangled perch and Pilbara tandan recruitment appeared to be low throughout the Project area.

1 INTRODUCTION

1.1 Background

Robe River Mining Co. Pty Ltd (the Proponent) is evaluating the potential development of the Mesa H iron ore deposit, located 16 km south-west of Pannawonica, in the West Pilbara region of Western Australia (Figure 1). The development envelope for Mesa H traverses the Robe River and lies adjacent to the existing Mesa J mine operation.

As part of the Mesa H development, dewatering of underlying groundwater will be required to allow mining of sections of ore (~20%) which occur below the water table (BWT). Options for disposal of excess dewatering water from the Mesa H development include discharge to an unnamed ephemeral tributary of the Robe River, between Mesa H and Mesa J, and/or discharge into Jimmawurrada Creek, east of Mesa J (Figure 1, or potentially an additional location north of Mesa H). The former two discharge points are currently used by the Mesa J operation.

The permanency and consistency of flow in the Robe River is already influenced by groundwater abstraction and dewatering discharge from existing mine operations (Aquaterra 2004). Groundwater drawdown and discharge from Mesa H may also affect aquatic ecosystems in the local vicinity. This includes a number of named permanent pools known to have ecological and cultural value, such as Gnieraoora (or Dthulurat) at Yeera Bluff (Figure 1).

Astron Environmental Service Pty Ltd (Astron) commissioned *Wetland Research & Management* (WRM) to design and conduct a baseline sampling program encompassing aquatic ecosystems of the Robe River both upstream and downstream of the Mesa H development (the "Project area"). The aim of the sampling program is to document current ecological condition of the system, and procure benchmark aquatic fauna and water quality data against which any future changes may be assessed post-commencement of the Mesa H development, including cumulative effects from dewatering drawdown ('drying') and discharge (quality and quantity). The permanency and consistency of flow in the Robe River is already influenced by groundwater abstraction and dewatering discharge from the Mesa J mine, and so the current sampling program will document "current" ecological condition moreso than "natural" condition. Where possible, monitoring sites established by Streamtec Pty Ltd (Streamtec) and The University of Western Australia (UWA) on the Robe River (Figure 1) have been included in the program. Since 1991, annual sampling for fish and benthic macroinvertebrates has been conducted by Streamtec/UWA as part of long-term monitoring for the Mesa J Project (Streamtec 1996, 1999, 2003, 2007, 2009, 2010, 2012 and 2014, Dobbs and Davies 2009).

1.1.1 Legislative framework

At a State level, native aquatic fauna are protected under the *Wildlife Conservation Act 1950* (WC Act) and their environment is protected under the *Environmental Protection Act 1986* (EP Act). This includes freshwater turtles, frogs, fish and invertebrates (including hyporheic and stygal invertebrates). Hyporheic invertebrates inhabit subsurface interstitial spaces in coarse creek bed sediments. Stygal invertebrates are aquatic, obligate groundwater-dwelling species known to be present in a variety of rock types and are often also present in the hyporheos.

The EP Act provides for environmental impact assessment (EIA) of proposals (and schemes) likely to have a significant effect on the environment. As part of the EIA process, the Act requires the Environmental Protection Authority of Western Australia (EPA) to report on key environmental factors to the Minister for Environment. Environmental factors and associated objectives are the EPA's basis for assessing whether a proposal (or scheme's) impact on the environment is acceptable. Two key environmental factors relate to water resources:

i) Hydrological Processes - with the objective "To maintain the hydrological regimes of groundwater and surface water so that environmental values are protected".

ii) Inland Waters Environmental Quality - with the objective "To maintain the quality of groundwater and surface water so that environmental values are protected".

Proponents are required to provide baseline information on these two factors (and others) in order to inform the EIA process.

The WC Act provides for species and ecological communities to be specially protected and listed as either 'threatened' because they are under identifiable threat of extinction, or 'priority' because they are rare, or otherwise in need of special protection. This encompasses species with small distributions (occupying an area of less than 10, 000 km^2) defined as short range endemics, or SREs (Harvey 2002, EPA 2009). The EPA's Guidance Statement 20 (EPA 2009) requires that impacts on SRE invertebrates be considered during the EIA process.

It can be difficult to determine whether or not a species belonging to a SRE Group is actually a species with a range <10,000 km^2. The Western Australian Museum (WAM) uses a three-tier classification scheme for SRE species which we have applied to hyporheic fauna in this report:

- **Confirmed SREs** are species with a known distribution range <10,000 km^2. The taxonomy is well known and the group is well represented in collections and/or via comprehensive sampling.

- **Potential SREs** are species that belong to a group where there are gaps in our knowledge of the taxon, either because the group is not well represented in collections, taxonomic knowledge is incomplete, or the distribution is imperfectly understood because sampling has been patchy.

- **Widespread (not SRE) species** have a known distribution range >10,000 km^2. The taxonomy is well known and the species is well represented in collections and/or via comprehensive sampling.

WAM further uses five sub-categories if a species is determined to be a "Potential SRE". These sub-categories are:

1. Data deficient: There are insufficient data available to determine SRE status, either because there is a lack of geographic and taxonomic information, or because the individuals sampled cannot be identified to species level (*e.g.* wrong sex, juvenile, damaged);

2. Habitat Indicators: The status of a species can be elucidated through its association with a particular habitat and vice versa;

3. Morphological Indicators: The status of a species can be determined through its morphological characteristics;

4. Molecular Evidence: DNA sequence data reveal patterns congruent or incongruent with SRE status for a species; and

5. Research & Expertise: Available research data and/or WAM expertise provide the basis for a decision about the species' status.

The Department of Parks and Wildlife (Parks and Wildlife) also maintains a list of priority fauna species that are of conservation importance but, for various reasons, do not meet the criteria for listing as threatened. Parks and Wildlife uses the International Union for Conservation of Nature (IUCN) Red List

criteria for assigning species and communities to threat categories. Not all Western Australian species listed by the IUCN are also listed by Parks and Wildlife.

Objectives for the management of potential impacts on water-dependent ecosystems are also outlined in the Western Australian Department of Water (DoW) Western Australian Water in Mining Guideline (DoW 2013) and include:

- Minimise the adverse effects of the abstraction and release of water on environmental, social and cultural values;
- Ensure the cumulative effects of mining operations are considered and managed;
- Use a monitoring and evaluation process, to adaptively manage the effects of abstractions and releases on the water resources;
- Maximise cooperation in water management activities between nearby water users, to reduce impacts on the environment;
- Plan for, and manage, the effects of climate variability and change.

At a Federal level, the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) provides for native fauna and their habitats to be specially protected and listed as nationally or internationally important. Relatively few aquatic species in Western Australia are listed as threatened or endangered under the WC Act or EPBC Act. Lack of knowledge of their distributions often precludes aquatic invertebrates for listing as threatened or endangered. The EPA has stated that listing under legislation should therefore not be the only conservation consideration in EIA (EPA 2004).

The current baseline sampling constituted a Level 1 survey for EIA, as described under the EPA's Environmental Assessment Guideline (EAG) No. 12 (EPA 2013), and in accordance with EAG No. 8 (EPA 2015), with the focus on hydrological processes and ecosystem maintenance. At the time of the survey (April/May 2016), the aforementioned EAGs were the most up-to-date EAGs availaible.

1.1.2 Other relevant policy - ANZECC/ARMCANZ (2000) Guidelines

The Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC/ARMCANZ 2000) "… provide an authoritative guide for setting water quality objectives required to sustain current, or likely future, environmental values (users) for natural and semi-natural water resources in Australia and New Zealand". These guidelines form part of the National Water Quality Management Strategy (NWQMS), a joint national approach to improving water quality in Australian and New Zealand waterways. The NWQMS was originally endorsed by two Ministerial Councils - the former Agriculture and Resources Management Council of Australia and New Zealand (ARMCANZ) and the former Australian and New Zealand Environment and Conservation Council (ANZECC).

State regulators have been known to apply the trigger values detailed in the ANZECC/ARMCANZ (2000) guidelines as compliance values for mining companies in the Pilbara, where developments may impact creeklines through dewatering and discharge operations. Yet, in some systems water quality data recorded during baseline surveys, conducted prior to any disturbance, do not actually meet the default ANZECC/ARMCANZ (2000) trigger values. Therefore, it is important to obtain adequate baseline water quality data and develop system-specific guidelines, as recommended in the ANZECC/ARMCANZ (2000) guidelines, to avoid issues with non-compliance as a result of inappropriate trigger values being used by regulators.

The ANZECC/ARMCANZ (2000) guidelines are currently under review and updates are provided by the Joint Steering Committee for the Revision on the Federal Department of the Environment and Energy website (www.environment.gov.au/water/quality/national; downloaded on 30 May 2016).

1.2 Scope of Works for Current Study

The scope of works for the current study was to establish riverine baseline monitoring sites, and to develop a robust dataset to allow statistical testing for potential change over time. Specifically, the scope of work included:

- Identification of baseline and future riverine monitoring sites, and where possible, include long-term monitoring sites established previously by Streamtec/UWA;
- Semi-qualitative sampling for aquatic fauna (microinvertebrates, hyporheic invertebrates, benthic macroinvertebrates, fish) and water quality to allow statistical comparison of any changes overtime;
- Qualitative visual assessment of general habitat conditions at all sites;
- Record opportunistic visual sightings of any turtle and frog species present;
- Identification of all specimens to the lowest taxonomic level practicable;
- An assessment of the conservation status of aquatic fauna recorded;
- Report water quality data against ANZECC/ARMCANZ (2000) guidelines for freshwater ecosystems;
- Preparation of a detailed technical report of all findings.

1.3 Rationale for Sampling Components of Aquatic Fauna

Microinvertebrates

Aquatic microinvertebrate fauna consists of microscopic fauna including micro-crustacea (ostracods, copepods and cladocera), protists and rotifers (nominally <53 μm in size). Aquatic microinvertebrates are used as bioindicators throughout the world for many reasons. The microinvertebrate community holds a strategic position in food webs (Bunn and Boon 1993, Zrum and Hann 1997, Jenkins and Boulton 2003). They provide a food source for higher trophic levels, such as macroinvertebrates (Bunn and Boon 1993, Jenkins and Boulton 2003), fish (King 2004, Vilizzi and Meredith 2009), and waterbirds (Crome 1985). Most fish species depend on microinvertebrates for their first feed after hatching (Geddes and Puckridge 1989). Therefore, any change in the microinvertebrate community will ultimately result in changes to the entire aquatic ecosystem. Microinvertebrates also have intimate contact with the surrounding environment, being planktonic, and continually exposed to the ambient water quality. Hence, they are vulnerable to environmental pollutants and can be a useful biomonitoring tool (Kaur and Ansal 1996).

Hyporheic fauna

The hyporheic zone, comprising subsurface interstitial spaces in coarse creek bed sediments, is recognised as a critical component of many streams and rivers (Edwards 1998). The hyporheic zone creates habitat and connectivity between surface and sub-surface (groundwater) zones, provides a rearing habitat and important refuge for aquatic invertebrates, and importantly in the context of the Pilbara region, buffering from floods (Palmer *et al.* 1992, Dole-Olivier and Marmonier 1992), disturbance in food supply (Edwards 1998) and drought (Cooling & Boulton 1993, Coe 2001, Hose *et al*. 2005). The aquatic fauna of hyporheic zones is collectively referred to as hyporheos. Typically, hyporheos have poor dispersal capabilities, are confined to discontinuous habitats, are highly seasonal (usually more active in the wet season following significant flows) and have low levels of fecundity, and are therefore commonly classified as SRE as defined by Harvey (2002)[1]. A number of taxa frequently encountered in hyporheic zones, including stygal amphipods, isopods and syncarids (crustaceans) are classified as SRE, and are therefore of high conservation value. The subterranean fauna of the Pilbara is characterised by high levels of diversity and short range endemism (Eberhard *et al*. 2005, Halse *et al*. 2014), with increasing aridity and cessation of surface flows over the last 60 – 70 million years causing once epigean

[1] Short range endemic as defined by Harvey (2002): a species occupying an area of less than 10, 000 km^2.

(surface dwelling) fauna to disperse and become isolated in groundwater environments (Finston *et al*. 2011).

Macroinvertebrates

Aquatic macroinvertebrates (nominally 53 - 250 µm in size) typically constitute the largest and most conspicuous component of aquatic invertebrate fauna in both lentic (still) and lotic (flowing) waters. Macroinvertebrates are used as a key indicator group in the bioassessment of the health of Australia's streams and rivers under the National River Health Program (Schofield and Davies 1996), and have inherent value for biological monitoring of water quality (ANZECC/ARMCANZ 2000). Macroinvertebrates are considered to be temporary residents if their life-cycle contains a winged-adult form (*e.g.* dragonflies, damselflies, mayflies, aquatic beetles, caddisflies, *etc.*), therefore being proficient in aerial dispersal between waterbodies (Gray and Fisher 1981). Permanent residents include those which can persist as larvae during periods of drought by aestivating or encysting in sediments (*e.g.* Baetidae, Simuliidae, Ceratopogonidae, Chironomidae), or produce desiccation-resistant propagules or eggs which hatch upon inundation (*e.g*. ciliates, rotifers, flatworms, nematodes, segmented worms and crustaceans) (Radzikowski 2013).

Fish

Historically, fish diversity has been used worldwide as an indicator of ecosystem health (*e.g.* Hugueny e*t al*. 1996, Oberdoff *et al.* 2002, Pont *et al.* 2006). Because fish continually inhabit the receiving water, they integrate the chemical, physical and biological 'histories' of the watercourse. Most fish species have a long life span and therefore reflect both long-term and current water quality. Sampling fish assemblages can be used to assess a range of environmental disturbances, such as changes in habitat, water quality and land use (Hugueny *et al.* 1996). Fish also tend to be the most conspicuous biota in freshwater systems, have significant social amenity and are relatively easy to sample and identify.

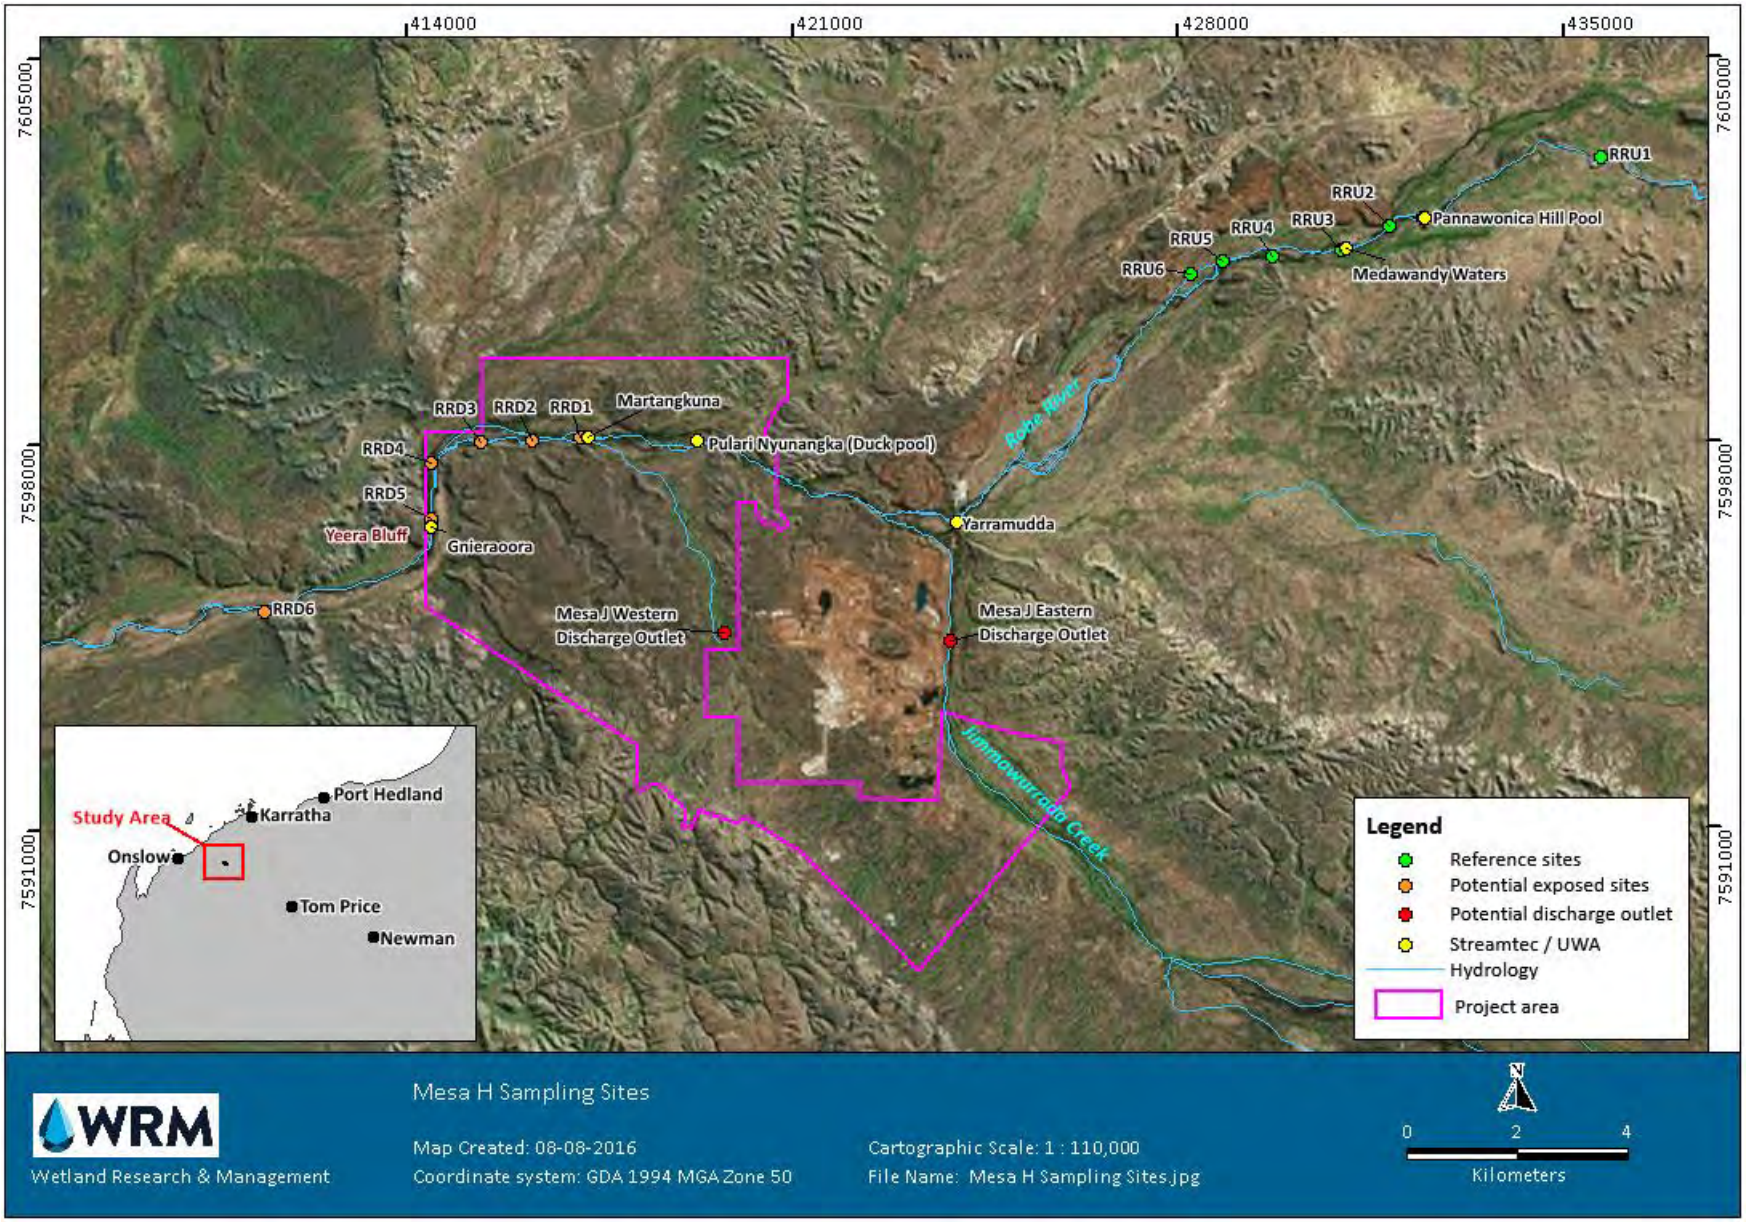

Figure 1. Location of Mesa H Project area and baseline aquatic ecosystem sampling sites (reference, potential exposed) and historic Streamtec/UWA sites ( ).

2 STUDY AREA

2.1 Climate

The Project area is located on the western edge of the Hamersley Ranges, approximately 100 km south-west of Karratha and south-west of Pannawonica. Climate of the region is semi-arid, with relatively dry winters and hot summers. The nearest long-term Bureau of Meteorology (BOM) gauging station is Pannawonica (no. 005069; 1971 - 2016), where total annual rainfall ranges from 113 to 700 mm, and monthly rainfall from 0 to 444 mm. Most rainfall occurs during the summer months (November to March) and is predominantly associated with cyclonic events; when flooding frequently occurs along creeks and rivers. Due to the nature of cyclonic events and thunderstorms, total annual rainfall in the region is highly unpredictable and individual storms can contribute several hundred millimetres of rain at one time.

Prior to sampling in April/May 2016, slightly above-average monthly rainfall was recorded in the latter part of 2015 (October & November) (Figure 2). However, total monthly rainfall was well below the 45-year average in the mid to late wet season of 2016, particularly during February, March and April (Figure 2). As such, there was no surface flow connecting pools along the Robe River at the time of sampling between 1st and 8th May. However, toward the end of the sampling period, a major storm event on the 5th - 6th May caused widespread flooding across the Robe River catchment, resulting in above average total rainfall for May (Figure 2). Pannawonica also recorded above average rainfall in June and July (Figure 2).

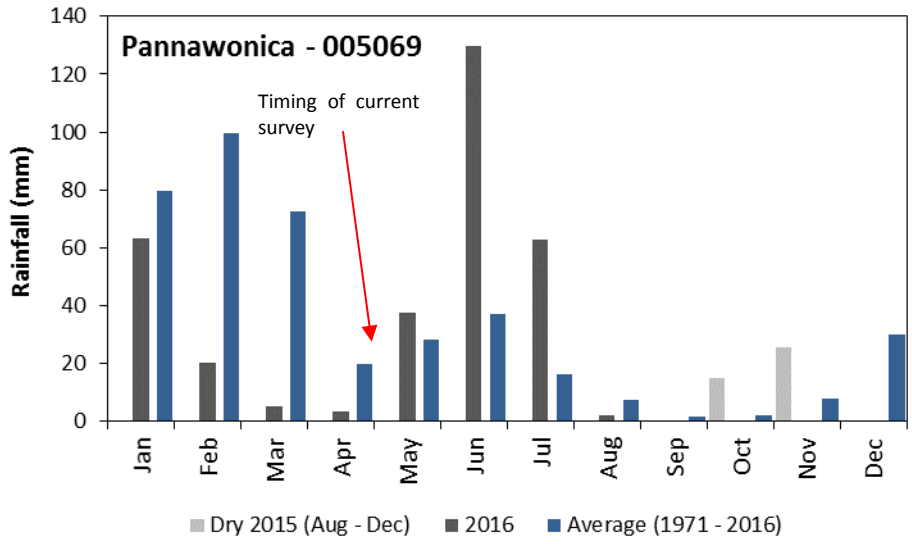

Figure 2. Average monthly rainfall (1971 – 2016) and total monthly rainfall (2016) for Bureau of Meteorology (BOM) Pannawonica Gauging Station (005069).

2.2 Hydrogeology

The Project area lies within the Robe River catchment, a significant river system in the region, with a catchment area of 7,571 km^2 and numerous braided tributaries (DoW 2012). The Robe River channel covers a linear distance of 190 km, 63% of which lies upstream of the Project area (EPA 1991). The immediate valley is 300 - 500 m wide. Jimmawurrada Creek is the only major tributary in the vicinity of the Project area, flowing northward along the eastern flank of Mesa J.

Jimmawurrada Creek joins the Robe River upstream of Mesa J (Figure 1). The Jimmawurrada Creek sub-catchment has an area of approximately 400 km^2 and constitutes the lower section of Bungaroo Creek

catchment, with a combined area of around 1,261 km^2 (DoW 2012). Both the Jimmawurrada and Bungaroo Creek catchments are included in the Bungaroo Creek Water Reserve that protects the water resources in these catchments and underlying aquifer that supply the West Pilbara Water Supply Scheme (WPWSS) (RDA 2013). The WPWSS delivers public drinking water to the towns of Karratha, Dampier, Roebourne, Cape Lambert and Point Samson (DoW 2012).

Surface flow in the Robe and tributary rivers is naturally ephemeral, typically only occurring in response to significant rainfall events and continuing for one to two months. There is one DoW streamflow gauging station on Robe River; Yarraloola (no. 707 002; 1972 - 2016), at the North West Coastal Highway crossing, 36 km west of the Project area. The maximum total monthly river discharge for the period of record at Yarraloola is 773.9 GL (February 2009) and the maximum instantaneous discharge is 12,203 m^3/sec (February 2009). Low or no flow typically occurs from July to December, when the river is reduced to a series of isolated pools. The number and permanence of these pools is dependent on antecedent rainfall and groundwater levels (Antao & Braimbridge 2010). Since streamflow records began at Yarraloola in 1972, 14 zero-flow years have been recorded, including seven in the last two decades (2002, 2003, 2007, 2010, 2012, 2013 & 2014).

The major aquifer underlying the Robe River is the gravelly alluvium which has a saturated thickness of up to 15 m adjacent the main channel and extends laterally up to 5 km across the Robe River Valley (Antao & Braimbridge 2010). Groundwater flow through the gravels maintains permanent pools in the Robe River. The gravelly aquifer is underlain by fractured, permeable Trealla Limestone and highly transmissive Robe Pisolite. Robe Pisolite is an iron-enriched pisolitic alluvial sedimentary rock that fills the broad valley between ridges of the Brockman Iron Formation, originally as ancestral drainage channels (palaeochannels) of the Robe River (commonly known as a Channel Iron Deposits (CID), and forms the target ore deposit at Mesa H (and Mesa J).

Groundwater flow in the Pisolite is towards the Robe River and where the Pisolite is deepest, probably contributes to baseflow within the Robe River (Aquaterra 2005). The gravel and Pisolite aquifers are recharged primarily *via* river discharge. Modelling by DoW indicates the aquifers have the potential to absorb a significant percentage of river flow; however, due to the unpredictable flow regime, recharge is very low in two out of every five years (Antao & Braimbridge 2010). Near the Jimmawurrada-Robe confluence, the Pisolite is very shallow and unsaturated. Stream-aquifer interaction upstream in the Bungaroo and Jimmawurrada valleys contributes to recharge along with direct rainfall infiltration.

2.3 Water Quality

2.3.1 Surface water

Water quality monitoring has been conducted quarterly at five pools in the Robe River and at the existing dewatering discharge point on Jimmawurrada Creek. The Robe River pools are located upstream (Medawandy Waters), adjacent to (Yarramudda) and downstream (Japanese, Martangkuna, Gnieraoora) of the existing mine operation (refer Figure 1 & Section 3). Pools have been monitored for pH, conductivity (EC), total dissolved solids (TDS), nitrogen and phosphorus, turbidity, total suspended solids (TSS) and biological and chemical oxygen demand. Dewatering discharge has been monitored for pH, TDS, TSS and concentration of dissolved metals (Al, As, Cd, Cr, Cu, Fe, Mn, Ni, Pb, Zn). Unfortunately, the limit of reporting for most metals was not sufficiently low to allow comparison against ANZECC/ARMCANZ (2000) default trigger values (TVs) for the protection of freshwater ecosystems. In general, dewatering discharge to Jimmawurrada Creek appeared to be of low salinity (< 800 mg/L TDS), low TSS (< 5 NTU) and with a pH range of 6.2 - 8.5. The water is a predominantly sodium bicarbonate and calcium bicarbonate type, indicative of recharge water (Aquaterra 2004).

Available long-term quarterly monitoring data for the Robe River pools (1992 - 2004) indicates surface waters to be fresh (453 - 1,400 µS/cm EC; 300 - 904 mg/L TDS), with pH values typically in the range 7.0 - 9.0, and relatively low turbidity (< 10 NTU) under baseflow conditions. Maximum salinity levels recorded during quarterly monitoring were in 2003 following two years of low rainfall. Salinity generally tends to be lower in upstream pools than in pools adjacent to, and downstream of Mesa J. Background levels of total nitrogen (N-total) and nitrate-nitrogen ($N\text{-}NO_3$) often exceed default ANZECC/ARMCANZ (2000) TVs for protection against eutrophication (0.15 mg/L N-total; 0.03 mg/L $N\text{-}NO_X$), with levels of up 3.45 mg/L N-total and 3.1 mg/L $N\text{-}NO_3$ recorded at Medawandy waters, upstream of Mesa J. In general $N\text{-}NO_3$ appears to constitute most of the N-total present in surface waters in the pools. There are no data on dissolved metal concentrations in the pools.

Long-term annual monitoring of Robe River pools by Streamtec/UWA indicated similar physicochemical water quality characteristics to those identified from quarterly monitoring by the Proponent; fresh (EC < 1,200 µS/cm), slightly acidic to alkaline (pH 6.6 - 8.3) waters with relatively low turbidity during the dry season (< 8 NTU), becoming markedly more turbid following wet season flood events (often exceeding 70 NTU) (Dobbs & Davies 2009, Streamtec 2014). There was significant spatial and temporal variation in dissolved oxygen (DO) levels (< 2 mg/L to > 12 mg/L), depending on time of day sampled and permanency of pools. N-total and total phosphorus (P-total) often exceeded ANZECC/ARMCANZ (2000) default TVs (Dobbs & Davies 2009, Streamtec 2014).

2.3.1 Groundwater

At the time of reporting, groundwater quality sampling in the Project area had been conducted on three occasions, in December 2015 and twice during 2016. A comprehensive suite of parameters was sampled in 10 bores; MB15MEH001 to 4, 6 to 9, and 13 to 14. This sampling will be followed by more comprehensive groundwater assessment during 2016. The December 2015 sampling suggests groundwater quality in the majority of the bores to be similar to surface waters, *i.e.* fresh (489 - 1,110 µS/cm, 452 - 822 mg/L TDS), circum-neutral to slightly alkaline (pH 7.3 - 7.7) and with relatively high DO levels (7.2 - 9.1 mg/L). Two bores had brackish water; MB15MEH013 (3,040 µS/cm, 2,770 mg/L) and MB15MEH014 (1,920 µS/cm, 1,450 mg/L). Groundwaters in most bores (except MB15MEH001) were enriched in $N\text{-}NO_3$ relative to ANZECC/ARMCANZ (2000) default TVs for surface waters for protection against eutrophication. Maximum concentration was 23.9 mg/L $N\text{-}NO_3$ in MB15MEH014. Default TVs have yet to be developed for groundwaters. In their absence, ANZECC/ARMACANZ (2000) recommend that default TVs for surface waters be applied with caution, acknowledging that they may not be representative of natural background concentrations in groundwater.

In three bores, dissolved concentrations of chromium (Cr), manganese (Mn) and/or zinc (Zn) were also in exceedance of ANZECC/ARMCANZ (2000) default 95% species protection level TVs[2] for surface waters. This included MB15MEH001 (Mn, Zn), MB15MEH004 (Zn), MB15MEH013 (Cr, Zn) and MB15MEH004 (Cr).

2.4 Cultural and Ecological Values

The Project area is located within the Hamersley sub-region of the Pilbara Biogeographic Region as categorised under the national Interim Biogeographic Regionalisation for Australia (IBRA). Existing tenure in the area is a mixture of unallocated and leased Crown land. The Mesa H development would be implemented under Mining Lease ML248SA, which covers the Project area and other deposits

[2] Note, default TV for Ni should be modified for water hardness (as $CaCO_3$) at the time of sampling using algorithms provided in Table 3.4.3 of ANZECC/ARMCANZ (2000).

throughout the Robe River valley. In addition to ML248SA, the Project area lies substantially within Yarraloola Station pastoral lease (PL 3114-1127). The lease is held by Robe River Iron Associates joint venture through the Yarraloola Pastoral Company, and managed by Rio Tinto. The Station was established in 1916 as a sheep station, but currently runs cattle.

Numerous Aboriginal sites of significance have been identified within the Robe River valley. The Native Title Claim of the Kuruma Marthudunera Native Title Claimant Group covers 15,717 km^2 south of Karratha, incorporating the Project area and Yarraloola Station (YMAC 2011). The entire Robe River, also known as Jajiwarra, is of significant cultural value to the Kuruma and Marthudunera people, in particular permanent pools such as Yarramudda and Weedai immediately upstream of the Project area, Dthulurat (Gnieraoora) at Yeera Bluff, Joordi (or Jongardi) 14 km downstream of Yeera Bluff, and Chalyarn Pool on Mungarathoona Creek, a tributary of the Robe River.

As the Pilbara has an arid and variable climate with irregular episodic rainfall events, sources of water are of high ecological value. The permanent pools of the Robe River are an important component of the river ecosystem, supporting a diverse range of aquatic fauna and specialised flora such as yellow bladderwort (*Utricularia australis*) and water chestnut (*Eleocharis dulcis*). The pools act as refuges for fauna during periods of drought (EPA 1991). The riparian zone in the vicinity of the Project area also supports woodlands of silver cadjeput (*Melaleuca argentea*) and eucalypt (*Eucalyptus camaldulensis*, *E. victrix*). Lower tree and shrub layers in these woodlands are atypical of the Fortescue Botanical District, and as such, warrant conservation (EPA 1991). Cyclonic events and associated rainfall can severely affect the riparian vegetation, re-arrange braided channels and alter the size and position of permanent pools through scouring and aggradation (Dobbs & Davies 2009). In March 2004 for example, a rain depression in the wake of tropical cyclone Monty resulted in record rainfalls (376.6 mm) that caused widespread flooding throughout the Robe River valley and its surrounding catchments (Aquaterra 2004). High flows and flash flooding associated with cyclone Monty uprooted much of the Cadjeput woodland along the river channel in the vicinity of the Jimmawurrada-Robe confluence.

A number of potential short range endemic (SRE) aquatic invertebrates are known from the vicinity of the Project area and potentially occur within drawdown and dewatering impact zones. These species include stygal amphipods, isopods and syncarids, which are also known to occur in the hyporheic zones of the Robe River and/or tributary rivers. Further discussion of these species is provided in Section 3.

3 REVIEW OF PREVIOUS AQUATIC FAUNA AND STYGOFAUNA SURVEYS

The most comprehensive surveys of aquatic fauna within the Project area are those of Streamtec/UWA, who have conducted annual sampling of Robe River pools since 1992 (Dobbs & Davies 2009, Streamtec 1996 - 2014). Other recent studies include the Parks and Wildlife Pilbara Biological Survey (PBS); a region-wide survey of aquatic invertebrates conducted between 2003 and 2006, as part of a broader biodiversity survey (see Pinder *et al.* 2010). The PBS featured a number of ephemeral, long-term and permanent waterbodies within the vicinity of the Project area, including Mungarathoona Creek to the west, Myannore Creek and Yarraloola Station Claypan to the north-west, Nyeetbury Spring on upper Bungaroo Creek to the south-east, Kumina Creek in the upper Robe, and two pools on the Cane River to the south-west (Pinder *et al*. 2010). Morgan and Gill (2004) studied the distribution of fishes in inland waters of Pilbara, sampling 171 sites across 21 river systems between 2000 and 2002. Nearby sites included two pools on the Robe River close to the Project area; two on the lower Robe west of Mesa A/Warramboo, two on the lower Fortescue River to the north-west, and one on the Cane River. WRM previously sampled aquatic invertebrates and fish at Nyeetbury Spring (2009 - 2015) and Yalleen Pool (2010 - 2011) on Bungaroo Creek under the Proponent's Regional Aquatic Fauna Program (see WRM 2016). In 2008 and 2009, baseline surveys for the Australian Premium Iron (API) West Pilbara Iron Ore Project (WPIOP) were conducted, including sites on Mungarathoona Creek, Red Hill Creek and the Cane River (WRM 2009).

Additionally, stygofauna[3] have been sampled by Biota Environmental Sciences in the Mesa A/Warramboo Yarraloola Borefield to the west (Biota 2006a), and within the Ken's Bore and Cardo Bore areas along Red Hill Creek to the south-west (Biota 2010). Bennelongia Environmental Consultants surveyed stygofauna within the Bungaroo Creek catchment in the Buckland Hills area (Bennelongia 2013). Stygofauna were also surveyed by Parks and Wildlife as part of the PBS, including 36 bores within the Robe River catchment, sampled between 2002 and 2005 (see Eberhard *et al*. 2009, Halse *et al.* 2014).

A review of previous aquatic fauna surveys conducted within 100 km of the Project area, including sites sampled, methods used, and notable fauna found, is presented in the following sub-sections. A summary of the studies is provided in Table 1 and the sampling locations are shown in Figure 3. Studies referenced in this review were either conducted by WRM for the Proponent, or were publicly available, or records sourced from the Parks and Wildlife database NatureMap (http://naturemap.dpaw.wa.gov.au). In addition, direct requests were therefore made to Parks and Wildlife in order to obtain additional information on distribution of threatened, priority and vulnerable aquatic fauna.

For each species, conservation significance was assessed by reference to the IUCN Red List of Threatened Species, Parks and Wildlife Threatened and Priority Fauna Lists, as well as The Australian Faunal Directory, The Australian National Insect Collection Database and WRM's in-house database for distribution and occurrence information. Collectively, the previous studies have identified a number of species of conservation significance and/or scientific interest, which have the potential to reside, either seasonally or permanently, within the Project area and its expected drawdown zone and/or dewatering discharge footprint (acknowledging hydrological modelling for drawdown and dewatering discharge was not completed at the time of the survey or reporting).

A summary of aquatic species (including hyporheic species) of conservation and/or scientific value known to occur, or likely to occur within the Project area, is provided in Table 2, at the end of Section 3.

[3] Obligate inhabitants of groundwater environments, *e.g.* aquifers, caves and hyporheic (interstitial) spaces. Morphological adaptations to such environments include reduced body size, lack of pigmentation, reduced or absent eyes, and elongated appendages (*e.g.* antennae).

Table 1. Summary of previous recent aquatic fauna studies (invertebrates and fish) conducted within a 100 km radius of the Mesa H Project area, together with methodologies. Studies are listed in chronological order. Stygofauna assessments appropriate to the Project area are also included. Codes for 'Fauna sampled': Macro = macroinvertebrate; Micro = microinvertebrate; Hypo = hyporheos; Stygo = stygofauna).

Program	Sampled by	Locations sampled	Fauna sampled	Methods used	Taxonomic level	Sampling dates	Reference
Aquatic Fauna (Surface Water and Hyporheos)							
Proponent Mesa J Project Aquatic Ecosystem Study (long-term)	Streamtec / UWA	Robe River pools: • Gnieraoora, Martangkuna, Pulari-Nyunangka, Japanese pool, Yarramudda, Medawandy Waters, Pannawonica Hill pool, Chundy Pool, Ngalooin, Mussel Pool.	Macro Fish	• Macro – kick sampling (250 µm net) all habitats, • Fish – seine net and visual observation (mask and snorkel).	Species	Annually between Nov - Mar, 1991 - 2013.	Streamtec (1996, 1998, 2002, 2007-2009, 2011, 2014); Dobbs and Davies (2009)
Fish Fauna of Pilbara inland waters	Murdoch Uni	• Robe River near Mesa H and J, • Lower Robe River, west of Mesa A/Warramboo, • Lower Fortescue River (40 km NE), • Cane River (75 km SW).	Fish	• Fish – seine nets, gill nets, cast nets, rod and line, and visual observation (mask and snorkel).	Species	Once between Dec 2000 - Nov 2002.	Morgan and Gill (2004)
Hyporheos of five Pilbara springs	Parks and Wildlife	• Nyeetbury Spring on Bungaroo Creek, Robe River catchment (33 km SE).	Hypo	• Stirring up sediments and sweeping with a 250 µm mesh dip net, • Digging up sediments to a depth of 30 cm and collecting fauna caught with 50 µm and 250 µm mesh nets (Karaman-Chappuis method).	Species	Sep 2001.	Halse *et al*. (2002)
Pilbara Biological Study (PBS)	Parks and Wildlife	• Chalyarn Pool, Mungarathoona Creek, Robe River catchment (20 km W), • Red Hill Creek Pool, Robe River catchment (30 km SW), • Nyeetbury Spring on Bungaroo Creek (33 km SE), • Duck Creek Pool on Duck Creek, Ashburton River catchment (46 km SE), • Myannore Creek (49 km NNW), • Yarraloola Station Claypan (65 km NNW), • 2 sites on Cane River; House Pool and Creek Pool (70-75 km SW), • Kumina Creek (74 km SW).	Macro Micro	• Macro - kick sampling (250 µm net) all habitats, • Micro – sweep netting (50 µm mesh).	Species	Aug/Sep 2003, Aug/Sep 2004, May 2005, May 2006.	Pinder *et al*. (2010)

Aquatic Fauna (Surface Water and Hyporheos)							
API WPIOP Baseline Aquatic Fauna Survey	WRM	• 2 sites on Mungarathoona Creek (20 km W), • 6 sites on Red Hill Creek, (40 km SW).	Macro Micro Hypo Fish	• Macro – kick sampling (250 µm net) all habitats, • Micro – sweep netting (53 µm net) water column, • Hypo – Karaman-Chappuis method (53 µm net), • Fish – seine nets and gill nets.	Species	Dec 2008, Apr 2009.	WRM (2009)
Proponent Regional Aquatic Program (long-term)	WRM	• Yalleen Pool on Bungaroo Creek (23 km SE), • Nyeetbury Spring on Bungaroo Creek (33 km SE).	Macro Micro Hypo Fish	• Macro – kick sampling (250 µm net) all habitats, • Micro – sweep netting (53 µm net) water column, • Hypo – Karaman-Chappuis method (53 µm net), • Fish – seine nets and gill nets.	Species	Ongoing, wet and dry seasons since 2009.	WRM (2013, 2016)
Stygofauna							
Pilbara Biological Study (PBS)	Parks and Wildlife	• 36 bores across the Robe River catchment	Stygo	• Replicate hauls with weighted plankton nets (50 µm and 150 µm mesh).	Species	3 wet and 3 dry season occasions 2002 - 2005.	Eberhard *et al.* (2005, 2009); Halse *et al.* (2014)
Robe River Mining Co. Mesa A/Warramboo Baseline Stygofauna Assessment	Biota	• 21 bores within the Warramboo area, Robe River catchment (45 km W) • 20 bores within the Yarraloola area, Robe River catchment (40 km W)	Stygo	• Hauls with weighted plankton nets (150 µm mesh).	Species	Oct 2005.	Biota (2006a)
API WPIOP Baseline Stygofauna Assessment	Biota	• 58 bores within the WPIOP tenement areas, Red Hill Creek catchment (40 km SW)	Stygo	• Hauls with weighted plankton nets (70 µm mesh).	Species	Jun 2008, Sep 2009.	Biota (2010)
Iron Ore Holdings Bungaroo South Subterranean Fauna Assessment	Bennelongia	• 61 bores within Bungaroo South tenement, immediately south of the Project area.	Stygo	• Replicate hauls with weighted plankton nets (50 µm and 150 µm mesh).	Species	Jul 2012, Oct 2012.	Bennelongia (2013)

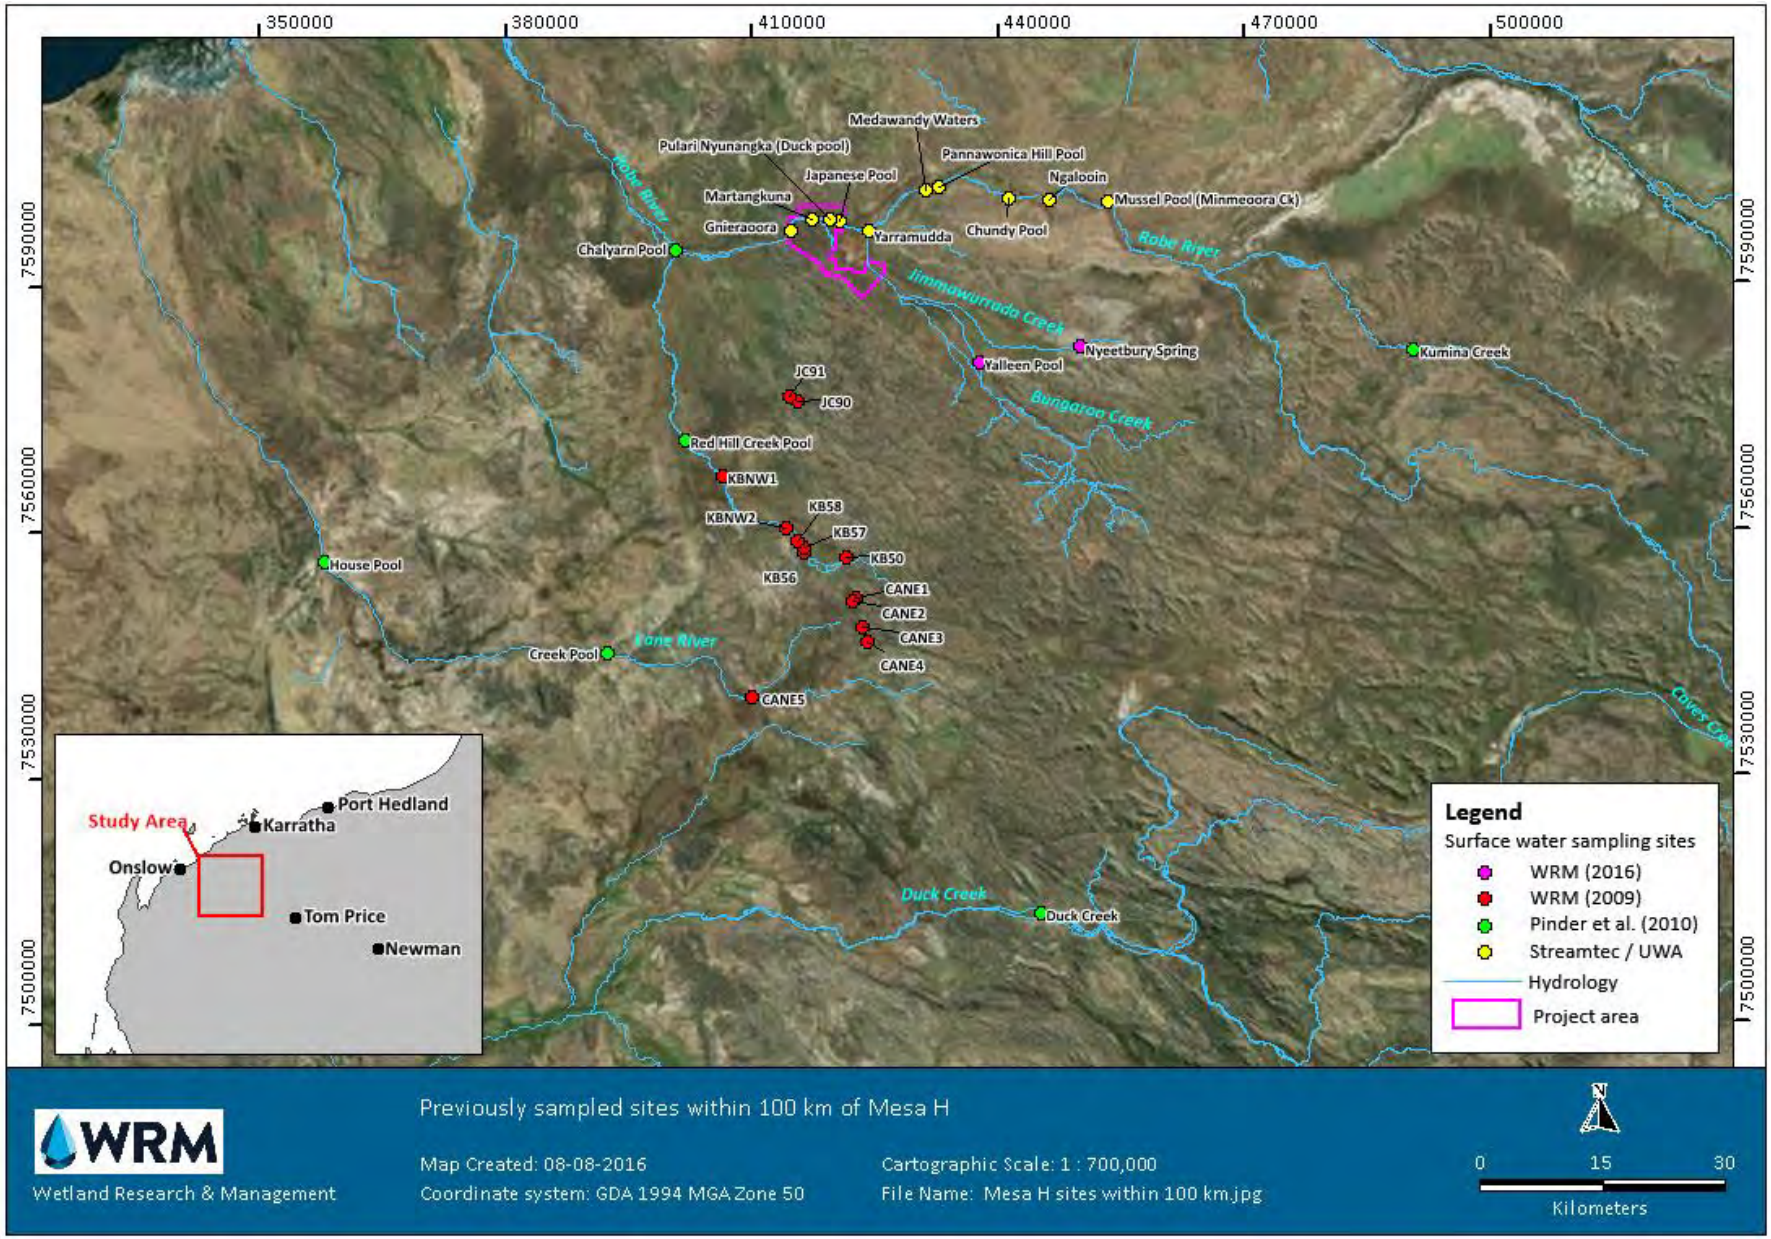

Figure 3. Locations previously sampled for aquatic invertebrates (Streamtec/UWA 1991 - 2014, WRM 2009 - 2016, Pinder *et al.* 2010) and fish (Streamtec 1991 – 2014) within 100 km of the Mesa H project area. Note, individual groundwater bores sampled for stygofauna (Biota 2006a, 2010, Eberhard 2009, Bennelongia 2013, Halse *et al.* 2014) are not detailed. Morgan and Gill (2004) did not provide GPS co-ordinates for their study of Robe River fish fauna.

3.1 Microinvertebrates (zooplankton)

The microinvertebrate fauna within the vicinity of the Project area is poorly known. Eight sites within 100 km of the Project area were sampled for microinvertebrates as part of the Parks and Wildlife PBS (Table 1). Pools sampled within the Robe River catchment included Chalyarn Pool (Mungarathoona Creek) and pools along Red Hill Creek, Myannore Creek, Kumina Creek, Nyeetbury Spring, Yalleen Pool and an ephemeral claypan on Yarraloola Station (Figure 3). Locations sampled outside the Robe River catchment included two pools on the Cane River to the south-west, and one on Duck Creek in the Ashburton River catchment (Figure 3). A combined total of 216 microinvertebrate taxa were recorded from these sites both within and outside of the Robe River catchment, sampled in August and September 2003/2004 (dry season) and May 2005/2006 (wet season). Wet season sampling appeared to favour microinvertebrate richness, with some of the most specious samples taken in May 2005 at House Pool on the Cane River (45 taxa), Red Hill Creek (42 taxa) and Chalyarn Pool (35 taxa).

WRM (2009) surveyed microinvertebrates in Mungarathoona Creek (two sites adjacent to the Jewel Cochrane development, to the south-east) and Red Hill Creek (six sites adjacent to Ken's Bore development) to the south east, as part of baseline aquatic surveys for API's WPIOP (Figure 3). A total 135 microinvertebrate taxa were recorded across two sampling events, conducted in December 2008 and April 2009 (WRM 2009).

WRM also conducts an ongoing aquatic fauna surveys under the Rio Tinto Pilbara Regional Program, which has previously included the microinvertebrate fauna of Yalleen Pool and Nyeetbury Spring on Bungaroo Creek (Figure 3). Biannual surveys collected a total 45 microinvertebrate taxa from Yalleen Pool, sampled between 2010 and 2011 (WRM 2013), and 160 taxa from Nyeetbury Spring, sampled between 2009 and 2016 (WRM 2016).

In each study, the microinvertebrate fauna was generally found to be typical of systems in the arid tropics (*e.g.* Koste and Shiel 1983, Tait *et al.* 1984, Smirnov and De Meester 1996, Segers *et al*. 2004). For example, in the nine featured PBS sites within the Robe River catchment (Table 1), species from the family Brachionidae (Rotifera) were poorly represented (14 taxa). This family tends to dominate temperate rotifer plankton, but is largely replaced by Lecanidae in tropic zones, as appears to be the case in the Pilbara (27 taxa; Pinder *et al.* 2010).

Microinvertebrate fauna of note (*i.e*. of conservation or scientific value) recorded from these studies included the stygal ostracod *Vestalenula matildae*, the rotifers *Colurella oblonga* and *Lecane noobijupi* and the cyclopoid copepod *Paracyclops* sp. 6. All these species have been recorded from within the Robe River catchment.

Vestalenula matildae was recorded at Mungarathoona Creek (Chalyarn Pool) during the PBS (Pinder *et al*. 2010). *V. matildae* is a recently described stygal species of ostracod known from groundwater (bores and wells) in the Ashburton River catchment (Government Well, Divide Well), DeGrey River catchment (Kylena Well, Home Well), and Sherlock River (Muorena Well). It has been recorded from hyporheic zones in the Ashburton (Yindabiddy Pool) and Fortescue River catchments (Weeli Wolli Spring), as well as surface waters in the Ashburton (Horrigans Pool), Fortescue (Gregory Gorge) and DeGrey (Coppin Gap, Chinaman Spring, Running Waters) (Martens and Rosetti 2002, Halse *et al*. 2002, Pinder *et al.* 2010, Schön *et al*. 2010). It appears to be endemic to the Pilbara, with no record to date of occurrence outside the region.

Colurella oblonga was collected at Nyeetbury Spring by WRM in 2012. This constituted the first record of *Colurella oblonga* from the Australian continent. This species is previously known from the southwest islands of Japan and from Europe (Dr Russel Shiel, University of Adelaide, pers. comm.).

Lecane noobijupi was collected from Nyeetbury Spring by WRM in 2011 and 2012, and from Red Hill Creek in 2009. This species is endemic to Western Australia, and appears to have a highly disjunct distribution. It was described from specimens collected from a wetland in the Muir-Unicup catchment in the south-west of the state (Lake Noobijup), and it had been thought to be restricted to that catchment (Segers and Shiel 2003). WRM has since recorded *Lecane noobijupi* from a number of locations throughout the Pilbara region, including Weeli Wolli Creek, Marillana Creek, Coondiner Creek, Mindy Mindy Creek and Kalgan Creek and (WRM 2016). Pinder *et al*. (2010) also recorded it from the DeGrey River. It would now appear that the Pilbara may be the normal locality of this species, and the Muir location in the south-west was an isolated occurrence.

Closer to the Project area, *Paracyclops* sp. 6 was collected from Chalyarn Pool, as well as Nyeetbury Spring and Kumina Creek (Pinder *et al*. 2010). This species is endemic to the Pilbara and is known from only 20 locations across the region, including the Ashburton River (Bobswim Pool, Fork Spring, Whiskey Pool, Cheela Spring, Paperbark Spring, Innawally Pool), Fortescue River (Palm Pool, Gregory Gorge, Palm Spring near Millstream, Joffre Creek), DeGrey River (Pelican Pool, Glen Herring Pool, Chinaman Spring, Minigarra Creek pools, Skull Springs and Bonnie Pool), Harding River (Springs Creek, Harding River Pool) and Sherlock River (Erawallana Spring and Pool Spring) (Pinder et al. 2010, WRM unpub. data).

Of the above-mentioned species, *Lecane noobijupi, Vestalenula matildae* and *Paracyclops* sp. 6 potentially occur within the Project area and its immediate vicinity but have a widespread distribution across the Pilbara.

3.2 Hyporheos

The hyporheos was not sampled by Streamtec/UWA during their long-term study of Robe River pools upstream, nor during the PBS (Pinder *et al.* 2010, Halse *et al.* 2014). However, biannual surveys of the hyporheos of upper Bungaroo Creek by WRM recorded a total of 22 hyporheic taxa from Yalleen Pool (WRM 2013) and 103 from Nyeetbury Spring (WRM 2016). Halse *et al.* (2002) recorded 62 hyporheic taxa from Nyeetbury Spring during one-off sampling in 2001. WRM (2009) also sampled the hyporheos of upper-Mungarathoona Creek and Red Hill Creek in 2008/2009, recording a combined total of 45 taxa.

Fauna of note collected during these studies included stygal amphipods and isopods that are likely SREs. Amphipods from the family Paramelitidae were collected from Yalleen Pool (WRM 2013), one site on Mungarathoona Creek, and three sites on Red Hill Creek (WRM 2009). These specimens were not able to be identified further than family level due to immaturity of life stage; however, they were considered likely to be SREs, given that most stygal Paramelitidae species are restricted to a small number of river systems within close geographical proximity to one-another (Finston *et al.* 2011).

At least three large isopod species are known from the subsurface zone of the Robe River catchment; *Pygolabis* sp. (Tainisopidae), *Tainisopus* sp. (Tainisopidae) and *Pilbarophreatoicus platyarthricus* (Amphisopodidae). Keable and Wilson (2006) documented *Pygolabis* sp. as occurring in the Robe River catchment but did not disclose the specific locality. Bennelongia (2013) also recorded P*ygolabis* sp. from two groundwater bores in the Bungaroo South area. All species of *Pygolabis* appear to be restricted to groundwaters and/or hyporheic zones of one or several creek drainages of the Pilbara region (Fortescue, Ashburton or Robe River catchments) (Keable and Wilson 2003) and at least some appear to be restricted to single sub-basins (Finston *et al.* 2009). Another undescribed, but closely related species, *Tainisopus* sp., is known to occur in the hyporheos of Nyeetbury Spring (Halse *et al.* 2002), as is *Pilbarophreatoicus platyarthricus* (WRM 2016). *P. platyarthricus* was first identified by Knott and Halse (1999) from Robe River specimens (including Chalyarn Pool), which were exclusively collected during the wet season "under cobbles in slow-flowing riffles … maintained by groundwater discharge." This species was also collected in surface water samples at Chalyarn Pool during the PBS (Pinder *at al.* 2010).

Although not specifically targeting hyporheic fauna, there have been a number of surveys of stygal communities in the vicinity of the Project area. These communities have taxa frequently encountered in hyporheic zones including SRE amphipods and isopods. These species may potentially occur in hyporheic zones within dewatering and drawdown zones in the Project area and the immediate vicinity.

The PBS sampled a total of 507 wells and drill holes across the Pilbara between 2002 and 2005, including 36 within the Robe River catchment area (Eberhard *et al.* 2005, 2009, Halse *et al.* 2014). A total of 110 stygal invertebrate taxa were recorded from bores in the Robe River catchment, including taxa belonging to the groups Oligochaeta (segmented worms), Polychaeta (bristle worms), Nematoda (round worms), Turbellaria (flat worms), Gastropoda (snails), Acarina (mites), Rotifera (wheel animals), Copepoda (copepods), Ostracoda (seed shrimps), Isopoda (aquatic slaters), Amphipoda (amphipods/side swimmers), Syncarida (syncarids) and Themosbaenacea (thermosbaenaceans). These taxa are also likey to occur within hyporheic zones of the Robe River. Out of the 110 taxa captured in the Robe River area, 83 were recorded from three or less bores (*i.e*. present at < 10% of bores), while just eight taxa were recorded from more than eight bores (*i.e.* present at > 20% of bores). It is possible that many of the uncommonly recorded stygofauna in this study are SREs.

Biota (2006a) sampled stygofauna from 21 bores within the Mesa A/Warramboo Project area and 20 bores in the Yarraloola area during 2005. In this study, a number of species which are occasionally encountered in hyporheic zones, such as stygal amphipods, copepods, and the themosbaenacean *Halosbaena tulki* were recorded, though it was noted that "there appears to be little in the way of a stygal community present at Warramboo". DNA sequencing delineated four new stygal amphipod species (Melitidae spp.), including two from the bores within the Mesa A/Warramboo Project area (Melitidae sp. A and sp. F), which currently are known only from the Mesa A/Warramboo Project area (Biota 2006a).

Biota (2010) sampled 58 bores in the Cardo East and Ken's Bore areas of the Red Hill Creek catchment. A number of potential SREs were recorded, including Paramelitidae (*Pilbarus* nr *millsi*, Paramelitidae sp. 2 and sp. 6), Melitidae (*Nedsia* spp., nr *Norcapensis* sp.), isopods (*Haptolana yarraloola*, *Kagalana tonde*, *Pygolabis* sp., *Pilbarophreatoicus platyarthricus*) and syncarids (*Bathynella* spp., Billibathynella sp. *Hexabathynella* sp. *Notobathynella sp.*).

Bennelongia (2013) sampled stygofauna in 61 bores within the Bungaroo South area in July and October 2012. Potential SREs recorded included Paramelitidae (Genus 2 sp. B12), Melitidae (*Nedsia* spp.), Neoniphargidae (nr *Wesniphargus*), the isopod *Pygolabis* sp. and syncarids (*Bathynella* spp., *Billibathynella* sp.).

3.3 Macroinvertebrates

Since 1991, Streamtec/UWA have conducted annual surveys for macroinvertebrates at seven long-term pools on the Robe River (Streamtec 1996 - 2014, Dobbs and Davies 2009). Pools include Medawandy Waters, Yarramudda, Japanese Pool, Martangkuna, Pannawonica Hill Pool, Pulari-Nyunangka, Gnieraoora (Figures 1 and 3). Four additional pools were included in the program during the 1990s; Chundy Pool, A1, Ngalooin and Mussel Pool (Figure 3). To date, over 112 macroinvertebrate taxa from 64 families have been recorded by Streamtec/UWA from 16 sampling occasions between February 1991 and December 2013. The most commonly encountered groups were the segmented Oligochaeta, Atyidae (freshwater prawns), Ephemeroptera (mayflies), Chironomidae (non-biting midges) and Dytiscidae (diving beetles). Streamtec/UWA noted that caddisflies (Trichoptera) were susceptible to changes in flow regime and water quality, with a decline in the number of species recorded following 1993, 2005, and 2012 cyclone events (Streamtec 2014).

The macroinvertebrate fauna of Chalyarn Pool (Mungarathoona Creek) was sampled during the PBS (Pinder *et al.* 2010). A total of 70 macroinvertebrate taxa were recorded at Chalyarn Pool in the wet season (May 2005), and 97 taxa were recorded in the dry season (August 2003). Other locations surveyed for macroinvertebrates in the vicinity of the Project area during the PBS included Red Hill Creek pools, Myannore Creek Pool and the Yarraloola Station claypan (Figure 3). A total of 196 macroinvertebrate taxa were recorded across these sites, sampled in August 2003/2004/2005 (dry season) and May 2003/2005/2006 (wet season). The most specious samples among these were collected at Red Hill Creek, with 90 taxa collected in both the wet and dry seasons (Pinder *et al.* 2010).

Macroinvertebrates from Mungarathoona Creek and Red Hill Creek were also sampled as part of baseline aquatic surveys for API's WPIOP area (WRM 2009). A total of 128 macroinvertebrate taxa were recorded across two sampling events; dry season (December) 2008 and wet season (April) 2009 (WRM 2009). The taxonomic list comprised Nematoda (roundworms), Hydrozoa (freshwater hydra), Oligochaeta (segmented worms), Gastropoda (snails and bivalves), Acarina (aquatic mites), Ephemeroptera (mayflies), Odonata (dragonflies and damselflies), Hemiptera (true bugs), Coleoptera (aquatic beetles), Diptera (aquatic fly larvae, including Chironomidae/midges), Trichoptera (caddisflies) and Lepidoptera (aquatic caterpillars).

The macroinvertebrate fauna of Yalleen Pool and Nyeetbury Spring on Bungaroo Creek have been sampled as part of the ongoing Pilbara Regional Aquatic Program for the Proponent (see WRM 2016). A total of 83 macroinvertebrate taxa were collected from Yalleen Pool from a total three sampling occasions; wet (March) and dry season (October) 2010 and wet season (March) 2011 (WRM 2013). A total of 190 macroinvertebrate taxa were recorded from Nyeetbury Spring from a total 13 occasions during biannual sampling (wet and dry seasons) between and October 2009 and May 2016 (WRM 2016).

The composition of macroinvertebrate taxa recorded during all of the above studies was typical of freshwater systems throughout the world (Hynes 1970), being dominated by Insecta (insects), within which Diptera (flies) and Coleoptera (beetles) were particularly well represented.

Of the macroinvertebrate fauna recorded from the Robe River catchment, two species are listed for conservation significance (IUCN Red List), and six are of scientific interest, being Pilbara endemics and/or relatively new to science. All potentially occur within the Project area. Three other Pilbara endemics have the potential to occur within the Project area (having been recorded within 100 km), and based on their known dispersal capabilities (*i.e.* with winged-adult forms with strong capacity for flight). These species are as follows:

- Conservation listed species recorded from the Robe River catchment:

  Eurysticta coolawanyah (Pilbara pin damselfly) (IUCN Near Threatened);
  Hemicordulia koomina (Pilbara emerald dragonfly) (IUCN Near Threatened);

- Pilbara endemic species recorded from the Robe River catchment:

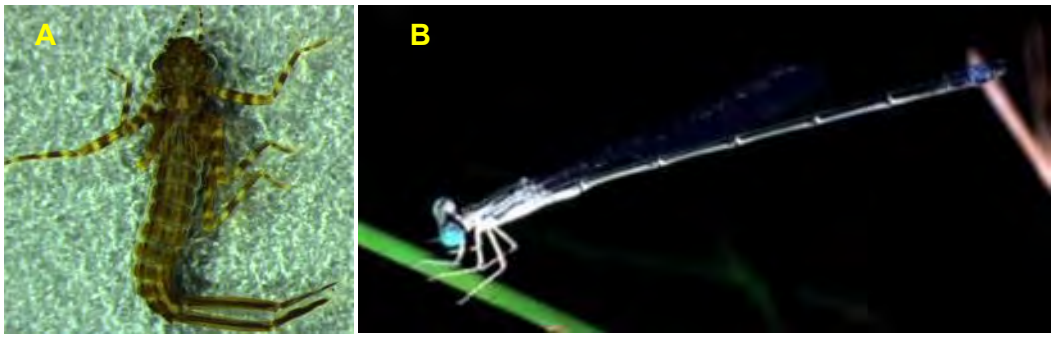
  Agriocnemis kunjina (Pilbara wisp damselfly);
  Ictinogomphus dobsoni (Pilbara tiger dragonfly);
  Nannophlebia injibandi (Pilbara archtail dragonfly);
  Tiporus tambreyi (diving beetle);
  Laccobius billi (water scavenger beetle);
  Haliplus halsei (crawling water beetle);

- Pilbara endemic species recorded from other locations within 100 km of the Project area:
  - *Sternopriscus pilbaraensis* (diving beetle);
  - *Tiporus lachlani* (diving beetle);
  - *Haliplus pilbaraensis* (crawling water beetle).

The Pilbara pin damselfly, *Eurysticta coolawanyah* (Plate 1A-B), is restricted to the Pilbara region, where it prefers riverine pools with an abundance of perching mediums (*e.g.* emergent reeds or overhanging riparian vegetation). *E. coolawanyah* has been collected from Robe River pools by Streamtec/UWA, and from Bungaroo Creek by WRM (2013, 2016). It has also been previously recorded at Chalyarn Pool (Pinder *et al.* 2010). *E. coolawanyah* is listed as Near Threatened[4] on the IUCN Red List of Threatened Species (IUCN 2016), based on its (initially recorded) restricted distribution to an area of less than 500 km^2, and it being thought to occur at less than five locations (Millstream Station, Nanuturra Pools, Palm Pool and the Millstream area); however, it has since been recorded from over 40 locations throughout the Pilbara (Pinder *et al*. 2010). Hawking (2009a) lists no known threats currently, or in the near future, to this species. WRM has encountered *E. coolawanyah* in habitats with a range in frequency of inundation and degree of persistence, including permanent/semi-permanent pools, permanent springs, ephemeral pools and sites permanently inundated and flowing due to dewatering discharge operations, for example at Weeli Wolli Spring.

The Pilbara emerald dragonfly, *Hemicordulia koomina* (Plate 1C-D), has been recorded by Streamtec/UWA from the Robe River, and from Red Hill Creek by Pinder *et al.* (2010). It is known to prefer large, permanent/semi-permanent pools. *H. koomina* is currently listed as Near Threatened on the IUCN Red List (IUCN 2016) but this listing is in need of revision given its more recent collections from numerous localities across several river catchments, including the Fortescue River (Hamersley Gorge, Fortescue Falls, Kalgan Creek), DeGrey River (Bamboo Springs, Minigarra Creek), Ashburton River system (Moreton Pool, Creek Pool near Mt Amy, Henry River pools, Pool at Gorge Junction), Sherlock River (Pool Spring) and Shaw River (Panorama Spring). Despite its widespread occurrence, *H. koomina* is infrequently collected, likely due to its preference for large, permanent pools, which are somewhat uncommon in the Pilbara region and inherently difficult to sample. The major threat to this species is considered to be loss of habitat (*i.e.* drying of permanent pools/waterways) through groundwater abstraction (Hawking 2009b).

Both of these species, particularly the large dragonfly *H. koomina*, are likely to have excellent dispersal capabilities in their winged-adult form (see Plate 1). Dispersal (the movement of individuals from one site to another) is an integral factor in determining the composition of biological communities (Palmer et *al*. 1996, Leibold *et al*. 2004). Aerial dispersal by winged-adult invertebrate fauna (*e.g.* Odonata, Coleoptera, Hemiptera, Ephemeroptera, Diptera and Trichoptera, *etc*.) has been recognised as the most important pathway for colonisation in arid and semi-arid wetlands (Gray and Fisher 1981). Heavy rainfall during the wet season also serves as a cue for many aquatic invertebrate taxa to migrate from perennial wetlands to colonise more ephemeral bodies of water (Lytle and Poff 2004). Given their proficient dispersal capabilities, and the record of these species at multiple locations within close proximity to the Project area, it is considered likely that macroinvertebrate sampling could reveal the presence of one or both of *E. coolawanyah* or *H. koomina* within the Project area.



[4] A species is listed under the IUCN Red List as Near Threatened when it has been evaluated against the criteria but does not qualify for Critically Endangered, Endangered or Vulnerable now, but is close to qualifying for or is likely to qualify for a threatened category in the near future (IUCN 2016).

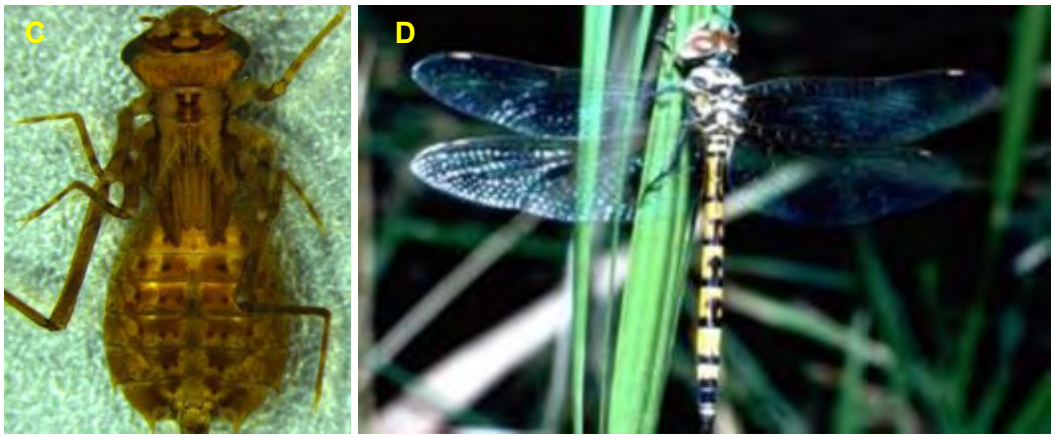


Plate 1. Pilbara pin damselfly, *Eurysticta coolawanyah* (A) nymph and (B) adult, and Pilbara emerald dragonfly *Hemicordulia koomina* (C) nymph and (D) adult (photos A and D courtesy of Jan Taylor ©).

The endemic Pilbara tiger dragonfly, *Ictinogomphus dobsoni*, is recorded infrequently and in low abundances from permanent still or sluggish waters of the Pilbara region (Watson 1991). It is known from a number of sites along the Fortescue, Robe, Ashburton, Yule, DeGrey and Sherlock rivers (DEC 2009, Pinder *et al*. 2010, CSIRO 2015). Near the Project area, *I. dobsoni* has been recorded from pools along the Robe River (Streamtec/UWA), Mungarathoona Creek (Chalyarn Pool) and Red Hill Creek (Pinder *et al*. 2010).

The Pilbara archtail dragonfly, *Nannophlebia injibandi*, is also restricted to the Pilbara region. This species was recorded infrequently during the PBS at Millstream Delta and Gregory Gorge in the Fortescue River catchment (Pinder *et al.* 2010). Within the vicinity of the Project area, *N. injibandi* has been recorded from Robe River pools near Mesa H (Streamtec/UWA) and from Red Hill Creek (WRM 2009).

The Pilbara wisp damselfly *Agriocnemis kunjina,* is a Pilbara endemic rarely encountered. It is previously known from Millstream, Harding River, and Tanberry Creek (ANIC Database); however, it was not recorded during the PBS (Pinder *et al.* 2010). *A. kunjina* is known from both still and flowing waters (Theischinger and Hawking 2006), and has been recorded from Robe River pools in the vicinity of the Project area (Streamtec/UWA) and from Yalleen Pool (WRM 2013).

The aquatic hydrophilid beetle *Laccobius billi* is a Pilbara endemic species that also is rarely collected. *L. billi* was only recorded from one site during the PBS; Cangan Pool on the Yule River (Pinder *et al.* 2010). WRM (2009) recorded *Laccobius billi* at Mungarathoona Creek and from a number of Red Hill Creek sites.

The haliplid beetles *Haliplus halsei* and *H. pilbaraensis* are both endemic to the Pilbara region, and are relatively new to science, having only been recently described (Watts and McRae 2010). Each species appears to occur widely throughout the Pilbara, and have been recorded at localities such as Glen Ross Creek, Coondiner Pool, the Fortescue Marsh, Moreton Pool, Paradise Pool, Munreemya Billabong, Wackilina Creek Pool, West Peawah Creek Pool, Harding River Pool, and an un-named creek in Millstream (Watts and McRae 2010). Closer to the Project area, *Haliplus halsei* has been recorded from Chalyarn Pool and Myannore Creek during the PBS (Pinder *et al*. 2010), while *Haliplus pilbaraensis* has been recorded from Red Hill Creek by WRM (2009).

The dytiscid beetle *Sternopriscus pilbaraensis* is endemic to the Pilbara, is relatively common and known from a range of systems, including Red Hill Creek, the Fortescue River (Gregory Gorge and Kalgan Pool), Ashburton River (Bobswim Pool, Yandabiddy Pool, Whiskey Pool, Ashburton at Gorge Junction, Innawally Pool and Rocky Island Pool), DeGrey River (Pool at Yarrie Homestead, Pelican pool on

Nullagine, Tanguin Rockhole, Paradise Pool, Munereemya Billabong, Carleecarleethong Pool, Minigarra Creek Pools, Bonnie Pool, Cookes Creek Pools, Running Waters and Pool on Tongolock), Rudall River (Watrara Creek Pool), Shaw River (Panorama Spring), Sherlock River (Kangan Pool) and the Harding River (Harding River Pool) (Pinder *et al.* 2010).

The diving beetles *Tiporus tambreyi* and *T. lachlani* are also relatively common and widespread across the region (Pinder *et al.* 2010, WRM unpub. data), though *T. lachlani* is less frequently encountered than its congener (Pinder *et al.* 2010, WRM unpub. data). In the vicinity of the Project area, *T. tambreyi* has been recorded from Robe River pools (Streamtec/UWA), Chalyarn Pool (Pinder *et al.* 2010) and Red Hill Creek (WRM 2009, Pinder *et al.* 2010), while *T. lachlani* has only been previously recorded from Red Hill Creek (Pinder *et al.* 2010).

3.4 Fish

The fish fauna of the Pilbara region is unique, with 13 freshwater species recorded from inland waters to date, including catadromous[5] species (Allen *et al.* 2002, Morgan and Gill 2004). Of the freshwater species, three (or possibly four) are considered endemic to the region. These include the golden gudgeon (*Hypseleotris aurea*), the Murchison River hardyhead (*Craterocephalus cuneiceps*), one undescribed eel-tailed catfish, the Pilbara tandan *Neosilurus* sp.[6], and the conservation listed Fortescue grunter (*Leiopotherapon aheneus*) (Morgan and Gill 2004). *L. aheneus* (Plate 2) is currently listed on the IUCN Red List of Threatened Species as Lower Risk/Near Threatened (IUCN 2016), and as a Priority 4 (P4)[7] species on the Parks and Wildlife Priority Fauna List (Parks and Wildlife 2016). The Fortescue grunter has a restricted distribution within the Pilbara, and is only known from the Fortescue, Robe and Ashburton River systems (Allen *et al*. 2002, Morgan and Gill 2004). This species is considered to be reasonably common within its range.

Plate 2. Fortescue grunter *Leiopotherapon aheneus.* Photo by Chris Hofmeester (WRM) ©.

Other known species from Pilbara inland waters include the spangled perch (*Leiopotherapon unicolor*), barred grunter (*Amniataba percoides*), western rainbowfish (*Melanotaenia australis*), bony bream (*Nematalosa erebi*), flathead goby (*Glossogobius giuris*), empire gudgeon (*Hypseleotris compressa*), Hyrtl's tandan (eel-tailed catfish; *Neosilurus hyrtlii*), blue catfish or lesser salmon catfish (*Arius graeffei*), and the Indian short-finned eel (*Anguilla bicolor*) (Allen *et al.* 2002, Morgan and Gill 2004, Beesley 2006). The most common and widespread species are spangled perch, western rainbowfish and bony bream (Plate 3). The western rainbowfish, for example, has a range extending from the Ashburton River in the Pilbara to the Adelaide River near Darwin, inhabiting rivers, creeks, swamps, lakes and reservoirs

[5] Catadromous fishes live in freshwater as juveniles or sub-adults, but migrate to marine habitats to spawn.

[6] Previously referred to as *Neosilurus hyrtlii*. Recent genetic evidence indicates the Pilbara species is distinct from elsewhere in Australia (Peter Unmack, National Evolutionary Synthesis Centre, North Carolina, pers. comm.).

[7] P4 species are those with limited distributions "in need of monitoring" (Parks and Wildlife 2016).

(Allen *et al.* 2002). Spangled perch and bony bream are considered to be two of Australia's most widespread freshwater fish species, found in drainages throughout the Pilbara, Kimberley, Northern Territory, Queensland, northern New South Wales, as well as in Lake Eyre and the Murray-Darling system (Allen *et al.* 2002).

In addition, the Pilbara Drainage Division contains two endemic cave fishes restricted to the North West Cape region; the blind gudgeon (*Milyeringa veritas*) and the blind cave eel (*Ophisternon candidum*) (Allen *et al.* 2002, Morgan and Gill 2004). Both *M. veritas* and *O. candidum* are listed as Vulnerable under the EPBC Act.

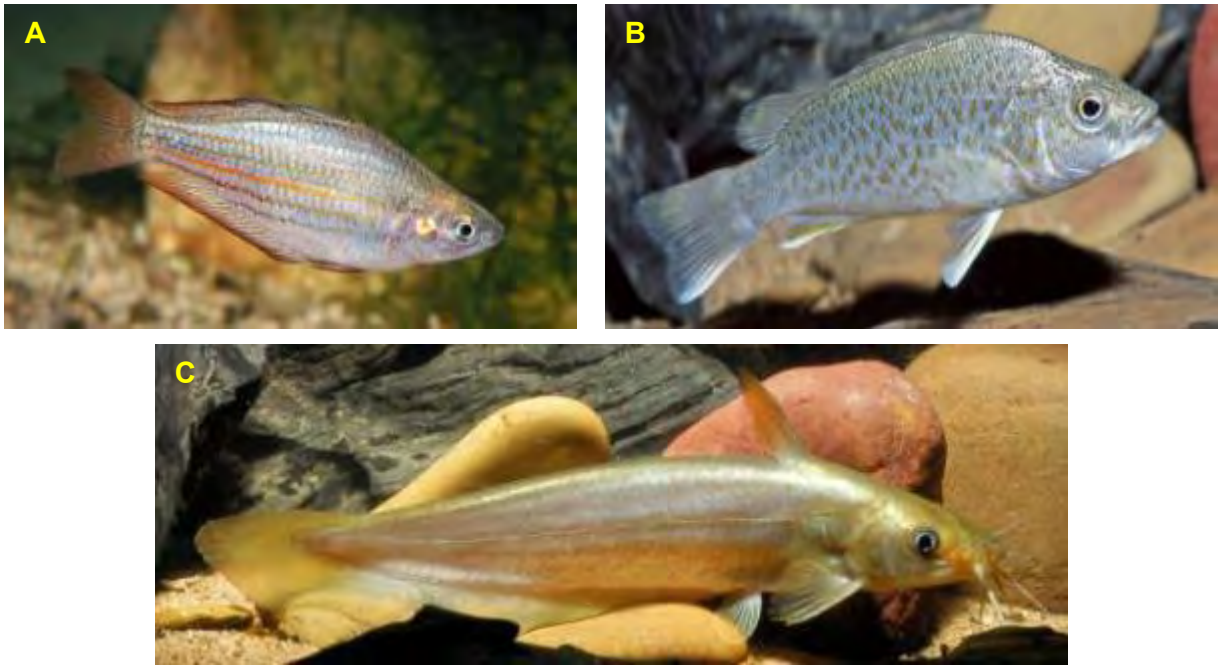

Plate 3. The three most commonly encountered freshwater fish species in the Pilbara; (A) western rainbowfish *Melanotaenia australis*, (B) spangled perch *Leiopotherapon unicolor* and (C) Pilbara tandan *Neosilurus* sp. (photos courtesy of Mark Allen ©).

Freshwater systems of the Pilbara also host a number of species that are considered to be of marine or estuarine origin, most of which have a non-obligatory freshwater juvenile phase. These commonly include barramundi (*Lates calcarifer*), mangrove jack (*Lutjanus argentimaculatus*), sea mullet (*Mugil cephalus*) and tarpon or ox-eye herring (*Megalops cyprinoides*) (Morgan and Gill 2004). The presence of marine/estuarine species in freshwater systems of the Pilbara is likely to be influenced by the frequency, timing and duration of flood events; the species listed above would only enter rivers if flooding coincided with their recruitment phase, while distance moved upstream is governed by the duration of the flood event (Morgan and Gill 2004). As floods recede, it is common for these species to become isolated in permanent upstream pools, forming small remnant populations that are cut-off from marine habitats (Morgan and Gill 2004).

Streamtec/UWA sampled the fish fauna of Robe River pools using seine nets, dip nets, and visual observation. Six freshwater fish species were recorded, including western rainbowfish, spangled perch, Pilbara tandan, barred grunter, bony bream and the conservation listed Fortescue grunter. Additionally, five marine vagrant/estuarine species were recorded, including tarpon, banded scat or striped butterfish (*Selenotoca multifasciata*), threadfin silver-biddy (*Gerres filamentosus*), sea mullet and mangrove jack.

Morgan and Gill (2004) surveyed four Robe River sites for fish using a combination of sampling methods (refer Table 1). Six freshwater species were again recorded (western rainbowfish, spangled perch, Pilbara tandan, barred grunter, bony bream and Fortescue grunter); however, no marine/estuarine

species were reported. Morgan and Gill (2004) also included historic records from the Western Australian Museum (WAM) that list empire gudgeon as occurring in the Robe River in the vicinity of the Project area.

The Department of Water (DoW) conducted a review of the ecological values of the lower Robe River, west of the North West Coastal Highway crossing point and Mesa A/Warramboo deposits, which included a summary of the freshwater and estuarine fish fauna of that reach (Antao and Braimbridge 2010). The review did not document any species from the lower Robe River that were not recorded by Streamtec/UWA or Morgan and Gill (2004).

WRM (2016) has recorded seven species from Nyeetbury Spring on upper Bungaroo Creek; Pilbara tandan, western rainbowfish, flathead goby, spangled perch, Fortescue grunter, barred grunter, and a fish that appears to be a hybrid between two of the three co-occurring terapontids (grunters; spangled perch, barred grunter and Fortescue grunter). At Yalleen Pool on Bungaroo Creek, WRM (2013) recorded only western rainbowfish, spangled perch and Pilbara tandan. WRM (2009) also surveyed the fish fauna of upper-Mungarathoona Creek, recording five species; western rainbowfish, spangled perch, Pilbara tandan, barred grunter and Fortescue grunter.

3.5 Other Fauna

3.5.1 Turtles

Although not typically targeted in aquatic surveys, one species of native turtle is known from the Pilbara region; the flat-shelled *Chelodina steindachneri.* This species has a widespread distribution throughout the Pilbara, having been recorded from most major river systems in the region, from the DeGrey River in the north to the Murchison River in the south (Kuchling 1988, WRM unpub. data). These turtles are adapted to survive drought by burrowing into the dry river beds (Kuchling 1988). Only one clutch of seven to eight relatively small eggs is laid each year; a pattern that appears to be adapted to a relatively long period of aestivation of up to three years (Kuchling 1988).

EPA (1991) note *Chelodina steindachneri* as present at Gnieraoora and Martangkuna, but do not state the source of the records, which was possibly the 1991 survey by Streamtec/UWA. Neither Antao and Braimbridge (2010) nor Pinder *et al.* (2010) document turtles. Similarly, turtles were not recorded or observed at upper-Mungarathoona Creek or Red Hill Creek by WRM (2009); however, given its widespread distribution across the Pilbara region, it is possible that *Chelodina steindachneri* may reside in pools in the vicinity of the Project area.

3.5.2 Frogs

The Pilbara is host to 13 species of frogs, three of which are endemic to the region; *Pseudophryne douglasi* (Gorge toadlet), *Uperoleia glandulosa* (Glandular toadlet) and *U. saxatilis* (Pilbara toadlet) (Tyler and Doughty 2009, Doughty *et al*. 2011). None of these species are currently listed for conservation significance, though *U. saxatilis* has only recently been described (Catullo *et al.* 2011). *U. saxatilis* is broadly distributed throughout the Pilbara, occurring in or near rocky creeks, and appears to be adapted to rocky landscapes (Catullo *et al.* 2011, Doughty *et al*. 2011). *U. glandulosa* has a more restricted distribution in the northern coastal Pilbara but penetrates inland along the Yule River drainage (Catullo *et al.* 2011, Doughty *et al*. 2011). *Pseudophryne douglasi* is a rare species that has an ancient relictual arid distribution separate from other toadlets (Doughty *et al*. 2011, WA Museum).

The Pilbara, Gascoyne and Murchison populations of the desert tree frog, *Litoria rubella*, are separated from Kimberley and Northern Territory populations by the Great Sandy Desert. *L. rubella* is known to

occur in a wide range of habitats across northern Australia, including northern Western Australia, Northern Territory, north-east of South Australia, Queensland, and northern New South Wales (Tyler and Knight 2011). The desert tree frog is commonly found sheltering under stones or bark around creeks and waterholes, and can breed at any time of year if water is present (Tyler and Knight 2011).

Frogs are difficult to survey in the Pilbara region, as captures are typically dependent on rainfall that is spatially and temporally variable (Doughty *et al*. 2011). Many frog species of the Pilbara aestivate over dry periods to avoid desiccation, emerging following rains to opportunistically breed and spawn (Tyler and Doughty 2009). No data were available on targeted frog surveys in the vicinity of the Project area, and although there have been a number of terrestrial vertebrate surveys (*e.g.* Biota 2005, 2006b, 2009, Strategen 2006), few have recorded frogs. Biota (2006a) recorded two species of Hylidae (tree frogs): *L. rubella* and *Cyclorana maini* - and one Myobatrachidae (southern frog) species *Uperoleia russelli* during baseline surveys for the Mesa A/Warramboo project area. In addition to *L. rubella* and *U. russelli*, Biota (2009) recorded the ornate burrowing frog *Platyplectrum ornatus* (formerly *Limnodynastes ornatus)* from the Red Hill Creek catchment.

3.6 Summary of Known Species of Conservation and/or Scientific Interest

Table 2 below provides a summary of known aquatic invertebrates (including hyporheos) and fish of conservation and/or scientific interest.

Table 2. Aquatic species (invertebrates and fish) of conservation and/or scientific value known to occur, or likely to occur, within the Project area.

Species	Common name	Scientific value	Conservation listing	Occurrence within 100 km of Project area	Likelihood of occurrence within the Project area	Occurrence elsewhere
Microinvertebrates						
Lecane noobjupi	Rotifer	WA endemic	N/A	Nyeetbury Spring, Red Hill Creek	High in surface waters	Weeli Wolli Ck, Marillana Ck, Coondiner Ck, Mindy Mindy Ck, Kalgan Ck and Un-named Ck, DeGrey R. Also in SW Western Australia
Paracyclops sp. 6	Copepod (micro-crustacean)	Pilbara endemic	N/A	Chalyarn Pool	High in surface waters	20+ locations Pilbara-wide
Vestalenula matildae	Ostracod (micro-crustacean)	Pilbara endemic	N/A	Chalyarn Pool	High in surface waters	Various systems of the Ashburton R., DeGrey R., Fortescue R. and Sherlock R.
Hyporheos						
Paramelitidae spp.	Stygal amphipods	Potential SRE	N/A	Yalleen Pool, Red Hill Ck, Mungarathoona Ck.	High in ground-waters and hyporheos	Unknown given family level identification.
Melitidae spp.	Stygal amphipods	Potential SRE	N/A	Bores across the Robe River catchment area	High in ground-waters; Low-moderate in hyporheos	Unknown given family level identification
Haptolana yarraloola	Stygal isopod	Potential SRE	N/A	Bores in the lower Robe River catchment area – Mesa A/Warramboo/Yarraloola	Low	Recently described species; known only from Mesa A/ Warramboo/Yarraloola bores
Kagalana tonde	Stygal isopod	Potential SRE	N/A	Bores in the lower Robe River catchment area – MesaA/Warramboo/Yarraloola	Low	Recently described genus and species; elsewhere known from Cane River and Hardey River catchments
Pilbarophreatoicus platyarthricus	Stygal isopod	Potential SRE	N/A	Chalyarn Pool, Nyeetbury Spring, Bores in the Robe River catchment area	High in ground-water and hyporheos	Weeli Wolli Ck, Coondiner Ck, Bobswim Pool (Ashburton R.)
Pygolabis sp.	Stygal isopod	Potential SRE	N/A	One undescribed species known from the Robe River catchment	High in ground-water and hyporheos	Uncertain. Members of this genus restricted to either Fortescue, Ashburton or Robe catchment groundwater and hyporheos
Tainisopus sp.	Stygal isopod	Potential SRE	N/A	Nyeetbury Spring	Low-moderate; only known from Nyeetbury Spring hyporheos	Unknown given genus level identification

Species	Common name	Scientific value	Conservation listing	Occurrence within 100 km of Project area	Likelihood of occurrence within the Project area	Occurrence elsewhere
Parabathynellidae spp.	Stygal syncarids	Potential SRE	N/A	Unknown given genus level identification	High in ground-waters; Low-moderate in hyporheos	Unknown given genus level identification
Macroinvertebrates						
Hemicordulia koomina	Pilbara emerald dragonfly	Pilbara endemic	IUCN, Near Threatened	Robe River pools, Red Hill Ck.	High in surface waters	Fortescue R., Coondiner Ck; now known to be widespread throughout the Pilbara, though infrequently collected
Eurysticta coolawanyah	Pilbara pin damselfly	Pilbara endemic	IUCN, Near Threatened	Chalyarn Pool, Robe River pools, Yalleen Pool	High in surface waters	Ashburton R. (Bobswim Pool); Kalgan Ck; Coondiner Ck; Fortescue R.
Ictinogomphus dobsoni	Pilbara tiger dragonfly	Pilbara endemic	N/A	Chalyarn Pool, Robe River pools, Red Hill Ck.	High in surface waters	Fortescue, Ashburton, Yule, DeGrey and Sherlock rivers
Nannophlebia injibandi	Pilbara archtail dragonfly	Pilbara endemic	N/A	Robe River pools, Red Hill Ck.	Low-Moderate in surface waters	Fortescue R. catchment, but uncommonly collected
Agriocnemis kunjina	Pilbara wisp damselfly	Pilbara endemic	N/A	Robe River Pools, Yalleen Pool	Low-Moderate in surface waters	Millstream, Harding River, Tanberry Ck; rarely collected
Haliplus halsei	Aquatic beetle	Pilbara endemic	N/A	Chalyarn Pool, Myannore Ck.	Low-Moderate in surface waters	Uncommonly collected from ephemeral systems and claypans, *e.g.* the Fortescue Marsh and Coondiner Pool
Haliplus pilbaraensis	Aquatic beetle	Pilbara endemic	N/A	Red Hill Ck.	Low-Moderate in surface waters	Uncommonly collected from ephemeral systems and claypans, *e.g.* the Fortescue Marsh and Coondiner Pool
Sternopriscus pilbaraensis	Diving beetle	Pilbara endemic	N/A	Red Hill Ck.	Moderate in surface waters	A range of systems across the Pilbara, fairly commonly collected
Tiporus tambreyi	Diving beetle	Pilbara endemic	N/A	Chalyarn Pool, Robe River pools, Red Hill Ck.	Moderate-High in surface waters	A range of systems across the Pilbara, very commonly collected
Tiporus lachlani	Diving beetle	Pilbara endemic	N/A	Red Hill Ck.	Low-Moderate in surface waters	A range of systems across the Pilbara, infrequently collected
Laccobius billi	Aquatic beetle	Pilbara endemic	N/A	Mungarathoona Ck, Red Hill Ck.	Low-Moderate in surface waters	Yule R. and Fortescue R.

Species	Common name	Scientific value	Conservation listing	Occurrence within 100 km of Project area	Likelihood of occurrence within the Project area	Occurrence elsewhere
Fish						
Leiopotherapon aheneus	Fortescue grunter	Pilbara endemic	IUCN Near Threatened; Parks and Wildlife P4	Robe River pools, Red Hill Ck., Mungarathoona Ck.	High in surface waters	Fortescue R (below Fortescue Marsh); Ashburton R.

4 METHODS FOR BASELINE SURVEYS

4.1 General

For the current baseline field sampling, WRM employed sampling design, methods and general approaches consistent with the following:

- Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC/ARMCANZ 2000);
- Environment Protection Authority (EPA) Guidance No. 20, Sampling of Short Range Endemic Invertebrate Fauna for Environmental Impact Assessment in Western Australia (EPA 2009);
- EPA Position Statement No. 3, Terrestrial Biological Surveys as an Element of Biodiversity Protection (EPA 2002);
- EPA Guidance No. 56, Terrestrial Fauna Surveys for Environmental Impact Assessment in Western Australia (EPA 2004).

Aquatic fauna sampling methods were also similar to the following:

- Streamtec/UWA surveys of benthic macroinvertebrates of the Robe River (see Dobbs and Davies 2009, Streamtec 2014);
- Parks and Wildlife surveys of benthic macroinvertebrates for the regional Pilbara Biological Survey (PBS) (see Pinder *et al.* 2010).

4.2 Licences

This study was conducted under Department of Fisheries (DoF) Exemption #2706 (Authority to Take Fish for Scientific Purposes), and Parks and Wildlife Licence SF010732 (Licence to Take Fauna for Scientific Purposes).

As a condition of these licences, taxa lists and reports are required to be submitted to the respective government departments, and have been done so.

4.3 Sampling Design and Sites

The sampling design is an mBACI (multiple Controls - Before/After - Control/Impact) type design (Keough and Mapstone 1995). Location and number of sites were selected to provide data for robust statistical analysis and to meet requirements of such a design. An mBACI design is considered ideal for impact assessment, as impacts may be placed in context with natural temporo-spatial catchment changes. An mBACI type design provides both benchmark information as well as a strong basis to detect future changes. Reference sites upstream of the Project area were selected to serve as the "control" for potentially impacted sites. Surveys conducted in April/May 2016 are part of the benchmark or "before" phase against which to assess any potential future changes.

Sampling was conducted during the late wet season, between 28th April and 7th May 2016.

A total of 12 pools were sampled along the main channel of the Robe River (Table 3 and Figure 1). Sites included six potentially exposed sites within the predicted surface extent of dewatering discharge, and six reference sites upstream of the Jimmawurrada Creek-Robe River confluence.

Table 3. Aquatic ecosystem sampling sites on the Robe River. Equivalent sites monitored by Streamtec/UWA are also indicated.

Type	WRM Site	Description	GPS co-ordinates (zone 50 K)		Date sampled	Maximum wetted width, length and depth of pool (m)			Streamtec/ UWA site
			Easting	Northing		Width	Length	Depth	
Reference	RRU1	Approx. 3.7 km upstream of Pannawonica Hill.	435628	7603253	05-05-16	20	100	1.2	
	RRU2	Approx. 600 m downstream of Streamtec/UWA site at Pannawonica Hill Pool; upper end of Medawandy Waters area, adjacent Mesa N.	431811	7602046	28-04-16	9	55	3.0	Pannawonica Hill
	RRU3	Approx. 1.6 km downstream of Pannawonica Hill, near Mesa N; within the Medawandy Waters area.	430912	7601562	28-04-16	5	3	1.0	Medawandy
	RRU4	Approx. 1.5 km downstream of RRU3; within the Medawandy Waters area, in the vicinity of Mesa M.	429677	7601439	28-04-16	20	120	1.0	
	RRU5	Approx. 1 km downstream of RRU4; within the Medawandy waters area, adjacent Mesa L.	428769	7601342	29-04-16	10	40	1.2	
	RRU6	Approx. 1 km upstream of Jimmawurrada Creek confluence; lower end of the Medawandy waters area, at base of Mesa L.	424573	7597240	07-05-16	12	40	0.6	
Potentially Exposed	RRD1	Martangkuna; approx. 600 m downstream of existing Mesa J dewatering discharge point (*i.e.* western discharge point).	417110	7598094	30-04-16	3	7	0.8	Martangkuna

	RRD3	Approx. 1 km downstream of RRD3.	415309	7598013	30-04-16	5	25	1.0	
	RRD4	Approx. 1.1 km downstream of RRD3; 1 km upstream of Yeera Bluff.	414419	7597633	29-04-16	20	150	2.0	
	RRD5	Gnieraroora / Dthulurat* at Yeera Bluff; 8.6 km downstream of existing Mesa J western discharge point.	414426	7596622	29-04-16	25	45	4.0	Gnieraoora
	RRD6	Approx. 12.5 km downstream of existing Mesa J western discharge point; within projected discharge footprint (at 20 ML/day).	411415	7594924	30-04-16	30	20	1.2	

* Dthulurat = Western Guruma name.

The original intent was that the assessment would utilise, wherever possible, long-term data from sites sampled by Streamtec/UWA; however, only two of these sites are located within the predicted footprint of surface discharge extent; Martangkuna (RRD1) and Gnieraoora/Dthulurat (RRD5). Therefore, four new sites (RRD2, RRD3, RRD4 and RRD6) were added to allow a more robust characterisation of ecological condition within this reach (Table 3 and Figure 1). These sites may also be exposed to any runoff from the Project area.

Of the sites sampled by Streamtec/UWA upstream of the Jimmawurrada-Robe confluence, two were selected as reference sites for the Project area; Medawandy and Pannawonica Hill Pool; however, only Medawandy (RRU3) held surface water at the time of sampling in April-May 2016. Therefore, five new reference sites were established within the Medawandy Waters area; RRU1, RRU2, RRU4, RRU5 and RRU6 (Table 3 and Figure 1). Site photographs are provided in Appendix 1.

The 2016 sampling was timed to correspond with recessional flow conditions at the end of the wet (April-May) season. It was considered that the end of the wet season would be a more ecologically important time of year to sample, as biological diversity would be expected to be at its highest. By comparison, lower biological diversity may be expected at the start of the wet season, as many invertebrate fauna would not yet have emerged/colonised the seasonal creeks.

4.4 Water Quality

At each site, pH, dissolved oxygen and temperature were measured *in situ* using hand-held Wissenschaftlich-Technische-Werkstätten (WTW) field meters. Meters were calibrated immediately prior to field surveys. Water depth was measured using a graduated pole. Undisturbed water samples were collected for laboratory analyses of major ions, alkalinity, dissolved metals, nutrients and total suspended solids (TSS). Water samples for nitrogen and phosphorus nutrient and dissolved metal analyses were filtered in the field through 0.45 µm nitrocellulose filters. To avoid contamination, all sample bottles and filtering equipment used for dissolved metals were acid-washed (0.1% nitric acid) prior to use. Bottles and filters used for nutrients weren't acid washed to avoid nitrogen contamination from nitric acid. Water samples for analysis of dissolved metals and nutrients were collected using nitrile gloves. All samples were double-wrapped in polyethylene zip-lock bags and kept cool on ice-packs in an esky while in the field and during transport. At the end of each field day, samples were either refrigerated (ions and metals) or frozen (nutrients). Samples were stored refrigerated or frozen for a maximum of 10 days prior to transport on ice to analytical laboratories at ChemCentre, Bentley, together with chain-of-custody forms. All water quality variables measured are summarised in Table 4.

4.4.1 Comparison against ANZECC/ARMCANZ Guidelines

Water quality data were compared against default ANZECC/ARMCANZ (2000) guidelines (trigger values) for the protection of freshwater ecosystems (provided in Appendix 2). Default trigger values (TVs) for 95% aquatic species protection were considered more appropriate than default TVs for 99% protection, given that the Robe River catchment in the vicinity of current mining operations is already slightly to moderately disturbed by historic mining and pastoral practices (Strategen 2006). In accordance with ANZECC/ARMCANZ (2000) however, the default 99% TVs were applied to bioaccumulating metals such as selenium. For metals and nutrients, dissolved concentrations (0.45 µm filtered samples) were compared to the default TVs. Filtered concentrations were considered a better reflection of the fraction that may be bioavailable. By contrast, comparison of the default TVs to the total metal or total nutrient concentration may overestimate the risk to the environment (ANZECC/ARMCANZ 2000).

Table 4. Measured and derived water quality and habitat parameters. Metals (Al, As, B, Ba, Cd, Co, Cr, Cu, Fe, Mn, Mo, Ni, Pb, S, Se, U, V, Zn) and nutrients ($N\text{-}NH_3$, $N\text{-}NO_2$, $N\text{-}NO_3$, $N\text{-}NO_X$, N-total, P-total) were measured as dissolved concentration. All units for water quality parameters are mg/L unless stated otherwise.

Water Quality Parameters	Code	Habitat Parameters	Code
Temperature (°C)	Temp	Maximum pool depth (m)	depth
pH (H^+)	pH	Maximum wetted length of pool (m)	length
Dissolved oxygen (%)	DO%	Mean wetted width of pool (m)	width
Dissolved oxygen (mg/L)	DO	Mineral substrates (total % cover within habitat)	min
Conductivity (µS/cm)	EC	Bedrock (% cover)	bedr
Redox (mV)	Redox	Boulders >256 mm (% cover)	boul
Alkalinity (as $CaCO_3$)	Alk	Cobbles 64-256 mm (% cover)	cobb
Ammonia	$N\text{-}NH_3$	Pebbles 16-64 mm (% cover)	pebb
Arsenic	As	Gravel 4-16 mm (% cover)	grav
Barium	Ba	Sand 1-4 mm (% cover)	sand
Boron	B	Silt <1 mm (% cover)	silt
Cadmium	Cd	Mean particle size (from substrate proportions)	phi
Calcium)	Ca	Emergent macrophyte (% cover)	emerg
Carbonate	CO_3	Submerged macrophyte (% cover)	submerg
Chloride (mg/L)	Cl	Floating macrophyte (% cover)	float
Chromium (µg/L)	Cr	Algae (% cover)	algae
Copper (µg/L)	Cu	Detritus (% cover)	detr
Hardness (as $CaCO_3$)	Hard	Riparian vegetation canopy (% canopy cover)	ripvegco
Hydrogen carbonate	HCO_3	Large woody debris (>10 cm diameter) (% cover)	LWD
Iron	Fe	Root mats (% cover)	rootm
Lead	Pb	Trailing riparian vegetation (% cover)	ripveg
Magnesium	Mg	Habitat diversity (total no. of habitat types)	habdiv
Manganese	Mn	Substrate compaction (1 = loose, to 5 = armoured)	compct
Nickel	Ni	Substrate diversity (total no. substrate types)	subdiv
Nitrate-nitrogen	$N\text{-}NO_3$		
Nitrite-nitrogen	$N\text{-}NO_2$		
Nitrogen oxides	$N\text{-}NO_X$		
Nitrogen-total	N-total		
Phosphorus-total	P-total		
Potassium	K		
Selenium	Se		
Sodium	Na		
Sulfate	$S\text{-}SO_4$		
Sulfur	S		
Total dissolved solids	TDS		
Total suspended solids	TSS		
Uranium	U		
Vanadium	V		
Zinc	Zn		

4.5 Habitat Characteristics

Details of habitat characteristics at each site were recorded (Table 4) to assist in explaining any patterns in faunal assemblages, particularly due to existing differences in benthic substrate composition. Habitat parameters were assessed for the approximately 10 m section of river over which each macroinvertebrate sample was collected. Water depth was measured with a graduated pole. Substrate type was visually assessed and recorded as estimated percent cover by bedrock, boulders, cobbles, pebbles, gravel, sand, silt and clay, from which mean particle size was determined using the phi scale. As an indication of habitat heterogeneity, the number of organic and inorganic substrate types

represented at each site was totalled. Habitat characteristics recorded included estimated percent cover by inorganic sediment, submerged macrophyte, floating macrophyte, emergent macrophyte, algae, large woody debris, detritus, roots and trailing vegetation.

WRM has specific worksheets for this task to ensure qualitative habitat recordings between sites are as comparable as possible. To limit variation due to different observers, all estimations were made by the same sampler.

4.6 Microinvertebrates (zooplankton)

Microinvertebrate samples were collected from each site by gentle sweeping over an approximate 15 m distance with a 53 µm mesh plankton net (Plate 4). Care was taken not to disturb the benthos (bottom sediments) during sampling. Samples were preserved in 70% ethanol and sent to Dr Russell Shiel at the University of Adelaide, South Australia, for processing. Dr Shiel is a world authority on microfauna, with extensive experience in fauna survey and impact assessment across Australasia, including the Pilbara.

Plate 4. Microinvertebrate sampling at RRD4.

Microinvertebrate samples were processed by identifying the first 200-300 individuals encountered in an agitated sample decanted into a 125 mm^2 gridded plastic tray, with the tray then scanned for additional missed taxa also taken to species and recorded as 'present'. Specimens were identified to the lowest taxon possible, *i.e*. species or morphotypes. Abundance data were reported as log_{10} scale abundance classes (*i.e.* 1 = individual, 2 = 2-10 individuals, 3 = 11-100 individuals, 4 = 101-1000 individuals, 5 = >1000). Where specific names could not be assigned, vouchers were established. These vouchers are held by Dr Shiel at Adelaide University, Adelaide, Australia.

4.7 Hyporheos

At each site, hyporheic sampling was conducted using the Karaman-Chappuis method (Delamare Deboutteville 1960). This involved digging a hole approximately 20 cm deep and 40 cm diameter in alluvial gravels in dry streambed adjacent to the water's edge, allowing the hole to infiltrate with water, and sweeping the water column with a modified 110 µm mesh plankton net (Plate 5). The water column was swept immediately after the hole had filled, and again after approx. 30 minutes, once other sampling had been conducted.

Plate 5. Hyporheic sampling at RRU3.

Samples were preserved in 70% ethanol and returned to the laboratory for processing. Any aquatic fauna present was removed from samples by sorting under a low power dissecting microscope. In-house expertise was used to identify the majority of hyporheic taxa using available published keys and through reference to the established voucher collections held by WRM. External specialist taxonomic expertise was sub-contracted to assist with Chironomidae (Dr Don Edward, UWA) and micro-crustacea (Dr Russel Shiel, University of Adelaide).

All taxa recorded from hyporheic samples were classified using the categories of Boulton (2001):

- stygobite, *i.e.* obligate groundwater species, with special adaptations to survive such conditions,
- permanent hyporheos stygophile, *i.e.* epigean[8] species that may occur in both surface and groundwaters, but is a permanent inhabitant of the hyporheic zone,
- occasional hyporheos stygophile, *i.e.* species that use the hyporheic zone seasonally or during early life history stages, or
- stygoxene, *i.e.* species that appear rarely and apparently at random in groundwater habitats; there by accident or seeking refuge during spates or drought; not specialised for dwelling permanently underground.

4.8 Macroinvertebrates

Macroinvertebrate sampling was conducted with a 250 μm mesh FBA pond net (Plate 6). All meso-habitats were sampled, including trailing riparian vegetation, woody debris, open water column and benthic sediments with the aim of maximising the number of species recorded. Each sample was washed through a 250 μm sieve to remove fine sediment, while leaf litter and other debris were carefully washed in the sieve and removed by hand. Samples were then preserved in 70% ethanol. In the laboratory, macroinvertebrates were removed from samples by sorting under a low power dissecting microscope.

Plate 6. Macroinvertebrate sampling at RRU5.

Collected specimens were identified to the lowest practicable level (typically genus or species) and enumerated to $\log_{10}$ scale abundance classes (*i.e.* 1 = individual, 2 = 2-10 individuals, 3 = 11-100 individuals, 4 = 101-1000 individuals, 5 = >1000). In-house expertise was used to identify invertebrate taxa using available published keys and through reference to the established voucher collections held by WRM. External specialist taxonomic expertise was sub-contracted to assist with Chironomidae (Dr Don Edward, UWA).

4.9 Fish

A number of fish sampling methods were used at each site in order to collect as many species and individuals as possible. Methods included electrofishing, seine nets and gill nets. Electrofishing was conducted with a Smith-Root Model LR24 battery powered backpack electrofisher (Plate 7A). Electrofishing is an extremely useful and efficient sampling tool in rivers with clear, low salinity, slow flow water. All meso-habitats within a maximum 40 m reach were shocked with the intention of recovering as many species/individuals as possible. Shocking was not continuous, but targeted areas of optimum habitat, whereby the operator would shock, move to a new habitat before shocking again, and so prevent fish being driven along in front of the electrical field.

Duplicate 30 m multi-panel gill nets were set at each site where there was sufficient depth of water (Plate 7B). Each net consisted of 6 x 5 m panels, with panels increasing in size from 1" to 6" stretched mesh size. The nets were set perpendicular to the bank, with the smallest mesh set against the bank, and the large mesh positioned into the channel with a float and weight to keep the nets in place. At

[8] Epigean – living or occurring on or near the surface of the ground.

each sampling location, two nets were set for approximately 2.5 hours. Nets were checked frequently to avoid fish deaths. Catch from the duplicate nets were combined to form one replicate sample from each sampling location.

Smaller species and juveniles were sampled by beach seine (10 m net, with a 2 m drop and 6 mm mesh) deployed in shallow areas where there was little vegetation or large woody debris. Typically, two seine hauls were made at each location to maximise the number of individuals caught.

All fish were identified in the field, measured for standard length (SL)[9], and then released alive. Fish nomenclature followed that of Allen *et al.* (2002). Fish measurements provided information on the size structure, breeding and recruitment of fish populations.

Plate 7. Example of electrofishing (left), and setting gill nets at RRU1 (right).

4.10 Data Analysis

Samples were grouped *a priori* into categories according to exposure; potentially exposed sites downgradient of the Jimmawurrada-Robe confluence (RRD) or reference sites upgradient of the Jimmawurrada-Robe confluence (RRU). Water quality and species richness (number of taxa) data were plotted in order to illustrate spatial differences. For comparison of species richness against previous studies, invertebrate taxonomy was standardised across datasets to account for differences in taxonomic resolution and/or advancements in taxonomic knowledge between studies (*i.e.* some taxa were condensed to family or order level to enable comparison). As such, taxa richness may appear lower than was originally reported in each study. Where sufficient numbers of each fish species were measured, length-frequency histograms of current data were plotted.

Univariate analyses (one-way ANOVA) was used to test for statistically significant (p <0.05) differences in water quality variables and micro- and macroinvertebrate species richness between groups (RRD, RRU). The assumptions of normality and homogeneity of sample variances were checked using Shapiro-Wilk and Levene's tests, respectively. Data were $\log_{10}(x+1)$ transformed where appropriate. All univariate analyses were performed using IBM SPSS Statistics (v21) software package.

Multivariate patterns in micro- and macroinvertebrate species assemblages were analysed using procedures from the PRIMER (v7) software package (Clarke and Gorley 2006). Non-metric Multi-Dimensional Scaling (nMDS) ordination plots (Clarke and Warwick 2001) were constructed to visualise differences between sites. nMDS ordinations were based on Bray-Curtis similarity measures for species abundance ($\log_{10}$ class) data. Ordinations were depicted as two-dimensional plots. The Analysis of

[9] Standard length (SL) - measured from the tip of the snout to the posterior end of the last vertebra or to the posterior end of the mid-lateral portion of the hypural plate (*i.e.* this measurement excludes the length of the caudal fin).

Similarity (ANOSIM) routine within PRIMER was used to test for significant ($p < 0.05$) differences in species assemblages between groups (RRD, RRU), based on both abundance (log_{10} class) and presence/absence data. The SIMPER routine within PRIMER was used to determine those species contributing most to the similarity/dissimilarity between significant site groupings identified by ANOSIM.

Too few taxa were recorded from hyporheic samples to warrant ANOVA or PRIMER analyses of these data.

4.11 Survey Limitations

Inherent physical sampling deficiencies are acknowledged as a barrier to sampling aquatic fauna, and in particular fish. For example, fish catch rates may have been hindered by the abundance of aquatic vegetation (macrophytes and algae) which physically obstructed seine and gill nets at some sites. This was somewhat compensated for by the use of a back-pack electrofisher, which generates a pulsed direct electrical current to draw fish out from under such habitat.

This study provides a snapshot of water quality conditions and faunal communities at a single point in time, and is unlikely to fully capture the range of temporal/seasonal variability within the Project area. Prior to sampling, total monthly rainfall at Pannawonica Gauging Station was well below the 45-year average, particularly during February, March and April. As such, there was no surface flow connecting pools along the Robe River, with pools heavily receded and even some fish mortality evident, possibly due to low overnight dissolved oxygen concentrations. The relative lack of rainfall leading up to the survey may also have caused recordings of some other water quality parameters, such as salinity and nutrients, to be higher than would be expected under “average” wet season baseflow conditions, due to evapo-concrentration effects and lack of flushing within the system. Dry conditions may also have affected aquatic faunal communities, particularly hyporheic fauna, which require saturation of the alluvium and strong connectivity between ground and surface waters, and fish, with many speces known to require higher baseflows and connectivity between pools to enable upstream migration and spawning.

5 RESULTS AND DISCUSSION

5.1 Water Quality

5.1.1 General

Raw data for spot measurements of water quality, made in conjunction with aquatic fauna sampling, are provided in Appendix 3. Water quality was highly variable amongst sites (Figures 4 and 5). Salinity levels ranged from fresh[10] (592 µS/cm, RRD5) to brackish (1,700 µS/cm, RRU6), pH from circum-neutral (6.9, RRU3) to slightly alkaline (7.9, RRU1), hardness from 230 mg/L (RRD2) to 520 mg/L (RRU6), total suspended solids from <1 mg/L (RRD4, RRU3, RRU4) to 34 mg/L (RRD5), and dissolved oxygen from hypoxic[11] (14.5%, RRU5) to supersaturated (134.9%, RRD6).

There were no obvious longitudinal gradients upstream or downstream of the Jimmawurrada-Robe confluence. Site RRU6 (located ~1 km upstream of the confluence), together with the downstream sites, tended to have higher salinity (as EC and TDS), alkalinity, hardness and concentrations of associated ions, than sites upstream (Figure 3). Maximum values for most of these parameters (*i.e.* EC, TDS, hardness, Na^+, Cl^+, Ca^{2+}, $S\text{-}SO_4$, Mg^{2+}) and for nitrogen (as N-total, $N\text{-}NO_X$, $N\text{-}NH_3$) were recorded at RRU6. Average concentration of K^+, $S\text{-}SO_4$ and total dissolved sulfur (S) was significantly higher downstream of the Jimmawurrada-Robe confluence (one-way ANOVA, Table 5).

Table 5. Summary results from one-way ANOVAs testing for significant (p <0.05) differences in mean concentrations of water quality parameters, upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Only significant results are shown. Mean (±SE) vales for untransformed data are also provided.

Water quality parameter	ANOVA (df = 1, 11)			Mean (±SE)	
	MS	F	p	RRD (n = 6)	RRU (n = 6)
Fe	0.005	9.52	0.012	0.05 (0.01)	0.12 (0.005)
K	23.24	21.96	0.001	8.4 (0.52)	5.6 (0.29)
S	352.08	35.62	<0.001	25.3 (0.95)	14.5 (1.54)
$S\text{-}SO_4$	2104.10	15.52	0.003	70.2 (4.67)	43.7 (4.83)

The significantly higher concentrations of some ions, most notably $S\text{-}SO_4$, and to a lesser extent Mg (Figure 4), downstream of the Jimmawurrada-Robe confluence, may reflect the influence of dewatering discharge from current mining operations. Some inter-site variability could also be attributed to differences in volume of the remnant pools sampled, and evapoconcentration effects under recessional flows. For example RRU6, where maximum values for a number of parameters were recorded, was the shallowest of the pools sampled (maximum water depth of 0.6 m), and supported extensive organic deposits and abundant macrophyte growth (*Typha* and *Potamogeton*) (Appendix 4). The relative abundance of macrophytes, algae and accumulated organics would also be expected to have varying effect on DO levels, pH and rates of nutrient recycling within each of the pools. The higher level of TSS recorded at Gnieraoora (RRD5) compared to all other sites (Figure 5) was likely due to recent cattle activity, which caused the physical disturbance and suspension of benthic sediments.

At most sites, Na^+ was the dominant cation, with Ca^{2+} sub-dominant, and HCO_{3-} the dominant anion, with Cl^- sub-dominant. The exception was RRU6, where Cl^- was dominant and HCO_{3-} sub-dominant. This suggests groundwater ingress had less influence on the water chemistry of the remnant pool at RRU6

[10] Fresh defined as < 1,500 µS/cm; brackish = 1,500 – 4,500 µS/cm; saline = 4,500 - 50,000 µS/cm; hypersaline > 50,000 µS/cm (DoE 2003). Classifications were presented as TDS (mg/L) in DoE (2003) so a conversion factor of 0.68 was used to convert to conductivity µS/cm as recommended by ANZECC/ARMCANZ (2000).

[11] Dissolved oxygen (DO) levels of zero percent saturation = anoxic; < 20% = defined as hypoxic; 100% = saturated; >100% = super-saturated; more oxygen is dissolved than would be in a state of equilibrium.

than at other pools, which may help to also explain the relatively higher salinity at RRU6 (*i.e*. less groundwater inflow to offset effects of evapoconcentration).

5.1.2 Exceedance of ANZECC/ARMCANZ default TVs

Exceedance of ANZECC/ARMCANZ default 95% TVs was recorded for EC, DO, dissolved zinc, N-total, N-NO_x and N-NH_3 at a number of sites upstream and downstream of the Jimmawurrada-Robe confluence (refer Appendix 3). No exceedance of ANZECC/ARMCANZ (2000) default TVs was recorded for any other parameter. Exceedances are discussed in the following sub-sections.

Electrical Conductivity (EC)

EC values were in exceedance of the ANZECC/ARMCANZ (2000) TV (250 μS/cm) at all sites sampled, although surface waters could still be classified as "fresh" (<1,500 μS/cm) at most sites (Figure 4). The relatively higher EC at RRU6 (1,700 μS/cm) constitutes "brackish" conditions, and was above EC levels reported during long-term monitoring of Robe River pools by Streamtec/UWA and the Proponent (*i.e.* 453 - 1,400 μS/cm). Elevated EC was again considered due to high levels of evapoconcentration in these isolated pools, a process common to surface waters in arid/semi-arid zones (Jolly *et al.* 2008). Although some dilution may occur following wet season rains, salinity can often remain high in arid-zone surface waters due to the variability of flows and flushing of stored salts (Jolly *et al.* 2008). ANZECC/ARMCANZ (2000) acknowledge that the default TV for EC may not be representative of local background levels in all areas of Australia. In such instances, ANZECC/ARMCANZ (2000) recommend developing site-specific trigger values (SSTVs) relevant to local conditions.

Dissolved Oxygen (DO)

Daytime DO saturation was below the ANZECC/ARMCANZ (2000) lower TV (80%) at the majority of sites, and above the upper TV (120%) at RRD6 (134.9%) (Figure 5 andAppendix 3). In aquatic ecosystems, low DO levels are typically considered of greater concern than high levels; however, super-saturated levels (>100%) during the day are often indicative of anoxic or hypoxic conditions at night. Low DO is commonly associated with standing pools (with little physical aeration) that support heavy organic loads (*e.g.* aquatic vegetation, algae, bacteria, *etc.*) (Caraco and Cole 2002). DO saturation is typically lowest in the early morning, following overnight consumption of oxygen through the respiratory processes of aquatic biota (Caraco and Cole 2002, Connolly *et al.* 2004, Flint *et al.* 2014). Sites which exhibited particularly low DO in the current study (*e.g.* RRU3 16.1%, RRU5 14.5%) were sampled early in the morning (*i.e.* between 0700 hrs and 0830 hrs), and also tended to support relatively high abundances of macrophytes and/or algae (Appendix 4). While the oxygen needs of aquatic biota differ between species and life history stages, values less than 50% saturation are associated with chronic responses in fish and macroinvertebrates (Connolly *et al.* 2004, Flint *et al.* 2014).

Super-saturation can occur when net photosynthesis exceeds total oxygen consumption in waterbodies, and is common in areas of high algal and macrophyte growth, particularly if spot measurements are taken later in the day (Caraco and Cole 2002). The organic habitat at RRD6, (134.9% DO) comprised emergent and submerged macrophyte (covering 50% of the site area; Appendix 4), and the spot measurement of DO was taken at 1230 hrs, when photosynthetic processes were likely near their peak. Waterbodies with super-saturated daytime DO are likely to experience overnight hypoxia or anoxia, as respiration by plants, algae, bacteria and other aquatic fauna deplete DO (Caraco and Cole 2002, Connolly *et al.* 2004, Flint *et al.* 2014).

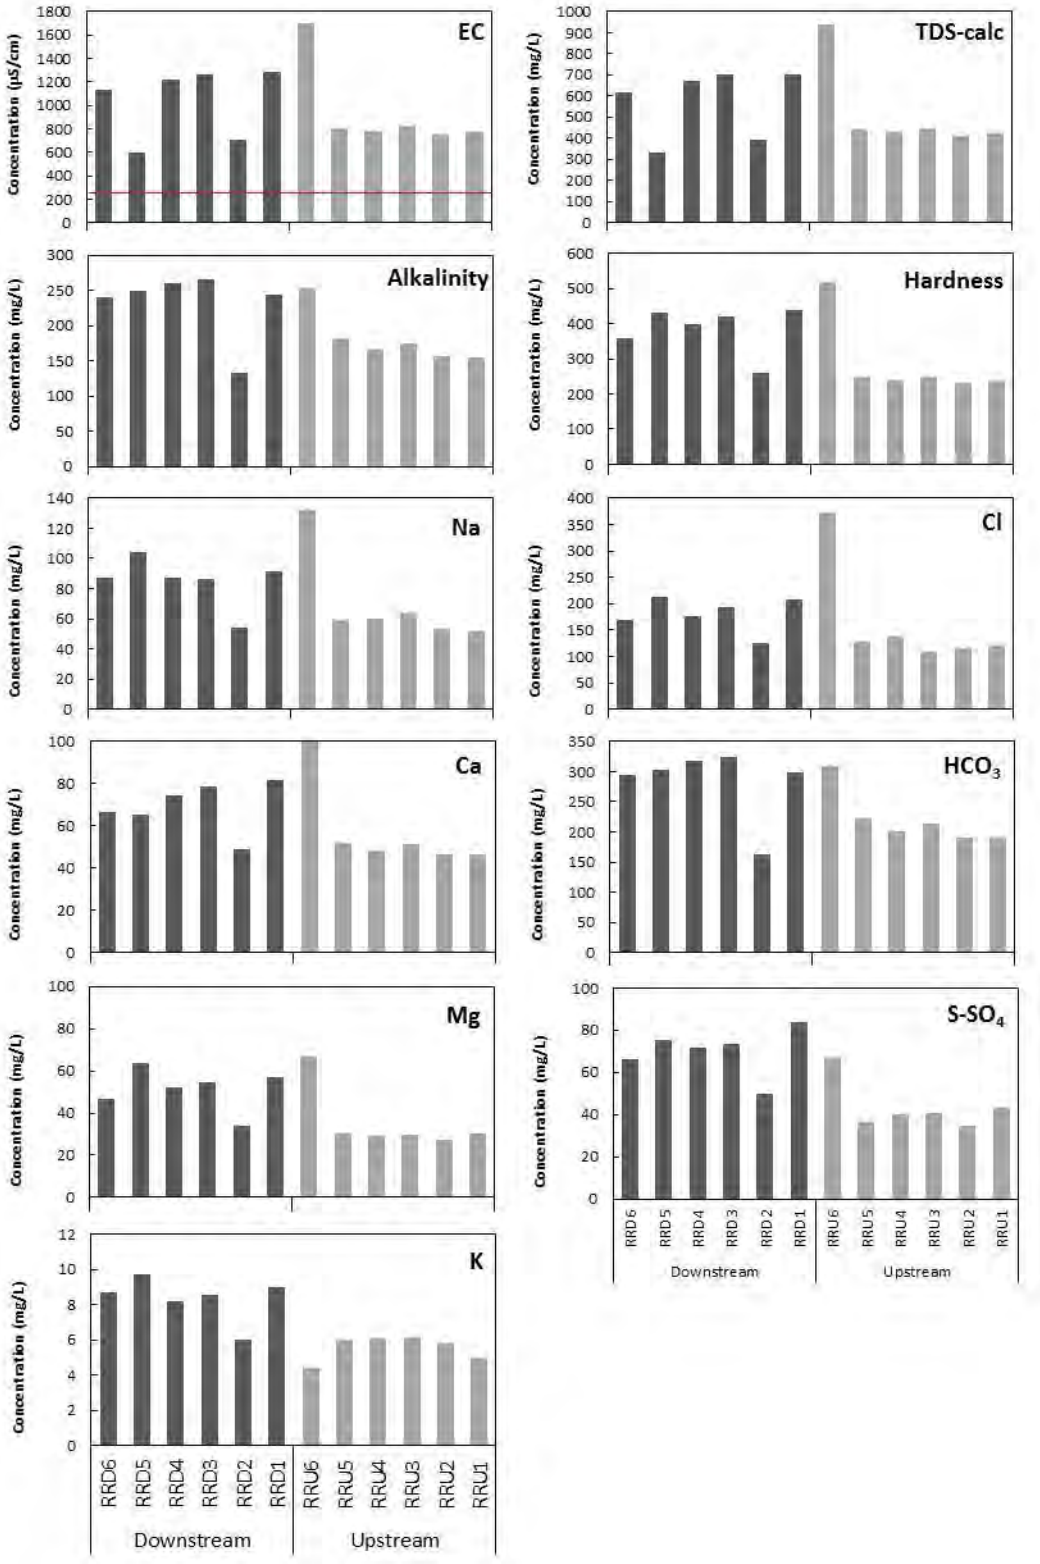

Figure 4. Comparison of EC, alkalinity, hardness and concentration of major ions amongst surface water sampling sites upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence. Refer Table 1 for explanation of site codes and Figure 1 for location of sites. ANZECC/ARMCANZ (2000) default 95% species protection level TV (unbroken red line) is indicated for relevant parameters.

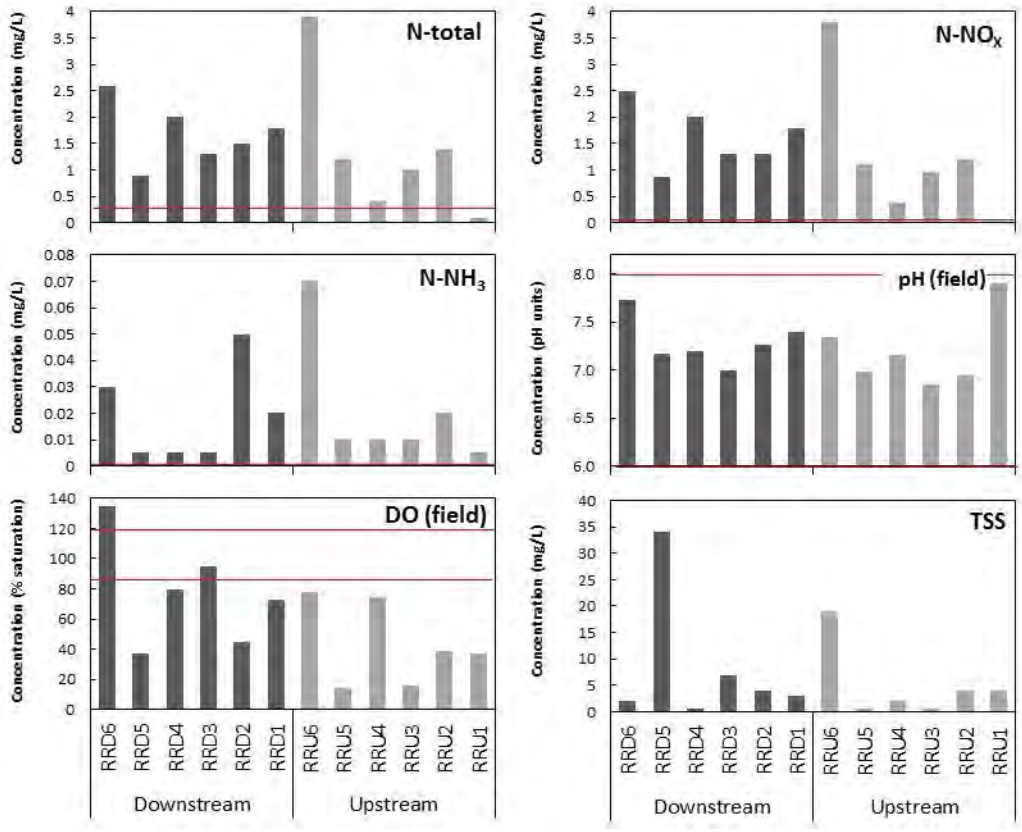

Figure 5. Comparison of N-total, N-NO_X, N-NH_3, pH, DO and TSS amongst surface water sampling sites upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence. Refer Table 1 for explanation of site codes and Figure 1 for location of sites. ANZECC/ARMCANZ (2000) default 95% species protection level TV (unbroken red line) is indicated for relevant parameters; upper and lower TVs are shown for pH and DO.

Dissolved zinc

Dissolved zinc (dZn) concentration was in exceedance of ANZECC/ARMCANZ (2000) TVs (0.008 mg/L) at RRU5 (0.012 mg/L) and RRD3 (0.011 mg/L) (Appendix 3). ANZECC/ARMCANZ (2000) provide algorithms to calculate hardness modified TVs (HMTVs), as hardness has an ameliorating effect on the toxicity of a number of metals including cadmium, lead, nickel and zinc[12]. However, once the algorithm was applied, concentrations of dZn at RRU5 and RRD3 still excceded HMTVs. Although elevated, it is unknown what proportion of dZn was labile (bioavailable) or unavailable through processes such as complexing with dissolved organic carbon. Where dissolved levels are elevated, ANZECC/ARMCANZ (2000) recommends testing for labile concentrations/bioavailability to assess if levels are likely to be toxic to aquatic fauna. Given that exceedances of the ANZECC/ARMCANZ (2000) TV were recorded at sites both upstream (reference) and downstream of the Jimmawurrada-Robe confluence, it is unlikely that current Mesa J discharge operations are influencing dZn levels in the Project area.

Nitrogen (N-total, N-NO_X, N-NH_3)

At most sites (except RRU1), N-total, N-NO_X and N-NH_3 exceeded ANZECC/ARMCANZ (2000) default 95% TVs for protection against eutrophication (0.3 mg/L N-total, 0.01 mg/L N-NO_X, 0.01 mg/L N-NH_4[13])

[12] HMTV algorithm for zinc = Default TV*(Hardness/30)^0.85.
[13] Ammonia was analysed as nitrogen-ammonia (N-NH_3), so a conversion factor of 1 was used to convert to nitrogen as ammonium (N-NH_4) for comparison against ANZECC/ARMCANZ (2000) default TV for protection against eutrophication.

(Figure 5 and Appendix 3). N-NO_X levels were greatly in exceedance, *i.e.,* 10 times the default TV at most sites. N-NO_3 constituted nearly all of the measured N-NO_X and N-total (Appendix 3).

In order to compare against the default 95% TV for nitrate as a toxicant (0.7 mg/L NO_3), N-NO_3 concentrations were converted to NO_3 concentration by multiplying by a factor of 4.4. NO_3 exceeded the default 95% TV for nitrate as a toxicant at most sites (except RRU1); however, the default toxicant TV is currently under review as being too conservative. The new ANZECC/ARMCANZ 95% TV for NO_3 as a toxicant is likely to be around 2 - 2.5 mg/L N-NO_3 (~11 mg/L NO_3) (R. van Dam, *eriss*, pers. comm.), and will incorporate most recent data from acute and chronic toxicity testing in New Zealand. Recently published guidelines for Canada also recommend a higher guideline of 2.9 mg/L N-NO_3 (~13 mg/L NO_3) for freshwaters (CCME 2014). In comparison to the proposed ANZECC/ARMCANZ TV of 2 - 2.5 mg/L N-NO_3, only the concentration at RRU6 (3.8 mg/L) was still in exceedance, though the concentration at RRD6 (2.5 mg/L) was close to exceedance. Similar elevated levels of N-NO_3 have been recorded at Medawandy Waters (3.1 mg/L N-NO_3, 3.45 mg/L N-total) during previous monitoring in the Project area (Rio Tinto unpub. data).

Elevated background levels of N-NO_3 and N-NH_3 within the Project area are unsurprising, given that the Robe River catchment is already effected by current and historic pastoral practices (Strategen 2006). Cattle, or evidence of high cattle use were observed at a number of pools during the survey. Elevated N-NO_3 and N-NH_3 in waterbodies caused by livestock disturbance can reduce acid-neutralising capacities of waterbodies, adversely affect the growth, survival and reproduction of aquatic fauna, and most notably stimulate eutrophication and algal blooms (Camargo and Alonso 2006). Another potential anthropogenic source is ammonium nitrate used in mine explosives, though groundwaters in arid zone areas across Australia are often naturally enriched in nitrate, as is the case in the current Project area (Magee 2009).

Significantly higher concentrations of some ions, most notably S-SO_4, and to a lesser extent Mg, as well as elevated N-total and N-NO_x downstream of the Jimmawurrada-Robe confluence (Figures 4 and 5), may also reflect the influence of current mining operations discharges on the water quality of the downstream reach. The elevated S-SO_4 and Mg may indicate presence of geochemical reactions, resulting in the release of these elements downstream of the existing discharge points. The elevated nitrogen levels may indicate discharge of groundwater elevated in nitrates, with groundwaters in the vicinity of current mining operations appearing to be enriched (*e.g.* up to 23.9 mg/L N-NO_3 in bore MB15MEH014) (Rio Tinto unpub. data). The relative contribution of anthropogenic and natural sources to nitrogen enrichment in surface and groundwater of the Project area is unknown, but discharge of nitrogen-enriched groundwater has resulted in elevated nitrate levels in surface waters downstream of other BWT mining operations in the Pilbara.

5.2 Microinvertebrates

5.2.1 Species richness and abundance

A total of 81 microinvertebrate taxa were recorded from the Project area in May 2016, of which 46 were present at potentially exposed sites downstream of the Jimmawurrada-Robe confluence, and 69 were recorded at upstream reference sites (Table 6 and Appendix 5). The list includes groups which could not be identified to species level due to unresolved taxonomy and/or immature specimens. Therefore, the total microinvertebrate species richness is likely to be greater than that reported. Microinvertebrate composition included Protista (protists), Rotifera (rotifers), Copepoda (copepods), Cladocera (water fleas) and Ostracoda (seed shrimp) (Table 6). Generally, Rotifera dominated microinvertebrate taxa at each site, with comparatively few Copepoda, Ostracoda and Cladocera. The microinvertebrate fauna was generally typical of that commonly recorded from tropical/sub-tropical freshwater systems

(*e.g.* Koste and Shiel 1983, Tait *et al.* 1984, Smirnov and De Meester 1996, Segers *et al*. 2004), with Lecanidae dominating within the Rotifera, with Brachionidae and other families less prominent (Appendix 5).

Table 6. Summary of higher-order microinvertebrate taxa composition in the Robe River, upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Refer Appendix 5 for full species list.

Microinvertebrates		Number of Taxa	
Scientific name	Common name	RRD (*n* = 6)	RRU (*n* = 6)
Protista	Protists	7	12
Rotifer	Rotifers	20	33
Micro-crustacea			
Cladocera	Water fleas	5	11
Copepoda	Copepods	9	6
Ostracoda	Seed shrimps	5	7
Total taxa richness		**46**	**69**

Microinvertebrate taxa richness ranged from 33 taxa at RRD6 and RRU5, to just one taxa at RRD5 (Figure 6). There was no significant difference in mean total taxa richness between downstream potentially exposed sites and upstream reference sites (one-way ANOVA, Table 7). Nor were there any significant upstream-downstream differences in taxa richness of major groups of microinvertebrate (rotifers, protists, micro-crustacea) (Table 7).

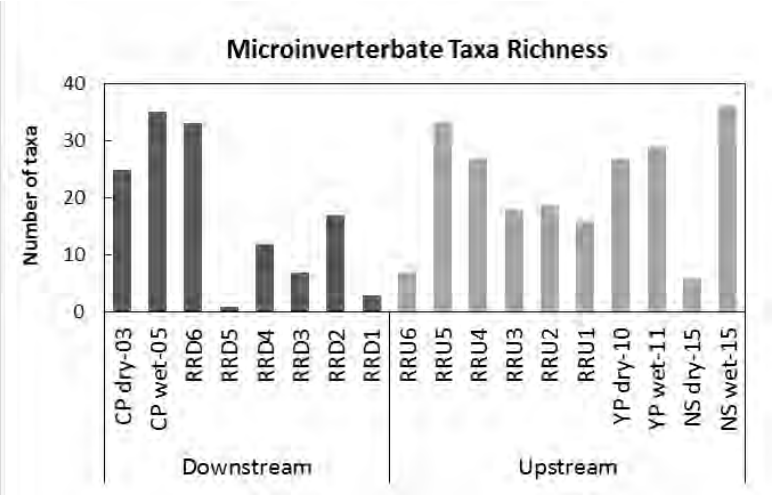

Figure 6. Microinvertebrate taxa richness recorded during the current study, upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence, compared with most recent data for nearby Chalyarn Pool (CP; Pinder *et al.* 2010), Yalleen Pool (YP; WRM 2013) and Nyeetbury Spring (NS; WRM 2016). Refer Figure 1 for location of sites.

Table 7. Summary results from one-way ANOVAs testing for significant (p <0.05) differences in taxa richness of major microinvertebrate groups, upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Mean (±SE) vales for untransformed data are also provided.

Microinvertebrate metric	ANOVA (df = 1, 11)			Mean (±SE)	
	MS	F	*p*	RRD (*n* = 6)	RRU (*n* = 6)
Total taxa richness	184.1	1.672	0.225	12.17 (4.81)	20.00 (3.69)
Protista richness	8.333	1.168	0.305	2.33 (0.92)	4.00 (1.24)
Rotifera richness	80.08	2.313	0.159	3.67 (2.46)	8.83 (2.34)
Micro-crustacea richness	3.000	0.183	0.183	6.17 (2.01)	7.17 (1.20)

5.2.2 Comparison against previous surveys

To provide spatial context for microinvertebrate fauna within the Project area, total taxa richness at each site within the Project area was compared against most recent data for nearby pools upstream and downstream of the Project area, *i.e.* Yalleen Pool and Nyeetbury Spring on upper Bungaroo Creek (WRM 2013, 2016), and Chalyarn Pool on Mungarathoona Creek (Pinder *et al.* 2010) (Figure 6). Each of these previous studies used similar microinvertebrate sampling techniques (sweep netting using 50 - 53 μm mesh FBA pond net) and taxonomic resolution to those approaches for the current study.

Some temporal variation was observed between wet and dry season sampling events, with the wet season favouring microinvertebrate taxa richness at Chalyarn Pool, Yalleen Pool and Nyeetbury Spring (Figure 6). At sites upstream of the Jimmawarruda-Robe confluence, taxa richness was spatially variable, with richness at RRU4 and RRU5 similar to that recorded at Yaleen Pool (both seasons) and Nyeetbury Spring in the wet-15 (Figure 6), and slightly higher than that recorded at RRU1, RRU2 and RRU3. Richness was lowest at Nyeetbury Spring in the dry-15, comparable to that recorded at RRU6 in the current study (Figure 6). Within the potentially exposed downstream reach, taxa richness at sites closest to the confluence (RRD1 to RRD5) was generally lower than that recorded at sites further downstream (RRD6 and Chalyarn Pool in both seasons) (Figure 6).

Large spatial (and temporal) variability in species richness and abundance are commonly reported for freshwater systems world-wide. Variation typically depends on factors such as flow regime (with lotic habitat generally favouring taxa richness), pool size, primary production rates and water quality parameters (Miquelis *et al.* 1998, Schiemer *et al*. 2001, Schöll *et al.* 2012). In Pilbara surface waters, microinvertebrate taxa richness is known to fluctuate markedly between sites and seasons (Pinder *et al.* 2010, WRM unpub. data). It is possible that below-average rainfall in the months prior to the current survey may have contributed to the somewhat lower microinvertebrate taxa richness recorded at sites such as RRD1, RRD3, RRD5 and RRU6. Pinder *et al.* (2010) found the wet season (higher rainfall) to generally favour taxa richness during the PBS, as was the case at Chalyarn, Yalleen and Nyteetbury (Figure 6); however, as these studies only provide a snapshot of the microinvertebrate fauna at pools within the Project area, the specific factors driving taxa richness and composition remain unknown.

5.2.3 Spatial variation in species assemblages

Multivariate analysis (ANOSIM) detected no significant difference in microinvertebrate species assemblage composition between upstream reference and downstream potentially exposed sites (Table 8), suggesting there was a high degree of natural variability and overlap amongst assemblages both upstream and downstream of the Jimmawarruda-Robe confluence. Although SIMPER analysis found only a 21% similarity of species assemblages between the upstream and downstream reaches, nMDS plotting displayed no discernible separation of upstream/downstream sites based on Bray-Curtis similarity (Figure 7). SIMPROF analysis did detect some clustering of sites, though with no clear patterns in relation to upstream/downstream location (Figure 7). For example, the upstream sites RRU1, RRU2 and RRU3 clustered with downstream site RRD2, and upstream sites RRU5 and RRU6 clustered with downstream site RRD6, based on similarity of microinvertebrate species assemblages (Figure 7). RRD1 and RRD3 also clustered with a high degree of similarity (Figure 7).

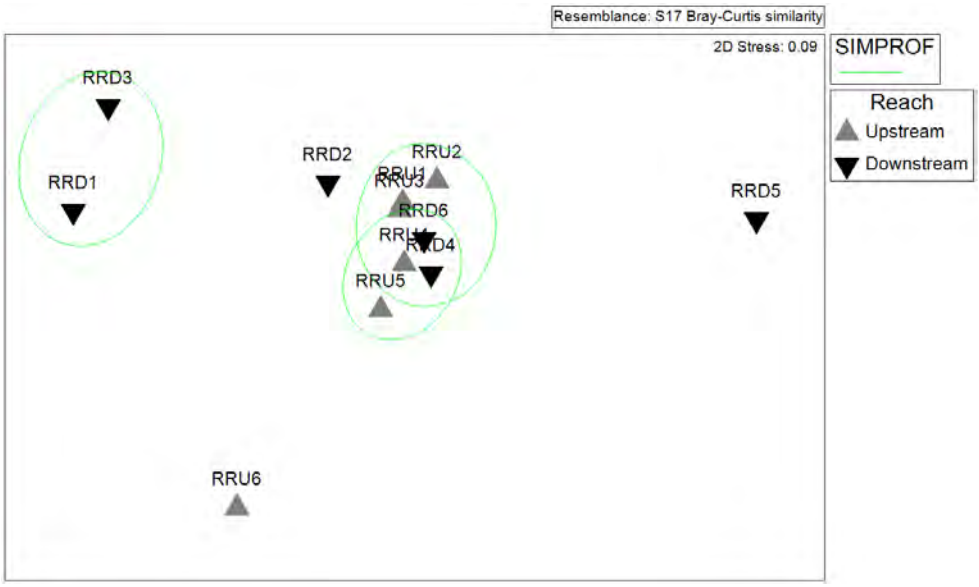

Figure 7. Plot of nMDS ordination on microinvertebrate species assemblages (log_{10} abundance class) upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Ordination based on Bray-Curtis similarity, with SIMPROF analysis as green circles overlain demonstrating significant clustering of sites. Refer Table 1 for explanation of site codes and Figure 1 for location of sites.

Table 8. Summary results from ANOSIM testing for significant (p <0.05) differences in microinvertebrate assemblages (Bray-Curtis similarity) upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence.

Microinvertebrate assemblage similarity (Bray-Curtis)	ANOSIM	
	R-statistic	*p*
Abundance (log_{10} class)	0.115	0.108
Presence/absence	0.137	0.097

The sampling design allows comparison of change in the similarity (Bray-Curtis) of microinvertebrate assemblages over time between reference and potential exposed sites. The premise being that if the degree of similarity between exposed and reference sites differs significantly over time (compared with pre-mine similarity), this would indicate mine-related response rather than stochastic variability due to factors such as climatic change.

5.2.4 Conservation significance of microinvertebrate fauna of the Project area

The majority of microinvertebrate taxa recorded from the Project area were common, ubiquitous species with Australasian or cosmopolitan distributions; however, the calanoid copepod *Eodiaptomus lumholtzi*, currently listed on the IUCN Red List of Threatened Species as Vulnerable (Reid 1996), was recorded at potentially exposed site RRD6. *E. lumholtzi* was assessed as Vulnerable in 1996 (IUCN ver. 2.3), as it was then known only from a few localities; Lake Woods in Northern Territory, Collinson's Lagoon at Ayr and Saltern Lagoon in the Valley of Lagoons, west of Ingham, Queensland. IUCN (2016) states this assessment requires updating because *E. lumholtzi* has since been recorded from many localities across the Australasian region. *E. lumholtzi* has been recorded previously by the authors at locations across the Pilbara region, including sites along Fortescue River, Coondiner Creek, Kalgan Creek, Weeli Wolli Creek, Koodaideri Springs, Caves Creek, Duck Creek and Cane River (WRM unpub. data). *E. lumholtzi* has also been found in Papua New Guinea, and is considered to have a pan-tropical distribution (Vlaardingerbroek 1989, WRM unpub. data).

Of scientific interest was the collection of an undescribed species of Lecanidae rotifer, *Lecane* n. sp., recorded both upstream and downstream of the Jimmawarruda-Robe confluence (RRU5 and RRD6). Morphologically, this species is similar to the described *Lecane quadridentata*, with the two variants synonymized by Segers (1995); however, the smaller Australian variant recorded in the current study is now recognised as a separate species, and forms part of a wider *L. quadridentata* species complex (Dr Russel Shiel, University of Adelaide, pers. comm.).

5.3 Hyporheic Fauna

5.3.1 Species richness and abundance

A total of 59 taxa were recorded from the hyporheic zone of pools in the Project area (Appendix 6). The majority of these taxa were classified as stygoxene (54%), *i.e.* species that appear in groundwater habitats by accident or seeking refuge during drought, and not specially adapted to subterranean inhabitation. Of these, 8% were classified as stygobitic, *i.e.*, obligate groundwater inhabitants with specialised morphological adaptations to survive in such environments (stygofauna). Of the remaining taxa, 31% were considered occasional hyporheic stygophiles (species that use the hyporheic zone seasonally or during early life history stages), 2% were possible hyporheic taxa, and 5% were unable to be classified (Appendix 6). Although classifications followed those of Boulton (2001), this type of analysis should be treated with some caution, as results are likely affected by available information on life history, taxonomic resolution, and interpretation of classification categories.

Hyporheic taxa richness (combined richness of stygobites, occasional hyporheic stygophiles and possible hyporheic fauna) ranged from two taxa at upstream reference site RRU2, to 12 taxa at potentially exposed downstream site RRD1 (Figure 8). Relatively high hyporheic taxa richness was also recorded at RRU6 (nine taxa), RRU4 and RRD2 (eight taxa), and RRU3 and RRD5 (seven taxa) (Figure 8). The high taxa richness encountered in the hyporheos of these sites, and because surface water was present at these sites despite below average rainfall in the months prior, suggests at least some connectivity between ground- and surface waters (*i.e.* they may be groundwater-supported pools).

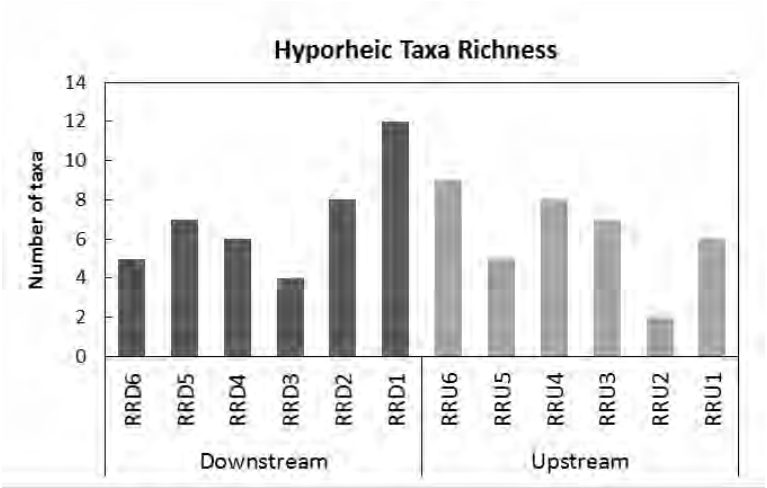

Figure 8. Hyporheic taxa richness (combined richness of stygobites, occasional hyporheic stygophiles and possible hyporheic fauna) of sites upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence.

5.3.2 Conservation significance of hyporheic fauna of the Project area

Of the fauna collected in hyporheic samples of the Project area, only the amphipod, *Nedsia* sp. is considered likely to be a potential SRE species.

Nedsia sp. (family Melitidae) was recorded from the hyporheic zones of RRU3, RRU4 and RRU6 upstream of the Jimmawurrada-Robe confluence, and RRD1, RRD2, RRD3 and RRD4 downstream of the confluence (Appendix 6). *Nedsia* amphipods were also recorded in the surface water macroinvertebrate samples of RRD3 and RRD4 (Appendix 7). These amphipods could not be confidently identified to species level due to a current lack of taxonomic resolution within the Melitidae amphipods and would require DNA sequencing.

Biota (2006a) recorded four genetically-distinct amphipods of the family Melitidae from bores in the Yarraloola area, downstream (west) of the Project area. A fifth distinct Melitidae lineage was recorded from the Bungaroo Creek area to the southeast (Biota 2006a). Interestingly, based on genetic evidence, each of the four Melitidae lineages from the Yarraloola area have been isolated from one-another for between 2.4 and 6.65 million years, highlighting the extreme degree of amphipod short-range endemism that can occur amongst aquifers in the region despite close geographical proximity (Biota 2006a). Biota (2010) and Bennelongia (2013) also recorded a high abundance of Melitidae amphipods from bores to the south of the current Project area. The majority of these specimens belonged to the genus *Nedsia* (*Nedsia* nr. *hulberti* and *Nedsia* spp.). It is currently unknown whether the *Nedsia* recorded in the current study represent one or more of the *Nedsia* species or Melitidae halotypes recorded by Biota (2006a, 2010) and Bennelongia (2013) or a separate species previously unrecorded.

Although not conservation listed or considered SRE species, the following are stygal species, with their presence indicating some connectivity between ground- and surface-waters. As such, they are of some interest.

The Thermosbaenacean *Halosbaena tulki* was recorded both upstream (RRU3) and downstream (RRD2, RRD3 and RRD4) of the Jimmawurrada-Robe confluence. *Halosbaena tulki* is the single species of Thermosbaenacean known from the Southern Hemisphere, where it appears to be restricted to the Pilbara region (Poore and Humphreys 1992). Thermosbaenacea are a rare order of crustacean, with approximately 16 species known worldwide, all of which are restricted to groundwater environments (Poore and Humphreys 1992). In the vicinity of the Project area, this species was previously collected from seven bores in the Yarraloola area by Biota (2006a).

The ostracod *Candonopsis* cf. *tenuis* is known to occur widely across Australia (DeDeckker 1982, Karanovic and Marmonier 2002), including groundwaters of the Pilbara (Halse *et al.* 2002). WRM has recorded *C.* cf. *tenuis* from the hyporheic zone of a number of sites in the Weeli Wolli Creek catchment, Coondiner Creek, Kalgan Creek, Hamersley Gorge and the Ashburton River (WRM unpub. data). During the current study, *C.* cf. *tenuis* was collected from the hyporheic zone of upstream reference site RRU6 (Appendix 6).

Vestalenula marmonieri is a stygal ostracod species known only from Western Australia and New Caledonia (Schön *et al.* 2010). This species is relatively widespread across the Pilbara region (being collected from over 50 locations by Pinder *et al.* (2010) during the PBS), though due to its preference for phreatic[14] environments, is most commonly associated with groundwater-fed systems such as Weeli Wolli Creek (WRM unpub. data). In the current study, *V. marmonieri* was recorded from potentially exposed downstream sites RRD1 and RRD5, and upstream reference site RRU1 (Appendix 6). *V.*

[14] Groundwater environments.

marmonieri was also collected in microinvertebrate samples of RRU1, RRU2, RRU3, RRU6, RRD2, RRD4 and RRD5 (Appendix 5).

5.4 Macroinvertebrates

5.4.1 Species richness and abundance

A total of 148 macroinvertebrate taxa were recorded from the Project area, of which 116 were present at sites downstream of the Jimmawurrada-Robe confluence, and 117 at upstream reference sites (Table 9, Appendix 7). In this context, "taxa" includes groups which could not be identified to species level, due to unresolved taxonomy and/or immaturity of specimens. Therefore, the total macroinvertebrate taxa richness at each site is likely greater than reported herein. The macroinvertebrate fauna comprised Cnidaria (freshwater hydra), Mollusca (freshwater snails and bivalves), Oligochaeta (aquatic segmented worms), Crustacea (amphipods and freshwater shrimp), Acarina (water mites), Collembolla (springtails), Odonata (dragonflies and damselflies), Ephemeroptera (mayflies), Hemiptera (true bugs), Coleoptera (aquatic beetles), Diptera (two-winged or "true" fly larvae), Trichoptera (caddisflies) and Lepidoptera (aquatic moth larvae; Table 9). Macroinvertebrate composition was typical of freshwater systems throughout the world (Hynes 1970), being dominated by Insecta (comprising 89% of all taxa), with Diptera (29%) and Coleoptera (32%) most prominent within this class. There were 46 singleton taxa recorded (*i.e.* those recorded from only one site), and 12 taxa were considered common taxa, *i.e.* they were present at over 80% of sites. These included the snail *Melanoides* spp., segmented worms (Oligochaeata spp.), the freshwater shrimp *Caridina indistincta*, the mayflies Baetidae spp. and *Cloeon* sp. Red Stripe, the pygmy backswimmer *Paraplea* spp., and the midge larvae/pupae Ceratopogonidae spp., Dasyheleinae spp., Chironomidae spp., *Polypedilum* sp. 1, *Larsia albiceps* and *Paramerina* sp. (Appendix 7).

Table 9. Summary of higher-order microinvertebrate taxa composition in the Robe River, upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Refer Appendix 7 for full species list.

Macroinvertebrates		Number of Taxa	
Scientific name	Common name	RRD (*n* = 6)	RRU (*n* = 6)
Cnidaria	Freshwater hydra	1	0
Oligochaeta	Aquatic worms	1+	1+
Gastropoda	Freshwater snails	4	5+
Bivalvia	Freshwater bivalves	0	1
Amphipoda	Stygal amphipods	2	0
Decapoda	Freshwater shrimps	1+	1+
Acarina	Water mites	1+	1+
Ephemeroptera	Mayflies	6	5
Odonata	Dragonflies and damselflies	14	14
Hemiptera	True bugs	18	16
Coleoptera	Aquatic beetles	30	35
Diptera	Two-winged flies	30	31
Trichoptera	Caddisflies	7	4
Lepidoptera	Aquatic moth larvae	2	2
	Total taxa richness	**116**	**117**

+ indicates a taxa could only be identified to genus/family/order level (not species level), and as such more than one species is likely to be present within this taxonomic group.

Macroinvertebrate taxa richness at upstream sites ranged from 34 taxa at RRU3 and RRU5, to 72 taxa at RRU1 (Figure 9). Richness at sites downstream of the Jimmawarruda-Robe confluence ranged from 38 taxa at RRD3 and RRD5, to 56 taxa at RRD2 (Figure 9). There was no significant difference in total

taxa richness between downstream potentially exposed sites and upstream reference sites (one-way ANOVA, Table 10). Nor were there any significant upstream-downstream differences in taxa richness of most major macroinvertebrate groups (Table 10). The exception was Ephemeroptera (mayflies), where mean richness was significantly higher at sites downstream of the confluence (4.3) compared to those upstream (2.5) (Table 10). This was largely due to the lower richness/absence of *Tasmanocoenis* sp. P/*arcuata* (Caenidae) and *Cloeon fluviatile* (Baetidae) at upstream sites, particularly RRU4 to 6 closest to the confluence.

Table 10. Summary results from ANOVAs testing for significant (p <0.05) differences in taxa richness of major macroinvertebrate groups (indicated by *), upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Mean (±SE) vales for untransformed data are also provided.

Macroinvertebrate metric	ANOVA			Mean (±SE)	
	MS	F	p	RRD (n = 6)	RRU (n = 6)
Total taxa richness	0.083	0.001	0.982	46.2 (3.5)	46.3 (6.1)
Diptera richness	0.000	0.000	1.000	14.0 (1.8)	14.0 (4.6)
Coleoptera richness	18.75	0.587	0.461	8.5 (2.4)	11.0 (2.2)
Hemiptera richness	0.333	0.035	0.855	6.3 (1.1)	6.0 (1.4)
Odonata richness	1.333	0.377	0.553	5.33 (0.6)	6.0 (0.9)
Trichoptera richness	1.333	1.429	0.260	1.7 (0.4)	1.0 (0.4)
Ephemeroptera richness	10.08	6.798	0.026*	4.3 (0.5)	2.5 (0.5)
Mollusca richness	0.083	0.068	0.799	2.7 (0.4)	2.8 (0.5)
Crustacea richness	0.750	-0.738	0.411	2.7 (0.5)	2.2 (0.3)

5.4.2 Comparison against previous studies

To provide spatial context for macroinvertebrate fauna within the Project area, total taxa richness at each site was compared against most recent data for nearby pools upstream and downstream, *i.e.* Yalleen Pool and Nyeetbury Pool on upper Bungaroo Creek (WRM 2013, 2016), and Chalyarn Pool on Mungarathoona Creek (Pinder *et al.* 2010) (Figure 9). Each of these previous studies used similar macroinvertebrate sampling techniques (kick-sweep netting using 250 µm mesh FBA pond net) and taxonomic resolution to those of the current study.

Taxa richness within the Project area (34 – 72 taxa) was generally comparable to that previously recorded for Yalleen Pool (39 – 45), Nyeetbury Spring (51 – 52) and Chalyarn Pool (49 – 77) (Figure 9). The lack of spatial variability in macroinvertebrate taxa richness between studies probably reflects the similar hydrological nature and size of these pools (*i.e.* all are either permanent/semi-permanent riverine pools, flowing only after heavy rainfall) because they are all within relatively close geographical proximity to one-another (*i.e.* within 20 – 30 km, and all part of the Robe River catchment). Pinder *et al.* (2010) noted riverine pools of the Pilbara (particularly those of the same catchment) generally display a high degree of homogeneity, in terms of macroinvertebrate species richness and composition, in comparison to similarly sized turbid wetlands and claypans.

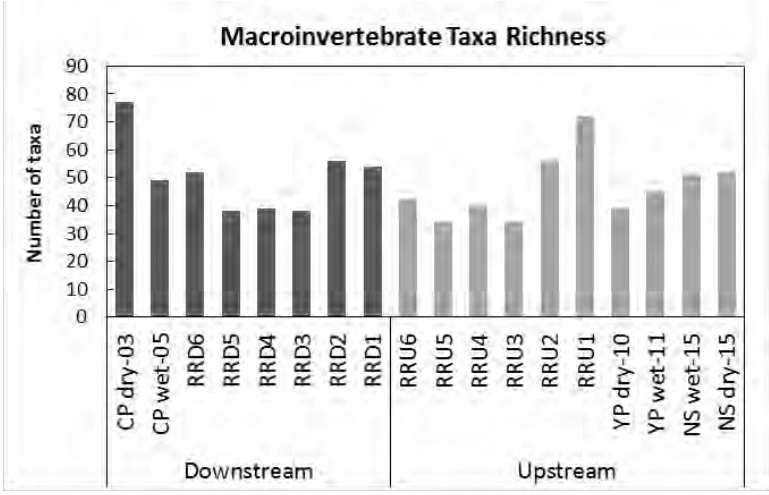

Figure 9. Macroinvertebrate taxa richness recorded during the current study, upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence, together with most recent data for nearby Chalyarn Pool (CP; Pinder *et al.* 2010), Yalleen Pool (YP; WRM 2013) and Nyeetbury Spring (NS; WRM 2016). Refer Figure 1 for location of sites.

To provide temporal/seasonal context for macroinvertebrate taxa richness in the current Project area, April/May (wet season) 2016 figures were compared against historic mean dry season taxa richness recorded at Robe River pools by Streamtec/UWA between 2002 and 2011[15]. Again, both studies utilised the same macroinvertebrate sampling technique (sweep netting using a 250 µm mesh FBA pond net), and taxonomy was standardised across datasets to account for inherent variation/advancements in taxonomic knowledge between studies (*i.e.* some taxa were condensed to family or order level to enable comparison). As such, taxa richness may appear lower than was originally reported in each study.

At the reach upstream of the Jimmawarruda-Robe confluence, mean dry season richness at Medawandy Waters (22) and Pannawonica Hill (23) were generally comparable to wet season taxa richness recorded at RRU3 (22), RRU4 (30), RRU5 (20) and RRU6 (26), but slightly lower than taxa richness recorded at RRU1 (54) and RRU2 (38) (Figure 10). Downstream of the confluence, mean dry season richness recorded at Gnieroora, Martangkuna, Pulari, Japanese Pool and Yarramudda (20 – 27 taxa) was also similar to wet season richness recorded at RRD1, RRD3, RRD4 and RRD5 (21 – 33 taxa), and only slightly lower than that recorded at RRD6 (41 taxa) and RRD2 (38 taxa). The apparent lack of seasonal variability in taxa richness likely reflects the capacity for pools of the Project area to hold water year-round (*i.e.* they are either permanent/semi-permanent), acting as refuge pools for migratory macroinvertebrates during the dry season, and generally favouring both temporary and permanent resident macroinvertebrate species over more ephemeral waterbodies (Sponseller *et al.* 2001, Pinder *et al.* 2010). Furthermore, Pinder *et al.* (2010) found there to be little seasonal variation in macroinvertebrate assemblages at permanent/semi-permanent riverine pools of the Pilbara region in comparison to more ephemeral waterbodies, particularly when flooding had not occurred prior to wet season sampling (as was the case in the current study). It must be noted that the current study provides only a snapshot of the macroinvertebrate fauna of the Project area and taxa richness could still vary considerably between time periods.

[15] The most recent round of macroinvertebrate data (2013) was not included in analysis, as Streamtec (2014) did not feature a raw species list. Earlier species lists (1996 & 1998) were not included in the analysis due to the vast improvements in taxonomic knowledge and microscope technology since those studies.

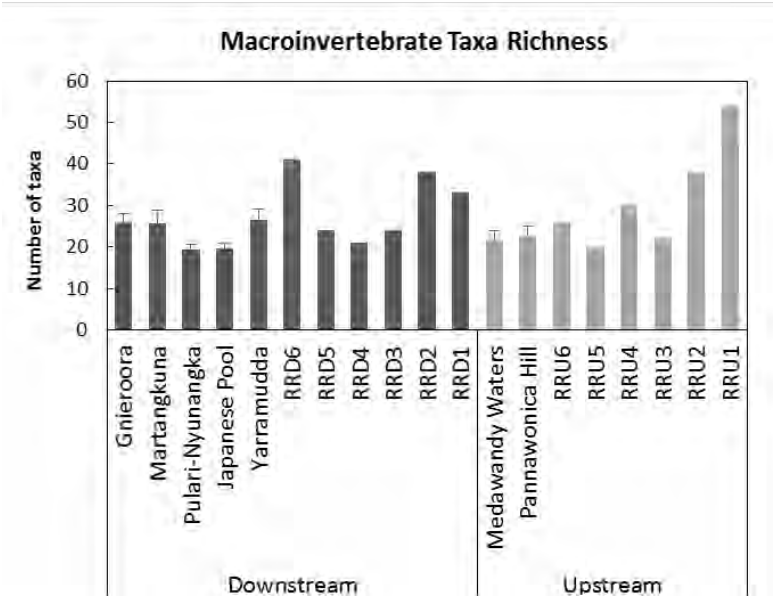

Figure 10. Comparison of standardised macroinvertebrate taxa richness recorded during the current study, with that recorded by Streamtec/UWA during long-term monitoring of Robe River pools. Refer Figure 1 for location of sites.

5.4.3 Spatial variation in species assemblages

Multivariate analysis (ANOSIM) detected no significant difference in macroinvertebrate species assemblage composition between upstream reference and downstream potentially exposed sites (Table 11), suggesting there was a high degree of natural variability and overlap amongst upstream/downstream sites. Although SIMPER analysis found only a 45% similarity of species assemblages between upstream and downstream sites, nMDS plotting displayed no distinguishable separation of upstream/downstream sites based on Bray-Curtis similarity (Figure 11), with SIMPROF analysis (not shown) detecting no clustering of these groups. One site (RRU3) was separate from all other sites, which is attributed to the low overall taxa richness (34) recorded at this site compared to others. As with taxa richness, the lack of variability in upstream/downstream macroinvertebrate assemblages likely reflects the relatively similar hydrological nature (permanent/semi-permanent) of pools in the Project area.

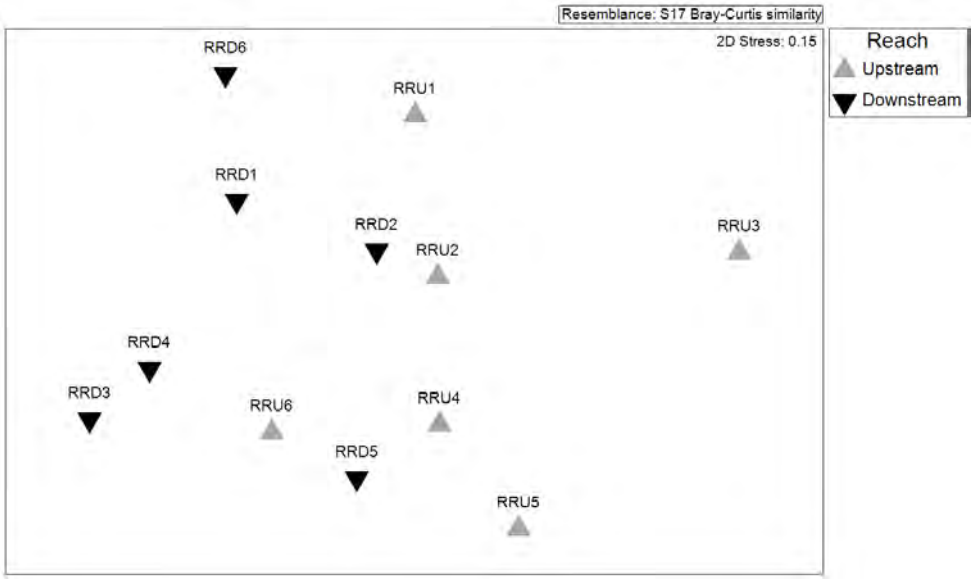

Figure 11. Plot of nMDS ordination on macroinvertebrate species assemblages (log_{10} abundance class) upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Ordination based on Bray-Curtis similarity. Refer Table 1 for explanation of site codes and Figure 1 for location of sites.

Table 11. Summary results from ANOSIM testing for significant (p <0.05) differences in macroinvertebrate assemblages (Bray-Curtis similarity) upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence.

Macroinvertebrate assemblage similarity (Bray-Curtis)	ANOSIM	
	R-statistic	*p*
Abundance (log_{10} class)	0.154	0.106
Presence/absence	0.111	0.186

5.4.4 Conservation significance of macroinvertebrate fauna of the Project area

The Pilbara pin damselfly, *Eurysticta coolawanyah* (family Isostictidae), is endemic to the Pilbara region, and is currently listed as Near Threatened on the IUCN Red List of Threatened Species (IUCN 2016). *Eurysticta coolawnyah* was recorded from two sites in the current study; RRD3 and RRD4, both downstream of the Jimmawarruda-Robe confluence (Appendix 7). *E. coolawanyah* is known from over 40 locations across the Pilbara (Pinder *et al.* 2010), and has been recorded by WRM from a number of riverine pools and springs along the Fortescue River, DeGrey River, Coondiner Creek, Kalgan Creek and Weeli Wolli Creek (WRM unpub. data). Along the Robe River, this species has been recorded consistently by Streamtec/UWA, as well as from Bungaroo Creek (WRM 2013) and Mugarathoona Creek (Pinder *et al.* 2010).

It is likely that both RRD3 and RRD4 are important refuge pools for *E. coolawanyah* in the area, as both are persistent waterbodies which support relatively high densities of emergent macrophyte (see Appendix 4). Damselflies (such as *E. coolawanyah*) are known to actively select sites with greater concentrations of emergent macrophyte, which are used for perching, mating and oviposition (egg-laying) (D'Amico *et al.* 2004, Rouquette and Thomson 2004, Ward and Mill 2005, Remsburg and Turner 2009).

Although the following species are not listed for conservation significance, they are endemic to the Pilbara region and therefore of some scientific interest. The Pilbara tiger dragonfly, *Ictinogomphus dobsoni* (family Lindeniidae), was collected at reference site RRU3, and potentially exposed sites RRD1, RRD4 and RRD6 (Appendix 7). This species appears to be relatively common across the Robe River

catchment, having been recorded from Chalyarn Pool, Red Hill Creek (Pinder *et al*. 2010) and a number of permanent/semi-permanent Robe River pools (Streamtec/UWA). Elsewhere, *I. dobsoni* has been recorded from many of the other major river systems of the Pilbara, including the Fortescue, Ashburton, Yule, DeGrey and Sherlock rivers (DEC 2009, Pinder *et al*. 2010, CSIRO 2015). Large pools within the Project area epitomise ideal refuge habitats for *I. dobsoni*, which is known to prefer still or sluggish permanent riverine waterbodies (Watson 1991).

The Pilbara endemic dytiscid beetle *Tiporus tambreyi* was recorded at reference sites RRU3, RRU4 and RRU6, and potentially exposed site RRD1 (Appendix 7). This species is common and ubiquitous across the region, and in the vicinity of the Project area, has been recorded from Robe River pools (Streamtec/UWA), Chalyarn Pool (Pinder *et al.* 2010) and Red Hill Creek (WRM 2009, Pinder *et al.* 2010).

The haliplid beetle *Haliplus pilbaraensis,* recorded from reference site RRU1 (Appendix 7), is endemic to the Pilbara region and relatively new to science (Watts and McRae 2010). This species appears to occur fairly widely throughout the Pilbara, and has been recorded at localities such as Glen Ross Creek, Coondiner Pool, the Fortescue Marsh, Moreton Pool, Paradise Pool, Munreemya Billabong, Wackilina Creek Pool, West Peawah Creek Pool, Harding River Pool, and an un-named creek in Millstream (Watts and McRae 2010). Closer to the Project area, *H. pilbaraensis* was previously recorded from Red Hill Creek (WRM 2009).

5.5 Fish

5.5.1 Species composition and abundance

A total of 3,515 individual fish were caught, measured and released in the Project area; 1,578 from upstream reference sites (RRU1 - 6), and 1,937 from sites downstream of the Jimmawarruda-Robe confluence (RRD1 - 6). Seven true freshwater taxa were recorded, including the western rainbowfish, spangled perch, Pilbara tandan (eel-tailed catfish), Fortescue grunter, barred grunter, bony bream, and a hybridised form of Terapontidae (grunter) (Table 12). Four species captured were of estuarine/marine origin, including milkfish, tarpon (ox-eye herring) (Plate 8), mullet and banded scat (striped butterfish) (Plate 8) (Table 12). Each of the freshwater species, with the exception of bony bream, was recorded both upstream and downstream of the Jimmawarruda-Robe confluence (bony bream were only recorded upstream of the confluence) (Table 12). The marine vagrant tarpon and mullet were also recorded both upstream and downstream of the confluence; however, milkfish and banded scat were only recorded from the downstream reach (Table 12). Each of these species, except milkfish, was previously recorded from the Robe River by Morgan and Gill (2004) and Streamtec/UWA.

Table 12. Summary of freshwater and estuarine/marine vagrant fish species recorded in the Project area, including scientific and common names. ✓ = fish species was present.

Origin	Species	Common name	Downstream						Upstream					
			RRD6	RRD5	RRD4	RRD3	RRD2	RRD1	RRU6	RRU5	RRU4	RRU3	RRU2	RRU1

	Mugil sp.	Mullet		✓				✓			✓		✓	
	Selenotoca multifasciata	Banded scat/striped butterfish	✓	✓	✓	✓	✓	✓						

There was no significant difference in mean abundance of fish upstream and downstream of the Jimmawarruda-Robe confluence (one-way ANVOA, $p = 0.433$), nor was there any significant difference in mean abundance of any of the individual species between the upstream and downstream reaches (one-way ANOVA, $p < 0.05$). There was a significant difference in mean species richness between upstream and downstream sites, with mean richness significantly higher downstream of the Jimmawarruda-Robe confluence (one-way ANVOA, $p = 0.008$). This was mainly due to the greater presence of estuarine species such as banded scat, milkfish and tarpon at the downstream reach (Table 12).

Western rainbowfish were the most abundant fish of the Project area, with a total of 2,401 individuals captured. Western rainbowfish were present at all sites, with 1,019 recorded from upstream reference sites (42%), and 1,382 recorded from downstream sites (48%) (Figure 12). Fortescue grunter (685 individuals) and spangled perch (203 individuals) were the second and third most abundant species of the Project area, respectively. Fortescue grunter were collected from all sites, with similar numbers captured both upstream (320 individuals; 47%) and downstream (365 individuals; 53%) of the Jimmawarruda-Robe confluence (Figure 12). Spangled perch were also present at all sites, with the majority recorded at upstream sites (145 individuals; 71%) (Figure 12). Of the remaining freshwater species, Pilbara tandan (34 individuals) were recorded at upstream sites RRU1, RRU2, RRU3, RRU5, and downstream sites RRD2, RRD3 and RRD4; barred grunter (47 individuals) were recorded at upstream sites RRU5 and RRU6, and at downstream sites RRD3, RRD4 and RRD5. Terapontidae hybrids (12 individuals) were recorded at upstream sites RRU1, RRU3, RRU5 and RRU6, and downstream sites RRD2 and RRD5 (Figure 12). Bony bream (5 individuals) were only recorded at upstream site RRU2.

Of the estuarine/marine fish species, tarpon (39 individuals) (Plate 8) were recorded at upstream sites RRU2, RRU4 and RRU5, and all sites downstream of the Jimmawarruda-Robe confluence (Figure 12). Mullet (33 individuals) were recorded at upstream sites RRU2 and RRU4, and downstream sites RRD1 and RRD5 (Figure 12). Banded scat (53 individuals) (Plate 8) were only recorded downstream of the confluence, but were present at all sites within that reach (Figure 12). Milkfish (7 individuals) were only recorded from downstream sites RRD4 and RRD6 (Figure 12).

Plate 8. The banded scat *Selenotoca multifaciata* (left) and the tarpon *Megalops cyprinoides* (right), captured downstream of the Jimmawarruda-Robe confluence.

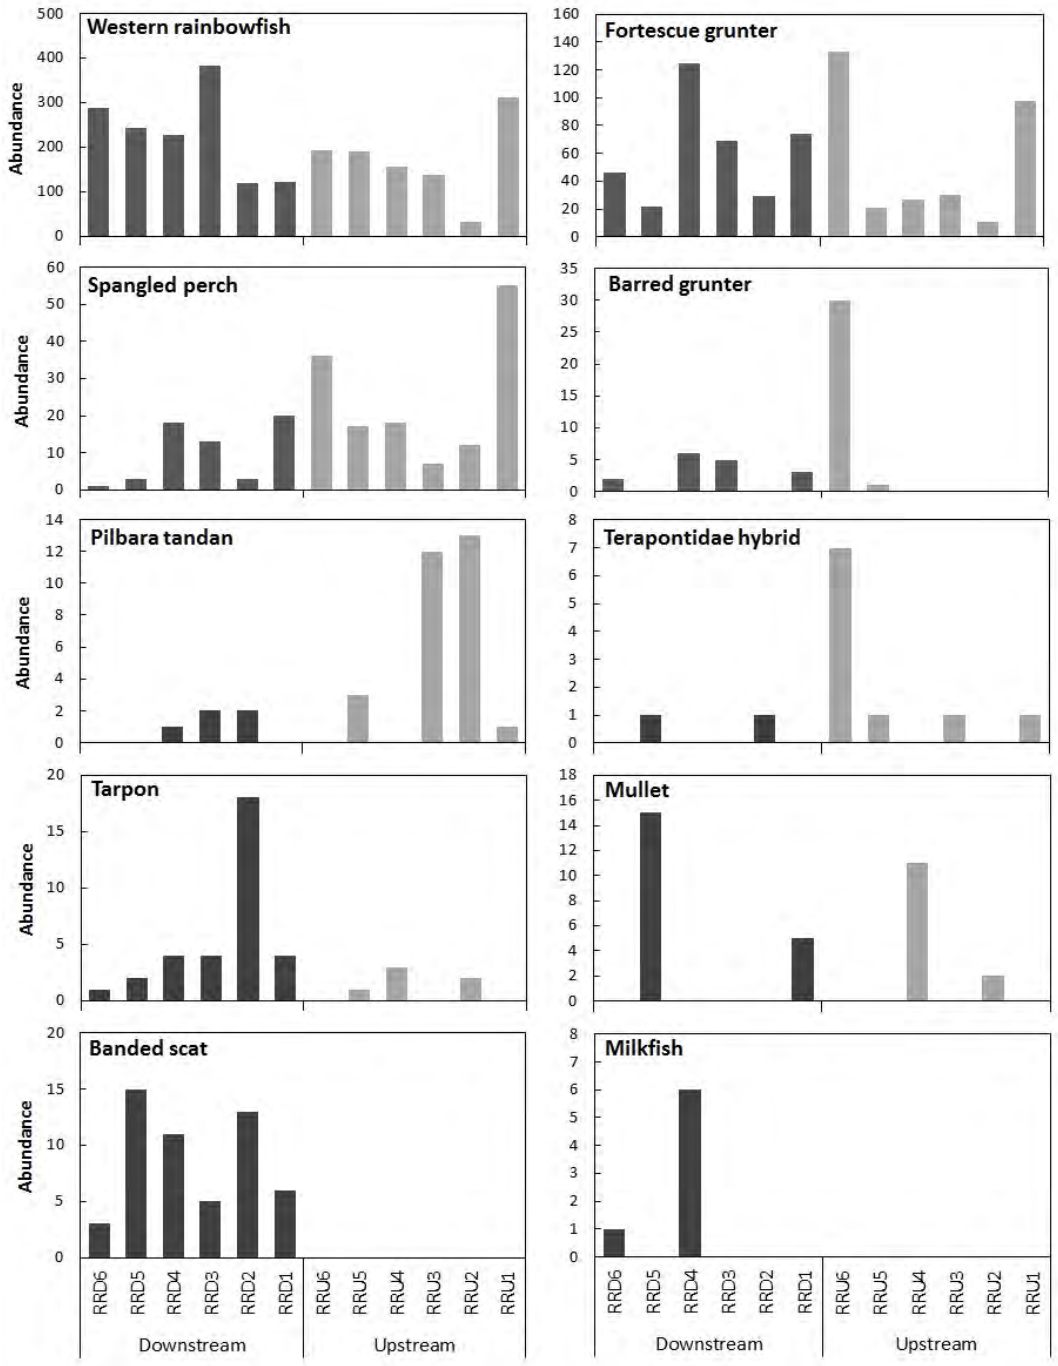

Figure 12. Abundance of each fish species recorded from upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence. Note: bony bream (*Nematalosa erebi*) were also recorded from the Project area, but were not plotted due to low overall abundance of this species.

5.5.2 Conservation significance of fish species

One conservation listed freshwater fish species was recorded from the Project area; the Pilbara endemic Fortescue grunter (*Leipotherapon aheneus*). Currently, the Fortescue grunter is listed on the IUCN Red List of Threatened Species as Lower Risk/Near Threatened (IUCN 2016), and as a Priority 4 (P4) species on the Department of Parks and Wildlife (Parks and Wildlife) Priority Fauna List (Parks and Wildlife 2016). This species is only known from the Fortescue, Robe and Ashburton River systems (Allen *et al*. 2002, Morgan and Gill 2004); however, it is considered to be common within this range, as is evidenced

by the ubiquitousness of this species across the current Project area, being the second most abundant fish collected (685 individuals) and occurring at all sites both upstream and downstream of the Jimmawarruda-Robe confluence (Table 12 and Figure 12).

The following species are not listed for conservation significance, but are of some scientific interest:

Individuals which appeared to be hybridised forms of two of the three co-occurring Robe River Terapontidae species (spangled perch, barred grunter and/or Fortescue grunter; Plate 9) were recorded from RRU1, RRU3, RRU5, RRU6, RRD2 and RRD5 (Table 12 and Figure 12). Hybridised grunters have been recorded from other Pilbara systems by the authors and others, including the Fortescue, Murchison and Ashburton rivers (Morgan and Gill 2006, Morgan *et al.* 2009, WRM 2016, WRM unpub. data). Morgan and Gill (2006) propose hybridisation between closely related fish species is not uncommon; however, the hybridisation of grunters in Pilbara river systems is not fully understood, and is of some interest, particularly if hybridisation results in the loss of species through replacement with reproductively unviable individuals, or if there is evidence of incipient speciation (the formation of a new species). Loss or replacement of a species is especially important in the case of the Fortescue grunter, as it is a nationally and internationally listed species of conservation significance.

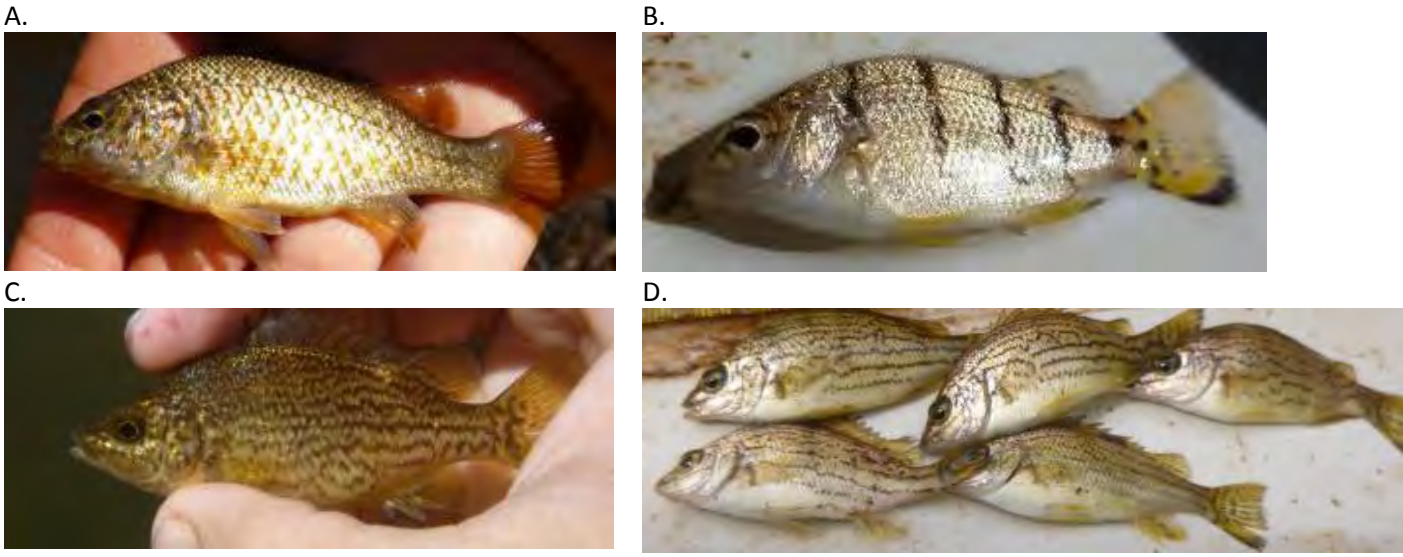

Plate 9. Terapontid hybridisation, illustrating (A) Spangled perch *Leiopotherapon unicolor,* (B) barred grunter *Amniataba percoides*, (C) Fortescue grunter *Leiopotherapon aheneus*, and (D) Terapontidae hybrids from RRU6, possibly sharing the features of barred and Fortescue grunter. Photographs by Chris Hofmeester (A, B and C)/WRM (D) ©.

None of the estuarine/marine fish species recorded in the Project area are endemic to the Pilbara region or currently listed for conservation significance. Milkfish (*Chanos chanos*) were not reported from the freshwater reaches of the Robe River by either Streamtec/UWA, Morgan and Gill (2004) or Antao and Braimbridge (2010). As such, collection of this species during the current study (along with its collection from further downstream) likely establishes a new record for the system. *Chanos chanos* is widely distributed across tropical and sub-tropical climes of the Indo-West Pacific region (Bagarinao 1994, Swanson 1998, Allen *et al.* 2002). This species is known to utilise fresh, brackish, oceanic and hypersaline lagoon environments (*i.e.* are euryhaline), being extremely efficient at osmoregulation during all life-history stages (Swanson 1998, Lin *et al.* 2003). In Australian waters, adult milkfish are pelagic schooling fish, inhabiting shallow, off-shore marine habitats. Spawning typically takes place offshore, following which juveniles migrate to sheltered estuaries. Sub-adult milkfish occasionally penetrate further upstream into freshwater reaches, before returning to the ocean to undergo sexual maturation and spawning (Bagarinao 1994, Allen *et al.* 2002).

5.5.3 Fish population structure

The reproductive strategies of freshwater fish species in the Pilbara are 'opportunistic' and 'periodic', reflecting the seasonal yet unpredictable nature of rainfall and streamflow in the region (Beesley 2006). Breeding of many species occurs during the wet season and during this time, multiple spawning events are known to occur (Beesley 2006). Further, the volume, hydrological regime and habitat complexity of Pilbara waterbodies can have a marked influence on fish population structure, with larger pools and more complex habitat considered generally advantageous for fish communities (Allen *et al.* 2002, Morgan *et al.* 2002, Morgan *et al.* 2009). Therefore, anthropogenically-induced alterations to streamflow patterns, water levels and water quality can have a discernible impact on life-history strategies and assemblage composition of local fish populations (Allen *et al.* 2002). Analysing population structure provides one means of characterising the health of fish assemblages at each site, and by extension the ecological processes driving aquatic communities within the waterbody. The presence of newly recruited and juvenile fish, for example, indicates recent spawning activity (and conditions conducive to such). Conversely, the presence of only sub-adult and adult (larger) fish may indicate a higher amount of predatory pressure on juvenile fish, and/or that conditions in pools are not conducive to spawning.

In order to examine population structures of the most ubiquitous freshwater fish of the Pilbara region (western rainbowfish, spangled perch and Pilbara tandan), length-frequency data for age-classes were estimated from published literature (*i.e.* Lake 1971, Bishop *et al.* 2001, Allen *et al.* 2002, Morgan *et al*. 2002, Beesley 2006; Table 13).

Table 13. Age-classes used in length-frequency analysis of Western rainbowfish, spangled perch and Pilbara tandan from the Project area. Age-classes are adapted from Lake (1971), Bishop *et al.* (2001), Allen *et al.* (2002), Morgan *et al*. (2002) and Beesley (2006).

Species	Age-class	Size mm SL
Western rainbowfish	New recruit	< 30
(*Melanotaenia australis*)	Juvenile	31-40
	Sub-adult	41-50
	Adult	> 51
Spangled perch	New recruit	< 30
(*Leiopotherapon unicolor*)	Juvenile	31-50
	Sub-adult	51-70
	Adult	> 71
Pilbara tandan	New recruit	< 30
(*Neosilurus* sp.)	Juvenile	31-70
	Sub-adult	71-90
	Adult	> 91

Western rainbowfish

Western rainbowfish breed throughout the year, with multiple spawning bouts that take full advantage of the region's intermittent rainfall and streamflow (Beesley 2006). Rainbowfish of the family Melanotaeniidae are usually sexually mature by the end of their first year (Allen *et al.* 2002). The size at sexual maturity can vary between river systems (typically around 50 mm SL), though western rainbowfish generally attain a maximum size of 110 mm total length (TL) (Allen *et al.* 2002).

The population structure of western rainbowfish at most upstream and downstream sites appeared to be healthy, with a variety of age-classes (new recruits, juveniles, sub-adults and adults) represented at RRU1, RRU4, RRU5, and RRD2 – RRD6 (Figure 13). New recruits and juveniles were particularly abundant at upstream site RRU4, and downstream sites RRD2, RRD4 and RRD6 (Figure 13), indicating spawning activity and good recruitment at these waterbodies. No western rainbowfish new recruits were recorded at RRD1, where sub-adults and adults (50 – 90 mm SL) dominated the population (Figure 13). Relatively low numbers of new recruits and juveniles (and low western rainbowfish numbers in general) were also recorded at RRU2 (Figure 13). Low recruitment of rainbowfish at RRD1 was possibly due to the small size of this pool, which also contained piscivorous species such as spangled perch, Fortescue grunter and barred grunter. Reduced depth and volume of small pools such as RRD1 inherently increases the risk of juvenile fishes to teleost (fish) and avian predation (Morgan *et al.* 2009). Conversely, low western rainbowfish abundance (and concurrent low abundance of new recruits and juveniles) recorded at RRU2 may have been related to the large size and volume of this pool, which would enable fish to avoid capture in seine and gill nets. Relatively low abundances of all fish species were recorded at RRU2, with the exception of Pilbara tandan, which are more commonly caught while electrofishing, rather than in seine and gill nets.

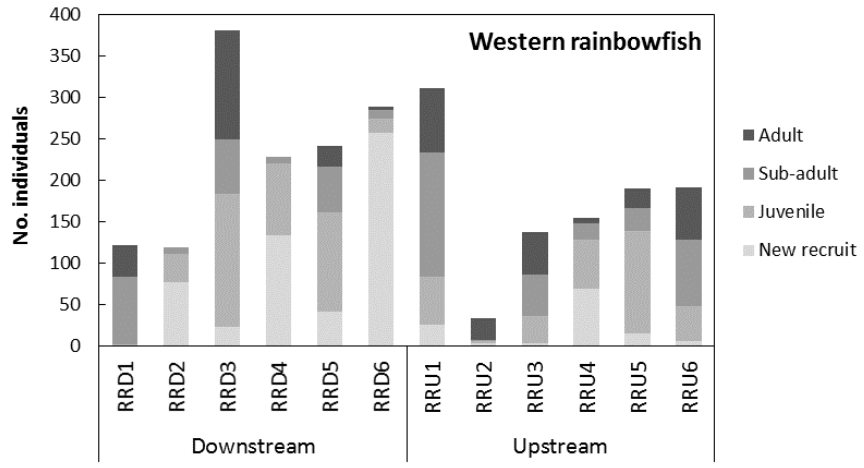

Figure 13. Abundance of western rainbowfish (*Melanotaenia australis*) age-classes recorded from each pool in the Project area.

Spangled Perch

Spangled perch are known to take advantage of wet season flooding to migrate upstream and breed (Bishop *et al.* 1995, Bishop *et al.* 2001, Pusey *et al.* 2004, Marsden and Power 2007). During this time, multiple spawning events are known to occur (Beesley 2006). In the Fitzroy River, Morgan *et al.* (2002) collected mature specimens at the beginning of the wet season, and larvae at the end of the wet season, indicating that spawning coincided with the flooding of the river. Spangled perch mature in their first year, at approximately 58 mm TL for males and 78 mm TL for females, and can reach a maximum size of 300 mm TL (Allen *et al.* 2002, Beesley 2006).

Spangled perch recruitment in the Project area appeared to be low, with new recruits (< 30 mm SL) only recorded at RRU1 and RRU2 upstream of the Jimmawarruda-Robe confluence, and RRD3 and RRD4 downstream of the confluence (Figure 14). Juveniles (31 - 60 mm SL) were also absent or recorded in low numbers at most sites (Figure 14). This reflects the high degree of variability in streamflow in the Project area, with low rainfall and streamflow leading up to the survey likely restricting spangled perch spawning activity. The exception was downstream site RRD3, where the spangled perch population comprised mainly juveniles (227 juveniles) (Figure 14). This suggests spangled perch may have spawned in or upstream of this pool recently following a flood event, with juveniles becoming isolated as waters

receded. RRD3 supported the highest abundance of spangled perch in the Project area (382 individuals), constituting 67% of all spangled perch caught during the survey; however, given the ubiquitousness of this species across the Pilbara, it is likely that larger populations reside at larger pools within the Project area. Catch per unit effort is likely reduced in these pools, such as RRU2, RRU4, RRU5, RRD4, RRD5 and RRD6, due to their size and depth, and presence of submerged debris (*e.g.* logs, branches, snags), which hinders seine and gill netting.

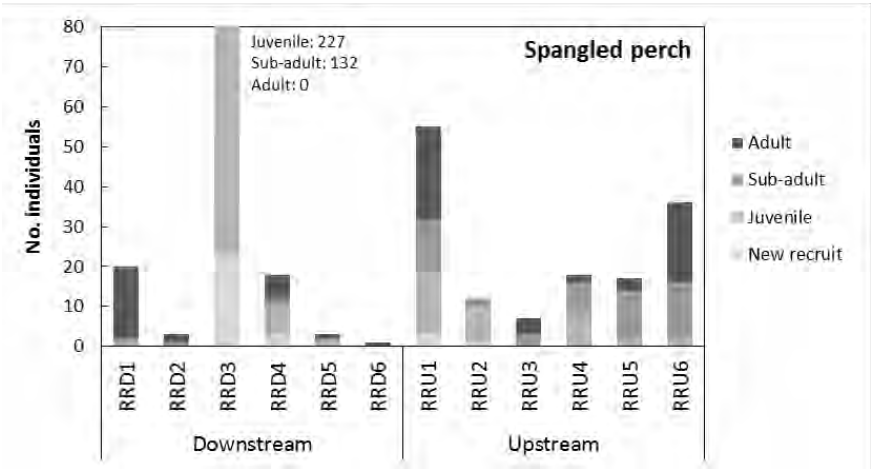

Figure 14. Abundance of spangled perch (*Leipotherapon unicolor*) age-classes recorded from each pool in the Project area. Note: column representing RRD3 is only partially displayed; the remainder of age-classes are given as text (new recruits are still displayed).

Pilbara tandan

Very little is known of the breeding ecology of the Pilbara tandan. Species of *Neosilurus* catfish usually attain a maximum size of only 200 mm SL, whereas similar species, such as *N. hyrtlii* and *N. ater*, can reach up to 400 mm TL (Lake 1971, Bishop *et al.* 2001). Breeding is thought to occur in the early wet season, where adults (> 91 mm SL) build their nests under large cobbles in flowing riffle zones (Bishop *et al*. 2001, Morgan *et al.* 2002). It is at this time when flooding increases the area and diversity of aquatic habitat available, while also initiating increases in plankton and other food sources (Bishop *et al.* 2001).

Pilbara tandan were collected in relatively low abundance throughout the Project area, with no new recruits (< 30 mm SL) recorded (Figure 15). Juvenile Pilbara tandan (31 – 70 mm SL) were only recorded at RRD2, RRU1 and RRU2 (Figure 15). Similar to spangled perch, low Pilbara tandan recruitment likely reflects the lack of streamflow in the Project area prior to the survey. Further, low overall catch rates of Pilbara tandan was likely due to the inherent difficulties in sampling this species. Like most other catfish, the Pilbara tandan is a benthic feeder, with techniques such as gill and seine netting generally limited in their ability to collect specimens due to the bottom-dwelling nature of these fish.

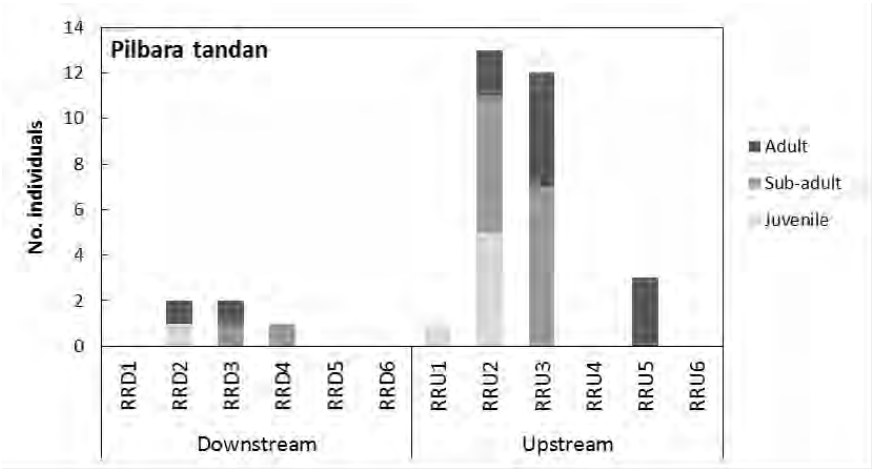

Figure 15. Abundance of Pilbara tandan (*Neosilurus* sp.) age-classes recorded from each pool in the Project area.

5.6 Other Fauna

No frogs or tadpoles were observed at any site in the current study. Although it is expected that some frogs do utilise pools within the Project area, the presence of large predatory fish, waterbirds and other predators (*e.g.* snakes) at these waterbodies would likely reduce survival rates of tadpoles in remnant pools.

No turtles were captured or observed in the Project area. EPA (1991) noted the native flat-shelled turtle, *Chelodina steindachneri,* was present at Gnieraoora and Martangkuna, but do not state the source of the records, which was possibly the 1991 survey by Streamtec/UWA for the Mesa J Project area.

6 SUMMARY AND CONCLUSIONS

This report summarises the results of wet season baseline sampling of aquatic ecosystems of the Robe River, both upstream and downstream of the proposed Mesa H development. The aim of the sampling program was to document the current ecological condition of the Robe River prior to the Mesa H development, which will require mine dewatering and surplus water discharge and may result in a surface discharge footprint along the Robe River. The current sampling program documents "current" ecological condition, moreso than "natural" condition due to the existing mine operations. In general, both water quality and aquatic fauna (microinvertebrate, hyporheic invertebrate, macroinvertebrate and fish) data indicated little ecological difference between "reference" sites upstream of the proposed development, and downstream sites that may be potentially exposed to dewatering discharge.

Water quality was highly variable amongst sites, with salinity levels ranging from fresh (592 µS/cm) to brackish (1,700 µS/cm), pH from circum-neutral (6.9) to slightly alkaline (7.9) and dissolved oxygen from hypoxic (14.5%) to supersaturated (134.9%). There were no obvious longitudinal gradients upstream or downstream of the Jimmawurrada-Robe confluence. Site RRU6, (~1 km upstream of the confluence) and the downstream sites, tended to have higher salinity (as EC and TDS), alkalinity, hardness and concentrations of associated ions, than sites upstream. This inter-site variability was attributed to differences in volume of the remnant pools sampled and evapoconcentration effects under recessional flows.

Exceedances of ANZECC/ARMCANZ default 95% TVs were recorded for nitrogen nutrients (N-total, N-NO_x and N-NH_3) at most sites upstream and downstream of the Jimmawurrada-Robe confluence. Elevated background levels of N-NO_3 and N-NH_3 within the Project area are unsurprising, given that the Robe River catchment is already effected by current and historic pastoral practices, with groundwaters also appearing to be enriched. Cattle, or evidence of high cattle use, were observed at a number of pools. Elevated N-total and N-NO_x downstream of the Jimmawurrada-Robe confluence may also reflect discharge of nitrogen-enriched groundwater from existing mine operations, though the relative contribution of anthropogenic and natural sources to nitrogen enrichment in surface waters of the Project area is unknown. With the exception of dissolved zinc at RRU5 and RRD3, no heavy metal analyte exceeded ANZECC/ARMCANZ default 95% TVs in the Project area.

A total of 81 microinvertebrate taxa were recorded from the Project area, of which 46 were present at potentially exposed sites downstream of the Jimmawurrada-Robe confluence, and 69 were recorded at upstream reference sites. The microinvertebrate fauna was generally typical of that commonly recorded from tropical/sub-tropical freshwater systems, comprising protists, rotifers, copepods, cladocerans (water fleas) and ostracods (seed shrimp), with Lecanidae dominating within the Rotifera. There were no significant differences in total mean microinvertebrate taxa richness between reference and potentially exposed sites, nor was there any significant difference in richness of any of the major microinvertebrate groups (protists, rotifers, micro-crustaceans) between these reaches.

Hyporheic sampling collected 59 taxa in total, the majority of which were species not specially adapted to groundwater environments (stygoxene); however, 8% were considered stygobitic (obligate groundwater inhabitants), 31% occasional hyporheic stygophiles (species that use the hyporheic zone seasonally or during early life history stages), and 2% possible hyporheic taxa. There were no obvious longitudinal gradients or patterns in hyporheic taxa richness between reference and potentially exposed sites, though hyporheic taxa richness was relatively high at RRD1, RRU6, RRD2 and RRU4, suggesting strong connectivity between ground- and surface- waters at these sites.

A total of 148 macroinvertebrate taxa were recorded from surface waters, with composition typical of freshwater systems throughout the world, being dominated by Insecta, in particular Diptera (true flies) and Coleoptera (aquatic beetles). There were no clear upstream/downstream gradients in

macroinvertebrate richness within the Project area, with no significant difference in mean total taxa richness, and mean richness of most major macroinvertebrate groups, between reference and potentially exposed sites. Similarly, multivariate analysis detected no distinguishable separation of reference or potentially exposed sites based on macroinvertebrate species assemblage structure.

3,515 individual fish, representing 11 species, were captured, measured and released in the Project area. True freshwater species included western rainbowfish, spangled perch, Pilbara tandan (eel-tailed catfish), Fortescue grunter, barred grunter, Terapontidae (grunter) hybrids and bony bream. Estuarine/marine vagrant fish species included milkfish, tarpon/ox-eye herring, mullet and banded scat/striped butterfish, the majority of which were recorded at downstream sites. The conservation listed Fortescue grunter (*Leipotherapon aheneus*; IUCN Lower Risk/Near Threatened; Parks and Wildlife Priority 4) was the second most abundant fish species of the Project area, recorded at all upstream and downstream sites. Similar to other fauna indices, there was no significant difference in mean total abundance of fish between upstream and downstream sites, nor was there any significant difference in mean abundance of each individual species between the reaches. Healthy (breeding) populations of western rainbowfish, the most abundant fish species of the Project area, were recorded from both the upstream and downstream reaches; however, spangled perch and Pilbara tandan recruitment appeared to be low throughout the Project area.

Including the Fortescue grunter, four species of conservation significance were recorded in the Project area, all of which were present at sites potentially exposed to dewatering discharge. These are summarised in Table 14 below:

Table 14. Summary of aquatic species of conservation significance (conservation listed or short range endemic) recorded from the Project area.

Species	Common name	Conservation significance	Occurrence within the Project area	Occurrence elsewhere
Microinvertebrates				
Eodiaptomus lumholtzi	Calanoid copepod	IUCN Vulnerable	RRD6	Koodaderi Spring, Homestead Trib., Mindy Mindy Ck., Cane R., NT & QLD.
Stygal / SRE invertebrates				
Nedsia spp.	Stygal amphipod	Potential short range endemic (data deficient)	RRD1 – 4, RRU3, RRU4 and RRU5	Uncertain, possibly bores within the Yarraloola Area
Macroinvertebrates				
Eurysticta coolawanyah	Pilbara pin damselfly	IUCN Near Threatened, Pilbara endemic	RRD3 and RRD4	Widespread throughout the Pilbara, though infrequently collected
Fish				
Leipotherapon aheneus	Fortescue grunter	IUCN Near Threatened, Parks and Wildlife Priority 4, Pilbara endemic	All sites	Robe R. catchment, Fortescue R. (below Fortescue Marsh); Ashburton R.

Current results indicate little ecological difference between "reference" sites upstream of the proposed Mesa H development, and downstream sites that may be potentially exposed to dewatering discharge operations. As such, these results provide a good starting point to enable the detection of potential ecological changes downstream of the Mesa H development caused by an altered abstraction and dewatering discharge regime. Data collected from reference sites upstream of Mesa H serve as the "control" for potentially exposed sites, while April/May 2016 data provide a snapshot of the "before"

condition, against which any future changes following mine development can be assessed. The premise being that if the degree of similarity between exposed and reference sites differs significantly over time (compared with pre-mine similarity), this would indicate mine-related response rather than stochastic variability due to factors such as climatic change.

Appendix 2. ANZECC/ARMCANZ (2000) trigger values

Table A2-1. ANZECC/ARMCANZ (2000) default trigger values for some physical and chemical stressors for tropical Australia for slightly disturbed ecosystems (TP = total phosphorus; FRP = filterable reactive phosphorus; TN = total nitrogen; NOx = total nitrates/nitrites; NH4+ = ammonium). Data derived from trigger values supplied by Australian states and territories, for the Northern Territory and regions north of Carnarvon in the west and Rockhampton in the east.

	TP ($\mu g\ L^{-1}$)	*FRP ($\mu g\ L^{-1}$)*	*TN ($\mu g\ L^{-1}$)*	*NOx ($\mu g\ L^{-1}$)*	*NH_4^+ ($\mu g\ L^{-1}$)*	*DO % saturation[f]*	*pH*
Aquatic Ecosystem							
Upland River[e]	10	5	150	30	6	90-120	6.0-7.5
Lowland River[e]	10	4	200-300[h]	10[b]	10	85-120	6.0-8.0
Lakes & Reservoirs	10	5	350[c]	10[b]	10	90-120	6.0-8.0
Wetlands[3]	10-50[g]	5-25[g]	350-1200[g]	10	10	90[b]-120[b]	6.0-8.0

b = Northern Territory values are 5µgL-1 for NOx, and <80 (lower limit) and >110% saturation (upper limit) for DO;
c = this value represents turbid lakes only. Clear lakes have much lower values;
e = no data available for tropical WA estuaries or rivers. A precautionary approach should be adopted when applying default trigger values to these systems;
f = dissolved oxygen values were derived from daytime measurements. Dissolved oxygen concentrations may vary diurnally and with depth. Monitoring programs should assess this potential variability;
g = higher values are indicative of tropical WA river pools;
h = lower values from rivers draining rainforest catchments.

Table A2-2. ANZECC/ARMCANZ (2000) Default trigger values for salinity and turbidity for the protection of aquatic ecosystems, applicable to tropical systems in Australia.

Aquatic Ecosystem		*Comments*
Salinity	***(µs/cm)***	
Upland & lowland rivers	20-250	Conductivity in upland streams will vary depending on catchment geology. The fist flush may result in temporarily high values
Lakes, reservoirs & wetlands	90-900	Higher conductivities will occur during summer when water levels are reduced due to evaporation
Turbidity	***(NTU)***	
Upland & lowland rivers	2-15	Can depend on degree of catchment modification and seasonal rainfall runoff
Lakes, reservoirs & wetlands	2-200	Most deep lakes have low turbidity. However, shallow lakes have higher turbidity naturally due to wind-induced re-suspension of sediments. Wetlands vary greatly in turbidity depending on the general condition of the catchment, recent flow events and the water level in the wetland.

Table A2-3. ANZECC/ARMCANZ (2000) default trigger values for toxicants at alternative levels of protection (µg/L).

	Trigger values for freshwater Level of protection (% species)			
Compound	***99%***	***95%***	***90%***	***80%***
METALS & METALLOIDS				
Aluminium pH > 6.5	27	55	80	150
Aluminium pH < 6.5	ID	ID	ID	ID
Arsenic (As III)	1	24	94	360
Arsenic (As IV)	0.9	13	42	140

Appendix 3. Water quality data

Results from spot measurement of surface water quality taken in conjunction with aquatic fauna sampling. ANZECC/ARMCANZ (2000) default TV for protection of 95% of freshwater species is also provided for comparison; ☐ ≥ default TV, ☐ ≥ 2x default TV, ☐ ≥ 10x default TV; note, for DO, values highlighted are less than the lower default TV.

* ANZECC/ARMCANZ (2000) provide only a low reliability TV for iron (Fe);

[A] Default TV shown is for AsV, as no default TV is provided for total arsenic;

[B] For bioaccumulating chemicals, ANZECC/ARMCANZ (2000) recommend using the default 99% species protection level TV;

[H] Default TV should be modified for water hardness using algorithms provided in Table 3.4.3 of ANZECC/ARMCANZ (2000);

[N] Default TV shown is for ammonium nitrogen, as N-NH_4^+, for protection against eutrophication. Default TV for protection against toxic effects of ammonia, as N-NH_3, is 0.9 mg/L.

Appendix 6. Hyporheic invertebrate data

Values are log_{10} abundance categories, where 1= 1 individual, 2 = 2-10 individuals, 3 = 11-100, 4 = 101-1000, and so on. Hyporheic fauna classifications (Class) followed those of Boulton (2001), where: X = stygoxene, O = occasional hyporheic stygophile, P = possible hyporheic taxa, S = stygobite and U = Unclassified.

(imm./dam) = taxa were too immature / damaged to be accurately identified to a lower taxonomic level.

(P) = taxa were in pupal form.

(L) = taxa were in larval form.

NB: some chironomid taxa are followed by their unique morphotype code (in parentheses).

Appendix 7. Macroinvertebrate data

Values are $\log_{10}$ abundance categories, where 1= 1 individual, 2 = 2-10 individuals, 3 = 11-100, 4 = 101-1000, and so on.

Appendix C: Conservation Categories for Flora, Fauna and Ecological Communities, and Categories for Introduced Flora

This page has been left blank intentionally.

Table C.1: Categories and definitions for EPBC Act listed flora and fauna species listed under the *Environment Protection and Biodiversity Conservation Act 1999*.

Conservation category	Definition
Extinct	Taxa with no reasonable doubt that the last member of the species has died.
Extinct in the wild	Taxa known to survive only in cultivation, in captivity or as a naturalized population well outside its past range; or it has not been recorded in its known and/or expected habitat, at appropriated seasons, anywhere in its past range, despite exhaustive surveys over a time frame appropriate to its life cycle and form.
Critically endangered (CR)	Taxa facing an extremely high risk of extinction in the wild in the immediate future, as determined in accordance with the prescribed criteria.
Endangered (E)	Taxa are not critically endangered; and are facing a very high risk of extinction in the wild in the near future, as determined in accordance with the prescribed criteria.
Vulnerable (V)	Taxa are not critically endangered or endangered; and are facing a high risk of extinction in the wild in the medium-term future, as determined in accordance with the prescribed criteria.
Conservation dependent (CD)	Taxa are the focus of a specific conservation program the cessation of which would result in the species becoming vulnerable, endangered or critically endangered; or the following subparagraphs are satisfied: i) the taxa is a species of fish; ii) the taxa is the focus of a management plan that provides management actions necessary to stop the decline of, and support the recovery of, the taxa so that its chances of long term survival in nature are maximized; iii) the management plan is in force under a law of the Commonwealth or of a State or Territory; iv) Cessation of the management plan would adversely affect the conservation status of the taxa Fish includes all taxa of bony fish, sharks, rays, crustaceans, molluscs and other marine organisms, but does not include marine mammals/reptiles.

Three categories exist for listing threatened ecological communities under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

Table C.2: Definitions and criteria for threatened ecological communities listed under the *Environment Protection and Biodiversity Conservation Act 1999*.

Categories of ecological communities	
Critically endangered	If, at that time, it is facing an extremely high risk of extinction in the wild in the immediate future, as determined in accordance with the prescribed criteria.
Endangered	If, at that time, it is not critically endangered and is facing a very high risk of extinction in the wild in the near future, as determined in accordance with the prescribed criteria.
Vulnerable	If, at that time, it is not critically endangered or endangered, and is facing a high risk of extinction in the wild in the medium-term future, as determined in accordance with the prescribed criteria.

Table C.3: Categories of threatened ecological communities (Department of Parks and Wildlife 2015b).

PD: Presumed Destroyed
An ecological community that has been adequately searched for but for which no representative occurrences have been located. The community has been found to be totally destroyed or so extensively modified throughout its range that no occurrence of it is likely to recover its species composition and/or structure in the foreseeable future. An ecological community will be listed as presumed totally destroyed if there are no recent records of the community being extant **and either** of the following applies (A or B): A) Records within the last 50 years have not been confirmed despite thorough searches of known or likely habitats **or** B) All occurrences recorded within the last 50 years have since been destroyed.
CR : Critically Endangered
An ecological community that has been adequately surveyed and found to have been subject to a major contraction in area and/or that was originally of limited distribution and is facing severe modification or destruction throughout its range in the immediate future, or is already severely degraded throughout its range but capable of being substantially restored or rehabilitated. An ecological community will be listed as **Critically Endangered** when it has been adequately surveyed and is found to be facing an extremely high risk of total destruction in the immediate future. This will be determined on the basis of the best available information, by it meeting **any one or more of** the following criteria (A, B or C): A) The estimated geographic range, and/or total area occupied, and/or number of discrete occurrences since European settlement have been reduced by at least 90% **and either or both** of the following apply (i or ii): i) geographic range, and/or total area occupied and/or number of discrete occurrences are continuing to decline such that total destruction of the community is imminent (within approximately 10 years); ii) modification throughout its range is continuing such that in the immediate future (within approximately 10 years) the community is unlikely to be capable of being substantially rehabilitated. B) Current distribution is limited, **and one or more** of the following apply (i, ii or iii): i) geographic range and/or number of discrete occurrences, and/or area occupied is highly restricted and the community is currently subject to known threatening processes which are likely to result in total destruction throughout its range in the immediate future (within approximately 10 years); ii) there are very few occurrences, each of which is small and/or isolated and extremely vulnerable to known threatening processes; iii) there may be many occurrences but total area is very small and each occurrence is small and/or isolated and extremely vulnerable to known threatening processes. C) The ecological community exists only as highly modified occurrences that may be capable of being rehabilitated if such work begins in the immediate future (within approximately 10 years).

En: Endangered

An ecological community that has been adequately surveyed and found to have been subject to a major contraction in area and/or was originally of limited distribution and is in danger of significant modification throughout its range or severe modification or destruction over most of its range in the near future.

An ecological community will be listed as **Endangered** when it has been adequately surveyed and is not Critically Endangered but is facing a very high risk of total destruction in the near future. This will be determined on the basis of the best available information by it meeting **any one or more** of the following criteria (A, B, or C):

A) The geographic range, and/or total area occupied, and/or number of discrete occurrences have been reduced by at least 70% since European settlement **and either or both** of the following apply (i or ii):

i) the estimated geographic range, and/or total area occupied and/or number of discrete occurrences are continuing to decline such that total destruction of the community is likely in the short term future (within approximately 20 years);

ii) modification throughout its range is continuing such that in the short term future (within approximately 20 years) the community is unlikely to be capable of being substantially restored or rehabilitated.

B) Current distribution is limited, **and one or more** of the following apply (i, ii or iii):

i) geographic range and/or number of discrete occurrences, and/or area occupied is highly restricted and the community is currently subject to known threatening processes which are likely to result in total destruction throughout its range in the short term future (within approximately 20 years);

ii) there are few occurrences, each of which is small and/or isolated and all or most occurrences are very vulnerable to known threatening processes;

iii) there may be many occurrences but total area is small and all or most occurrences are small and/or isolated and very vulnerable to known threatening processes.

C) The ecological community exists only as very modified occurrences that may be capable of being substantially restored or rehabilitated if such work begins in the short-term future (within approximately 20 years).

VU: Vulnerable

An ecological community that has been adequately surveyed and is found to be declining and/or has declined in distribution and/or condition and whose ultimate security has not yet been assured and/or a community that is still widespread but is believed likely to move into a category of higher threat in the near future if threatening processes continue or begin operating throughout its range.

An ecological community will be listed as **Vulnerable** when it has been adequately surveyed and is not Critically Endangered or Endangered but is facing a high risk of total destruction or significant modification in the medium to long-term future. This will be determined on the basis of the best available information by it meeting **any one or more of** the following criteria (A, B or C):

A) The ecological community exists largely as modified occurrences that are likely to be capable of being substantially restored or rehabilitated.

B) The ecological community may already be modified and would be vulnerable to threatening processes, is restricted in area and/or range and/or is only found at a few locations.

C) The ecological community may be still widespread but is believed likely to move into a category of higher threat in the medium to long term future because of existing or impending threatening processes.

Possible threatened ecological communities that do not meet survey criteria or that are not adequately defined are added to the Priority Ecological Community Lists under Priorities 1, 2 and 3. Ecological Communities that are adequately known, and are rare but not threatened or meet criteria for Near Threatened, or that have been recently removed from the threatened list, are placed in Priority 4. These ecological communities require regular monitoring. Conservation Dependent ecological communities are placed in Priority 5.

Table C.4: Definitions and criteria for priority ecological communities (Department of Parks and Wildlife 2015b).

P1: Priority One – Poorly-known ecological communities
Ecological communities that are known from very few occurrences with a very restricted distribution (generally ≤5 occurrences or a total area of ≤ 100ha). Occurrences are believed to be under threat either due to limited extent, or being on lands under immediate threat (e.g. within agricultural or pastoral lands, urban areas, active mineral leases) or for which current threats exist. May include communities with occurrences on protected lands. Communities may be included if they are comparatively well-known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under immediate threat from known threatening processes across their range.
P2: Priority Two – Poorly-Known ecological communities
Communities that are known from few occurrences with a restricted distribution (generally ≤10 occurrences or a total area of ≤200ha). At least some occurrences are not believed to be under immediate threat of destruction or degradation. Communities may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under threat from known threatening processes.
P3: Priority Three – Poorly-Known ecological communities
(i) Communities that are known from several to many occurrences, a significant number or area of which are not under threat of habitat destruction or degradation or: (ii) communities known from a few widespread occurrences, which are either large or with significant remaining areas of habitat in which other occurrences may occur, much of it not under imminent threat, or; (iii) communities made up of large, and/or widespread occurrences, that may or may not be represented in the reserve system, but are under threat of modification across much of their range from processes such as grazing by domestic and/or feral stock, and inappropriate fire regimes. Communities may be included if they are comparatively well known from several localities but do not meet adequacy of survey requirements and/or are not well defined, and known threatening processes exist that could affect them.
P4: Priority Four
Ecological communities that are adequately known, rare but not threatened or meet criteria for Near Threatened, or that have been recently removed from the threatened list. These communities require regular monitoring. (i) Rare. Ecological communities known from few occurrences that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These communities are usually represented on conservation lands. (ii) Near Threatened. Ecological communities that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable. (iii) Ecological communities that have been removed from the list of threatened communities during the past five years.
P5: Priority Five – Conservation dependent ecological communities
Ecological communities that are not threatened but are subject to a specific conservation program, the cessation of which would result in the community becoming threatened within five years.

Table C.5: Conservation codes for Western Australian flora and fauna under the *Wildlife Conservation Act 1950*.

Code	Conservation category	Definition
S1	Schedule 1 of the Wildlife Conservation (Specially Protected Fauna) Notice and Wildlife Conservation (Rare Flora) Notice under the Wildlife Conservation Act 1950.	Taxa that is rare or likely to become extinct, as critically endangered taxa.
S2	Schedule 2 of the Wildlife Conservation (Specially Protected Fauna) Notice and Wildlife Conservation (Rare Flora) Notice under the Wildlife Conservation Act 1950.	Taxa that is rare or likely to become extinct, as endangered taxa.
S3	Schedule 3 of the Wildlife Conservation (Specially Protected Fauna) Notice and Wildlife Conservation (Rare Flora) Notice under the Wildlife Conservation Act 1950.	Taxa that is rare or likely to become extinct, as vulnerable taxa.
S4	Schedule 4 of the Wildlife Conservation (Specially Protected Fauna) Notice and Wildlife Conservation (Rare Flora) Notice under the Wildlife Conservation Act 1950.	Taxa that is presumed to be extinct.
S5	Schedule 5 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Birds that are subject to international agreements relating to the protection of migratory birds.
S6	Schedule 6 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Fauna that are of special conservation need being species dependent on ongoing conservation intervention.
S7	Schedule 7 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Declared to be fauna that is in need of special protection, otherwise than for the reasons mentioned.

Note: Schedules 5, 6, and 7 are only related to conservation significant fauna.

Threatened fauna and flora (Schedule 1) are further ranked by the Department according to their level of threat using IUCN Red List criteria:

- CR: Critically Endangered - considered to be facing an extremely high risk of extinction in the wild.
- EN: Endangered - considered to be facing a very high risk of extinction in the wild.
- VU: Vulnerable - considered to be facing a high risk of extinction in the wild.

Taxa that have not yet been adequately surveyed to be listed under Schedule 1 or 2 are added to the Priority Flora and Priority Fauna Lists under Priorities 1, 2 or 3. These three categories are ranked in order of priority for survey and evaluation of conservation status so that consideration can be given to their declaration as threatened flora or fauna. Taxa that are adequately known, are rare but not threatened, or meet criteria for Near Threatened, or that have been recently removed from the threatened list for other than taxonomic reasons, are placed in Priority 4. These taxa require regular monitoring. Conservation Dependent species are placed in Priority 5.

Table C.6: Priority species under Western Australian *Wildlife Conservation Act 1950*.

P1: Priority One – Poorly known taxa
Taxa that are known from one or a few collections or sight records (generally five or less) which are potentially at risk. All occurrences are either: very small; or on lands not managed for conservation, e.g. agricultural or pastoral lands, urban areas, road and rail reserves, gravel reserves, and active mineral leases; or otherwise under threat of habitat destruction or degradation. Taxa may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements and appear to be under immediate threat from known threatening processes. Such taxa are in urgent need of further survey.
P2: Priority Two – Poorly known taxa
Taxa that are known from one or a few collections (generally five or less), some of which are on lands managed primarily for nature conservation, e.g. national parks, conservation parks, nature reserves, and other lands with secure tenure being managed for conservation. Taxa may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements and appear to be under threat from known threatening processes. Such taxa are in urgent need of further survey.
P3: Priority Three – Poorly known taxa
Taxa that are known from several localities and does not appear under imminent threat, or from few but widespread localities with either large population size or significant remaining areas of apparently suitable habitat, much of it not under imminent threat. Taxa may be included if they are comparatively well known from several localities but do not meet adequacy of survey requirements and known threatening processes exist that could affect them. Such taxa are in urgent need of further survey.
P4: Priority Four: Rare, near threatened and other taxa in need of monitoring
(a) Rare. Taxa that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These taxa are usually represented on conservation lands. (b) Near Threatened. Taxa that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable. (c) Taxa that have been removed from the list of threatened species during the past five years for reasons other than taxonomy.
P5: Priority Five: Conservation dependent taxa
Taxa that are not threatened but are subject to a specific conservation program, the cessation of which would result in the taxa becoming threatened within five years.

The management of introduced flora species in Western Australia is regulated through the *Biosecurity and Agriculture Management Act 2007* (BAM Act). A list of declared pests, including 'pest' plants is provided under the BAM Act, which has been updated to incorporate a number of other Acts that are administered by DAFWA (2015). Declared pests can fall into two categories: one that relates to the prevention of introducing the species or eradicating it; and the other relates to managing the species and whether it can be kept (i.e. for scientific purposes, education or other purpose).

The threat and risk posed to site-specific biodiversity values, influences to rehabilitation success, primary production, infrastructure assets or human health will differ depending on the unique characteristics of each site and the associated land management practice or operation. Therefore site or project specific weed assessments and priorities should be reviewed for each project.

As per introduced flora species, the BAM Act seeks to establish a modern biosecurity regulatory scheme to prevent serious animal pests from entering the State and becoming established, and to minimise the spread and impact of any that are already present within the State. Declared animal pests fall into three categories as Gazetted under the BAM Act (DAFWA 2015). These categories are outlined in Table C.7.

Table C.7: Declared pests categories as gazetted under the *Biosecurity and Agriculture Management Act 2007* (Department of Agriculture and Food 2016).

Category	Description
C1 (Exclusion)	Pests will be assigned to this category if they are not established in Western Australia and control measures are to be taken, including border checks, in order to prevent them entering and establishing in the State.
C2 (Eradication)	Pests will be assigned to this category if they are present in Western Australia in low enough numbers or in sufficiently limited areas that their eradication is still a possibility.
C3 (Management)	Pests will be assigned to this category if they are established in Western Australia but it is feasible, or desirable, to manage them in order to limit their damage. Control measures can prevent a C3 pest from increasing in population size or density or moving from an area in which it is established into an area which currently is free of that pest.

Table C.8: IUCN Red List Conservation Categories of Threatened Species.

Category	Description
Critically Endangered (CR)	A taxon is Critically Endangered when the best available evidence indicates that it is considered to be facing an extremely high risk of extinction in the wild.
Endangered (EN)	A taxon is Endangered when the best available evidence indicates that it is considered to be facing a very high risk of extinction in the wild.
Vulnerable (VU)	A taxon is Vulnerable when the best available evidence indicates that it is considered to be facing a high risk of extinction in the wild.
Near Threatened (NT)	A taxon is Near Threatened when it has been evaluated against the criteria but does not qualify for Critically Endangered, Endangered or Vulnerable now, but is close to qualifying for or is likely to qualify for a threatened category in the near future.
Least Concern (LC)	A taxon is Least Concern when it has been evaluated against the criteria and does not qualify for Critically Endangered, Endangered, Vulnerable or Near Threatened. Widespread and abundant taxa are included in this category.

East Perth WA 6004

Attention: Natalie Cadd

Dear Natalie Cadd,

REQUEST FOR THREATENED AND PRIORITY FLORA INFORMATION

I refer to your request of 14 September 2015 for Threatened (Declared Rare) and Priority Flora information in the Pannawonica area. The search was conducted within the area of the coordinates you submitted with an additional 20km buffer.

A search was undertaken for this area of **(1)** the Department's *Threatened (Declared Rare) and Priority Flora* database (for results, see "TPFL" – coordinates are GDA94), **(2)** the *Western Australian Herbarium Specimen* database for Threatened and Priority flora species opportunistically collected in the area of interest (for results, see "WAHERB"- coordinates are GDA94 – see condition number 4 in the attached 'Conditions in Respect of Supply') and **(3)**, the Department's *Threatened and Priority Flora List* [this list is searched using 'place names'. This list, which may also be used as a species target list, contains species that are declared rare (Conservation Code R or X for those presumed to be extinct), poorly known (Conservation Codes 1, 2 or 3), or require monitoring (Conservation Code 4) – for results, *if any*, see "TP List"]. The results are attached electronically to this email.

Attached also are the conditions under which this information has been supplied. Your attention is specifically drawn to the ninth point, which refers to the requirement to undertake field investigations for the accurate determination of Threatened and Priority flora occurrence at a site. *The information supplied should be regarded as an indication only of the Threatened and Priority flora that may be present and may be used as a target list in any surveys undertaken.*

The information provided does not preclude you from obtaining and complying with, where necessary, land clearing approvals from other agencies.

An invoice for $ 300 (plus GST) to supply this information will be forwarded.

It would be appreciated if any populations of Threatened and Priority flora you encounter in the area could be reported to this Department to ensure their ongoing management.

If you require any further details, or wish to discuss Threatened and Priority flora management, please contact Dr Ken Atkins, Manager, Species and Communities Branch, on (08) 9334 0455.

Yours faithfully

Jessica Donaldson

Government of **Western Australia**
Department of **Parks and Wildlife**

THREATENED AND PRIORITY FLORA INFORMATION

Conditions with Respect to the Supply of Information

- The data supplied may not be provided to any other organisations, nor be used for any purpose other than for the project for which it has been originally provided for; without the prior consent of the Executive Director, Department of Parks and Wildlife.
- Specific locality information for threatened flora is regarded as confidential, and should be treated as such by receiving organisations. Specific locality information for threatened flora may not be used in reports without the written permission of the Executive Director, Department of Parks and Wildlife. Reports may only show generalised locations at a low resolution or, where necessary, show specific locations without identifying species. Species and Communities Branch is to be contacted for guidance on the presentation of threatened flora information.
- The Department of Parks and Wildlife respects the privacy of private landowners who may have threatened and priority flora on their property. Threatened and priority flora locations identified in the data as being on private property should be treated in confidence, and contact with property owners must only be made through the Department of Parks and Wildlife.
- The development of the Perth Herbarium database was not originally intended for electronic mapping (eg. GIS ArcView). The latitude and longitude coordinates for each entry are not verified prior to being data based. It is only in recent times that collections have been submitted with GPS coordinates. Therefore, be aware when using this data in ArcView that some records may not plot to the locality description given with each collection.
- Acknowledgment of the Department of Parks and Wildlife as the source of data is to be made in any published material and cited as Parks and Wildlife (2015) Threatened and Priority Flora Database Search for [search area] accessed on the [date of search]. Prepared by the Species and Communities Branch for [Requesters name and company] for [purpose of search].
- Copies of all such publications are to be forwarded to the Department of Parks and Wildlife, Attention; the Manager, Species and Communities Branch.

Disclaimers with Respect to the Supply of Information

- Receiving organisations should note that while every effort has been made to prevent errors and omissions in the data, they may be present. The Department of Parks and Wildlife accepts no responsibility for this.
- Receiving organisations must also recognise that the database is subject to continual updating and amendment, and such considerations should be taken into account by the user.
- It should be noted that the supplied data does not necessarily represent a comprehensive listing of the threatened flora of the area in question. Its comprehensiveness is dependent on the amount of surveys carried out within a specified area. The receiving organisation should consider engaging a botanist, if required, to undertake a survey of the area under consideration.

ABBREVIATIONS USED IN THE WESTERN AUSTRALIAN HERBARIUM DATABASE

Geocode Method - The method that was used to record the latitude and longitude.

Auto - Indicates that the coordinate data in the record was created automatically (i.e. by software), usually by creating a coordinate from information provided in the Nearest Named Place or Locality textual description fields.

GAP - Acronym for "Generalised Arbitrary Point" as used in HISPID. GAP indicates that the coordinate data was obtained manually from the Nearest Named Place or Locality textual description fields.

GPS - Acronym for "Global Positioning System". GPS indicates that the coordinate data in the record was obtained from a GPS unit by the collector of the specimen.

MAN - Shorthand for manual. MAN indicates that the coordinate data was created by hand using some method not allowed for by one of the other manual Geocode Method values, in particular, TOPO, GAP, or GPS.

TOPO - Shorthand for topographic map. TOPO indicates that the coordinate data was obtained by plotting textual locality details against a topographic map.

None - Indicates that no coordinate data has been supplied by the collector.

Unknown - Indicates that there is no known method for determining the coordinate data. Should be used if the collector provided no indication of how they sampled the specimen's coordinate data.

PREC (Precision) - precision ratings for coordinates.

Precision 1: Absolutely precise (to nearest 100m or nearest second) and must be GPS determined. For example 35°26'42"S 123°40'26"E

Precision 2: Falling within a diameter of 3km (ca 2 minutes) or if no GPS mentioned in collecting notes. (The location must be able to be pinpointed on a 1:250 000 map, a spot locality. For example 35°26'42"S 123°40'26"E

Precision 3: Falling within a diameter of 10km (ca 7 minutes) or for degrees and minutes, where seconds have not been given. For example 35°26'_"S 123°40'_"E

Precision 4: Falling within a diameter of ca 50km (30 minutes). For example 35°26'_"S 123°40'_"E

Precision 5: Where a location is a prescribed large geographical area within a state or only the state is given. Diameter is greater than 50km. For example 35°_'_"S 123°_'_"E

Precision 6: used when localities are New Holland, Eastern Australia or Not given. Fields will be left blank.

Department of Parks and Wildlife

CONSERVATION CODES

For Western Australian Flora and Fauna

T Threatened species

Listed as Specially Protected under the *Wildlife Conservation Act 1950,* published under Schedule 1 of the Wildlife Conservation (Specially Protected Fauna) Notice for Threatened Fauna and Wildlife Conservation (Rare Flora) Notice for Threatened Flora (which may also be referred to as Declared Rare Flora).

- Fauna that is rare or likely to become extinct are declared to be fauna that is in need of special protection
- Flora that are extant and considered likely to become extinct, or rare and therefore in need of special protection, are declared to be rare flora

Species* which have been adequately searched for and are deemed to be, in the wild, either rare, at risk of extinction, or otherwise in need of special protection, and have been gazetted as such.
The assessment of the conservation status of these species is based on their national extent.

X Presumed extinct species

Listed as Specially Protected under the *Wildlife Conservation Act 1950,* published under Schedule 2 of the Wildlife Conservation (Specially Protected Fauna) Notice for Presumed Extinct Fauna and Wildlife Conservation (Rare Flora) Notice for Presumed Extinct Flora (which may also be referred to as Declared Rare Flora).

Species which have been adequately searched for and there is no reasonable doubt that the last individual has died, and have been gazetted as such.

IA Migratory birds protected under an international agreement

Listed as Specially Protected under the *Wildlife Conservation Act 1950,* listed under Schedule 3 of the Wildlife Conservation (Specially Protected Fauna) Notice.

Birds that are subject to an agreement between the government of Australia and the governments of Japan (JAMBA), China (CAMBA) and The Republic of Korea (ROKAMBA), relating to the protection of migratory birds.

S Other specially protected fauna

Listed as Specially Protected under the *Wildlife Conservation Act 1950.* Fauna declared to be in need of special protection, otherwise than for the reasons mentioned for Schedules 1, 2 or 3, are published under Schedule 4 of the Wildlife Conservation (Specially Protected Fauna) Notice.

Threatened Fauna and Flora are ranked according to their level of threat using IUCN Red List categories and criteria. *For example:* Carnaby's Cockatoo (*Calyptorynchus latirostris*) is listed as 'Specially Protected' under the *Wildlife Conservation Act 1950,* published under Schedule 1, and referred to as a 'Threatened' species with a ranking of 'Endangered'.

CR Critically Endangered - considered to be facing an extremely high risk of extinction in the wild.

EN Endangered - considered to be facing a very high risk of extinction in the wild.

VU Vulnerable - considered to be facing a high risk of extinction in the wild.

A list of the current rankings can be downloaded from the Parks and Wildlife Threatened Species and Communities webpage at http://dpaw.wa.gov.au/plants-and-animals/threatened-species-and-communities/

P Priority species

Species that maybe threatened or near threatened but are data deficient, have not yet been adequately surveyed to be listed under the Schedules of the Wildlife Conservation (Specially Protected Fauna) Notice or the Wildlife Conservation (Rare Flora) Notice, are added to the Priority Fauna or Priority Flora Lists under Priorities 1, 2 or 3. These three categories are ranked in order of priority for survey and evaluation of conservation status so that consideration can be given to their declaration as threatened flora or fauna. Species that are adequately known, are rare but not threatened, or meet criteria for near threatened, or that have been recently removed from the threatened list for other than taxonomic reasons, are placed in Priority 4. These species require regular monitoring. Conservation dependent species that are subject to a specific conservation program are placed in Priority 5.

Assessment of Priority codes is based on the Western Australian distribution of the species, unless the distribution in WA is part of a contiguous population extending into adjacent States, as defined by the known spread of locations.

1: Priority One: Poorly-known species

Species that are known from one or a few locations (generally five or less) which are potentially at risk. All occurrences are either: very small; or on lands not managed for conservation, e.g. agricultural or pastoral lands, urban areas, road and rail reserves, gravel reserves and active mineral leases; or otherwise under threat of habitat destruction or degradation. Species may be included if they are comparatively well known from one or more locations but do not meet adequacy of survey requirements and appear to be under immediate threat from known threatening processes. Such species are in urgent need of further survey.

2: Priority Two: Poorly-known species

Species that are known from one or a few locations (generally five or less), some of which are on lands managed primarily for nature conservation, e.g. national parks, conservation parks, nature reserves and other lands with secure tenure being managed for conservation. Species may be included if they are comparatively well known from one or more locations but do not meet adequacy of survey requirements and appear to be under threat from known threatening processes. Such species are in urgent need of further survey.

3: Priority Three: Poorly-known species

Species that are known from several locations, and the species does not appear to be under imminent threat, or from few but widespread locations with either large population size or significant remaining areas of apparently suitable habitat, much of it not under imminent threat. Species may be included if they are comparatively well known from several locations but do not meet adequacy of survey requirements and known threatening processes exist that could affect them. Such species are in need of further survey.

4: Priority Four: Rare, Near Threatened and other species in need of monitoring

(a) Rare. Species that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These species are usually represented on conservation lands.
(b) Near Threatened. Species that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable.
(c) Species that have been removed from the list of threatened species during the past five years for reasons other than taxonomy.

5: Priority Five: Conservation Dependent species

Species that are not threatened but are subject to a specific conservation program, the cessation of which would result in the species becoming threatened within five years.

*Species includes all taxa (plural of taxon - a classificatory group of any taxonomic rank, e.g. a family, genus, species or any infraspecific category i.e. subspecies, variety or forma).

DEPARTMENT OF ENVIRONMENT AND CONSERVATION

THREATENED AND PRIORITY ECOLOGICAL COMMUNITIES INFORMATION

CONDITIONS IN RESPECT OF SUPPLY OF INFORMATION

1. All requests for data are to be made in writing to the Director General, Department of Environment and Conservation Attention: Species and Communities Branch

2. The data supplied may not be supplied to other organisations, nor be used for any purpose other than for the project for which they have been provided, without the prior written consent of the data custodian (Val English), Species and Communities Branch.

3. Specific locality information for threatened and priority ecological communities (TECs/PECs) is regarded as confidential, and should be treated as such by receiving organisations. Specific locality information for TECs/PECs may not be used in public reports without the written permission of the Director General, Department of Environment and Conservation. Publicly available reports may only show generalised locations (ie buffer locations). The TEC database manager is to be contacted for guidance on the presentation of TEC/PEC information.

4. Note that the Department of Environment and Conservation respects the privacy of private landowners who may have threatened and priority ecological communities on their property. Locations of TECs/PECs identified in the data as being on private property should be treated in confidence, and contact with property owners made through the Department of Environment and Conservation.

5. Receiving organisations should note that while every effort has been made to prevent errors and omissions in the data provided, they may be present. The Department of Environment and Conservation accepts no responsibility for this.

6. Receiving organisations must also recognise that the Threatened Ecological Communities database is subject to continual updating and amendment, and such considerations should be taken into account by the user.

7. It should be noted that the supplied data do not necessarily represent a comprehensive listing of the threatened and priority ecological communities of the area in question. Its comprehensiveness is dependant on the amount of survey carried out within the specified area. Private property has been relatively little surveyed. The receiving organisation should employ a consultant, if there is any likelihood of the presence of any threatened or priority ecological community, to undertake a survey of the area under consideration.

8. Acknowledgment of the Department of Environment and Conservation as source of the data is to be made in any published material. Copies of all such publications are to be forwarded to the Department of Environment and Conservation, Attention: Manager, Species and Communities Branch.

Conservation Codes
T - Rare or likely to become extinct
X - Presumed extinct
IA - Protected under international agreement
S - Other specially protected fauna
1 - Priority 1
2 - Priority 2
3 - Priority 3
4 - Priority 4
5 - Priority 5

[1] For NatureMap's purposes, species flagged as endemic are those whose records are wholely contained within the search area. Note that only those records complying with the search criterion are included in the calculation. For example, if you limit records to those from a specific datasource, only records from that datasource are used to determine if a species is restricted to the query area.

Australian Government

Department of the Environment

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 25/07/16 16:03:50

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	None
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	8
Listed Migratory Species:	7

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	12
Whales and Other Cetaceans:	None
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Commonwealth Reserves Marine:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	10
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Listed Threatened Species		[Resource Information]
Name	Status	Type of Presence
Birds		
Pezoporus occidentalis Night Parrot [59350]	Endangered	Species or species habitat may occur within area
Rostratula australis Australian Painted Snipe [77037]	Endangered	Species or species habitat may occur within area
Mammals		
Dasyurus hallucatus Northern Quoll, Digul [331]	Endangered	Species or species habitat known to occur within area
Macroderma gigas Ghost Bat [174]	Vulnerable	Species or species habitat likely to occur within area
Macrotis lagotis Greater Bilby [282]	Vulnerable	Species or species habitat likely to occur within area
Rhinonicteris aurantia (Pilbara form) Pilbara Leaf-nosed Bat [82790]	Vulnerable	Roosting known to occur within area
Plants		
Lepidium catapycnon Hamersley Lepidium, Hamersley Catapycnon [9397]	Vulnerable	Species or species habitat likely to occur within area
Reptiles		
Liasis olivaceus barroni Olive Python (Pilbara subspecies) [66699]	Vulnerable	Species or species habitat known to occur within area

Listed Migratory Species		[Resource Information]
* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.		
Name	Threatened	Type of Presence
Migratory Marine Birds		
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Hirundo rustica Barn Swallow [662]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
[Motacilla cinerea](#)		
Grey Wagtail [642]		Species or species habitat may occur within area
[Motacilla flava](#)		
Yellow Wagtail [644]		Species or species habitat may occur within area
Migratory Wetlands Species		
[Charadrius veredus](#)		
Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
[Glareola maldivarum](#)		
Oriental Pratincole [840]		Species or species habitat may occur within area
[Pandion haliaetus](#)		
Osprey [952]		Species or species habitat known to occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
[Apus pacificus](#)		
Fork-tailed Swift [678]		Species or species habitat likely to occur within area
[Ardea alba](#)		
Great Egret, White Egret [59541]		Species or species habitat known to occur within area
[Ardea ibis](#)		
Cattle Egret [59542]		Species or species habitat may occur within area
[Charadrius veredus](#)		
Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
[Glareola maldivarum](#)		
Oriental Pratincole [840]		Species or species habitat may occur within area
[Haliaeetus leucogaster](#)		
White-bellied Sea-Eagle [943]		Species or species habitat likely to occur within area
[Hirundo rustica](#)		
Barn Swallow [662]		Species or species habitat may occur within area
[Merops ornatus](#)		
Rainbow Bee-eater [670]		Species or species habitat may occur within area
[Motacilla cinerea](#)		
Grey Wagtail [642]		Species or species habitat may occur within area
[Motacilla flava](#)		
Yellow Wagtail [644]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Pandion haliaetus		
Osprey [952]		Species or species habitat known to occur within area
Rostratula benghalensis (sensu lato)		
Painted Snipe [889]	Endangered*	Species or species habitat may occur within area

Extra Information

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Columba livia		
Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Mammals		
Capra hircus		
Goat [2]		Species or species habitat likely to occur within area
Equus asinus		
Donkey, Ass [4]		Species or species habitat likely to occur within area
Felis catus		
Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Mus musculus		
House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus		
Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Vulpes vulpes		
Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Cenchrus ciliaris		
Buffel-grass, Black Buffel-grass [20213]		Species or species habitat likely to occur within area
Parkinsonia aculeata		
Parkinsonia, Jerusalem Thorn, Jelly Bean Tree, Horse Bean [12301]		Species or species habitat likely to occur within area
Prosopis spp.		
Mesquite, Algaroba [68407]		Species or species

Name	Status	Type of Presence
		habitat likely to occur within area

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

For species where the distributions are well known, maps are digitised from sources such as recovery plans and detailed habitat studies. Where appropriate, core breeding, foraging and roosting areas are indicated under 'type of presence'. For species whose distributions are less well known, point locations are collated from government wildlife authorities, museums, and non-government organisations; bioclimatic distribution models are generated and these validated by experts. In some cases, the distribution maps are based solely on expert knowledge.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Acanthaceae					
1.	12088	*Rostellularia adscendens var. clementii*			
Acanthizidae					
2.	24260	*Acanthiza apicalis (Broad-tailed Thornbill, Inland Thornbill)*			
3.	24265	*Acanthiza uropygialis (Chestnut-rumped Thornbill)*			
4.	25530	*Gerygone fusca (Western Gerygone)*			
5.	24271	*Gerygone fusca subsp. fusca (Western Gerygone)*			
6.	30948	*Smicrornis brevirostris (Weebill)*			
Acariformes					
7.		*Acariformes sp.*			
8.		*Acarina sp.*			
9.		*Oribatida group 1 (PSS)*			
10.		*Oribatida group 4 (PSS)*			
11.		*Oribatida group 5 (PSS)*			
12.		*Oribatida sp. 4 (PSW)*			
13.		*Trombidioidea sp.*			
Accipitridae					
14.	25535	*Accipiter cirrocephalus (Collared Sparrowhawk)*			
15.	25536	*Accipiter fasciatus (Brown Goshawk)*			
16.	24283	*Accipiter fasciatus subsp. didimus (Brown Goshawk)*			
17.	24285	*Aquila audax (Wedge-tailed Eagle)*			
18.	25538	*Aquila morphnoides (Little Eagle)*			
19.	24289	*Circus assimilis (Spotted Harrier)*			
20.	25540	*Elanus caeruleus (Black-shouldered Kite)*			
21.	24293	*Haliaeetus leucogaster (White-bellied Sea-Eagle)*		IA	
22.	24295	*Haliastur sphenurus (Whistling Kite)*			
23.	25542	*Milvus migrans (Black Kite)*			
Actinopodidae					
24.		*Missulena rutraspina*			
Aegothelidae					
25.	25544	*Aegotheles cristatus (Australian Owlet-nightjar)*			
Aeolosomatidae					
26.		*Aeolosoma sp. 1 (PSS)*			
Aeshnidae					
27.		*Hemianax papuensis*			
Agamidae					
28.	30833	*Amphibolurus longirostris (Long-nosed Dragon)*			
29.	25458	*Ctenophorus caudicinctus (Ring-tailed Dragon)*			
30.	24865	*Ctenophorus caudicinctus subsp. caudicinctus (Ring-tailed Dragon)*			
31.	24872	*Ctenophorus femoralis (Dune Dragon)*			
32.	25459	*Ctenophorus isolepis (Crested Dragon, Military Dragon)*			
33.	24874	*Ctenophorus isolepis subsp. citrinus (Crested Dragon, Military Dragon)*			
34.	24876	*Ctenophorus isolepis subsp. isolepis (Crested Dragon, Military Dragon)*			
35.	24882	*Ctenophorus nuchalis (Central Netted Dragon)*			
36.	24886	*Ctenophorus reticulatus (Western Netted Dragon)*			
37.	25510	*Pogona minor (Dwarf Bearded Dragon)*			
38.	24907	*Pogona minor subsp. minor (Dwarf Bearded Dragon)*			
Aizoaceae					
39.	44241	*Trianthema glossostigmum*			
40.	44305	*Trianthema pilosum*			
41.	44362	*Trianthema triquetrum*			
Alaudidae					
42.	25545	*Mirafra javanica (Horsfield's Bushlark, Singing Bushlark)*			
Amaranthaceae					
43.	2647	*Alternanthera angustifolia*			
44.	2648	*Alternanthera denticulata (Lesser Joyweed)*			
45.	2651	*Alternanthera nana (Hairy Joyweed)*			
46.	2653	*Alternanthera pungens (Khaki Weed)*	Y		
47.	31076	*Amaranthus cochleitepalus*			
48.	2660	*Amaranthus cuspidifolius*			
49.	2663	*Amaranthus interruptus (Native Amaranth)*			
50.	2666	*Amaranthus mitchellii (Boggabri Weed)*			

	Name ID	Species Name	Naturalised	Conservation Code	[1]Endemic To Query Area
51.	20018	*Amaranthus undulatus*			
52.	18361	*Gomphrena affinis subsp. pilbarensis*			
53.	2680	*Gomphrena cunninghamii*			
54.	2690	*Ptilotus aervoides*			
55.	2694	*Ptilotus appendiculatus*			
56.	2696	*Ptilotus astrolasius*			
57.	2698	*Ptilotus auriculifolius*			
58.	2699	*Ptilotus axillaris (Mat Mulla Mulla)*			
59.	2704	*Ptilotus calostachyus (Weeping Mulla Mulla)*			
60.	2711	*Ptilotus clementii (Tassel Top)*			
61.	2725	*Ptilotus fusiformis*			
62.	2728	*Ptilotus gomphrenoides*			
63.	2734	*Ptilotus incanus*			
64.	2738	*Ptilotus latifolius (Tangled Mulla Mulla)*			
65.	41001	*Ptilotus nobilis subsp. nobilis (Yellow Tails)*			
66.	2747	*Ptilotus obovatus (Cotton Bush)*			
67.	11396	*Ptilotus obovatus var. obovatus*			
68.	2766	*Ptilotus villosiflorus*			
Ameiridae					
69.		*Inermipes sp. 2 (PSS)*			Y
70.		*Stygonitocrella sp.*			
71.		*Stygonitocrella trispinosa*			
72.		*Stygonitocrella unispinosa*			
Ameroseiidae					
73.		*Amerosius pulmosus*			Y
Amphipoda					
74.		*Amphipoda sp.*			
Amphisopodidae					
75.		*Pilbarophreatoicus platyarthricus*			
Anatidae					
76.	24312	*Anas gracilis (Grey Teal)*			
77.	24316	*Anas superciliosa (Pacific Black Duck)*			
78.	24318	*Aythya australis (Hardhead)*			
79.	24321	*Chenonetta jubata (Australian Wood Duck, Wood Duck)*			
80.	24322	*Cygnus atratus (Black Swan)*			
81.	24325	*Dendrocygna eytoni (Plumed Whistling Duck)*			
Ancylidae					
82.		*Ferrissia sp.*			
Anhingidae					
83.	25553	*Anhinga melanogaster (Darter)*			
84.	24332	*Anhinga melanogaster subsp. novaehollandiae (Darter)*			
Apiaceae					
85.	6218	*Daucus glochidiatus (Australian Carrot)*			
Araliaceae					
86.	6202	*Astrotricha hamptonii (Ironplant)*			
87.	6278	*Trachymene oleracea*			
88.	19043	*Trachymene oleracea subsp. oleracea*			
Araneidae					
89.		*Backobourkia collina*			
Arcellidae					
90.		*Arcella gibbosa (ex P2)*			
91.		*Arcella sp.*			
92.		*Arcella sp. P1*			
Ardeidae					
93.	25557	*Ardea garzetta (Little Egret)*			
94.	25559	*Ardea intermedia (Intermediate Egret)*			
95.	41324	*Ardea modesta (Eastern Great Egret)*		IA	
96.	24340	*Ardea novaehollandiae (White-faced Heron)*			
97.	24341	*Ardea pacifica (White-necked Heron)*			
98.	25564	*Nycticorax caledonicus (Rufous Night Heron)*			
Arecaceae					
99.	1042	*Phoenix dactylifera (Date Palm)*	Y		
Arrenuridae					

	Name ID	Species Name	Naturalised	Conservation Code	[1]Endemic To Query Area
100.		*Arrenurus ensifer*			
101.		*Arrenurus harveyi*			
102.		*Arrenurus liliaceus*			
103.		*Arrenurus purpureus*			
104.		*Arrenurus rouxi*			
105.		*Arrenurus sp.*			
106.		*Arrenurus sp. 9 (nr pseudaffinis) (PSW)*			
107.		*Arrenurus sp. nov. 2 (PSS)*			
108.		*Arrenurus tripartitus*			
109.		*Arrenurus vanderpalae*			
Artamidae					
110.	25566	*Artamus cinereus (Black-faced Woodswallow)*			
111.	24352	*Artamus cinereus subsp. melanops (Black-faced Woodswallow)*			
112.	25567	*Artamus leucorynchus (White-breasted Woodswallow)*			
113.	24355	*Artamus minor (Little Woodswallow)*			
114.	24356	*Artamus personatus (Masked Woodswallow)*			
Ascidae					
115.		*Protogamasellus dispar*			Y
116.		*Protogamasellus massula*			Y
117.		*Protogamasellus mica*			
Asphodelaceae					
118.	1364	*Asphodelus fistulosus (Onion Weed)*	Y		
Asteraceae					
119.	7822	*Angianthus acrohyalinus (Hook-leaf Angianthus)*			
120.	7866	*Blumea tenella*			
121.	14090	*Calocephalus beardii*			
122.	7893	*Calocephalus knappii*			
123.	7906	*Calotis plumulifera*			
124.	19762	*Centipeda minima subsp. macrocephala*			
125.	35558	*Flaveria trinervia (Speedy Weed)*	Y		
126.	29594	*Helichrysum luteoalbum (Jersey Cudweed)*			
127.	12635	*Olearia fluvialis*			
128.	13494	*Pentalepis trichodesmoides*			
129.	42160	*Pentalepis trichodesmoides subsp. trichodesmoides*			
130.	17817	*Pluchea dunlopii*			
131.	17816	*Pluchea ferdinandi-muelleri*			
132.	43944	*Pluchea longiseta*			
133.	8168	*Pluchea rubelliflora*			
134.	8192	*Pterocaulon sphacelatum (Apple Bush)*			
135.	8193	*Pterocaulon sphaeranthoides*			
136.	13310	*Rhodanthe margarethae*			
137.	8240	*Streptoglossa odora*			
Atrochidae					
138.		*Cupelopagis? n. sp.*			
Aturidae					
139.		*Austraturus sp. P2 (PSW)*			
140.		*Axonopsella nr truza (PSW)*			
141.		*Axonopsella sp.*			
142.		*Axonopsella sp. P2 (PSW)*			
Atyidae					
143.		*Caridina indistincta*			
Baetidae					
144.		*Baetid genus 1 WA sp. 1 (KIM_UWA)*			
145.		*Baetidae sp.*			
146.		*Cloeon sp.*			
Bathynellidae					
147.		*Bathynellidae sp.*			
Bdelloidea					
148.		*Bdelloidea sp.*			
149.		*Bdelloidea sp. 2:2*			
Belostomatidae					
150.		*Diplonychus eques*			
151.		*Lethocerus distinctifemur*			
Bogidiellidae					

	Name ID	Species Name	Naturalised	Conservation Code	[1]Endemic To Query Area
152.		*Bogidiellidae sp.*			
153.		*Bogidiellidae sp. 1 (PSS)*			
Boidae					
154.	25318	*Antaresia perthensis (Pygmy Python)*			
155.	25241	*Antaresia stimsoni subsp. stimsoni (Stimson's Python)*			
156.	25320	*Aspidites melanocephalus (Black-headed Python)*			
157.	25236	*Aspidites ramsayi (Woma)*		S	
158.	25238	*Liasis olivaceus subsp. barroni (Pilbara Olive Python)*		T	
Boraginaceae					
159.	6706	*Heliotropium cunninghamii*			
160.	6712	*Heliotropium heteranthum*			
161.	6713	*Heliotropium ovalifolium*			
162.	17031	*Heliotropium transforme*			
163.	11750	*Trichodesma zeylanicum var. zeylanicum*			
Bovidae					
164.	24251	*Bos taurus (European Cattle)*	Y		
Brachionidae					
165.		*Brachionus cf. nilsoni (CB)*			
166.		*Brachionus dichotomus*			
167.		*Brachionus sericus*			
168.		*Keratella procurva*			
169.		*Plationus patulus*			
170.		*Platyias quadricornis*			
Brassicaceae					
171.	3037	*Lepidium phlebopetalum (Veined Peppercress)*			
Bufonidae					
172.	42306	*Platyplectrum spenceri (Centralian Burrowing Frog)*			
Burhinidae					
173.	24359	*Burhinus grallarius (Bush Stone-curlew)*			
Caenidae					
174.		*Tasmanocoenis arcuata*			
175.		*Tasmanocoenis sp. E (PSW)*			
176.		*Tasmanocoenis sp. M (PSW)*			
177.		*Tasmanocoenis sp. P (PSW)*			
178.		*Wundacaenis dostini*			
Camelidae					
179.	24254	*Camelus dromedarius (Dromedary, Camel)*	Y		
Campanulaceae					
180.	37480	*Lobelia arnhemiaca*			
181.	36880	*Lobelia heterophylla subsp. pilbarensis*			
Campephagidae					
182.	25568	*Coracina novaehollandiae (Black-faced Cuckoo-shrike)*			
183.	24363	*Coracina novaehollandiae subsp. subpallida (Black-faced Cuckoo-shrike)*			
184.	24367	*Lalage tricolor (White-winged Triller)*			
Candonidae

Department of the Environment

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 21/09/15 10:16:32

Summary
Details
- Matters of NES
- Other Matters Protected by the EPBC Act
- Extra Information

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	None
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	7
Listed Migratory Species:	10

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	12
Whales and Other Cetaceans:	None
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Commonwealth Reserves Marine:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	10
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Listed Threatened Species		[Resource Information]
Name	Status	Type of Presence
Birds		
Pezoporus occidentalis Night Parrot [59350]	Endangered	Species or species habitat may occur within area
Rostratula australis Australian Painted Snipe [77037]	Endangered	Species or species habitat may occur within area
Mammals		
Dasyurus hallucatus Northern Quoll [331]	Endangered	Species or species habitat known to occur within area
Macrotis lagotis Greater Bilby [282]	Vulnerable	Species or species habitat likely to occur within area
Notoryctes caurinus Kakarratul, Northern Marsupial Mole [295]	Endangered	Species or species habitat may occur within area
Rhinonicteris aurantia (Pilbara form) Pilbara Leaf-nosed Bat [82790]	Vulnerable	Roosting known to occur within area
Reptiles		
Liasis olivaceus barroni Olive Python (Pilbara subspecies) [66699]	Vulnerable	Species or species habitat known to occur within area

Listed Migratory Species		[Resource Information]
* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.		
Name	Threatened	Type of Presence
Migratory Marine Birds		
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Hirundo rustica Barn Swallow [662]		Species or species habitat may occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Motacilla cinerea Grey Wagtail [642]		Species or species

Name	Threatened	Type of Presence
		habitat may occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Migratory Wetlands Species		
Ardea alba Great Egret, White Egret [59541]		Species or species habitat known to occur within area
Ardea ibis Cattle Egret [59542]		Species or species habitat may occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
Glareola maldivarum Oriental Pratincole [840]		Species or species habitat may occur within area
Pandion haliaetus Osprey [952]		Species or species habitat known to occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Ardea alba Great Egret, White Egret [59541]		Species or species habitat known to occur within area
Ardea ibis Cattle Egret [59542]		Species or species habitat may occur within area
Charadrius veredus Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
Glareola maldivarum Oriental Pratincole [840]		Species or species habitat may occur within area
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Species or species habitat likely to occur within area
Hirundo rustica Barn Swallow [662]		Species or species habitat may occur within area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area
Motacilla cinerea Grey Wagtail [642]		Species or species

Name	Threatened	Type of Presence
		habitat may occur within area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area
Pandion haliaetus Osprey [952]		Species or species habitat known to occur within area
Rostratula benghalensis (sensu lato) Painted Snipe [889]	Endangered*	Species or species habitat may occur within area

Extra Information

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Columba livia Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Mammals		
Capra hircus Goat [2]		Species or species habitat likely to occur within area
Equus asinus Donkey, Ass [4]		Species or species habitat likely to occur within area
Felis catus Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Mus musculus House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Vulpes vulpes Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Cenchrus ciliaris Buffel-grass, Black Buffel-grass [20213]		Species or species habitat likely to occur within area

Name	Status	Type of Presence
Parkinsonia aculeata Parkinsonia, Jerusalem Thorn, Jelly Bean Tree, Horse Bean [12301]		Species or species habitat likely to occur within area
Prosopis spp. Mesquite, Algaroba [68407]		Species or species habitat likely to occur within area

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

For species where the distributions are well known, maps are digitised from sources such as recovery plans and detailed habitat studies. Where appropriate, core breeding, foraging and roosting areas are indicated under 'type of presence'. For species whose distributions are less well known, point locations are collated from government wildlife authorities, museums, and non-government organisations; bioclimatic distribution models are generated and these validated by experts. In some cases, the distribution maps are based solely on expert knowledge.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Conservation Codes
T - Rare or likely to become extinct
X - Presumed extinct
IA - Protected under international agreement
S - Other specially protected fauna
1 - Priority 1
2 - Priority 2
3 - Priority 3
4 - Priority 4
5 - Priority 5

[1] For NatureMap's purposes, species flagged as endemic are those whose records are wholely contained within the search area. Note that only those records complying with the search criterion are included in the calculation. For example, if you limit records to those from a specific datasource, only records from that datasource are used to determine if a species is restricted to the query area.

Table F.1: Vegetation Classification System (Specht 1970) as modified by Aplin (1979).

Stratum	70-100% cover	30-70% cover	10-30% cover	2-10% cover	<2% cover
Trees > 30 m	Tall closed forest	Tall open Forest	Tall woodland	Tall open woodland	Scattered tall trees
Trees 10-30 m	Closed forest	Open forest	Woodland	Open woodland	Scattered trees
Trees < 10 m	Low closed forest	Low open forest	Low woodland	Low open woodland	Scattered low trees
Shrubs > 2 m	Tall closed scrub	Tall open scrub	Tall shrubland	Tall open shrubland	Scattered tall shrubs
Shrubs 1-2 m	Closed heath	Open heath	Shrubland	Open shrubland	Scattered shrubs
Shrubs < 1 m	Low closed heath	Low open heath	Low shrubland	Low open shrubland	Scattered low shrubs
Hummock grasses	Closed hummock grassland	Hummock grassland	Open hummock grassland	Very open hummock grassland	Scattered hummock grasses
Grasses, sedges, herbs	Closed tussock grassland/ sedgeland/ herbland	Tussock grassland/ sedgeland/ herbland	Open tussock grassland/ sedgeland/ herbland	Very open tussock grassland/ sedgeland/ herbland	Scattered tussock grasses/ sedges/ herbs

Table F.2: Summary of vegetation condition scale, as adapted from Trudgen (1988).

Vegetation condition	Condition description
Excellent	Pristine or nearly so, no obvious signs of damage caused by human activities since European settlement.
Very Good	Some relatively slight signs of damage caused by human activities since European settlement. For example, some signs of damage to tree trunks caused by repeated fire, the presence of some relatively non-aggressive weeds, or occasional vehicle tracks.
Good	More obvious signs of damage caused by human activity since European settlement, including some obvious impact on the vegetation structure such as that caused by low levels of grazing or slightly aggressive weeds.
Poor	Still retains basic vegetation structure or ability to regenerate to it after very obvious impacts of human activities since European settlement, such as grazing, partial clearing, frequent fires or aggressive weeds.
Very Poor	Severely impacted by grazing, very frequent fires, clearing or a combination of these activities. Scope for some regeneration but not to a state approaching good condition without intensive management. Usually with a number of weed species present including very aggressive species.
Completely Degraded	Areas that are completely or almost completely without native species in the structure of their vegetation; i.e. areas that are cleared or 'parkland cleared' with their flora comprising weed or crop species with isolated native trees or shrubs.

Table F.3: Fauna habitat condition scale (Thompson and Thompson 2010).

Habitat condition	Condition description
High Quality Fauna Habitat (1.0)	These areas closely approximate the vegetation mix and quality that would have been in the area prior to any human induced disturbance. The habitat has connectivity with other habitats and is likely to support the most natural vertebrate fauna assemblage.
Very Good Fauna Habitat (0.8)	These areas show minimal signs of human induced disturbance (e.g. grazing, clearing, fragmentation, weeds) and retain almost all of the characteristics of the habitat had it not been disturbed. The habitat has connectivity with other habitats, and fauna assemblages in these areas are likely to be minimally affected by disturbance.
Good Fauna Habitat (0.6)	These areas show signs of human induced disturbance (e.g. grazing, clearing, fragmentation, weeds) but generally retain many of the characteristics of the habitat had it not been disturbed. The habitat still retains some connectivity with other habitats but fauna assemblages in these areas are likely to be affected by disturbance. Fauna assemblages in these areas are likely to be similar to what might be expected in this habitat.
Disturbed Fauna Habitat (0.4)	These areas show signs of human induced significant disturbance (e.g. mining, clearing, tracks and roads). Many of the trees, shrubs and undergrowth have died or have been cleared. These areas may be in the early succession and regeneration stages. Areas may show signs of significant grazing, contain an abundance of weeds or have been damaged by vehicles or machinery. Habitats are fragmented or have limited connectivity with other fauna habitats. Fauna assemblages in these areas are likely to differ significantly from what might be expected in the area had the disturbance not occurred.
Highly Degraded Fauna Habitat (<0.2)	These areas often have a significant human induced loss of vegetation, and / or a large number of vehicle tracks and / or have been completely cleared, and / or areas have been heavily grazed or farmed. There is limited or no fauna habitat connectivity. Fauna assemblages in these areas are likely to differ significantly from what existed prior to the disturbance, and are often depleted compared to what existed prior to the disturbance.

Water Sources					
Pool 1	Level 1 survey (Astron 2014)	414390	7597485	Permanent pool of the Robe River, likely to support MNES bat species, migratory bird species and other conservation significant fauna species.	
Pool 2	Level 1 survey (Astron 2014)	414415	7596570	Permanent pool of the Robe River, likely to support MNES bat species, migratory bird species and other conservation significant fauna species.	
Pool 3	Phase 1 Level 2 survey (Astron 2016)	414405	7596615	Permanent pool of the Robe River with abundant Typha. Important habitat for migratory listed birds.	

Site ID	Survey	MGA Zone 50 K		Reason	Photograph
		Easting (mE)	Northing (mN)		
Pool 4	Phase 1 Level 2 survey (Astron 2016)	417192	7598072	Permanent pool of the Robe River with abundant Typha. Important habitat for migratory listed birds.	
Pool 5	Phase 1 Level 2 survey (Astron 2016)	418060	7598016	Permanent pool of the Robe River with abundant Typha. Important habitat for migratory listed birds.	
Pool 6	Riparian Community Assessment	411435	7594952	Permanent pool of the Robe River with abundant Typha. Important habitat for migratory listed birds.	

Site ID	Survey	MGA Zone 50 K		Reason	Photograph
		Easting (mE)	Northing (mN)		
Pool 7	Riparian Community Assessment	420290	7597902	Small but deep permanent pool of the Robe River.	
Pool 8	Riparian Community Assessment	414438	7596216	Permanent pool of the Robe River with abundant Typha. Important habitat for migratory listed birds.	
Pool 9	Riparian Community Assessment	412021	7595303	Small but deep permanent pool of the Robe River.	

Site ID	Survey	MGA Zone 50 K		Reason	Photograph
		Easting (mE)	Northing (mN)		
Pool 10	Middle Robe and East Deepdale Level 2 Fauna Assessment (Astron 2015)	423718	7596616	Permanent pool of the Robe River with abundant Typha. Important habitat for migratory listed birds. Northern Quoll and Pilbara Olive Python scats recorded nearby, Pilbara Leaf-nosed Bat calls recorded nearby.	
Pool 11	Middle Robe and East Deepdale Level 2 Fauna Assessment (Astron 2015)	429712	7601411	Permanent pool of the Robe River with abundant Typha. Northern Quoll recorded nearby.	
Pool 12	Riparian Community Assessment	419813	7598056	Small but deep permanent pool of the Robe River.	No photo
Pool 13	Riparian Community Assessment	420948	7597275	Small but deep permanent pool of the Robe River.	No photo

Appendix J: Threatened and Priority Flora Species Likelihood of Occurrence within the Survey Area

This page has been left blank intentionally.

Table J.1: Likelihood of occurrence of Threatened and Priority flora recorded within 20 km of the Mesa H survey area (Astron 2016b, NatureMap (Department of Parks and Wildlife 2016a), TPFL (Department of Parks and Wildlife 2015c), TP List (Department of Parks and Wildlife 2015d), WAHerb (Department of Parks and Wildlife 2015e)). The TP List database is searched using place names. As a result, many of the records obtained from this database may occur beyond 50 km of the Mesa H survey area.

Species	Habit and flowering information	Life Form	Habitat	Likelihood of occurrence	
				Pre-survey	Post-survey
Threatened					
Thyrptomene wittwerii	Spreading or rounded shrub, 0.5 m to 1.5 (-2.1) m high. White-cream flowers in April, July or August.	Perennial	Skeletal red stony soils. Breakaways, stony creek beds.	Unlikely	Unlikely
Priority 1					
Bothriochloa decipiens var. *cloncurrensis*	Herbaceous grass, to 1.4 m high.	Perennial	Seasonally damp depression. Stony clay plain.	Potential	Unlikely
Triodia sp. Pannawonica (B.M. Anderson & M.D. Barrett BMA 89)	Hummock grass.	Perennial	Shale	Unlikely	Unlikely
Priority 2					
Dicladanthera glabra	Spreading herb or shrub, to 0.6 (-1) m high.	Perennial	Alluvium. Along watercourses, near rock pools.	Potential	Unlikely
Euphorbia australis var. *glabra*	Herb	Annual	Creek banks. Red brown loam, some pebbles.	Potential	Potential
Pentalepis trichodesmoides subsp. *hispida*	Multi-stemmed shrub to 0.8 m high. Flowers July to October.	Perennial	Summits of ridges, cobbled slopes, outcrops, banks of creeks and edges of basalt screes.	Unlikely	Unlikely
Stylidium weeliwolli	Herb, 0.1 m to 0.25 m high, throat appendages 4, rod-shaped. Pink and red flowers from August to September.	Annual	Gritty sand soil, sandy clay. Edge of watercourses.	Likely	Potential

Species	Habit and flowering information	Life Form	Habitat	Likelihood of occurrence	
				Pre-survey	Post-survey
Priority 3					
Eragrostis surreyana	Grass. Culms erect or decumbent, 5-8 (-13) cm tall. Panicle linear, 9 cm to 13 cm long; 0.5 cm to 1.3 cm wide.	Annual	Soak area. Red-brown sandy clay.	Potential	Potential
Indigofera sp. Bungaroo Creek (S. van Leeuwen 4301)	Shrub or herb 0.2 m to 2 m high. May to July.	Perennial	Drainage lines, creeks in hills or plains. Brown silty loam.	Potential	Potential
Pleurocarpaea gracilis	Rounded shrub to 0.5 m. June to October.	Perennial	Summit of rounded hill, slopes, skeletal red gritty soil over massive Brockman Iron Formation rock.	Unlikely	Unlikely
Solanum albostellatum	Low herb or shrub to 0.2 m high. March.	Perennial	Floodplains, slight bedrock outcrops. Red brown silty clay loam. Cracking clay.	Unlikely	Unlikely
Terminalia supranitifolia	Spreading tangled tree or shrub to 3 m high.	Perennial	Sandy soils or among basalt rocks.	Unlikely	Unlikely
Triodia sp. Robe River (M.E. Trudgen et al. MET 12367)	Hummock grass. June, July, September.	Perennial	Mesa tops and edges; breakaways; hillsides and hilltops.	Unlikely	Recorded
Priority 4					
Goodenia nuda	Erect to ascending herb to 0.5 m high. Yellow flowers, April to August.	Short-lived perennial	Alluvial soils over ironstone, floodplains, valleys, watercourses, orange-brown alluvial sand over ironstone.	Potential	Unlikely
Rhynchosia bungarensis	Compact, prostrate shrub, to 0.5 m high. May to November.	Short-lived perennial	Pebbly, shingly coarse sand amongst boulders. Banks of flow line in the mouth of a gully in a valley wall.	Likely	Recorded

Appendix K: Fauna Species Lists

This page has been left blank intentionally.

Table K.1: Amphibian species list – results of database searches, literature reviews and Astron survey results.

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
HYLIDAE										
Cyclorana maini	Sheep Frog					x			x	
Litoria rubella	Little Red Tree Frog					x			x	
MYOBATRACHIDAE										
Pseudophryne douglasi	Gorge Toadlet								x	
Uperoleia russelli	Northwest Toadlet					x			x	
Uperoleia saxatilis	Pilbara Toadlet					x			x	
BUFONIDAE										
Platyplectrum spenceri	Centralian Burrowing Frog					x				

Table K.2: Reptile species list – results of database searches, literature reviews and Astron survey results.

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
AGAMIDAE										
Amphibolurus longirostris	Long-Nosed Dragon					x			x	x
Ctenophorus caudicinctus	Ring-tailed Rock Dragon					x			x	
Ctenophorus femoralis	Dune Dragon					x				
Ctenophorus isolepis isolepis	Military Sand Dragon					x			x	
Ctenophorus nuchalis	Central Netted Dragon					x			x	
Ctenophorus reticulatus	Western Netted Dragon					x				
Pogona minor minor	Bearded Dragon					x			x	
DIPLODACTYLIDAE										
Crenadactylus ocellatus	Clawless Gecko					x			x	
Diplodactylus bilybara	Western Fat-tailed Gecko					x			x	
Diplodactylus galaxias						x			x	
Diplodactylus mitchelli						x				
Diplodactylus savagei						x			x	
Lucasium stenodactylum	Pale-snouted Ground Gecko					x			x	
Lucasium wombeyi						x			x	
Oedura marmorata	Marbled Velvet Gecko					x			x	
Rhynchoedura ornata	Beaked Gecko					x			x	
Strophurus ciliaris						x				
Strophurus elderi	Jewelled Gecko					x			x	
Strophurus wellingtonae						x				
CARPHODACTYLIDAE										
Nephrurus levis pilbarensis									x	
Nephrurus wheeleri cinctus	Banded Knob-tailed Gecko					x			x	
Nephrurus wheeleri wheeleri	Banded Knob-tailed Gecko					x			x	
GEKKONIDAE										
Gehyra pilbara						x			x	
Gehyra punctata	Spotted Rock Dtella					x			x	

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Gehyra variegata	Variegated Tree Dtella					x			x	
Hemidactylus frenatus	Asian House Gecko	*				x			x	
Heteronotia binoei	Bynoe's Gecko					x			x	x
Heteronotia spelea	Pilbara Cave Gecko					x			x	
PYGOPODIDAE										
Delma butleri									x	
Delma elegans						x			x	
Delma nasuta						x			x	
Delma pax						x			x	
Delma tincta						x			x	
Lialis burtonis	Burrton's Legless Lizard					x			x	
Pygopus nigiceps						x			x	
EUGONGYLIDAE										
Carlia munda						x			x	
Carlia triacantha						x				
Cryptoblepharus plagiocephalus									x	
Cryptoblepharus buchananii						x				
Cryptoblepharus ustulatus						x			x	
Menetia greyii						x			x	
Menetia surda surda						x			x	
Morethia ruficauda exquisita	Fire-tailed Skink					x			x	
AGAMIDAE										
Ctenotus brooksi						x				
Ctenotus calurus						x				
Ctenotus duricola						x			x	
Ctenotus grandis titan						x			x	
Ctenotus hanloni						x			x	
Ctenotus helenae						x			x	
Ctenotus pantherinus	Leopard Ctenotus					x			x	
Ctenotus rubicundus						x			x	

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Ctenotus quattuordecimlineatus						x				
Ctenotus saxatilis	Rock Ctenotus					x			x	
Ctenotus schomburgkii						x			x	
Ctenotus serventyi						x			x	
Eremiascincus isolepis						x			x	
Eremiascincus faciolatus									x	
Lerista bipes						x			x	
Lerista flammicauda						x			x	
Lerista ips						x				
Lerista muelleri						x			x	
Lerista verhmens						x				
Notoscincus butleri	Lined Soil-crevice Skink				P4	x			x	
Notoscincus ornatus						x			x	
EGERNIIDAE										
Cyclodomorphus melanops	Slender Blue-tongue					x			x	
Egernia cygnitos						x				
Ergenia depressa						x				
Ergenia formosa						x			x	
Ergenia pilbarensis	Pilbara Skink					x			x	
Tiliqua multifasciata	Central Blue-tongue					x			x	
VARANIDAE										
Varanus acanthurus	Spiny-tailed Monitor					x			x	
Varanus brevicauda	Short-tailed Pygmy Monitor					x			x	
Varanus bushi	Pilbara Mulga Monitor					x			x	
Varanus caudolineatus						x				
Varanus eremius	Pygmy Desert Monitor					x			x	
Varanus giganteus	Perentie					x			x	
Varanus gouldii	Bungarra					x			x	
Varanus hamersleyensis	Southern Pilbara Rock Monitor					x			x	

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Varanus panoptes panoptes						x			x	
Varanus pilbarensis									x	
Varanus tristis tristis	Racehorse Monitor					x			x	
TYPHLOPIDAE										
Anilios ammodytes						x			x	
Anilios ganei					P1	x			x	
Anilios grypus	Beaked Blind snake					x			x	
Anilios hamatus									x	
Anilios pilbarensis						x			x	
BOIDAE										
Antaresia perthensis	Pygmy Python					x			x	
Antaresia stimsoni stimsoni	Stimson's Python					x			x	
Aspidites melanocephalus	Black-headed python					x			x	
Liasis olivaceus barroni	Pilbara Olive Python		VU	S3		x	x		x	
ELAPIDAE										
Acanthopis wellsi	Pilbara Death Adder					x			x	
Brachyurophis approximans						x			x	
Demansia psammophis cupreiceps	Yellow-faced Whipsnake					x			x	
Demansia rufescens	Rufous Whipsnake					x			x	
Furina ornata	Moon Snake					x			x	
Parasuta monachus						x			x	
Pseudechis australis	Mulga Snake					x			x	
Pseudonaja mengdeni	Western Brown Snake					x			x	
Pseudonaja modesta	Ringed Brown Snake					x			x	
Pseudonaja nuchalis	Gwardar; Northern Brown Snake					x				
Simoselaps anomalus	Desert Banded Snake					x				
Suta fasciata	Rosen's Snake					x			x	
Suta punctata	Spotted Snake					x				

Table K.3: Bird species list – results of database searches, literature reviews and Astron survey results.

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
DROMAIIDAE										
Dromaius novaehollandiae	Emu					x		x	x	
PHASIANIDAE										
Coturnix ypsilophora	Brown Quail					x			x	
ANATIDAE										
Anas gracilis	Grey Teal					x		x	x	
Anas superciliosa	Pacific Black Duck					x		x	x	x
Aytha australis	Hardhead					x		x		x
Cygnus atratus	Black Swan					x		x	x	
Chenonetta jubata	Australian Wood Duck					x			x	
Dendrocygna eytoni	Plumed Whistling Duck					x				
Dendrocygna arcuata	Wandering Whistling Duck								x	
Nettapus pulchellus	Green Pygmy Goose								x	
PODICIPEDIDAE										
Tachybaptus novaehollandiae	Australasian Grebe					x		x	x	x
Poliocephalus poliocephalus	Hoary-headed Grebe					x		x	x	
COLUMBIDAE										
Columba livia	Domestic Pigeon	*				x	x			
Geopelia cuneata	Diamond Dove					x		x	x	
Geopelia striata placida	Peaceful Dove					x		x	x	
Geophaps plumifera	Spinifex Pigeon					x		x	x	
Ocyphaps lophotes	Crested Pigeon					x		x	x	
Phaps chalcoptera	Common Bronzewing					x		x	x	x
Phaps histrionica	Flock Bronzewing					x				
PODARGIDAE										
Podargus strigoides	Tawny Frogmouth					x		x	x	
CAPRIMULGIDAE										
Eurostopodus argus	Spotted Nightjar					x			x	x

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
AEGOTHELIDAE										
Aegotheles cristatus	Australian Owlet-nightjar					x			x	
APOPDIDAE										
Apus pacificus	Fork-tailed Swift		Mi	S5			x		x	
ANHINGIDAE										
Anhinga novaehollandiae	Darter					x		x	x	
PHALACROCORACIDAE										
Phalacrocorax melanoleucos	Little Pied Cormorant							x	x	
Phalacrocorax varius	Pied Cormorant							x	x	x
Phalacrocorax sulcirostris	Little Black Cormorant								x	
PELECANIDAE										
Pelecanus conspicillatus	Australian Pelican					x		x	x	x
CICONIIDAE										
Ephippiorhynchus asiaticus	Black-necked stork								x	
ARDEIDAE										
Ardea ibis	Cattle Egret		Mi	S5			x		x	
Ardea intermedia	Intermediate Egret					x	x		x	
Ardea modesta	Eastern Great Egret		Mi	S5		x	x	x	x	
Ardea garzetta	Little Egret					x			x	
Ardea novaehollandiae	White-faced Heron					x		x	x	x
Ardea pacifica	White-necked Heron					x		x	x	x
Butorides striata	Striated Heron							x		
Nycticorax caledonicus	Nankeen Night-heron					x		x	x	
THRESKIORNITHIDAE										
Platalea flavipes	Yellow-billed Spoonbill								x	
Threskiornis spinicollis	Straw-necked Ibis					x		x	x	
ACCIPITRIDAE										
Accipiter cirrocephalus	Collared Sparrowhawk					x			x	
Accipiter fasciatus fasciatus	Brown Goshawk					x		x	x	
Aquila audax	Wedge-tailed Eagle					x		x	x	

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Circus approximans	Swamp Harrier					x				
Circus assimilis	Spotted Harrier					x		x	x	
Elanus scriptus	Letter-winged Kite				P4	x				
Elanus caeruleus	Black-shouldered Kite					x			x	
Lophoictinia isura	Square-tailed Kite					x		x		
Haliaeetus leucogaster	White-bellied Sea Eagle						x	x	x	
Haliastur sphenurus	Whistling Kite					x		x	x	x
Haliastur indus	Brahminy Kite							x		
Hieraaetus morphnoides	Little Eagle					x		x	x	
Milvus migrans	Black Kite					x		x	x	
Panidon haliaetus	Eastern Osprey		Mi	S5			x			
FALCONIDAE										
Falco cenchroides cenchroides	Australian Kestrel					x		x	x	
Falco berigora berigora	Brown Falcon					x		x	x	
Falco longipennis	Australian Hobby					x		x	x	
RALLIDAE										
Gallirallus philippensis	Buff-banded Rail					x				
Fulica atra	Eurasian Coot					x		x	x	x
Porzana tabuensis	Spotless Crake					x			x	
Tribonyx ventralis	Black-tailed Native-hen								x	
OTIDIDAE										
Ardeotis australis	Australian Bustard					x		x	x	
BURHINIDAE										
Burhinus grallarius	Bush Stone-curlew					x			x	
RECURVIROSTRIDAE										
Himantopus himantopus	Black-winged Stilt					x			x	
CHARADRIIDAE										
Charadrius veredus	Oriental Plover		Mi	S5			x			
Charadrius ruficapillus	Red-capped Plover							x		
Charadrius leschenaultii	Greater Sand Plover		Mi	S5				x		

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Elseyornis melanops	Black-fronted Dotterel					x		x	x	
Erythrogonys cinctus	Red-kneed Dotterel								x	
Vanellus tricolor	Banded Lapwing					x		x		
CINCLOSOMATIDAE										
Psophodes occidentalis	Chiming Wedgebill					x				
ROSTRATULIDAE										
Rostratula benghalensis australis	Australian Painted Snipe		EN	S2			x			
SCOLOPACIDAE										
Actitis hypoleucos	Common Sandpiper					x		x		
Calidris acuminata	Sharp-tailed Sandpiper			S5		x				
Numenius phaeopus	Whimbrel			S5				x		
Tringa glareola	Wood Sandpiper			S5		x		x	x	
Tringa nebularia	Common Greenshank			S5				x		
TURNICIDAE										
Turnix velox	Little Button-quail					x		x	x	
GLAREOLIDAE										
Glareola maldivarum	Oriental Pratincole		Mi	S5			x			
PSITTACIDAE										
Platycercus zonarius zonarius	Australian Ringneck					x		x	x	x
Melopsittacus undulatus	Budgerigar					x		x	x	
Nymphicus hollandicus	Cockatiel					x		x	x	
Pezoporus occidentalis	Night Parrot		EN	S2		x	x			
CACATUIDAE										
Cacatua sanguinea	Little Corella					x		x	x	x
Cacatua roseicapilla	Galah					x		x	x	
CUCULIDAE										
Cacomantis pallidus	Pallid Cuckoo					x		x	x	
Chrysococcyxs basalis	Horsfield's Bronze Cuckoo					x		x	x	x
Chrysococcyxs osculans	Black-eared Cuckoo								x	
Centropus phasianinus	Pheasant Coucal							x	x	

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
STRIGIDAE										
Ninox connivens	Barking Owl					x			x	
Ninox boobook boobook	Southern Boobook Owl					x		x	x	
TYTONIDAE										
Tyto javanica	Eastern Barn Owl					x				
ACLEDINIDAE										
Dacelo leachii leachii	Blue-winged Kookaburra					x		x	x	
Todiramphus pyrrhopygia	Red-backed Kingfisher					x		x	x	
Todiramphus sanctus	Sacred Kingfisher					x		x	x	
MEROPIDAE										
Merops ornatus	Rainbow Bee-eater		Mi	S5		x	x	x	x	x
PTILONORHYNCHIDAE										
Ptilonorhynchus maculatus guttatus	Western Bowerbird					x			x	
MALURIDAE										
Amytornis striatus	Striated Grasswren					x		x	x	
Malurus lamberti assimilis	Variegated Fairy-wren					x		x	x	x
Malurus leucopterus	White-winged Fairy-wren					x		x	x	
Stipiturus ruficeps	Rufous Crowned Emu-wren								x	
ACANTHIZIDAE										
Acanthiza apicalis	Inland Thornbill					x			x	
Acanthiza uropygialis	Chestnut-rumped Thornbill					x			x	
Gerygone fusca	Western Gerygone					x			x	x
Gerygone tenebrosa	Dusky Gerygone							x		
Smicrornis brevirostris	Weebill					x		x	x	x
PARDALOTIDAE										
Pardalotus punctatus	Spotted Pardalote					x				
Pardalotus rubricatus	Red-browed Pardalote					x		x	x	
Pardalotus striatus	Striated Pardalote					x			x	
MELIPHAGIDAE										

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Acanthagenys rufogularis	Spiny-cheeked Honeyeater					x		x	x	
Certhionyx variegatus	Pied Honeyeater					x			x	
Epthianura tricolor	Crimson Chat					x			x	
Ptilotula keartlandi	Grey-headed Honeyeater							x	x	
Ptilotula penicillatus	White-plumed Honeyeater							x	x	x
Gavicalis virescens	Singing Honeyeater							x	x	
Lichmera indistincta	Brown Honeyeater					x		x	x	x
Manorina flavigula	Yellow-throated Miner					x		x	x	
Melithreptus gularis	Black-chinned Honeyeater					x			x	
Sugomel niger	Black Honeyeater					x			x	
POMATOSTOMIDAE										
Pomatostomus supercilious	White-browed Babbler					x				
Pomatostomus temporalis	Grey-crowned Babbler					x		x	x	x
CAMPEPHAGIDAE										
Coracina maxima	Ground Cuckoo-shrike					x				
Coracina novaehollandiae	Black-faced Cuckoo-shrike					x		x	x	
Lalage tricolor	White-winged Triller					x		x	x	
PACHYCEPHALIDAE										
Colluricincla harmonica	Grey Shrike-thrush					x		x	x	x
Oreoica gutturalis	Crested Bellbird					x		x	x	
Pachycephala melanura	Mangrove Golden Whistler							x		
Pachycephala lanioides	White-breasted Whistler							x		
Pachycephala rufiventris	Rufous Whistler					x		x	x	x
Cincloramphus cruralis	Brown Songlark					x		x	x	
Cincloramphus mathewsi	Rufous Songlark					x		x	x	
ARTAMIDAE										
Artamus cinereus melanops	Black-faced Woodswallow					x		x	x	
Artamus leucorynchus	White-breasted Woodswallow							x	x	
Artamus minor	Little Woodswallow					x			x	

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Artamus personatus	Masked Woodswallow					x			x	
CRACTICIDAE										
Cracticus torquatus	Grey Butcherbird								x	
Cracticus nigrogularis	Pied Butcherbird					x		x	x	
Cracticus tibicen	Australian Magpie					x		x	x	
DICRURIDAE										
Rhipidura albiscapa	Grey Fantail					x			x	x
Rhipidura phasiana	Mangrove Grey Fantail							x		
Rhipidura leucophrys leucophrys	Willie Wagtail					x		x	x	x
Grallina cyanoleuca	Magpie-lark					x		x	x	x
CORVIDAE										
Corvus bennetti	Little Crow					x		x	x	
Corvus orru	Torresian Crow					x		x	x	x
PETROICIDAE										
Melanodryas cucullata	Hooded Robin					x			x	
Petroicas goodenovii	Red-capped Robin					x			x	
ALAUDIDAE										
Mirafra javanica	Horsfield's Bushlark					x		x	x	
Mirafra cantillans	Singing Bushlark								x	
ACROCEPHALIDAE										
Acrocephalus australis	Australian Reed Warbler								x	x
LOCUSTELLIDAE										
Eremiornis carteri	Spinifex-bird					x		x	x	
TIMALIIDAE										
Zosterops luteus	Yellow White-eye							x		
HIRUNDINIDAE										
Cheramoeca leucosternus	White-backed swallow					x				
Hirundo neoxena	Welcome Swallow							x	x	
Hirundo rustica	Barn Swallow		Mi	S5			x			
Petrochelidon ariel	Fairy Martin					x		x	x	

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Petrochelidon nigricans	Tree Martin					x		x	x	
DICAEIDAE										
Dicaeum hirundinaceum	Mistletoebird					x		x	x	
ESTRILDIDAE										
Emblema pictum	Painted Finch					x		x	x	
Neochmia ruficauda subclarescens	Star Finch (Western)					x		x	x	x
Taeniopygia guttata	Zebra Finch					x		x	x	
MOTACILLIDAE										
Anthus australis	Australian Pipit					x		x	x

Table L.1: Likelihood of occurrence of conservation listed vertebrate fauna species listed as potentially occurring in the vicinity of the survey area.

Scientific name (common name)	Conservation codes			Preferred habitat	Likelihood of occurrence	
	EPBC Act	WC Act	Parks and Wildlife		Pre-survey	Post-survey
Reptiles						
Notoscincus butleri (Lined Soil-crevice Skink)			P4	Arid, rocky, near coastal Pilbara regions. Associated with spinifex-dominated areas near creeks and river margins.	Low	Low
Anilios ganei (Blindsnake)			P1	Little information is available on this species but it is believed to be associated with moist gorges and gullies.	Low	Low
Liasis olivaceus barroni (Pilbara Olive Python)	VU	S3		Generally rocky habitats in close association to permanent and semi-permanent water sources.	High – previously recorded	High
Birds						
Apus pacificus (Fork-tailed Swift)	Mi	S5		Largely aerial species independent of the terrestrial environment.	Moderate	Moderate
Ardea ibis (Cattle Egret)	Mi	S5		Largely wetland species however can exploit drier open habitats more than other heron species.	Moderate	Moderate
Ardea modesta (Eastern Great Egret)	Mi	S5		Wide range of wetland habitats (for example inland and coastal, freshwater and saline, permanent and ephemeral).	High – previously recorded	High
Elanus scriptus (Letter-winged Kite)			P4	The Letter-winged Kite is a bird of open country and grasslands in arid and semi-arid Australia, where there are tree-lined streams or water courses.	Moderate	Moderate
Panidon haliaetus (Eastern Osprey)	Mi	S5		Favours coastal areas, especially the mouths of large rivers, lagoons and lakes.	Low	Low

Scientific name (common name)	Conservation codes			Preferred habitat	Likelihood of occurrence	
	EPBC Act	WC Act	Parks and Wildlife		Pre-survey	Post-survey
Charadrius veredus (Oriental Plover)	Mi	S5		Breeding habitat includes arid grasslands, saltpans; non-breeding habitat includes grasslands, salt-fields, and coastal regions.	Low	Low
Charadrius leschenaultii (Greater Sand Plover)	Mi	S5		This species is almost entirely coastal, inhabiting littoral and estuarine habitats. They mainly occur on sheltered sandy, shelly or muddy beaches with large intertidal mudflats or sandbanks, as well as sandy estuarine lagoons.	Low	Low
Rostratula benghalensis (sensu lato) (Australian Painted Snipe)	EN	S2		Shallow terrestrial freshwater wetlands, temporary/permanent lakes, swamps and claypans with emergent grass, sedges, rushes and samphire.	Moderate	Moderate
Actitis hypoleucos (Common Sandpiper)	Mi	S5		Non-breeding migrant to a wide variety of habitats, such as riverbanks, estuaries, freshwater seeps on coastal shores, tidal creeks, mangrove swamps and saltmarshes.	Moderate	Moderate
Calidris acuminata (Sharp-tailed Sandpiper)	Mi	S5		Muddy edges of shallow fresh/brackish wetlands with emergent sedges, saltmarsh, grass and low vegetation.	Moderate	Moderate
Numenius phaeopus (Whimbrel)	Mi	S5		Primarily found in coastal habitats such as beaches, dunes, mudflats and mangroves however there are also scattered inland records.	Low	Low
Tringa glareola (Wood Sandpiper)	Mi	S5		Occurs mainly on freshwater wetlands of the inland interior and arid regions.	Moderate	Moderate
Tringa nebularia (Common Greenshank)	Mi	S5		Inland wetlands and coastal habitats of varying salinity. Typically large mudflats, saltmarsh, mangroves and seagrass	Moderate	Moderate
Glareola maldivarum (Oriental Pratincole)	Mi	S5		Feeds in the air and roosts on bare ground besides water	Moderate	Moderate

Scientific name (common name)	Conservation codes			Preferred habitat	Likelihood of occurrence	
	EPBC Act	WC Act	Parks and Wildlife		Pre-survey	Post-survey
Merops ornatus (Rainbow Bee-eater)	Mi	S5		Lightly wooded, preferably sandy soil, near drainage channels and creek lines.	High – previously recorded	Recorded
Hirundo rustica (Barn Swallow)	Mi	S5		Coastal open country generally, especially near surface water and man-made structures such as bridges and power wires.	Low	Low
Mammals						
Dasycercus blythi (Brush-tailed Mulgara)			P4	Triodia hummock and Acacia shrublands of sand or sandy-loam.	Low	Low
Dasyurus hallucatus (Northern Quoll)	EN	S2		Dissected rocky escarpments and rocky eucalypt woodland.	High – previously recorded	High
Sminthopis longicaudata (Long-tailed Dunnart)			P4	Common in rocky screes with hummock grassland and Acacia shrubs, tall open shrubland and woodlands.	Low	Low
Macrotis lagotis (Greater Bilby, Dalgyte)	VU	S3		Sand or sandy-loam in hummock grassland (Triodia species) and or Acacia shrublands.	Low	Low
Notoryctes caurinus (Northern Marsupial Mole)	EN			Lives primarily underground of sand dunes and sandy soils along river flats.	Low	Low
Macroderma gigas (Ghost Bat)	VU	S3		A wide range from rainforest, monsoon and vine scrub in the tropics to open woodlands and arid areas.	High – previously recorded	High
Rhinonicteris aurantia (Pilbara form) (Pilbara Leaf-nosed Bat)	VU	S3		Deep warm, humid caves or rock cracks.	High – previously recorded	High

Scientific name (common name)	Conservation codes			Preferred habitat	Likelihood of occurrence	
	EPBC Act	WC Act	Parks and Wildlife		Pre-survey	Post-survey
Leggadina lakedownensis (Short-tailed Mouse, Karekanga)			P4	Open tussock and hummock grassland, Acacia shrubland and savannah woodland on alluvial clay/sandy soils.	Low	Low
Pseudomys chapmani (Western Pebble-mound Mouse)			P4	Gentle rocky slopes, hills and spurs with small pebble surface cover and sparse vegetation.	Low	Low

Table P.1: Vascular flora species list for the survey area.

Family	Species name	Conservation status	Weed
Aizoaceae	*Trianthema triquetrum*		
Amaranthaceae	*Alternanthera nana*		
	Amaranthus cuspidifolius		
	Amaranthus undulatus		
	Aerva javanica		*
	Gomphrena cunninghamii		
	Ptilotus appendiculatus		
	Ptilotus astrolasius		
	Ptilotus auriculifolius		
	Ptilotus axillaris		
	Ptilotus calostachyus		
	Ptilotus incanus		
	Ptilotus nobilis subsp. *nobilis*		
	Ptilotus obovatus		
Araliaceae	*Trachymene oleracea* subsp. *oleracea*		
Arecaceae	*Livistona alfredii*	P4	
Asteraceae	*Bidens bipinnata*		*
	Flaveria trinervia		*
	Helichrysum luteoalbum		
	Lactuca serriola		*
	Pluchea rubelliflora		
	Pterocaulon sphaeranthoides		
	Sonchus oleraceus		*
	Streptoglossa liatroides		
Boraginaceae	*Heliotropium pachyphyllum*		
Brassicaceae	*Lepidium pholidogynum*		
Campanulaceae	*Lobelia arnhemiaca*		
	Wahlenbergia tumidifructa		
Capparaceae	*Capparis spinosa* var. *nummularia*		
Chenopodiaceae	*Dysphania* sp.		
Cleomaceae	*Cleome viscosa*		
Convolvulaceae	*Bonamia pilbarensis*		
	Evolvulus alsinoides var. *villosicalyx*		
	Ipomoea muelleri		
	Ipomoea polymorpha		
Cucurbitaceae	*Citrullus colocynthis*		*

Family	Species name	Conservation status	Weed
Cucurbitaceae	*Cucumis variabilis*		
Cyperaceae	*Cyperus vaginatus*		
	Eleocharis geniculata		
	Schoenoplectus subulatus		
Euphorbiaceae	*Adriana tomentosa*		
	Euphorbia australis		
	Euphorbia biconvexa		
	Euphorbia boophthona		
	Euphorbia hirta		*
	Euphorbia schultzii		
Fabaceae	*Acacia bivenosa*		
	Acacia colei var. *ileocarpa*		
	Acacia elachantha		
	Acacia pyrifolia var. *pyrifolia*		
	Acacia sclerosperma subsp. *sclerosperma*		
	Acacia synchronicia		
	Acacia trachycarpa		
	Acacia trachycarpa x tumida var. *pilbarensis*		
	Acacia tumida var. *pilbarensis*		
	Crotalaria novae-hollandiae		
	Indigofera boviperda		
	Indigofera monophylla		
	Petalostylis labicheoides		
	Rhynchosia bungarensis	P4	
	Rhynchosia minima		
	Senna ferraria		
	Senna notabilis		
	Sesbania formosa		
	Tephrosia rosea var. Fortescue creeks (M.I.H. Brooker 2186)		
	Tephrosia sp. B Kimberley Flora (C.A. Gardner 7300)		
	Tephrosia sp. Fortescue (A.A. Mitchell 606)		
	Vachellia farnesiana		*
	Vigna lanceolata var. *lanceolata*		
Goodeniaceae	*Goodenia lamprosperma*		
Lamiaceae	*Ocimum basilicum*		*
Loranthaceae	*Lysiana casuarinae*		
Marsileaceae	*Marsilea* sp.		
Malvaceae	*Abutilon lepidum*		
	Abutilon sp. Dioicum (A.A. Mitchell PRP 1618)		

Family	Species name	Conservation status	Weed
Malvaceae	*Corchorus crozophorifolius*		
	Corchorus lasiocarpus subsp. *parvus*		
	Gossypium australe		
	Gossypium robinsonii		
	Malvastrum americanum		*
	Melochia pyramidata		*
	Sida fibulifera		
	Sida rohlenae subsp. *rohlenae*		
	Sida sp. Articulation below (A.A. Mitchell PRP 1605)		
	Sida sp. Pilbara (A.A. Mitchell PRP 1543)		
	Triumfetta appendiculata		
	Triumfetta ?chaetocarpa		
	Triumfetta clementii		
	Triumfetta johnstonii		
	Waltheria indica		
Molluginaceae	*Mollugo molluginea*		
Moraceae	*Ficus aculeata* var. *indecora*		
Myrtaceae	*Eucalyptus camaldulensis* subsp. *refulgens*		
	Eucalyptus victrix		
	Melaleuca argentea		
	Melaleuca glomerata		
Nyctaginaceae	*Boerhavia coccinea*		
Oleaceae	*Jasminum didymum* subsp. *lineare*		
Papaveraceae	*Argemone ochroleuca* subsp. *ochroleuca*		*
Passifloraceae	*Passiflora foetida* var. *hispida*		*
Phyllanthaceae	*Flueggea virosa* subsp. *melanthesoides*		
	Notoleptopus decaisnei var. Orbicularis (A.B. Craig 428)		
	Phyllanthus maderaspatensis		
Plantaginaceae	*Stemodia grossa*		
Poaceae	*Cenchrus ciliaris*		*
	Cenchrus setiger		*
	Chloris barbata		*
	Cynodon dactylon		*
	Cymbopogon ambiguus		
	Dactyloctenium radulans		
	Echinochloa colona		*
	Enneapogon caerulescens		
	Eriachne mucronata		
	Eriachne pulchella subsp. *dominii*		

Family	Species name	Conservation status	Weed
Poaceae	*Eriachne tenuiculmis*		
	Eulalia aurea		
	Paraneurachne muelleri		
	Paspalidium clementii		
	Setaria verticillata		*
	Sporobolus australasicus		
	Themeda triandra		
	Triodia epactia		
	Triodia sp. Robe River (M.E. Trudgen et al. MET 12367)	P3	
	Triodia wiseana		
Polygonaceae	*Rumex vesicarius*		*
Proteaceae	*Grevillea wickhamii*		
	Hakea chordophylla		
Solanaceae	*Datura leichhardtii*		*
	Solanum cleistogamum		
	Solanum diversiflorum		
	Solanum horridum		
	Solanum nigrum		*
Surianaceae	*Stylobasium spathulatum*		
Typhaceae	*Typha domingensis*		
Violaceae	*Hybanthus aurantiacus*

Table Q.2: Descriptions of Priority flora recorded in the survey area.

Species	Description	Habitat
Triodia sp. Robe River (M.E. Trudgen et al. MET 12367) P3	Hummock grass (WAHerb 1998-2016).	Rocky outcrops, breakaways, hillslopes and crests, and drainage lines (WAHerb 1998-2016).
Livistona alfredii P4	Perennial tree-like monocot (palm), to 10 m high (WAHerb 1998-2016).	Occurs on edges of permanent pools (WAHerb 1998-2016).
Rhynchosia bungarensis P4	Compact, prostrate shrub to 0.5 m high. Flowers yellow (WAHerb 1998-2016).	Pebbly, shingle coarse sand amongst boulders. Banks of flow line in the mouth of a gully in a valley wall (WAHerb 1998-2016).

Table Q.4: Description of introduced flora recorded in the survey area.

Species	Description	Habitat
**Aerva javanica* (Kapok Bush) 	An erect, much-branched perennial, herb between 0.4 m and 1.6 m high. It has white woolly flowers arranged in spikes between January and October (WAHerb 1998-2016).	Often on sandy soils, along drainage lines (WAHerb 1998-2016).
**Argemone ochroleuca* subsp. *ochroleuca* (Mexican Poppy) 	An erect, prickly, glaucous annual herb between 0.2 m and 1 m in height with white, cream and yellow flowers between February/March and July/November (WAHerb 1998-2016).	Generally along creek edges, riverbanks and roadsides. Occurs in red/white/grey sand and red-brown clay loam (WAHerb 1998-2016).
**Bidens bipinnata* (Bipinnate Beggartick) 	An erect annual herb growing to 1 m high. Produces yellow flowers from March to September (WAHerb 1998-2016).	Occurs in a variety of soils including alluvium, clay, loam over sandstone and limestone. Habitat preferences include rivers, creeks, coastal areas and rocky hillsides (WAHerb 1998-2016).
**Cenchrus ciliaris* (Buffel Grass) 	A tufted or sometimes stoloniferous perennial grass between 0.2 m and 1.5 m in height with purple, ciliate flowers between February and October. Seedheads form a dense hairy cylindrical spike to 10 cm long (WAHerb 1998-2016).	**C. ciliaris* favours sand but may also establish in loamy and clayey soils. It is a widespread weed of roadsides, creek lines and river edges (WAHerb 1998-2016).

Species	Description	Habitat
**Cenchrus setiger* (Birdwood Grass) 	An erect, tussock, stoloniferous perennial grass that grows to 0.5 m high. It has cream to purple flowers that occur from April to May (WAHerb 1998-2016).	**C. setiger* favours brown sands, red loam and pindan soils. It is often found on sand dunes, plains, rangelands, stony hillsides and floodplains (WAHerb 1998-2016).
* *Chloris barbata* (Purpletop Chloris) 	Annual or perennial (short-lived), grass, between 0.4 m and 1.1 m high. It has purple flowers in February or between April and October (WAHerb 1998-2016).	Occurs on white or red sand, loam, and black clay, often on sand dunes and river levees (WAHerb 1998-2016).
**Citrullus colocynthis* (Colocynth) 	A trailing perennial, herb or climber with deeply lobed, scabrous leaves. It has greenish yellow flowers between January and October. Fruits are a spherical melon, mottled green and yellow or all yellow with dull yellow-brown seeds (WAHerb 1998-2016).	Commonly occurs on sandy, rocky, stony loam, clay and wet soils; often in floodplains and disturbed areas (WAHerb 1998-2016).
**Cynodon dactylon* (Couch Grass) 	A rhizomatous (or stoloniferous), prostrate perennial grass from 0.05 m to 0.3 m high. Flowers are green or purple June to November (WAHerb 1998-2016).	**C. dactylon* occurs in sand, loam or clay habitats (WAHerb 1998-2016).

Species	Description	Habitat
**Datura leichhardtii* (Native Thornapple) 	A stout annual herb, between 0.2 m and 1 m high. It has solitary white flowers between June and October. The fruits are bright green (WAHerb 1998-2016).	Occurs mostly on alluvial soils, often along watercourses (WAHerb 1998-2016).
**Echinochloa colona (*Awnless Barnyard Grass) 	A tufted annual grass between 0.2 m and 0.9 m high. It has a green/purple inflorescence between February and July (WAHerb 1998-2016).	Occurs on black sand and black clay, near watercourses and swamps (WAHerb 1998-2016).
**Euphorbia hirta (*Asthma Plant) 	An erect or prostrate much branched hairy annual herb, growing between 0.1 m and 0.8 m high. Leaves are opposite, narrowly ovate with dark red blotches. Yellow-green-white axillary flowers are produced between January and October (WAHerb 1998-2016).	Occurs on alluvial soils, often along watercourses (WAHerb 1998-2016).
**Flaveria trinervia* (Speedy Weed) 	An erect annual herb, with ovate leaves. It has yellow flowers clustered to form a dense inflorescence (WAHerb 1998-2016).	Occurs in a variety of soils, particularly sandy and clayey sites. Typically occurs in drainage lines (WAHerb 1998-2016).

Species	Description	Habitat
**Lactuca serriola* (Prickly Lettuce) 	Erect annual or biennial herb 0.4 m to 2 m high. Flowers yellow, October to February (WAHerb 1998-2016).	Roadsides, gardens, cultivated fields, disturbed sites (WAHerb 1998-2016).
**Malvastrum americanum* (Spiked Malvastrum) 	An erect, hairy perennial herb or shrub between 0.5 m and 1.3 m in height. Flowers are yellow and orange, between April and July (WAHerb 1998-2016).	**M. americanum* occurs in a variety of sandy and clayey soils, as well as in limestone and calcrete. It typically occurs along stony ridges and hillsides, floodplains and along drainage lines (WAHerb 1998-2016).
**Melochia pyramidata* (Basil) 	A sprawling to erect woody perennial shrub 0.3 m to 1.5 m high. Flowers are white or pink or purple or blue, flowering from March to October (WAHerb 1998-2016).	**M. pyramidata* grows in alluvium, sand and black clay, and occurs along rivers and creeks (WAHerb 1998-2016).
**Ocimum basilicum* (Basil) 	Aromatic annual or perennial herb to 0.6 m high. Blue-purple, pink and/or white flowers from February to August (WAHerb 1998-2016).	Sandy soils and disturbed areas (WAHerb 1998-2016).

Species	Description	Habitat
**Passiflora foetida* var. *hispida* (Stinking Passion Flower) 	A woody climber to 9 m high with an unpleasant smell. It produces cream-white or blue flowers from February to November (WAHerb 1998-2016).	**P. foetida* var. *hispida* is commonly found in coastal areas, rivers and creek banks (WAHerb 1998-2016).
**Phoenix dactylifera* (Date Palm) 	A perennial tree-like monocot (palm) between 0.4 m to 8 m high. It produces flowers from July to September (WAHerb 1998-2016).	It is found on the edges of permanent pools and watercourses (WAHerb 1998-2016).
**Rumex vesicarius* (Ruby Dock) 	An erect, fleshy annual herb to 1 m high. Produces red-pink flowers from July to September (WAHerb 1998-2016).	Occurs in a variety of habitats and soils, including sandy alluvial and gravelly ironstone soils. Often occurs along roadsides and other disturbed areas (WAHerb 1998-2016).
**Setaria verticillata* (Whorled Pigeon Grass) 	A loosely tufted annual grass, 0.1 m to 1.3 m high. It flowers from December to June (WAHerb 1998-2016).	**S. verticillata* is found on sand, clay and loam. It is a common weed of disturbed areas and riverine edges (WAHerb 1998-2016).

Species	Description	Habitat
**Solanum nigrum* (Black Berry Nightshade) 	An erect perennial (short-lived) herb or shrub from 0.3 m to 1 m high. It produces flowers from January to December. It has dull black or purplish fruits (WAHerb 1998-2016).	It is a common weed in agriculture and bushland. Occurs in disturbed areas, pastures, creeklines, wetlands, woodland in sand, yellow-clayey sand, brown gritty clay, red sandy clay (WAHerb 1998-2016).
**Sonchus oleraceus* (Common Sowthistle) 	An erect, fleshy annual herb to 1 m high. Produces red-pink flowers from July to September (WAHerb 1998-2016).	Occurs in a variety of habitats and soils, including sandy alluvial and gravelly ironstone soils. Often occurs along roadsides and other disturbed areas (WAHerb 1998-2016).
**Vachellia farnesiana* (Mimosa Bush) 	An erect, sprawling, thicket-forming shrub or tree up to 4 m in height. It has dark grey, rough bark, pinnate leaves and long stiff thorns at right angles to the stems. Branchlets are also covered in rough, light coloured “wart”-like markings. It produces globular yellow flowers from June to August (WAHerb 1998-2016).	**V. farnesiana* favors low lying areas, disturbed areas and river and creeks banks (WAHerb 1998-2016).

1 INTRODUCTION

In the West Pilbara region of Western Australia the Robe River drains a sizeable portion of the catchment of the Western Hamersley Ranges. The historic paleo-channel of this River system has formed a string of pisolitic mesa shaped hills (also known as Channel Iron Deposits (**CID**)). Concurrent to this process, the hydrology of the West Pilbara in combination with local geology and topography have created the current pathway of the drainage has formed the Robe River, which provides habitats, riparian ecosystems and ecological values of local and potentially sub-regional significance.

As part of the process of recovering CID mineral resources, consideration of the potential to impact these local environmental assets is essential. For riparian systems, where the resident biological features are typically a clear reflection of the hydrological (and physical) characteristics of the river system, identifying the sensitivity and significance of these features is critical to inform an assessment of potential hydrological change.

In addition to considering potential impacts, the respective spatial distribution and significance of the ecological values present are of key importance to better understand the characteristics of riparian communities in the Robe River. Of particular focus is the distribution of Groundwater Dependent Ecosystems (**GDE**s) and Groundwater Dependent Vegetation (**GDV**) within the area, in addition to the varying scales of hydrological sensitivity held by resident vegetation types throughout the relevant stretches of the Robe River.

The groundwater dependent ecosystems of Australia represent a diverse, yet distinct component of the nation's biological diversity. Based on initial work by Hatton and Evans (1998), and further considerations by SKM (2001); six major types have been identified:

- **terrestrial vegetation** – vegetation communities and dependent fauna that have seasonal or episodic dependence on groundwater;
- **river base flow systems** – aquatic and riparian ecosystems that exist in or adjacent to streams that are fed by groundwater base flow;
- **aquifer and cave ecosystems** – aquatic ecosystems that occupy caves or aquifers;
- **wetlands** – aquatic communities and fringing vegetation dependent on groundwater fed lakes and wetlands;
- **terrestrial fauna** – native animals that directly use groundwater rather than rely on it for habitat;
- **estuarine and near-shore marine ecosystems** – coastal, estuarine and near shore marine plant and animal communities whose ecological function has some dependence on discharge of groundwater.

Three GDEs are of relevance to the Robe River; Pools (Wetland or River base-flow system types), Riparian Vegetation (Terrestrial vegetation type), and stygofaunal assemblages (Aquifer and cave ecosystem type).

The current study focusses on identifying GDV as an indicator for the presence of "Terrestrial Vegetation" type GDEs. As part of this process, key pools within the study area will be delineated to provide information about the distribution and abundance of Aquifer type GDEs.

Vegetation mapping is one of the primary tools for identifying key riparian ecological values; their spatial location within a system; and their inherent sensitivity to perturbations. Accurate, sufficiently detailed and complete riparian vegetation mapping is also important for guiding current and future riparian monitoring, and contextualising local to sub-regional significance. Furthermore; when considering in detail the potential for complex hydrological impacts, a more detailed scale of mapping is required for accurate, measured and more meaningful management and mitigation.

The four key aims of this study are:

1. To gather widespread, detailed and high confidence spatial information on the distribution of Robe River GDV, particularly those Obligate Phreatophytic Vegetation (**OPV**) communities surrounding resources in the Robe Valley.

2. Gather and incorporate information on the structure, age distribution, maturity and potential permanence/transience of resident OPV communities such that the resultant vegetation mapping is more strongly positioned to assess significance and groundwater dependence.

3. Describe and map all riparian communities throughout the study area, to a high level of detail, and in a manner prioritising the identification of all potentially groundwater dependent ecosystems and their distribution.

4. Based on the structure, maturity and distribution of mapped phreatophytic vegetation: provide an interpretation of the significance and inherent sensitivity of these communities to potential hydrological change in the form of interpreted risk mapping throughout the area of interest.

The current report outlines the Stage 1 work undertaken to achieve these aims within the relevant stretches of the Robe River surrounding Rio Tinto Robe Valley operations. Figure 1-1 shows the extent of the current study area and the boundaries of previous flora and vegetation surveys.

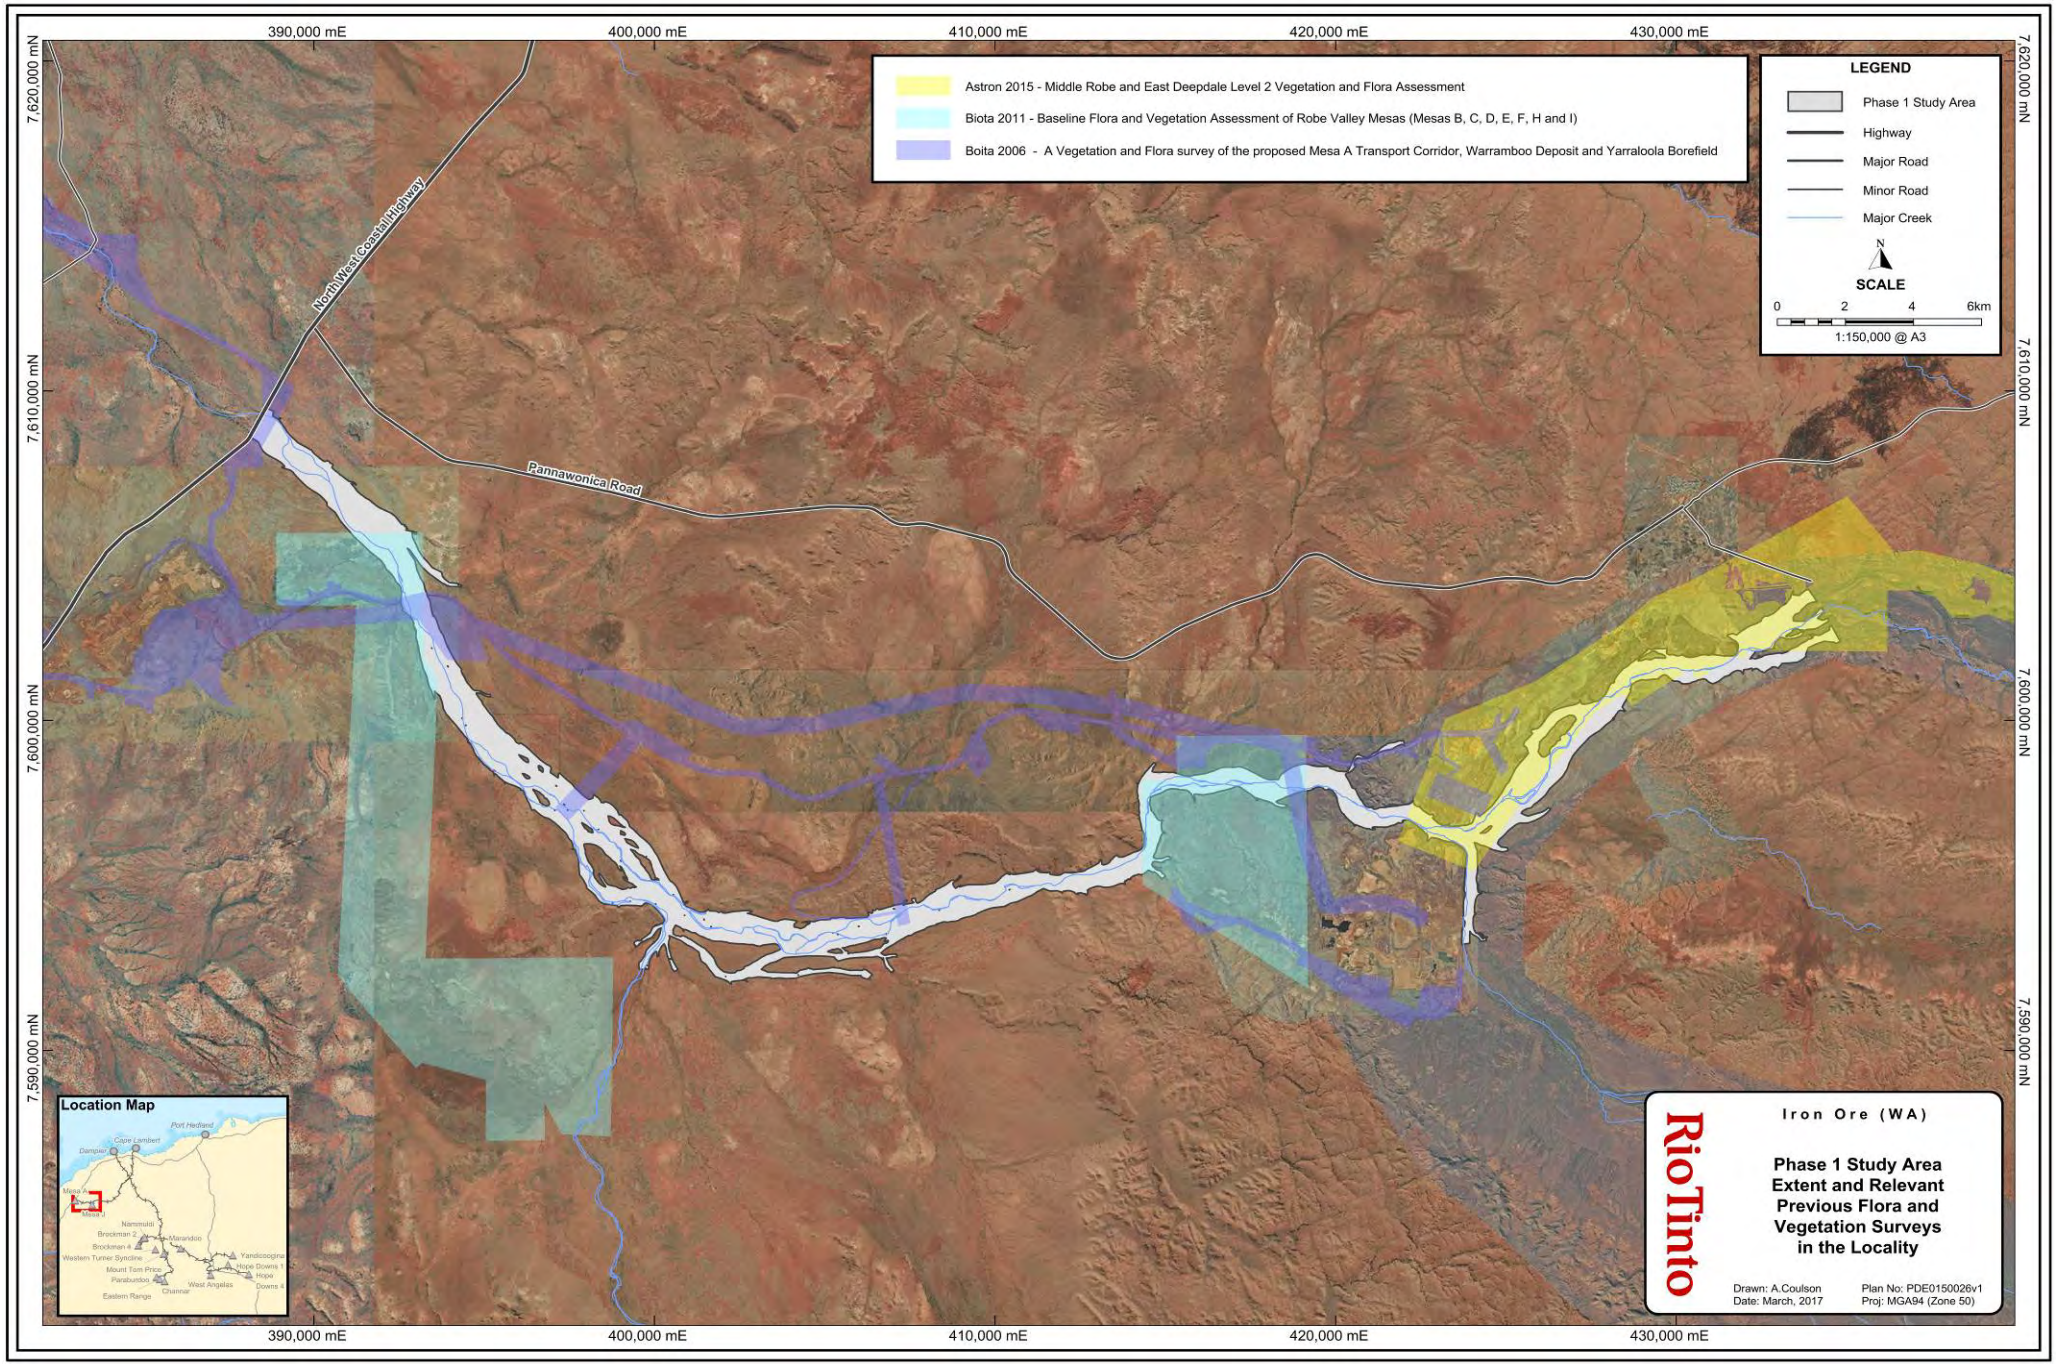

Figure 1-1: Extent of Robe River covered by the Stage 1 Study Area; includes the study boundaries of previous key flora and vegetation surveys.

2 BACKGROUND

2.1 RIVERS OF THE PILBARA REGION

The Pilbara is a relatively large arid region of the North West of WA. This region incorporates a number of large rivers which includes but is not limited to; the De Grey, Maitland, Harding, Turner, Oakoaver, Nullagine, Shaw, Yule, Fortescue Ashburton and Robe. Within the Pilbara region; major catchment divides are provided by the Chichester and Hamersley Ranges. The Chichester Range, a great undulating plateau forms a water shed between north flowing river systems (including the Harding, Maitland, Yule Turner and De-Grey) and the westerly flowing Fortescue River. The north flowing rivers begin dendritic and lead downstream to well-developed coastal drainage systems; with braided channels and discontinuous anabranches. On the southern flank of the Chichester Range and the north and south flanks of the Hamersley Plateau; streams are generally relatively short, dendritic, and often terminate in coalescing outwash fans on the alluvial plains of the Fortescue and Ashburton Rivers. The Fortescue River is long but is interrupted by extensive floodout lowlands of the Fortescue Marsh and associated claypans (Massini 1988).

The ephemeral rivers of the Pilbara are generally dry, experiencing major seasonal flows in a number of rivers almost every year. These flows are typically derived from tropical lows and cyclones which frequent the tropical north between December and April.

2.2 PHREATOPHYTIC VEGETATION / SPECIES, AND GROUNDWATER DEPENDENT ECOSYSTEMS IN THE PILBARA

Riparian systems of the Pilbara bioregion are subjected to extremely seasonal and variable hydrologic regimes in which stream flow typically occurs following cyclonic rainfall events (Ruprecht and Ivanescu 2000). Large flow events can result in the formation of isolated pools, replenish floodplain soil moisture and recharge groundwater within the riparian system.

In creeks and rivers of the Pilbara, groundwater is typically contained within shallow, unconsolidated sedimentary aquifers close (<20 m) to the surface (Landman 2001). In some instances, groundwater reaches the surface and natural springs are formed, maintaining permanent surface water pools. These shallow aquifers and springs often support GDEs; natural ecosystems that require access to groundwater to meet some or all of their water requirements to maintain their communities of plants and animals, and ecological processes (Sommer and Froend 2011).

While this study is focused on identifying GDV as an indicator of the broad “terrestrial vegetation” GDE type, it is also of importance to consider the hydrogeological processes and characteristics which might be supporting such vegetation to further understand the potential dependency of local phreatophytic vegetation. In recognition of the river landforms which are the focus of this study, it is also pertinent to consider broad GDE linked to such landforms and how they might influence the characteristics of local GDV. In Australia, several types of GDEs have been recognised (Clifton and Evans 2001), including river base-flow systems that comprise lotic aquatic and riparian ecosystems that rely wholly or partially on groundwater for their maintenance, function and integrity. Base flow is the component of total stream flow that is derived from groundwater, and reflects aquifer permeability, local and regional geology, bank and floodplain storage and the topography of the water table (Newson 1994). Under certain geomorphic conditions, some of this groundwater enters

streams and rivers from discrete springs and seeps, frequently supporting specialised aquatic fauna and flora (Williams *et al.* 1997; Halse *et al.* 2002; Fensham *et al.* 2004). More commonly, most base flow derives from groundwater that seeps in from the channel margins and floodplains via the parafluvial zone or enters from below via the hyporheic zone. The hyporheic zone is defined as the saturated sediments below and alongside the river channel where stream and groundwater exchange, and its functional significance to the ecology of surface river ecosystems is being increasingly recognised (Brunke and Gonser 1997; Boulton *et al.* 1998; Dent *et al.* 2000).

In many rivers draining arid and semi-arid Australia, discharge for most of the time is solely from the base flow (Boulton and Williams 1996). Furthermore; in many ephemeral rivers of the arid tropical zone, base flow typically only ever appears as very intermittent surface expressions (pools). For this reason, the ongoing interaction of the various source and sink components which influence the magnitude and at times cessation of local base flow, are generally wholly unknown.

GDEs comprise plant species that, in the absence of rainfall, rely directly on groundwater (and associated surface expressions) but may also contain grass and herbaceous species relying on recent rainfall (Sommer and Froend 2011). Plant species which draw water from the saturated zone (the phreatic zone) or capillary fringe of the water table are known as phreatophytes and the presence of GDEs is often inferred from the presence of such species (Eamus *et al.* 2006). Phreatophytes can usually be found along streams where there is a steady flow of surface or groundwater, or consistent still pools in areas where the water table is near the surface.

At the opposite end of the scale is a “xerophyte”, which is essentially a species of plant which has adapted to survive in an environment with little access to water (Salisbury and Ross 1992). Terms used to describe the water use strategies of plants occupying various positions within the Phreatophyte to Xerophyte scale are: “Obligate Phreatophyte”; “Facultative Phreatophyte”; and “Vadophyte”.

It is generally considered that any vegetation that uses groundwater is potentially at risk of impact if it occurs in a location where the groundwater would be lowered beyond assumed natural groundwater variation. However, the impact on vegetation from lowering the groundwater table is likely to be relative to the species’ dependence upon groundwater, and on the alternative sources of moisture available to it in any one situation. For example, plants that rely on water sourced directly from the groundwater table (phreatophytes) are more likely to show signs of decline or be lost than those that can rely on sources of soil moisture (i.e. vadophytes) such as precipitation and soil pore moisture anomalies from other sources. An assessment of the groundwater dependence of species present within the study area has been informed by a desktop literature review, with specific reference to previous vegetation association mapping and an understanding of the surface water and underlying groundwater environment.

Not all phreatophytic species display the same degree of dependency on groundwater and the dependency within species has been shown to vary both spatially and temporally (Eamus and Froend 2006). Obligate phreatophytes are those species for which access to groundwater is critically important to their presence in the landscape. Such species can only inhabit areas where they have access to groundwater in order satisfy at least some proportion of their environmental water requirements (**EWR**) (Eamus *et al.* 2006). Facultative phreatophytes, on the other hand, are plant species for which access to groundwater is not necessarily important to their presence in the

landscape. Facultative phreatophytes may utilise groundwater to satisfy a proportion of their EWR but, if required, may also satisfy their total EWR via stored soil water reserves (Eamus *et al.* 2006).

The tree species *Eucalyptus camaldulensis* subsp*. refulgens* Brooker & M.W. McDonald (River Red Gum), *Eucalyptus victrix* L.A.S.Johnson & K.D.Hill (Coolibah) and *Melaleuca argentea* W.Fitzg (Silver Cadjeput – historically identified as *M. leucadendra*) are the three most common phreatophytic species within riparian systems of the Pilbara bioregion. A fourth, *Sesbania formosa*, while less widespread and less accepted as a phreatophytic species, is also a relevant phreatophyte in Pilbara riparian systems. The presence of these species is often used to infer the presence of a GDE. These species vary in their degree of dependence on groundwater and this variation has a strong influence on their patterning and abundance within riparian systems. The most dependent of these species upon groundwater is *Melaleuca argentea*, which is considered to be an obligate phreatophyte.

Melaleuca argentea have previously been recorded within the study area in varying quantities. *Sesbania formosa*, another potentially obligate phreatophyte, is commonly scattered throughout those more mesic communities present within the study area. Table 2-1 presents an interpretation of the different classes of groundwater dependence (water use strategies) relevant to riparian plant groups in the Pilbara, and the most relevant species considered as being attributable to each. It should be noted that some of the detail presented in this table is the culmination of substantial observational experience gained by the author in the Pilbara. While broad concepts presented tend to be agreed with by relevant studies, some of the nuances presented in Table 2-1 are neither well accepted nor adequately supported by empirical data. Instead the detail is presented as a guide as to how these species are broadly observed to behave, for the purpose of informing the risk assessment conducted in this report. What is generally well accepted is that *Melaleuca argentea* is an obligate phreatophyte, and that *Eucalyptus camaldulensis* and *E. victrix* are facultative phreatophytes. Generally speaking there is a paucity of data on the remainder of species presented in the table.

Table 2-1: Tree species dependence on groundwater*

Species dependence on Groundwater	Plant Physiology/water use strategy	Relevant Species in the Pilbara
High	Obligate Phreatophyte	*Melaleuca argentea, Sesbania formosa (?)*
Moderate	Facultative phreatophyte (in anomalous cases a vadophyte)	*Eucalyptus camaldulensis*
Low to Moderate	Vadophyte or Facultative phreatophyte (in anomalous cases)	*Eucalyptus victrix, Melaleuca glomerata and Eucalyptus xerothermica*
Low (virtually negligible)	Xerophyte	E.g. *Eucalyptus leucophloia*, *Corymbia hamersleyana*, *Corymbia deserticola*, Corymbia candida

*The degrees of dependence on groundwater implied in this table are more relevant to specific species listed in this table rather than individuals of each species. It is acknowledged that individuals of a specific species may have established under conditions of high water availability, and thus may possess high degrees of groundwater dependence (and vise versa). Furthermore plant water use strategies listed are not mutually exclusive; vadophytes may access groundwater, and vice versa, phreatophytes will also access vadose soil water.

Vegetation associations occurring along the main drainage channels and associated flood plains within the study area support three native tree species that are considered to be at moderate or lower risk from groundwater drawdown: *Eucalyptus camaldulensis* subsp*. refulgens* (moderate risk);

Eucalyptus victrix (low to moderate risk); and *Corymbia candida* (low to minimal risk). These tree species are classified facultative phreatophytes or at times as vadophytes.

Eucalyptus camaldulensis is the most widespread Australian Eucalypt species and is known to tolerate an apparently wide range of water regimes (Colloff 2014). Eucalyptus camaldulensis (River Red Gum) is considered a facultative phreatophyte as it obtains its water for transpiration via three main sources: groundwater, river flooding (which over tops creek and river banks thereby replenishing floodplain soil moisture), and rainfall (Wen *et al*. 2009). The degree to which *E. camaldulensis* depends on groundwater and soil moisture has been found to vary both spatially and temporally (Mensforth *et al*. 1994, O'Grady *et al*. 2009, Wen *et al*. 2009, O'Grady *et al*. 2010). *E. camaldulensis* typically occurs along inland rivers and may be dependent on shallow groundwater for survival, although the root system may penetrate considerably deeper than 10 m. Studies in the Pilbara indicate that *E. camaldulensis* occurring along the larger drainage lines may have access to groundwater up to 21 m below the surface (AGC Woodward-Clyde 1992). Investigations at Marillana Creek found the vigour of large *E. camaldulensis* trees (>10 m tall) declined in response to lowering of groundwater levels caused by test pumping of water, while the vigour of smaller *E. camaldulensis* remained unchanged (Onshore Environmental 2013). This observation suggests that the species is capable of being both a vadophyte and a phreatophyte, using the former strategy when young and the latter strategy when mature (Halpern, Glink Maunsell 1999). Muir Environmental (1995) indicates that River red gum (*E. camaldulensis*) and Coolibah (*E. victrix*) are generally not restricted in their occurrences along Marillana Creek and thus cannot be considered as being true phreatophytes, but as vadophytes (i.e. primarily unsaturated soil dependent). In the case of *E. camaldulensis*, general observations in the Pilbara by Rio Tinto Botanists suggests that there is some degree of restriction to the distribution of this species along large creeks, and so the concept that this species can be both a phreatophyte and a vadophyte (depending on the circumstances) appears most accurate.

Eucalyptus victrix is a small to medium sized eucalypt which typically occurs on the drier zones of creeks and rivers throughout semi-arid Western Australia. Like *E. camaldulensis*, *E. victrix* is also considered to be a facultative phreatophyte. This species has been shown to access groundwater in areas where the depth to groundwater is low (O'Grady *et al.* 2009) but in non-riparian habitats, has also been shown to exploit shallow soil water to meet its transpiration needs (Grigg *et al.* 2008). *Eucalyptus victrix* is known to inhabit an ephemeral wetland (i.e. Mount Bruce Flats, Karijini National Park) despite the absence of a permanently saturated regolith (Rio Tinto 2011a). Comparisons of groundwater and stem xylem water stable isotope compositions as well as pre-dawn and midday leaf water potential measurements suggest that *E. victrix* within the Mount Bruce Flats in Karijini National Park uses water drawn from the unsaturated soil profile during extended dry periods (Rio Tinto 2011a). Further to this, *Eucalyptus victrix* (and potentially *Corymbia candida*) are generally considered to be examples of vadophytes being relatively drought tolerant but susceptible to decline when groundwater becomes limiting (Muir Environmental 1995).

Melaleuca argentea is a tree which grows to approximately 20 m (and higher) and is found along larger watercourses of the Pilbara. *Melaleuca argentea* is thought to be dependent on groundwater almost exclusively to meet its water requirements and is therefore considered to be an obligate phreatophyte (Lamontagne *et al.* 2005, Graham *et al.* 2003, Landman *et al.* 2003, O'Grady *et al.* 2006). Due to its dependence on groundwater, this species is typically found in parts of creeks and rivers characterised by permanently inundated pools and springs or where the water table is

permanently close to the surface (McLean *et al.* 2013). *Melaleuca argentea* is generally considered to be the plant taxon within the Hamersley Ranges at highest risk of impact through changes to groundwater availability associated with drawdown.

The water use characteristics of *E. camaldulensis, E. victrix* and *M. argentea* influences their response to mining related impacts such as dewatering and discharge. Dewatering, which causes localised lowering of groundwater levels, may be expected to have a significant impact on the health of *M. argentea* but lesser impacts on *E. victrix* and *E. camaldulensis*, provided adequate soil moisture is maintained from periodic, rainfall-generated stream flow. On the other hand, artificial discharge of surplus groundwater along ephemeral creeks and rivers may favour *M. argentea* (resulting in increased recruitment and vigour) by creating a perennial hydrologic regime. Change from a steady-state ephemeral hydrologic regime to a more perennial one may adversely impact *E. victrix* and to a lesser extent *E. camaldulensis*. Florentine (1999) found that *E. victrix* exhibits some tolerance to waterlogging (e.g. production of adventitious roots) but overall growth, transpiration rate and net photosynthesis are negatively affected under waterlogged conditions. By contrast, *E. camaldulensis* is considered to be one of the most waterlogging-tolerant eucalypt species (Bell 1999; van der Moezel *et al.* 1988), though empirical studies of its waterlogging tolerance in the Pilbara bioregion are lacking and results may be somewhat dependent on subspecies. At the local and micro scale the impacts of excess water will differ depending on the substrate and channel morphology and thus the relative position of trees (particularly on a vertical plane) to available water.

Probably the most important concept to consider when classifying the water use of plant species by attributing particular species to one of the above described water use strategies, is that typically plants and their associated environments do not always behave in definitive manners. While the physiological constraints and demands of the plant tend to be quite definite, the way in which the environment provides for this physiology and the way in which the plant acquires its needs from the environment can vary quite considerably in time and space (O'Grady *et al*. 2009). The most relevant area of variability in relation to the risk of death from changes in water availability is represented by a plants ratio of resource allocation between its canopy and root systems. The size and distribution of a plants root system (and conversely the size of its canopy and associated water demands) has a direct link to its ability to acquire sufficient moisture when soil conditions change (Salisbury and Ross 1992). The rate of water availability change therefore has important consequences for the ability of a plant to re-allocate these resources in time and therefore potentially to transition between the bounds of a phreatophyte and a vadophyte. Furthermore; the stem density of the vegetation a tree resides in has a strong influence on the stand water demands per unit of area and hence the resources available for each individual tree to compete for.

Another important point to consider when assigning species or communities to phreatophytic water use strategies is the source of moisture. While phreatophytic species are considered to be dependent on groundwater this is not always accurate in the context of the typical definition for groundwater. Groundwater is often considered to be represented by the underlying water table, but in the case of plant water use it is more accurately any source of water on, in or under the ground as long as its presence remains fairly consistent. For example; phreatophytic species can establish because stream morphology and/or underlying geology are such that specific areas sustain consistent alluvial water bodies or surface water pools and patches of moisture which are perched well above the underlying groundwater table. Subsequently these communities can be sustained by intermittent but relatively consistent fluvial flows, regardless of the behavior of deeper groundwater bodies. The reason such distinctions are important, is that in an impact assessment scenario,

potential changes to clearly detectable and therefore more broadly evident groundwater aquifers often comprise the only measurable features of hydrological influence acting on riparian systems. However despite such a focus, changes to broad scale groundwater features can often occur with little or no influence on small scale aquifers and surface water features consistently present in certain fluvial positions and situations.

The resounding message which becomes apparent when considering phreatophytic species is that not all phreatophytic species are equal. Each species considered has evolved in a different habitat using different life strategies and each habitat has varying degrees of water availability. An additional layer of complexity is represented by the various niches which these species have adapted to take advantage of within each habitat. As a result *Eucalyptus victrix* and *E. camaldulensis* have quite different adaptive capabilities and as such can survive and prosper in quite different water availability regimes.

GDEs and their associated species and landforms represent features of elevated ecological value. Phreatophytic species often represent fast growing pioneers which are highly resistant to disease. They also provide, shelter, specialised foraging grounds, and nesting/denning areas for native fauna. Phreatophytes are also known to be indicators of potable groundwater, and to provide water purification services, as their roots are known to fix heavy metals via the provision of bacteria driven filtration (World Heritage Encyclopedia 2014).

GDEs, generally represent areas with relatively permanent water (surface and/or groundwater), and as such tend to support relatively dense and diverse vegetation communities. Such vegetation tends to contain an above average proportion of mesic perennial and ephemeral species diversity, and so represents repositories of genetic diversity which are often restricted in their distribution and areal extent. Coupled with the diversity of fauna species (particularly avifauna, and nocturnal invertebrate fauna) which they support; their value is generally accepted to be high. It is for this reason that those species which are considered obligate phreatophytes, and therefore most dependent on water permanence, are those species which are the key indicators for the presence of these high value ecosystems. As an obligate phreatophyte *Melaleuca argentea* is a key indicator species for the Pilbara; the distribution, abundance and age structure of this species in the environment is often the best available measure for the presence and quality of high value groundwater dependent ecosystems. However, communities which occur in generally ephemeral habitats, and which do not possess an "obligate phreatophytic species" such as *Melaleuca argentea*, but instead only possess facultative phreatophytes such as *Eucalyptus camaldulensis;* can also be described as GDEs. For this reason it becomes important to make the distinction between general groundwater dependent ecosystems/vegetation, and those which are more specifically highly groundwater dependent, or "truly phreatophytic".

In the Pilbara, *M. argentea* is widely considered a strict obligate phreatophyte, and because of the potentially variable water use strategies of some of the other phreatophytic species in the Pilbara (namely facultative phreatophytes), *M. argentea* clearly represents the best indicator for true groundwater dependence. Therefore to provide a term or label which can be used to make the distinction between the less significant vegetation types, generally dominated by one or more facultative of phreatophytic species (general GDEs) and those adequately possessing "true" or obligate phreatophytes, the terms "Obligate Phreatophytic Vegetation" (**OPV**), and "Facultative Phreatophytic Vegetation (**FPV**) are proposed.

For the purpose of this study, the label/term "Obligate Phreatophytic Vegetation" (OPV) is defined as representing communities which:

> *Encompass vegetation associations and sub-associations, whose structure is at least co-dominated by one obligate phreatophyte, namely Melaleuca argentea (i.e. possesses vegetation described as being dominated by one or more species within the tree or tall shrub stratum and which includes the obligate phreatophyte Melaleuca argentea as one of these described dominant species). Note: this is not a well-recognized term, and has been created for the purpose of this and other studies from associated, well accepted terms such as "Obligate Phreatophytes" and "Groundwater Dependent Vegetation").*

The distinction this term makes is important for this study, as communities in which this species comprises a significant component, are best placed to indicate perennial water availability, and therefore indicate the distribution of ecological values associated with permanent water availability. By making this distinction this study can then differentiate between OPV and more commonly distributed GDEs represented by facultative phreatophytic vegetation (FPV) such as the *Eucalyptus camaldulensis* woodlands which tend to surround OPV. Consequently, for the purpose of this study, and to aid in the process of assessing the significance of riparian communities and their distribution within the study area; communities and vegetation associations/sub-associations within which *Melaleuca argentea* forms a co-dominant species are described as OPV (Obligate Phreatophytic Vegetation). The remaining communities only dominated by other facultative phreatophytic species (but potentially including those possessing *M. argentea* as an associated species only), are from here on in to be termed "Facultative Phreatophytic Vegetation" (**FPV**).

While it is acknowledged that such terms are not accepted in the wider ecological community, their use in this type of assessment is advantageous. Obviously it is acknowledged that vegetation includes all plant species in an area/ecosystem/habitat, and whilst some species may be phreatophytic, many are not. As a result the Terms OPV and FPV are not suggesting all components of the vegetation in question are groundwater dependent. Instead such labels are suggesting that the presence of the relevant phreatophytes are important riparian characteristics/components of the vegetation; particularly in relation to targeted vegetation surveys focusing on potential presence of GDE's. Phreatophytic components whose continued existence is likely dependent on continued access to groundwater are distinctive in terms of their attribution to vegetation units. For such vegetation; hydrological change leading to phreatophyte removal would in turn convert the resident vegetation into a vegetation unit which is compositionally, structurally and functionally different to the original unit to which the OPV/FPV label was applied.

The set of statutory listings for vegetation communities and ecosystems by the WA State or Commonwealth Government are not exhaustive and are generally based on a system of nomination, such that they do not represent a systematic treatment of features of high value or significance. Therefore unlisted flora and vegetation may be locally or regionally significant for similar reasons to those features chosen or nominated for listing. The EPA's Factor Guideline for flora and vegetation states that flora may be considered significant if the flora is locally endemic or associated with a restricted habitat type (e.g. surface water or groundwater dependent ecosystems), and vegetation may be considered significant if it provides an important function required to maintain ecological integrity of a significant ecosystem (EPA 2016a). However, this is not the only means by which biota can be attributed significance. Based on the *Technical Guide; Flora and Vegetation Surveys for*

Environmental Impact Assessment (EPA 2016b), and other sources; vegetation may be significant because its areal extent is below a threshold level and a range of other reasons, including:

- scarcity;
- high diversity or species richness;
- high diversity or species richness within special functional plant groups (e.g. mesic species, ephemeral taxa, xerophytic taxa etc.);
- unusual species, or range extension species;
- novel combinations of species (associations);
- a role as a refuge;
- a role as a key habitat for threatened species or large populations representing a significant proportion of the local to regional total population of a species;
- being representative of the range of a vegetation association (particularly; a good local and/or regional example of an association in "prime" habitat, at the extremes of known range, recently discovered range extensions, or isolated outliers of the main range);
- of restricted distribution at a local/sub-regional/regional scale or occupying a rare landform; and
- exceptional condition.

When considering development and associated impacts to vegetation, it is also important that a measure of sensitivity/resilience and in relevant cases transience be considered and attributed to riparian features of significance so that an element of risk can be attributed to their ultimate significance.

While *Melaleuca argentea* dominated/co-dominated communities generally represent the high significance OPV communities of the Pilbara because of their associated values and local perennial water availability, it is this dependence on a perennial water source which makes them the most sensitive to anthropogenic hydrological changes. Despite the inherent sensitivity of these communities the age structure and distribution of the respective sub-associations of *M. argentea* co-dominated communities present has some degree of influence on their sensitivity to impact. While young obligate phreatophyte individuals (when compared to mature individuals), typically tend to be more sensitive to changes in groundwater height (than mature individuals); this is not the full picture. Compared to mature obligate phreatophyte individuals; the temporal stability of young individuals/populations is generally significantly reduced due to the magnitude of peak flow scouring/deposition processes. Furthermore areas devoid of mature individuals can indicate that water availability is not stable enough to support their long term development. Based on field observations, the distribution of OPV communities dominated by a young age class appear to be restricted to specific habitats and areas where water availability is changing (either reducing, or increasing). As a result it is inferred that riparian OPV communities with an age frequency distribution restricted to young to semi-mature age classes are likely to delineate zones within the fluvial system where flow patterns and locally higher variability in water availability are limiting factors determining that the presence of OPV is highly transient. This temporal instability inferred to be a character of immature OPV communities is most likely to be a product of the increased degree of hydrological variability present in such areas. This conclusion is supported by the fact that

an age structure dominated by a narrow age range can often be aligned with a significant and recent hydrological (and/or potentially physical change) change that has enabled a mass colonisation event. Importantly; if hydrological change is high in such areas, and vegetation stability is low, then this will also determine that the vegetation supported will be inherently variable and so will the attributed significance. As a consequence; for such communities it is concluded that the significance of resident communities at any one time is significantly reduced.

For mature OPV communities the opposite is generally true. Those communities with structures increasingly dominated by large mature obligate phreatophytes are delineating the areas where vegetation is relatively stable and water availability is highly consistent thus enabling colonisation and development of high value ecosystems. The temporal stability and significant ecological values provided by such climax OPV determine that the attributed significance is inherently high. Furthermore; the most mature and commensurately significant representations of *M. argentea* woodland/forest are likely to be the most sensitive to change due to their generally high water demands (per unit of area), often broader lateral distribution within the fluvial profile, and their mature age frequency distribution. *Melaleuca argentea* communities which fall in between these two ends of the scale of maturity will generally possess sensitivities and associated significance commensurate to their water demands, predominant age and maximum distance from areas of consistent water availability.

2.3 LANDSCAPE FEATURES, FLUVIALS SYSTEMS AND THEIR ROLE IN SUPPORTING HIGH-VALUE RIPARIAN VEGETATION COMMUNITIES WITHIN THE HAMERSELY SUB-REGION

The climate of the Pilbara is essentially classified as arid-tropical possessing an average precipitation to evaporation ratio of less than 0.2 (McKnight and Hess 2000). With precipitation generally falling within the range of 250-450 mm, the Pilbara can be mistaken for being semi-arid, but with high average temperatures and an average evaporation rate in the vicinity of 2,000 mm per year, the effective precipitation in the region is minimal and therefore classified as arid. Because of such climatic factors, water gaining sites which are exposed to surface water supply from larger catchments and which can lock away significant amounts of water from evaporation, become quite important. Such fluvial systems create riparian corridors which provide refuge for a diversity of moisture loving species which wouldn't otherwise be present in areas possessing a similar climate classification. Consequently these features provide value to the region as custodians of biological diversity through their provision of ecological services and habitat diversity/complexity.

Beyond the general importance and functions of large river/creek systems in hot and often dry climates such as that of the Pilbara; drainage systems which provide the right catchment size and subsequent environmental conditions to create surface or groundwater permanence are considered most valuable. Those factors helping to create or contribute to surface and groundwater permanence within fluvial systems are generally represented by combinations of underlying geology (such as porous or impervious lithologies), topographic confinement, elevation, slope, meander shape and creek profile. Other landscape factors influencing water availability within fluvial systems can also be represented by the intersection of local perched aquifers, the distribution and size of groundwater recharge zones, sources and sinks to river base-flow, adjacent extensive clay-pan landforms (important for storage and sustained moisture release) and physical intersection of barriers to groundwater flow. These factors and more combine to provide the range of unique conditions valuable for the maintenance of permanent water availability and consistent groundwater levels. This value is primarily a product of the highly restricted and diverse ecosystems

they can sustain, and by association the fauna assemblages they support. These landscape attributes become increasingly valuable in arid environments due to the restricted distribution of their associated habitats and their ability to buffer the influence of climate variability and change.

2.4 THE ROLE OF MESIC SPECIES, PHREATOPHYTIC VEGETATION AND GDES IN IDENTIFYING VARYING DEGREES OF WATER AVAILABILITY

Within the Pilbara, riparian habitats which provide permanent surface or groundwater access are only common along certain reaches of the regions large river systems. While the more mesic reaches of such river systems are not common, they are large, and OPV is generally common through such areas. Beyond the river systems of the Pilbara, the remaining representations of OPV are quite restricted to parts of those large creek systems which function as drainage for significant catchments and contain optimal substrate conditions to maintain perennial surface and groundwater sources.

As discussed earlier; in the Pilbara, obligate phreatophytes such as *Melaleuca argentea* are highly dependent on permanent access to shallow freshwater. As a result of this dependence; this species is considered one of the best indicators of water permanence in the Pilbara. In general; the structure and composition of river and creekline vegetation tends to be driven by the degree of moisture present, and so vegetation is an important indicator of surface and groundwater permanence and can be used to assess the associated value and significance of the system. This approach is important as there are often no effective alternatives (at a finer scale) for establishing water permanence in an area. Human records are generally not extensive or detailed enough to truly determine if a site actually possesses surface or groundwater permanency. Furthermore, climatic factors can have a strong influence from year to year, and the underlying water table heights established from an often limited array of bores are difficult to accurately interpolate. Generally, the best and often only true indicator (over relevant timescales) of surface and groundwater permanence is the composition and structure of resident vegetation.

In the Pilbara, a list of sub-perennial to perennial moisture indicating (i.e. combinations of moisture present from 1 or more sources such as soil pore moisture, groundwater, capillary fringe etc.) genera/species (mesic indicator species) are likely to contain a number of the species presented in order of importance within Table 2-2 (Western Australian Herbarium 2018) (bold species identifies the best indicators). It should be noted that a paucity of information available on the ecophysiology of the majority of the species listed in Table 2-2 determines that empirical data to determine whether these species truly possess plant functional traits associated with low water use efficiency is relatively unavailable. Instead their attribution to mesic-habitats/wetlands and the implied hierarchy within this list is based on known spatial distribution patterns (some gained from the Western Australian Herbarium (2018), with the remainder gained from field observations by the author). Consequently, riparian zones or water gaining sites which contain *Melaleuca argentea* and varying proportions of the following species are considered to provide good evidence of perennial water availability. Conversely if a riparian zone instead only supports some of the mid-level species/genera in this table moisture availability is considered to be below, but approaching levels equivalent to perennial/permanent availability. It is important to note that it is not yet clear which of these species are more associated with increasing volumes of water, or which are more associated with increasing degrees of consistency in availability. What is clear is that their presence is clearly correlated with increasing degrees of water availability and consistency, and therefore of value as an indicator of either.

Table 2-2: Flora genera and species of the Pilbara determined to be good indicators of increasingly high moisture availability/consistency.

• ***Melaleuca argentea***	• *Samolus spp.*

Note: Species in **bold** identify some of the best upper level indicators of moisture availability / permanence. Order of importance reads down the page, left to right.

While the species composition of vegetation provides a significant insight into water permanency; an additional level of detail on the degree of water permanency is observable in the structure of the vegetation present. This essentially involves making inferences about the degree and extent of permanency based on the age structure and relative dominance of resident obligate phreatophyte populations. If water remains permanently available to these phreatophytic species then at least a percentage of the population is likely to present as “semi-mature” to “mature” individuals of approximately 40-100 cm diameter. While environmental perturbations such as floods and similar peak flow events will have an influence on the age structure; where conditions are suitable, it is still considered likely that mature trees (older large individuals) will resist flooding and remain to provide insight into the stability of the moisture conditions present over reasonable temporal scales.

In addition to the maturity of OPV communities; the degree of lateral restriction within the fluvial system may also be a good indicator of groundwater proximity and persistence. In many cases within the Pilbara, woodlands of OPV are represented by a very thin (almost single tree width) strip of vegetation which forms on the banks (often the lowest colonisable position in the landscape) of some permanent to near permanent surface pools. In some areas mature OPV vegetation is spread across a broader lateral range of the bed; indicating more general groundwater persistence through a larger proportion of the creek profile, and thus providing greater habitat and structural diversity

values. Laterally broader representations appear to be relatively restricted in their distribution within the Hamersley subregion, and can be considered locally to sub-regionally significant.

Beyond the more extensive and significant stands of *M. argentea/Eucalypt* spp. woodland; where water availability is generally perennial; surface and groundwater availability in the remaining sections of the larger Hamersley Range fluvial systems are generally more variable. However at the smaller scale, fluvial landforms and features such as bends & corners, constricted channels and complimentary small scale geological anomalies can combine to more consistently retain surface water (or close proximity groundwater and small perched alluvial aquifers) than the majority of the general creek bed. In such cases, narrow isolated patches of OPV can be found lining large pools or occupying the low points in the bed profile.

The remainder of the phreatophytic vegetation within fluvial systems of the Hamersley Ranges are essentially represented by woodland (to open forests) of *E. camaldulensis* and/or *E. victrix* over patches of mixed low open woodland/tall open shrubland scattered throughout anabranching channels and broad, open bed zones. This vegetation community is typically one of the more common of the larger topographically confined riparian systems within the Hamersley Ranges (i.e. those dissecting range systems rather than occupying the finer soils of plains and broad alluvial valleys). The other more common and least significant community on systems such as these is represented by low open woodland (to scattered low trees) of *Eucalyptus victrix* over mixed *Acacia* spp. tall open shrublands. In the larger riparian systems, this community typically occupies the outer drier extremities, high flow channels, and elevated points within the fluvial profile with less frequent flooding and inundation.

2.5 STUDY AREA

The study area determined to be the focus of this work incorporates a 60 km stretch of the Robe River and approximately 3 km of Jimmawurrada Creek. With over two thirds of the area of interest located within the Yarraloola Pastoral Station and the remainder within Yalleen Station, the combined area of both River and Creek systems are herein referred to as the “study area”. The stretch of the Robe River represented by the study area is wholly located within the Hamersley subregion of the Pilbara Bioregion (IBRA 7.1) (DoE 2014a).

The boundaries of this study area are presented in Figure 2-1 (and previously in Figure 1-1).

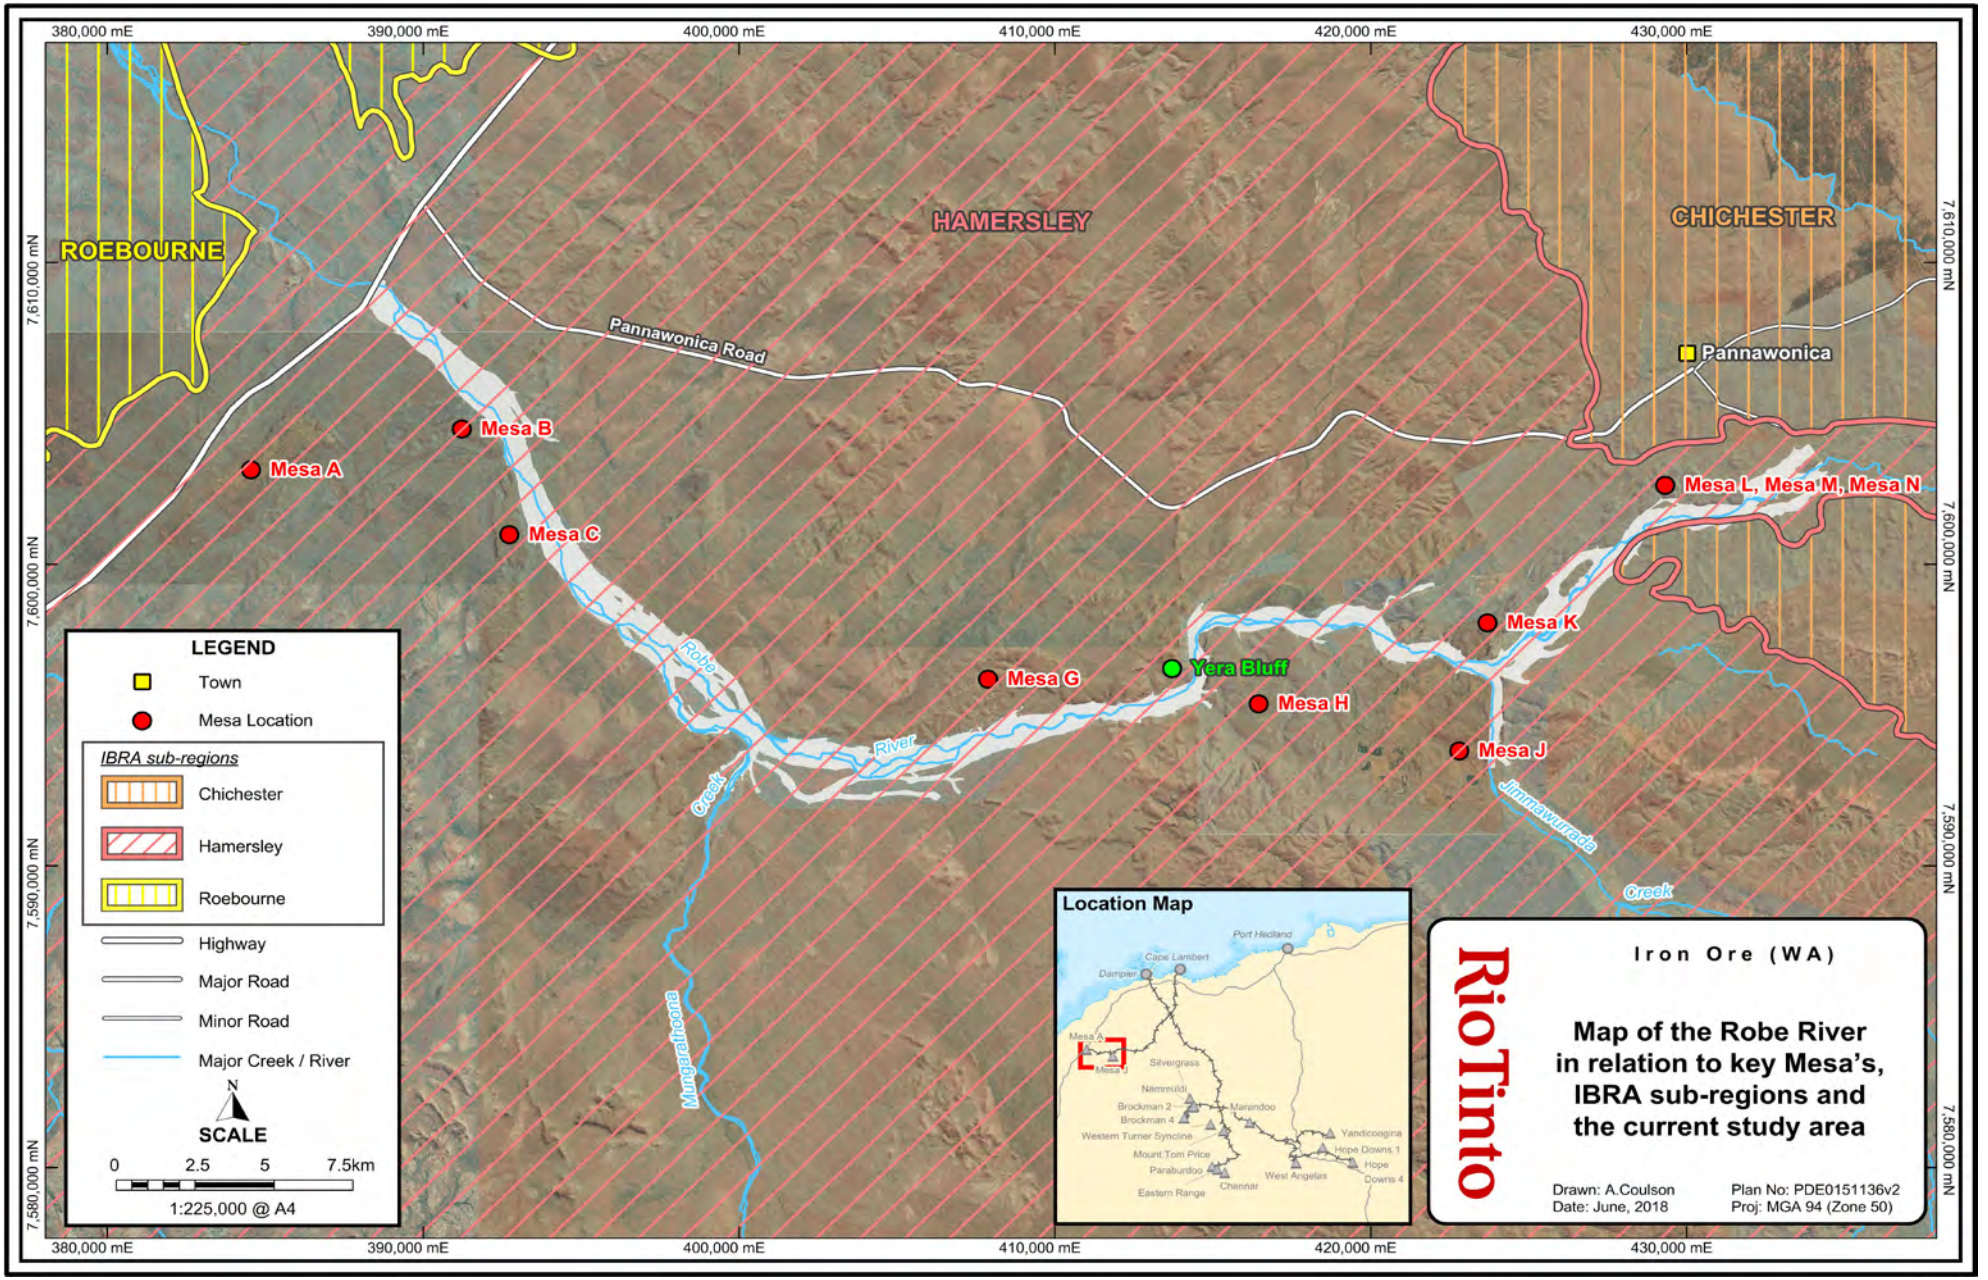

Figure 2-1: Map of the Robe River in relation to key mesas, IBRA sub-regions and the current study area.

2.6 THE ROBE RIVER RIPARIAN SYSTEM

The Robe River is situated in the north-west corner of the Pilbara region of Western Australia. The river itself is approximately 280 km long and has a catchment size of 3,350 km^2. The headwaters rise in the Hamersley Range near Marana Spring then flow in a north westerly direction through the Robe Valley, crossing the North West Coastal Highway near the Pannawonica turnoff then discharging into the Indian Ocean near Robe Point. The Robe River has three main tributaries; Jimmawurrada Creek & Mungarathoona Creek, both of which are partly covered by this survey; and Kumina Creek.

The Robe River is ephemeral and surface water is restricted to a series of permanent pools that act as important refugia for native fauna through the dry season. Those pools which are considered relatively permanent are described in long term monitoring work conducted by Dobbs & Davies (2009). Key pools identified in the study area are presented in the vegetation mapping within section 4.1.

The Pilbara biogeographical region is characterised by low annual rainfall (annual average 400 mm) and, when coupled with high annual evapo-transpiration rates (e.g. typically about 12 times the annual rainfall) results in restricted aquatic ecosystems. Pannawonica receives the majority of its rainfall over summer in association with cyclone events. Peaks in rainfall typically occur during January to March with months of lowest rainfall occurring in September and October.

Rainfall is highly episodic as well as highly variable and rainfall across years can be highly unpredictable with significant variation in annual rainfall. The coefficient of variation (**CV**) for the Pilbara ranges from 0.4 to 0.7 in comparison with a CV for south-west Western Australia of 0.2 and for the Kimberley of 0.3 (DoE 2004). River discharge patterns are tightly coupled to the seasonality of rainfall events. Following trends in rainfall data, maximum flows are typically recorded between January and April and low or no flow from September to December. As a result the Robe River experiences periodical flooding. The Robe River was last in full flood following Cyclone Monty in 2004. In 2009; following heavy rainfall, the river burst its banks cutting roads and railway lines.

The Robe River / Jimmawurrada Creek riverine habitat is dominated by moderately-dense to dense mixed woodlands to open forests of Cajeput (*Melaleuca argentea*), River Red Gum (*Eucalyptus camaldulensis*) and Coolibah (*Eucalyptus victrix*). The open understorey of tall shrubs is dominated by *Petalostylis labicheoides* and *Acacia trachycarpa* with scattered *Sesbania formosa* and *Gossypium robinsonii* over sedges and mixed herbs. Filamentous green algae are common in the waterways, together with emergent macrophytes, such as *Typha domingensis*, *Potamogeton* and *Vallisneria* species, and fringing rushes such as *Schoenoplectus* sp. and *Eleocharis* sp. Further from the water's edge, the narrow zone of riparian vegetation gives way to low plains of soft spinifex (*Triodia epactia*) and hard spinifex (*Triodia wiseana*) steppe with scattered gums *Eucalyptus leucophloia* (Snappy Gum) and *Corymbia hamersleyana* over-mixed *Acacia* species, *Hakea chordophylla* and *Grevillea pyramidalis* (Beard 1975a; 1975b).

Major disturbances to river bed and pool vegetation have resulted from variation in the pattern and volume of rainfall. The local topography, and resultant force of floodwaters can uproot young to semi-mature plants and other plants may die from being submerged for extended periods. Qualitative assessments of riparian vegetation have shown significant physical uprooting evident in both riparian and floodplain vegetation. These changes were a direct result of the high flows and

widespread flooding associated with high flow events, particularly Tropical Cyclone Monty in early March 2004. In the Robe River, the distribution and abundance of the weed, Indian Water Fern (*Ceratopteris thalictroides*), is considered related to both patterns of river flow and unrestricted livestock access to drainage channels (Streamtec 2008).

The peak flow patterns and flow regime of the Robe River, coupled with the confining topography in the areas of relevance to this study have determined that the resultant river profile is dominated by a large and broad gravel bed flood zone flanked by rarely breached terraces or steep rocky sides. Within the broad gravel bed, a main (primary) incised low-flow channel, and one or more secondary incised channels punctuate the relatively flat gravel bed zone. In certain zones, raised finer grained sediment islands support woodlands over hummock/tussock grass communities, while the bulk of more densely vegetated communities are restricted to within and flanking the primary and secondary incised channels. In some areas secondary channels leave the main gravel bed and follow other low zones before re-joining further downstream. Terrace zones are substantially higher than the gravel bed, and are generally composed on fined grained sediments with shrublands over relatively dense hummock/tussock grasslands. A cross-sectional schematic of this typical creek profile within the study area is provided in Plate 2-1.

In initial reports (ecologia & Streamtec 1992); pools within the Robe River were considered dependant on the high rates of algal primary production to drive ecological processes. High algal growth is often observed in monitored pools and it is likely that this is a major contributor to secondary water quality issues as the vegetation decays i.e. highest levels of nutrients have been recorded in pools with increased algal growth and increased turbidity levels.

Stream discharge volumes and water levels of the Robe River are monitored by the Department of Water (**DoW**) at the Yarraloola gauging station (DoW 2017). At present, the Robe River has experienced a relatively extended dry period (with respect to flows) after a relatively long period of seasonally wet years (see Figure 2-2). Recently, water levels in the River were anecdotally reported to be the lowest they have been observed for over two decades (Mr Peter Davies, pers. comm., 28 March 2017).

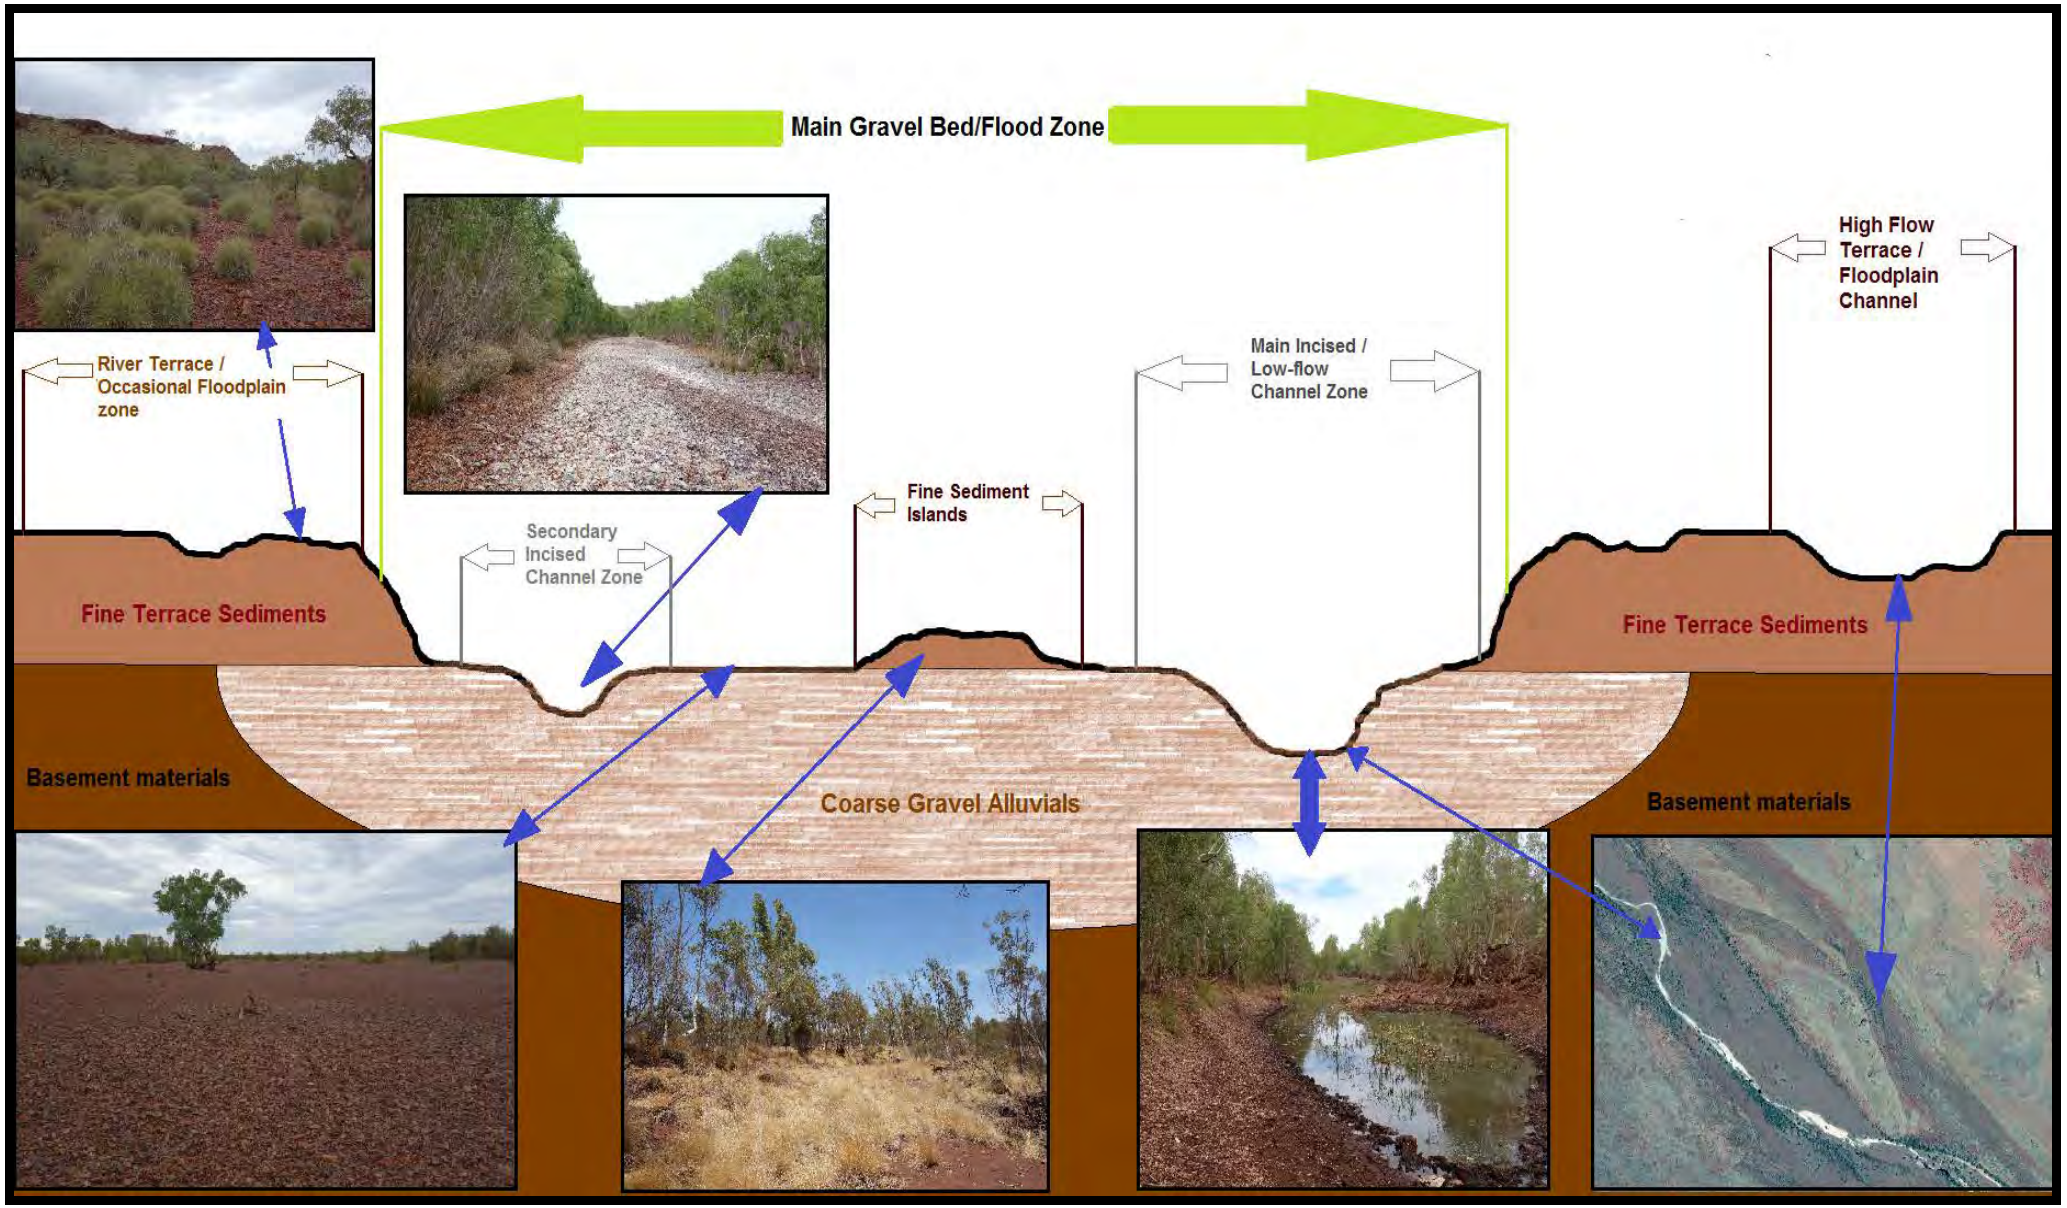

Plate 2-1: Cross-section schematic showing the typical channel profile of the Robe River within the study area, along with photos illustrating the typical appearance of key zones.

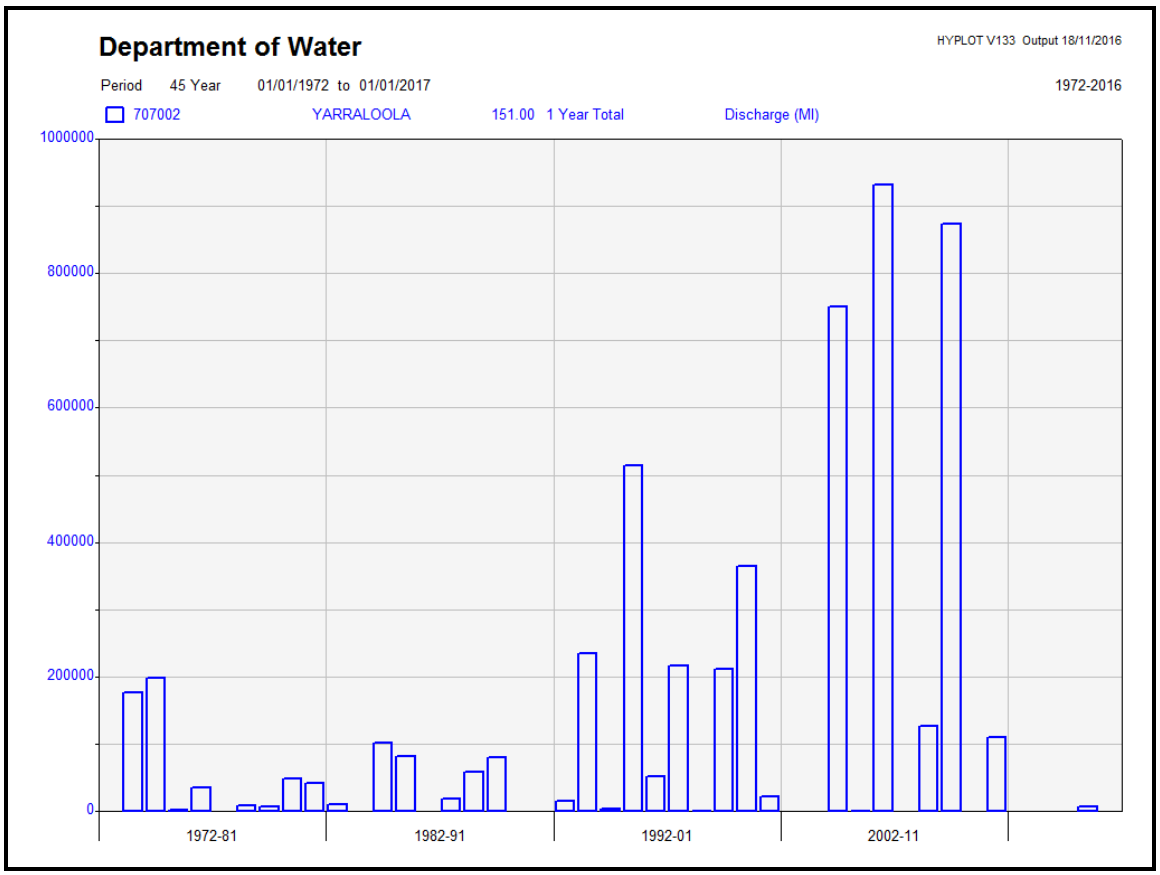

Figure 2-2: Department of Water (DoW 2016) historical river flow data from the Yarraloola gauging station on the Robe River.

2.7 JIMMAWURRADA CREEK

Jimmawurrada Creek, and the adjoining Bungaroo Creek, is part of a pair of broad, low-gradient valleys (with substantial adjoining rugged upland areas), which are prone to flooding after seasonal, tropical storms and cyclones. Cutting through the Buckland Hills and Mount Dempster areas, the creek valleys are bounded to the south, and in some parts to the north by steep scarps, mostly formed of the resistant Dales Gorge member of the Brockman Iron Formation (Rio Tinto 2011b). The Bungaroo Valley is approximately 0.5 km wide at the upstream end and 4 km wide where it confluences with Jimmawurrada Creek about 30 km downstream. The valley formed by Jimmawurrada Creek is approximately 9 km wide at the eastern end. Both valleys (particularly Bungaroo Valley) contain numerous braided, dry creek beds that are prone to flooding during the wet season (Rio Tinto 2011b).

Bungaroo Creek joins Jimmawurrada Creek in the lower part of the catchment area, to provide approximately 1600 square kilometres of total catchment area. On its own, Jimmawurrada Creek has a catchment area of about 400 square kilometres, while the catchment for Bungaroo Creek is in the order of 1200 square kilometres.

2.8 ROBE RIVER HYDROGEOLOGY

The major aquifer underlying the Robe River is contained within the gravelly alluvium which has a saturated thickness of up to 15 m adjacent to the main channel and extends laterally up to 5 km across the Robe River Valley (Antao & Braimbridge 2010). Groundwater flow through the gravels is thought to maintain permanent pools in the Robe River (Wetland Research and Management (WRM) 2016). The gravelly aquifer is underlain by fractured, permeable Trealla Limestone and highly transmissive Robe Pisolite. Robe Pisolite is a pisolitic alluvial sedimentary rock that fills the broad

valley between ridges of the Brockman Iron Formation and outcrops along the Robe palaeochannel (EPA 1991). The ore deposits at in the mesas along the Robe Valley are CIDs derived from pisolite limonite within the Robe Pisolite. The CID is comprised of iron ore detritus from weathering and erosion of the Brockman and Marra Mamba Iron Formations (Morris & Ramanaidou 2007).

Groundwater flow in the Pisolite is towards the Robe River and where the Pisolite is deepest, probably contributes to base-flow within the Robe River (Aquaterra 2005). The gravel and Pisolite aquifers are recharged primarily via river discharge. Modelling by DoW indicates the aquifers have the potential to absorb a significant percentage of river flow, however, due to the unpredictable flow regime, recharge is very low in two out of every five years (Antao & Braimbridge 2010). Near the Jimmawurrada-Robe confluence, the Pisolite is very shallow and unsaturated. Stream-aquifer interaction upstream in the Bungaroo and Jimmawurrada valleys contributes to recharge along with direct rainfall infiltration (WRM 2016).

2.9 PREVIOUS SURVEYS

A significant amount of survey work has been conducted in the Robe Valley locality since mining development began in the 1980's. Table 2-3 outlines the relevant flora and vegetation surveys conducted in the area which intersects the Robe River. The most relevant and recent studies have been conducted by Astron Environmental Services Pty Ltd and Biota Environmental Sciences Pty Ltd (Table 2-3). This body of work has essentially sampled/surveyed a riparian environment which had already seen some degree of impact from pastoralism, mining and from surplus dewater discharge from mining activities at Mesa J and natural events (cyclones, flooding and fires). The survey boundaries of previous relevant flora and vegetation studies are presented in Figure 1-1 in relation to the Boundary of the current study area. A recently conducted flora and vegetation survey (MWH Australia Pty Ltd (MWH) 2016) which intersects the Robe River in the vicinity of Mesa A, does not shed any additional light on the riparian communities of the Robe, as it covers the same region of the Robe River as that covered by Biota (2011). The sampling work conducted as part of MWH's 2016 survey does however elevate the survey coverage in this area to that of a seasonal survey given that Biota only conducted one phase of sampling in 2011.

Table 2-3: Summary of relevant vegetation and flora surveys intersecting the Robe River.

Study (Reference)	Area Surveyed Within Study Area	Survey Description Survey Timing (Conditions for Plant Growth)	Available Data
Middle Robe and East Deepdale Level 2 Vegetation and Flora Assessment, September 2015 (Astron Environmental Services Pty. Ltd.) (Astron 2015) (plus an additional phase of work conducted by ecologia (2013)	11,816 ha	Two phase (Level 2 - Detailed) vegetation and flora assessment survey of the Middle Robe to East Deepdale area to expand upon previous work conducted by Biota (2006), Astron (2011), and ecologia (2013). 15 to 27 June 2015 (favourable); 21 September to 3 of October 2015 (acceptable). ecologia – single phase – July & August 2012 (Sub-Optimal conditions)	– Quadrats/relevés/mapping notes. – Conservation significant flora and weeds. – Floristic analysis – Vegetation mapping. – Vegetation condition assessment. – Species list.
Baseline Flora and Vegetation Assessment of Robe Valley Mesas (Mesas B, C, D, E, F, H and I), April 2011 (Biota Environmental Sciences) (Biota 2011) (plus an additional phase of work conducted by Astron (2014)).	9,494 ha	Single phase (level 1 – reconnaissance) vegetation and flora assessment of various mesas in the vicinity of Pannawonica. This comprised; Mesa B (980 ha), Mesa C (850 ha), Mesa D (737 ha), Mesa E (1,502 ha), Mesa F (2,626 ha), Mesa H (2,252 ha), and Mesa I (547 ha). 11 to 19 October 2011 (sub-optimal) Second phase conducted by Aston 2014 (acceptable conditions)	– Quadrats/relevés/mapping notes. – Conservation significant flora and weeds. – Vegetation mapping. – Vegetation condition assessment. – Species list.
Level 2 Flora and Vegetation Survey: Mesa B-C, Warramboo BWT, Highway to Tod Bore and Mesa A Extension, August 2016 (MWH Australia Pty. Ltd. (MWH) 2016).		Two Phase (Level 2 – Detailed) vegetation and flora assessment over a study area that incorporated four separate Project Areas; Mesa B-C, Highway to Tod Bore, Warramboo BWT and Mesa A Extension, as well as the establishment of a vegetation monitoring program and baseline assessment at Warramboo Creek. 8 to 21 June 2015 (acceptable) 2 to 8 September 2015 (sub-optimal) 3 and 8 May 2016 (sub-optimal)	– Quadrats/relevés/mapping notes. – Conservation significant flora and weeds. – Floristic analysis – Vegetation mapping. – Vegetation condition assessment. – Vegetation monitoring establishment – Species list.
A Vegetation and Flora Survey of the Proposed Mesa A Transport Corridor, Warramboo Deposit and Yarraloola Borefield, January 2006 (Biota 2005; Biota 2006)	7,878 ha	Two phase (seasonal) vegetation and flora survey of two transport corridors (haul road (500m wide) and Rail (200m wide)) from Mesa A to Mesa J, the Warramboo deposit study area (approximately 2.5 x 2.5 km in size), and a bore field on Yarraloola station with pipeline corridor to Mesa A. July 2004 (Favourable) September 2005 (Favourable)	– Quadrats/relevés/mapping notes. – Conservation significant flora and weeds. – Floristic analysis – Vegetation mapping. – Vegetation condition assessment. – Species list.

2.9.1 Resultant Vegetation Mapping

Previous vegetation mapping covering the study area has been completed at a resolution commensurate with the environmental impact assessment (**EIA**) objectives for which it was commissioned. Generally, flora and vegetation surveys conducted for the purpose of EIAs are commissioned with the aim of sampling and documenting all the values present. As a result sampling effort is spread widely and the level of detail attained is typically proportionate to the size of the area, number of landforms present, and the extent of areas of elevated ecological value.

The "Middle Robe" flora and vegetation survey conducted by Astron (2015) represents the most detailed and extensive of the vegetation models available on the Robe River. This mapping provides an important platform for the current study; however the objectives of the current study determined that mapping with much greater spatial confidence and at a finer resolution was required. Improving the spatial confidence and detail of riparian vegetation mapping would help increase knowledge in the riparian zone and increase the understanding of the local environmental values (and their distribution), and hence increase the effectiveness of environmental management. The key point of difference between the current study and previous vegetation studies is the consideration of age structures within OPV, the resultant degree of differentiation proposed within these communities and the focus on accurately mapping the distribution of the higher sensitivity OPV and Facultative Phreatophytic Vegetation (**FPV**) communities.

3 METHODOLOGY

3.1 VEGETATION MAPPING WITH A FOCUS ON GDE CHARACTERISTICS AND DISTRIBUTION

3.1.1 Introduction

To achieve the vegetation mapping aims of this study; a "Targeted Survey" was conducted as defined under the EPA Technical Guidance; Flora and Vegetation Surveys for Environmental Impact Assessment (EPA 2016b). The vegetation mapping conducted as part of this study focused on gathering high confidence and relatively detailed information on the distribution and characteristics of GDEs within the Robe River. This was achieved by primarily focusing on gathering information about the maturity and distribution of OPV. A secondary data focus was placed on gathering information on the distribution of FPV; particularly the distribution patterns exhibited by *Eucalyptus camaldulensis* (River Red Gums). The primary focus on OPV is motivated by the fact that this vegetation represents that possessing the highest degree of sensitivity to surface and groundwater hydrological changes potentially associated with mining.

As the most hydrologically sensitive Pilbara communities are typically those with a significant component of *Melaleuca argentea*; an initial review was undertaken to identify desktop tools and resources suitable for helping identify the likely distribution of OPV communities. A field plan capable of ground-truthing the predicted and potential spatial distribution markers for OPV and FPV communities in the study area was developed following completion of the desktop mapping process. This field plan was also developed with the aim of compiling additional fine scale information about the spatial distribution and composition of other less sensitive/significant vegetation communities (FPV) within the study area, for the purpose of supplementing the vegetation mapping process.

The desktop resources and mapping, together with the field plan allow for the acquisition of a relatively comprehensive dataset on the spatial distribution (mapping) of key riparian vegetation communities throughout the study area. This desktop and field-based assessment is also designed in a way which collects information which provides a framework for contextualising and assessing the potential for hydrological changes to impact riparian communities in the study area.

It should be noted that the vegetation mapping process and the resultant field survey effort attributed to the study area was conducted on riparian units occurring within the major riparian habitats of the study area. As part of this process, a high degree of survey effort was afforded to the riparian units in the main incised channel zone (low flow channels) of the river compared to the outer fringing communities and the river terrace and outer floodplain communities (see plate 2-1 for a schematic of the key river profile features of the Robe River).

In an effort to maintain the logic and intent of coding attributed to recent GDE mapping conducted by the author, the same coding regime as Rio Tinto (2015) was attributed to vegetation types identified in this study.

With respect to data collection methods; this survey noted the adequate amount of Quadrat/Relevé based data collection which has previously been conducted within various parts of the study area. This survey also noted that mapping traverses had previously been used to a lesser extent than quadrat/relevé based techniques in the riparian zone of the study area. Coupled with the GDE focus of the study; it was concluded that the degree of information on the associated floristic composition

of riparian communities already captured within the Robe Valley area was sufficient to meet the objectives of this study. Mapping traverses were, therefore, considered to be the most effective method for targeted vegetation mapping in this study. Mapping traverses, generally comprise walking through the target area and regularly taking notes and spatial information on the apparent vegetation associations/sub-associations present, and the location and pattern of boundaries which separate them (see Section 3.1.3). By aligning these traverses to maximise their potential to regularly test the spatial position of these vegetation boundaries, the resultant traverse pattern quickly establishes an effective and extensive database with which to correlate on ground vegetation distribution with vegetation signatures present within aerial photography. The use of mapping traverses oriented to repeatedly intersect and establish the location of vegetation boundaries allows for the development of robust (high confidence) fine scale vegetation mapping in the areas investigated.

It should be noted that vegetation mapping is essentially a model, such that the spatial validity of boundaries and the vegetation associations depicted to lie within those boundaries, is only true a portion of the time. In general, the proportion of time which the model is correct is directly correlated to the amount of ground-truthing which is done per unit area of the model, and the scale of the community descriptions created. The third influencing factor is generally considered to be the complexity of environmental factors influencing vegetation ecology, but for the surveyor this is an uncontrolled factor and is therefore not generally considered in detail.

For the vegetation mapping model presented as a part of this study; a key aim was to provide a high degree of accuracy in relation to the spatial location and distribution of resident OPV communities. As a result the degree of ground-truthing effort conducted within the core riparian zone (particularly the incised channel zone) was very high, such that the mapping is considered to be significantly more accurate than typical quadrat/relevé dominated sampling methodology and subsequent vegetation mapping undertaken in typical flora and vegetation surveys within WA.

3.1.2 Tools developed at a desktop level for increasing the effectiveness of in field mapping traverses

Photosynthesising vegetation covering the Robe River was assessed using Normalised Difference Vegetation Index (**NDVI**) images generated from high resolution (0.5 m pixel) remotely sensed digital multispectral imagery (**DMSI**). NDVI relies on the fact that photosynthetic organisms have the unique characteristic of reflecting nearly all infra-red electromagnetic radiation, and absorbing significant amounts of the red visible wavelength of electromagnetic radiation (used for photosynthesis) (Specterra Services 2010). As a result, an index calculating the ratio between the intensity of the two wavelength ranges provides a simple measure of vegetation cover/density or greenness. NDVI imagery of the relevant river stretches were visually assessed by a specialist botanist for patterns in and occurrences of high-density vegetation signatures (i.e. areas where a comparatively high degree of vegetation cover was evident in comparison to surrounding riparian vegetation cover signatures) likely to indicate the presence of mesic conditions, and therefore potential GDEs. GDEs such as OPV are recognised to be associated with a high degree of water availability and often groundwater presence. This persistent presence of moisture generally facilitates the establishment of relatively dense combined vegetation cover (i.e. canopy cover, combining with shrub and groundcover strata to provide aerially dense cover signatures) when compared to surrounding, more widespread riparian vegetation. Areas of the riparian system showing comparatively higher measures of vegetation cover are often the areas where groundwater

is close enough to the surface to provide adequately consistent soil moisture availability and conditions suitable for the establishment of species such as *M. argentea*. Plate 3-1 presents an example of a high density NDVI signature and one example of a sparse NDVI signature. At a desktop level, anomalously high vegetation cover signatures were identified and mapped throughout the study area, and used in conjunction with NDVI maps for the purpose of guiding field based ground-truthing of mesic vegetation signatures. Plate 3-2 presents an example of the summarised NDVI imagery (for the stretch from Yeera Bluff to the confluence with Jimmawurrada Creek) produced over the study area which was used as a supporting tool for the GDE interpretation and ground-truthing process.

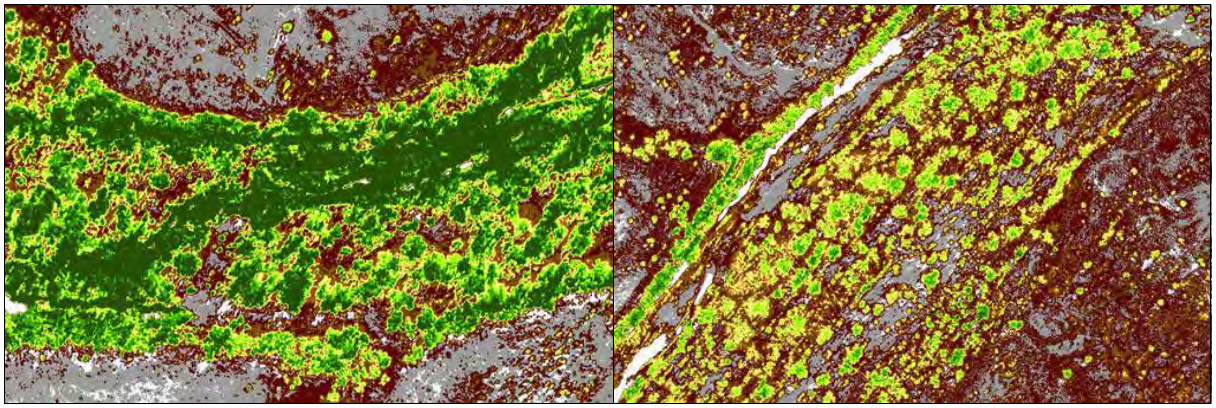

Plate 3-1: Samples of NDVI image showing a high density NDVI (vegetation cover) signature on the left and a sparse cover NDVI signature on the right

Historical aerial photography and true colour DMSI was also visually assessed to identify and digitally map areas of anomalously dense vegetation and consistently formed canopy cover which might identify the spatial location of OPV or more mesic FPV. As part of this process; an alternative set of digital polygons were produced which represented the pure shrubland communities, and separately all the open woodland and above treed riparian communities.

Polygons digitised from both NDVI images, DMSI and historical aerial photography were uploaded to a GPS, along with other relevant environmental layers such a 50k hydrology and historical vegetation mapping.

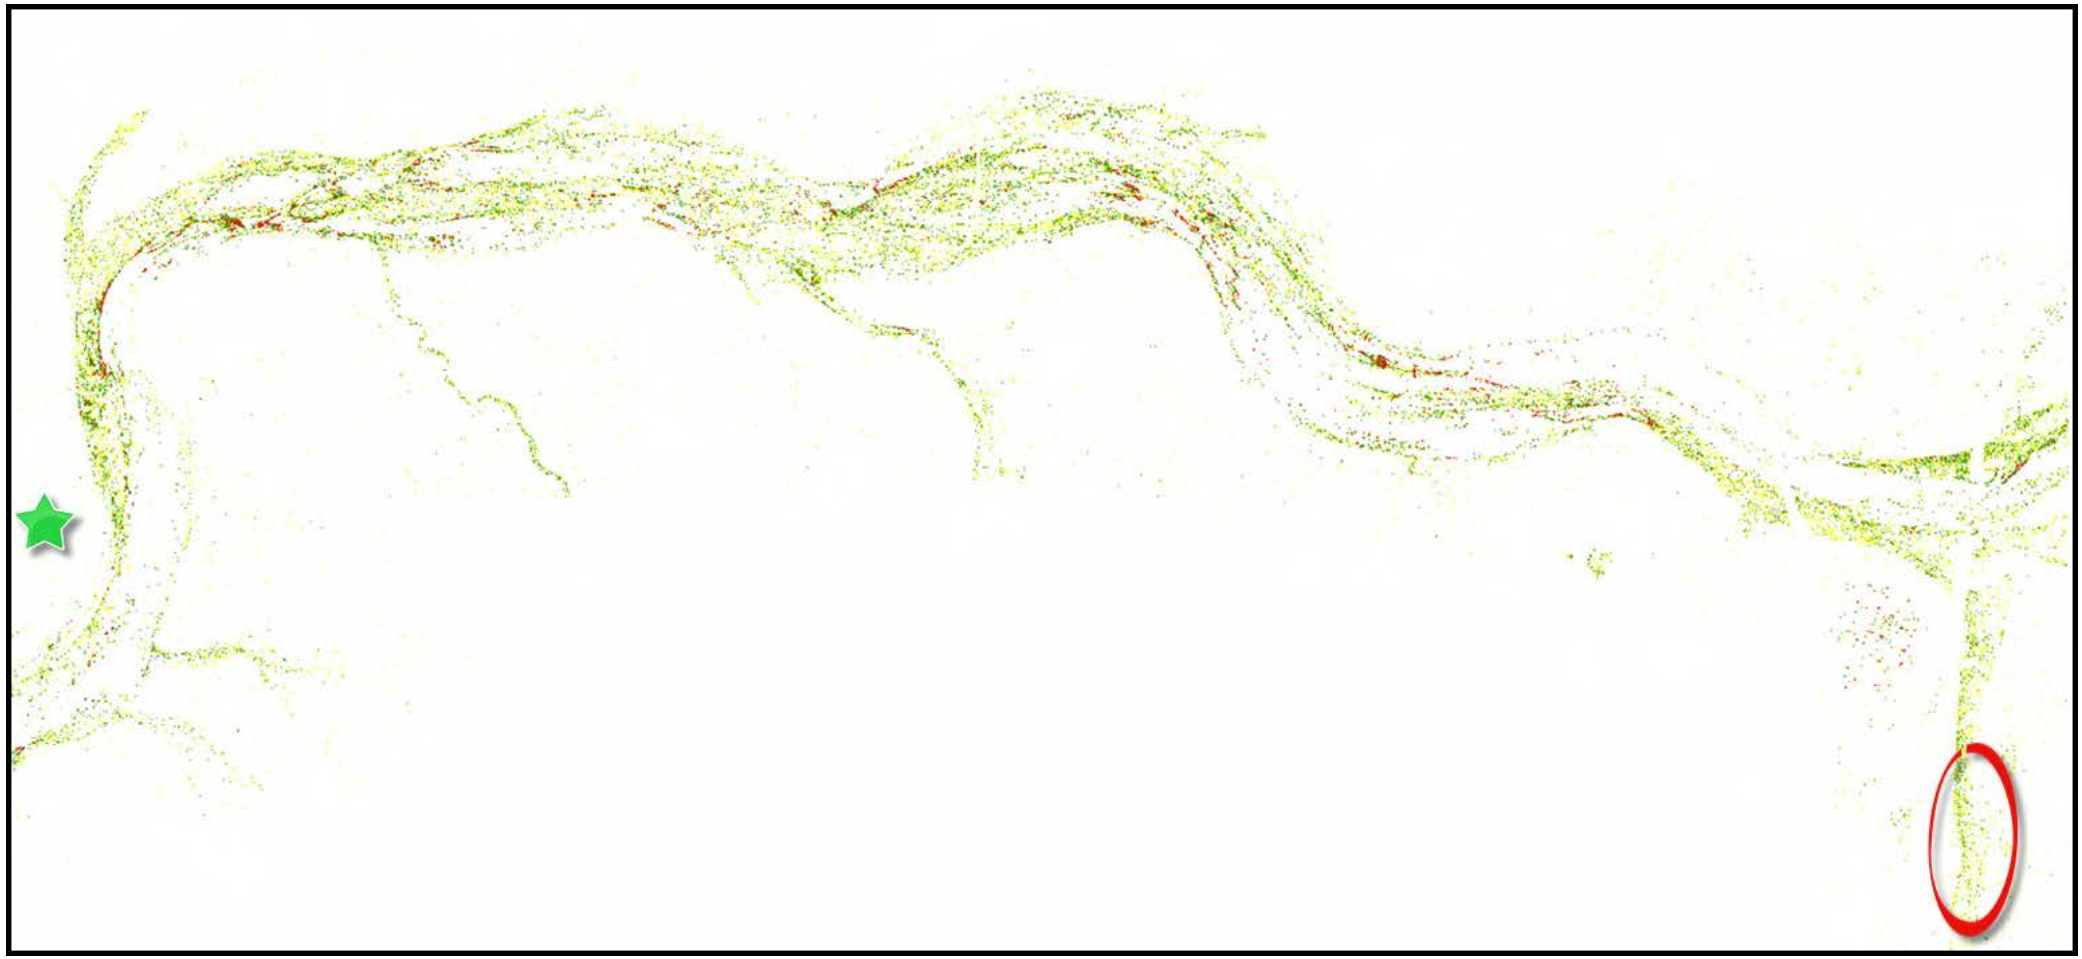

Plate 3-2: Example of the summarised NDVI imagery produced as a ground truthing tool for use when surveying the Robe River (between Yeera Bluff (position indicated by green star) and Jimmawurrada Creek (identified by red circle))

3.1.3 Ground-truthing and Mapping Refinement Field Work

A field data collection framework was devised to focus on the following key tasks within the Robe River study area:

- Traverse the entire width of the gravel bed and incised channel profile (while periodically intersecting the inner portion of the adjacent terrace features) and key high-flow channels to gain an understanding of the ecology and distribution of significant riparian communities present within their boundaries. In addition; gaining an overarching awareness of the variability, morphology and spatial distribution of the different creek profiles and associated substrates present throughout;
- Ground-truthing of all relevant identified dense vegetation signatures and anomalous NDVI signatures to confirm the presence/absence of phreatophytic species (namely *Melaleuca argentea*, and to a lesser extent useful GDE indicator species such as *Eucalyptus camaldulensis, Acacia ampliceps, Sesbania formosa*, Cyperaceae spp., etc.) and associated communities, and
- Record specific data about the spatial boundaries/distribution of OPV, and the size and age structure (and spatial boundaries) of *Melaleuca argentea* populations encountered throughout.

Within the relevant section of the Robe River; the incised channel width is variable but generally observed to be in the order of 300 to 1,000 m wide, and likely inundated by 3-5 year ARI (Average Recurrence Interval) stream flow events. Due to the surrounding topography of the relevant stretch of the Robe River, the surrounding terrace/floodplain zone is relatively narrow for the most part due to the wide gravel bed zone effectively incorporating a significant proportion of the river floodplain.

It was anticipated that these key tasks would be carried out by directing field traverses and associated survey effort in a way which ultimately was a guided by the interaction of four key drivers to traverse pattern:

1. Firstly; it was determined that typical vegetation distribution patterns were likely to be aligned in a linear fashion parallel to the direction of primary/secondary and minor flow channels. A traverse pattern which intersected perpendicular to these perceived boundaries was deemed most effective at ground-truthing digitised vegetation polygons and collecting the most representative spatial dataset for the fine scale extrapolation of vegetation boundaries. Therefore a zig-zag style traverse pattern was determined the best technique to use when traversing the creek.
2. The second process was the use of the NDVI image and desktop NDVI, DMSI and aerial photo signature mapping to influence the surveyor's fine scale travers pattern decisions. Essentially this relates to the process of aiming successive zig-zag traverses across the creek in a manner which will intersect digitised vegetation patches of most relevance to mapping GDE presence. This process of successive aiming is primarily driven by the use of the desktop mapping tools previously described or by visual cues described below in point 3.
3. The density, height and distribution of the vegetation present would determine that not every part of the creek could be viewed and assessed for the presence of OPV. To reduce the chance of missing such communities the direction and path of successive meanders would also be influenced by the visual cues to these communities which were gathered each time the surveyor moved through sections of the creek which allowed clear view of vegetation over longer distances.
4. The final driver to traverse pattern was the observed patterns in the morphology and variability of the creek profile. Such patterns and characteristics significantly influence the associated distribution patterns of phreatophytic vegetation, and can therefore be interpreted in field to predict the ongoing distribution of such vegetation. In certain river sections;

interpretation of these morphological patterns (in concert with desktop mapping) gave additional confidence that certain zones of the creek were devoid of OPV, thus allowing much smaller wavelength zig-zag traverse patterns to be employed. This in turn meant that lateral traverse distances were typically much smaller allowing a much greater degree of focus on the most relevant river bed zones.

The resultant traverse pattern and data capture array realised in the field is presented in Figures 3-1 to 3-8 as track logs and data points recorded via GPS. Throughout this traverse pattern; the following types of data were recorded at the resultant array of waypoints recorded within the study area.

- "Structurally Present" or "Structurally Absent" *Melaleuca argentea* populations – "Structurally Present" equating to a cover/abundance considered as comprising a dominant/co-dominant structural component of the stratum which it occupies, and not generally representing a cover/abundance below 1-2 %. "Structurally Absent" represents either not detected within the vicinity of the record whatsoever or only present as an associated species. For the purpose of this work, and more generally; associated species are defined as those species not comprising a dominant structural component of vegetation and typically not representing a cover/abundance above 1-2 %.
- The presence of *M. argentea* if only present as an associated species. In these cases records were generally prefixed with an "N" cover/abundance so that its cumulative distribution could be considered spatially.
- The intersected boundary locations of riparian communities where *M. argentea* populations are deemed "Structurally Present" (i.e. OPV).
- The cover/abundance *M. argentea* populations recorded as a "Structurally Present" (i.e. representing a dominant/co-dominant member of the vegetation).
- The position (and where able to be easily conveyed; the dimensions) of any sizeable "patches", "strips", or "thin strips" of riparian vegetation where *M. argentea* was considered "Structurally Present". In most cases, where appropriate, the close alignment/association of such "patches" with bodies of water or clear channels was noted in the data recorded.
- The size class (as a proxy of age) range of any recorded *M. argentea* populations and any spatial boundary points which are relevant to the recorded size-class range – In all cases the recordings were for the population either in the vicinity of the recorder ("internal" record) or throughout the area delineated by the relevant recorded spatial boundary points ("boundary" record). These size classes were inferred based on a visual assessment of the average trunk diameter, or the average range of trunk diameters present throughout the relevant population in sight. The size class/range determined at data points was allocated to populations via the use of terms which represented the various size classes used. In many cases (where appropriate – i.e. the size structure showed minimal variability) an average size class was recorded (such as Young), and in other areas where size structure was more variable a range was given (i.e. Young to Semi-Mature-minus). The size class terms used were:
  - 'Mature' (M);
  - 'Semi Mature Plus' (SM+);
  - 'Semi Mature' (SM);
  - 'Semi Mature Minus' (SM-);
  - and 'Young' (Y).

  The definition of each of these size classes and the representative terms used in the field are presented in Table 3-1.

- Mapping notes – general notes on vegetation or mesic species present at point locations. This often involved assigning vegetation to pre-determined associations/sub-associations or previously identified and mapped riparian communities/units.
- Photo points – points where multiple photographs (minimum 4) were taken of the vegetation surrounding the record. These were used to gather a quick database of vegetation information across the study area. This data is particularly relevant in areas of more benign (from a GDE perspective) vegetation where detailed information was not required, but for which high resolution photos help to significantly increase the accuracy of the entire vegetation model produced.

The above data collection framework was used to collect data in the field over two field trips conducted by Rio Tinto Botanist Jeremy Naaykens and with the assistance of RTIO Environment staff Hanouska Bishop and Caitlin O'Neil. The first field trip focused on the downstream half of the study area and was conducted from the 18th to the 23rd of December 2016. The second field trip focussed on the upstream section and was conducted from the 14th to the 20th of January 2017.

Table 3-1: Definitions for the stem size classes used to classify the average trunk diameter (or range of trunk diameters) of *Meleleuca argentea* populations encountered in the field, and allocate these populations to a perceived age class (or age class range) and an infered degree of permanency.

Stem Size classes (as a proxy for age)	***Melaleuca argentea* individuals/populations which were visually estimated to possess:**	**Vegetation which was generally dominated by individuals/populations of this size (but not larger) were generally inferred to :**
M - Mature trees	Trunk diameter(s) at knee to waist height in the **Range of 50cm and above**	Represent areas where bed and subsurface conditions are likely to have consistently supported *M. argentea* communities for a relatively long period of time within the relevant section of river bed. For this reason, their presence in this location was considered to be stable and therefore of higher significance when considering potential for impact.
SM(+) - Semi Mature plus	Trunk diameter(s) at knee to waist height in the **Range of 30-45cm**	Represent areas where bed and subsurface conditions have somewhat consistently supported *M. argentea* communities within the relevant section of river bed. However, in such areas, conditions may have only become suitable for *M. argentea* to proliferate in the last 10 years or more.
SM - Semi Mature	Trunk diameter(s) at knee to waist height in the **Range of 20-30cm**	Represent areas where bed and subsurface conditions are either only moderately variable or have more recently become suitable to support *M. argentea* communities within the relevant section of river bed. Communities dominated by this size class are often fringing secondary channels within the main river bed and appear to be more influenced by surface water regimes than increasingly mature *M. argentea* communities.
SM(-) - Semi Mature minus	Trunk diameter(s) at knee to waist height in the **Range of 10-20cm**	Represent areas where bed and subsurface conditions are likely to either be quite variable, or have changed in recent to very recent times, such that *M. argentea* populations are now supported. Communities possessing a dominance of *M. argentea* individuals in this size class are most likely to represent areas which are currently only able to support more transient populations of this species.
Y - Young	Trunk diameter(s) at knee to waist height in the **Range of less than 10cm**	Represent areas where bed and subsurface conditions are likely to either be too variable, or have changed in very recent times, such that *M. argentea* populations are now supported. Communities possessing a dominance of *M. argentea* individuals in this size class are most likely to represent areas which are currently only able to support more transient populations of this species. For this reason the significance attributed to their presence (when considering potential for impact) is heavily reduced due to their likelihood of being absent more often than not.

Note: *M. argentea* populations were allocated to size classes in the field based on visual estimates of trunk diameter and as such there is some potential for inaccuracy. In all cases the recordings were a range estimate for the entire population in view of the recorder. In many cases (where appropriate – i.e. the size structure showed minimal variability) an average size class was recorded (such as Young), and in other areas where the size structure was more variable a range was given (i.e. Young **to** Semi-Mature-minus). Diameter estimates are based on the diameter at knee to waist height of the observer, as the branching habit of individuals in the younger size classes make it impractical to estimate diameter at breast height – a more commonly used standard for tree diameter measurements.

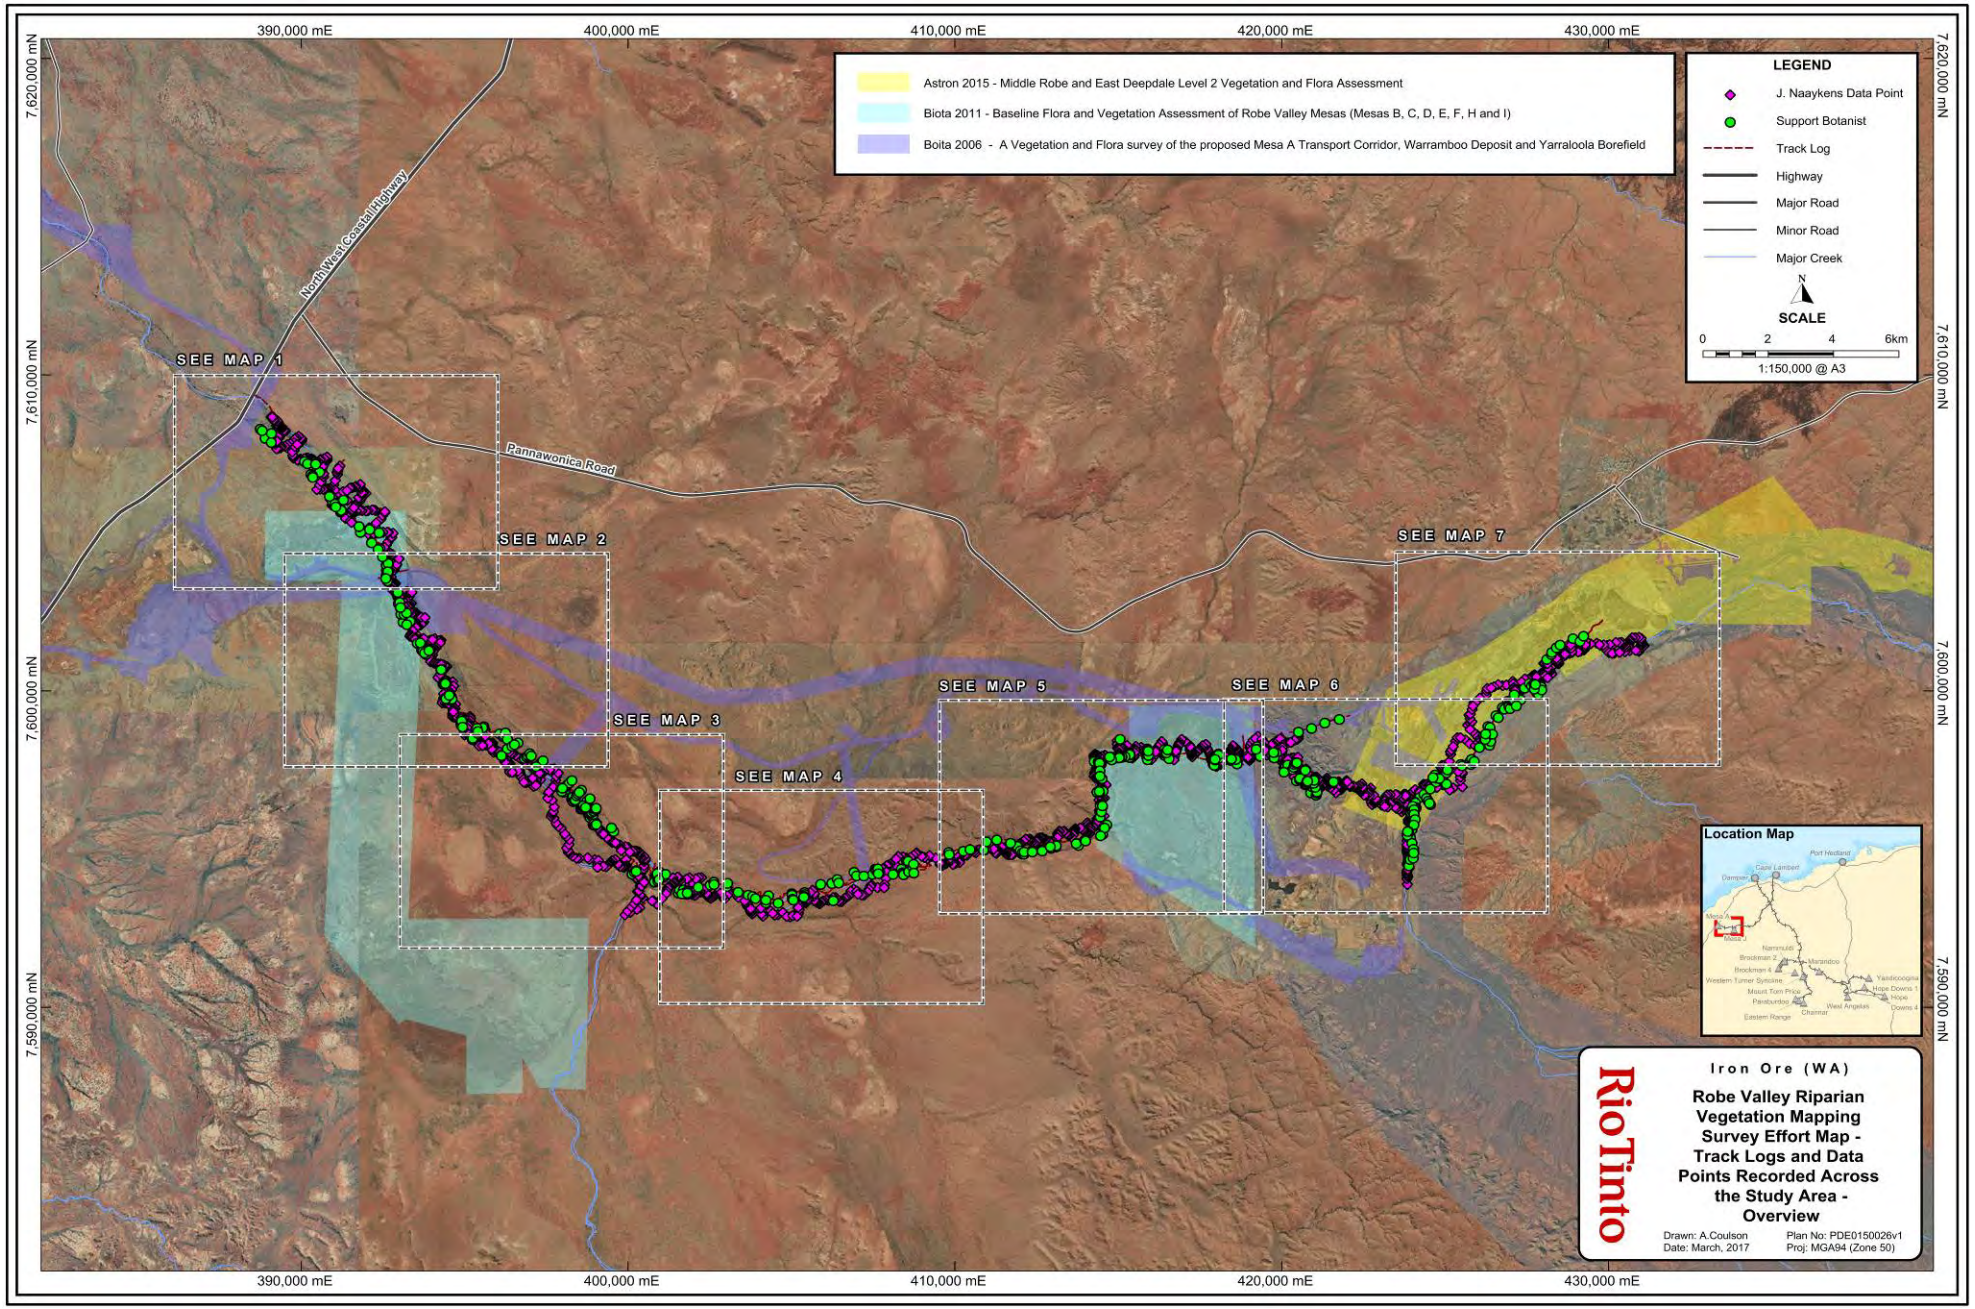

Figure 3-1: Overview of survey effort maps 1 to 7. Maps 1 -7 depict the survey effort conducted within the study area by showing the track logs and data points collected throughout using a GPS. This map also shows the most relevant previous riparian vegetation mapping surveys conducted across the study area.

3.1.4 Post Field Work Vegetation Mapping

Classification and mapping of OPV communities across the study area

Following field acquisition, data was entered within Microsoft Excel and uploaded to a GIS (Mapinfo Pro, Encom Discovery 2011). This GIS data was initially analysed to gain a broad scale understanding of the distribution of OPV within the study area. Once general distribution patterns were established and considered in relation to the location of different river reaches, adjacent topographical features and broad patterns of river morphology, all data relating to OPV were used to identify and classify 6 different OPV community types across the study area;

1. a "Mature" *Melaleuca argentea* (**MA**) dominated closed forest.
2. a "Mature" MA dominated open forest.
3. a variable "Mature" (to "Semi-mature") woodland co-dominated by MA and *E. camaldulensis*
4. a variable "Young" to "Semi-mature" low woodland (to tall shrubland) of MA and *Eucalyptus* pp.
5. a "Young" shrubland (to open shrubland) of MA *and E. camaldulensis* saplings
6. a "Young" (to "Semi-mature") low open forest of *MA* (low trees to saplings).

These six communities were split on their structural and compositional characteristics and by their degree of "Maturity" (inferred from recorded size class ranges). Therefore; the inferred degree of structural/compositional stability and inherent significance is able to be reasonably attributed to each. Using the complete OPV dataset and commonly accepted data point correlation and extrapolation techniques, the spatial boundaries of all OPV communities encountered in the study were mapped at a fine scale. Correlation and extrapolation techniques generally involve the correlation of vegetation data with aerial photo signatures and the subsequent extrapolation of that data across the extent of the relevant aerial signature. These polygons were mapped to represent areas where the cover/abundance of *M. argentea* was deemed to comprise a significant component of the resident community's structure and therefore represent a co-dominant/dominant structural component as opposed to merely an associated species.

Factors used in the process of allocating various patches of OPV encountered in the field to one of the six OPV communities included the following.

1. the variability/range of the inferred age structure recorded (inferred based on trunk size classes) within a mapped vegetation patch.
2. the maximum inferred *M. argentea* size for each representative vegetation patch.
3. the general structure and composition (particularly the presence absence of key mesic indicator species) of the vegetation within which the *M. argentea* populations occurred.
4. the distribution of each community in relation to key morphological features of the river (e.g. fringing pools, fringing scoured channels, outer banks, high flow channels etc.).

Once all occurrences of these OPV communities were mapped; for the purpose of presentation within this study, certain communities were amalgamated to produce a simpler complete vegetation model. Of the 6 community types from the preceding list; the 6th was combined with the 3rd type, and the 5th combined with the 4th type. The "Young" (to "Semi-mature") low open forest of MA (Type 6) was combined with the variable mature woodland (Type 3) due to its generally close spatial association with mature communities alongside large relatively permanent pools. Amalgamation of this community with the other more transient and less significant "Young to Semi-Mature" structured communities is considered incongruent from sensitivity, significance and spatial standpoints, despite the some similarities in age and physical structure.

The amalgamation of types 4 and 5 was an obviously complimentary choice and determined sound from all relevant standpoints.

Mapping FPV communities present within the study area

Following the OPV mapping process; the remaining wooded riparian associations (generally representing FPV) co-occurring with and often surrounding the OPV were refined based on targeted mapping notes, photo points, and interpretation of community and species specific aerial photo signatures.

The key task of this final mapping component was to establish, and spatially delineate FPV communities with a tree strata either dominated by *Eucalyptus camaldulensis* or co-dominated by *E. camaldulensis* and *E. victrix* (FPV), but which does not contain *Melaleuca argentea* as a co-dominant species. *Eucalyptus camaldulensis* is widely considered to be the more groundwater dependent of the riparian eucalypts which commonly occur in the study area. While *Eucalyptus victrix* is generally considered to be a facultative phreatophytic species, it is also recognised that this species is less reliant on groundwater access than *E. camaldulensis*, and more easily able to survive solely on vadose soil water sources. For this reason, mapping the distribution of *E. camaldulensis* (outside of OPV) is an important secondary step in the process of mapping varying degrees of community related groundwater dependence.

E. camaldulensis distribution mapping essentially either requires regular field notes on the presence/absence and abundance of *E. camaldulensis* in the field, or relies on some presence absence field data to help enable accurate interpretation of species specific aerial photo signatures. Within the Robe River; it was noted that canopy and stem related visual cues which often allow relatively confident differentiation between these two species were not clearly aiding this differentiation process during the field survey. For this reason, aerial photo interpretation was the key tool used for mapping the distribution of *E. camaldulensis*, and *E. victrix* in this study. This process was aided significantly by the use of recent high resolution (0.5 m) true colour DMSI imagery. High resolution 4-band aerial imagery enabled individuals/populations of *Eucalyptus camaldulensis* to be identified on GIS and therefore accurately mapped as either representing dominant or co-dominant vegetation communities. In order of relative usefulness in the Robe river locality; Individuals or groups of *Eucalyptus camaldulensis* within the riparian environment were distinguished on aerial photography from *E. victrix* on the basis of:

1. the generally darker green canopy colour signature of *E. camaldulensis*;
2. the generally denser canopy cover signature of *E. camaldulensis*;
3. the generally dissimilar branch signature of *E. camaldulensis* canopy architecture; and
4. the generally larger (spatial extent) canopy footprint of *E. camaldulensis*.

The available aerial photography was considered to be of a quality suitable for the application of the above described visual assessment and was found to be robust when ground-truthed using field data. Some more obvious and presentable examples of the aerial signature of *E. camaldulensis* trees from Weeli Wolli Creek are provided below in Plate 3-3. The examples presented in Plate 3-3 were generally chosen due to their location on an open floodplain, where canopy density is reduced and as such surrounding canopy species don't inhibit the display of the above described characters, thus making them easier for the reader to appreciate/visualise. Plate 3-4 shows examples of key eucalypt aerial signatures from the Robe River

All vegetation types mapped as part of this study, were described using Aplins' (1979) framework for "Vegetation Structural Classes" (Specht 1970). This framework is presented in Appendix 1, along with vegetation condition scale used in this study (Trudgen 1988). As such all communities (**Table 4-1**)

established as part of this study are generally considered to represent sub-associations. Community descriptions were created by identifying dominants (where present) for all relevant strata available, rather than restricted to the three traditional strata, such that they represent relatively detailed vegetation descriptions, approximately equivalent to level 5 mapping within the National Vegetation Information System (**NVIS**) (DoE 2014b).

Given the Stage 1 status of this study; some vegetation types mapped and described as part of this study are potentially more accurately classified as associations, or are lacking some of the structural/compositional differentiation which comes from sampling over multiple phases (as part of a detailed survey (EPA 2016b)). Furthermore; some of the non-core riparian communities of the high-flow and terrace riparian habitats are yet to be properly described and delineated throughout the study area. Given the focus of this study is on delineating groundwater dependent ecosystems the reduced level of detail provided for such communities is considered relatively inconsequential and of low significance when considering potential impacts.

Plate 3-3: Aerial photos showing examples of *Eucalyptus camaldulensis* canopies (inside orange polygon) on high resolution aerial photography (Weeli Wolli Creek)

Note: Beyond the more obvious shrub features, the majority of the remaining eucalypt canopies present in these plates are considered to be *E. victrix* as indicated by the relatively obvious white branch and trunk colouration, open branching habit and lighter foliage colour.

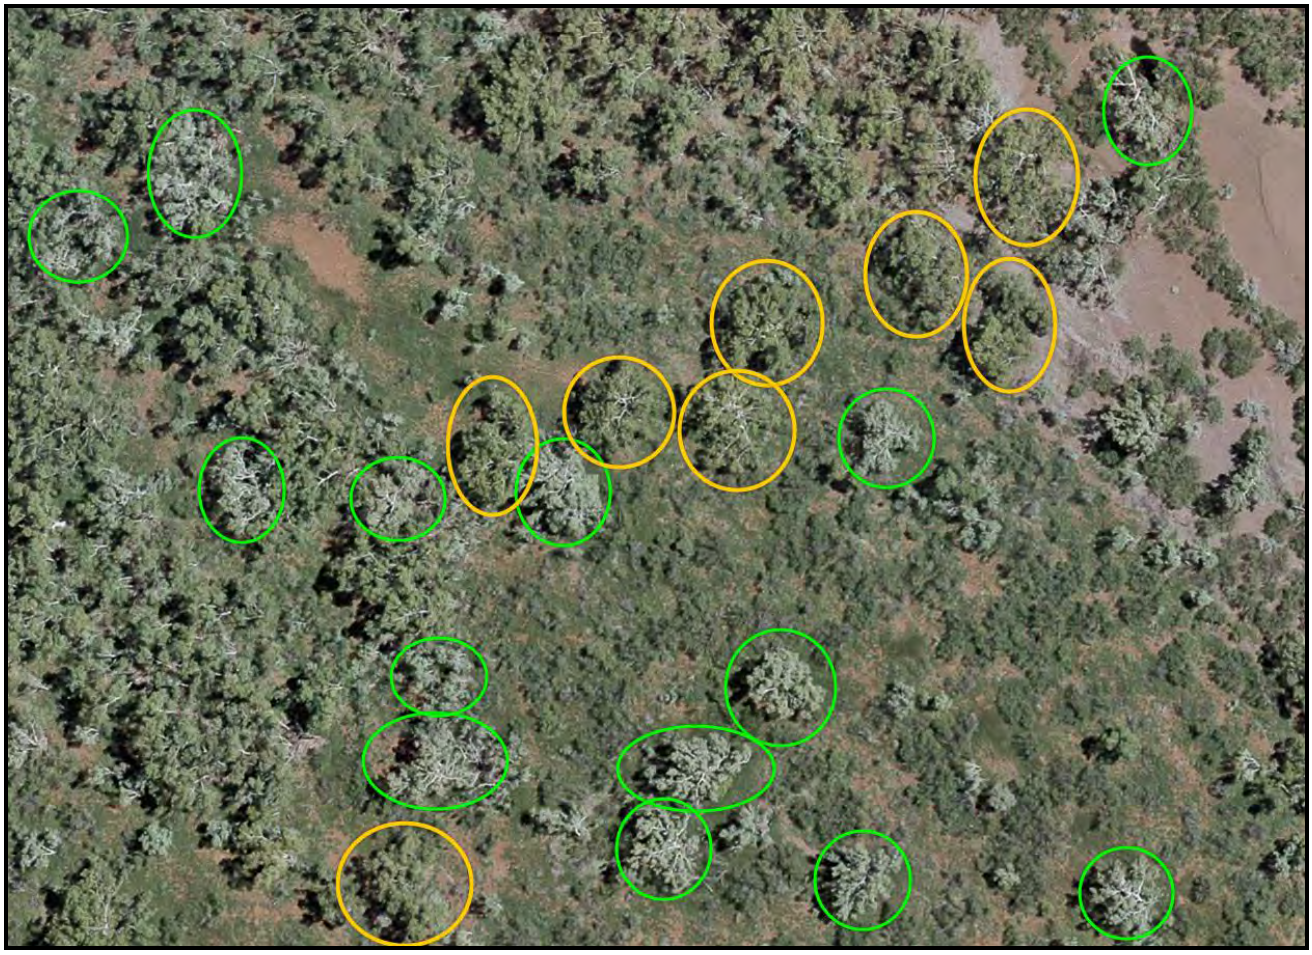

Plate 3-4: Aerial photos showing examples of Eucalyptus camaldulensis canopies (inside orange polygons), and E. victrix (inside green polygons), on high resolution aerial photography within the Robe River (April 2017)

3.2 SIGNIFICANCE FRAMEWORK USED TO ASSESS THE LOCAL SIGNIFICANCE OF RIPARIAN COMMUNITES MAPPED WITHIN THE STUDY AREA

For the purpose of incorporating a sense of "quantification" to the process of attributing significance to riparian communities within the study area, the following "framework for Significance" was developed in Rio Tinto 2015 and adapted in this study as a means of providing a more systematic qualitative assessment of significance:

Key steps for considering the relevant factors/attributes are:

1. Part one - consider the number and magnitude of ecological values associated with or provided by a biological feature.
2. Part two - determine the distribution and therefore degree to which it is restricted in the environment, the degree of representation (the degree to which a vegetation unit is represented by other communities outside of the study area), and potential rarity of this feature within local, sub-regional, and regional scales.
3. Part three – consider the condition of the biological feature, and its inherent resilience to perturbation.

Once determined, the combined consideration of parts one and two result in the determination of an initial significance rating. The inherent sensitivity or resilience of a feature to perturbation will tend to increase or decrease the likelihood of impact, as well as the consequences of the impact. In addition, the current condition of the feature at the time of consideration will have an influence on its significance. In order to incorporate sensitivity/resilience and locally known potential anthropogenic impacts into the resultant

significance, it is proposed that for this study, a final "Resultant Local Significance rating" will be determined via part three of the framework and used to attribute an alternative and more locally measured significance to the biological features being assessed.

In addition to the considering physical and biological condition of a feature; this final significance will incorporate some consideration of the inherent risks and potential consequences of development on this feature into the attributed resultant significance. The result of this framework is that ultimately the final resultant local Significance will in turn provide a more measured guidance to management and mitigation as development is undertaken or continued.

3.3 LIMITATIONS OF THIS STUDY

Overarching

- For the most part the study area was easily accessed.
- Base flow in the Robe River was anecdotally much reduced preceding (for at least 1-2 years prior) and at the time of the first survey. Rainfall/seasonal conditions and flowering/fruiting conditions were sub-optimal. However because the GDE focus of this study determined that key interests surrounded the distribution of perennial species this was not generally a limiting factor. Instead the sub-optimal seasonal conditions allowed relatively unrestricted vehicular access and traverse patterns to be conducted throughout the river bed. In addition; the unusually low water levels enabled collection of information on the spatial distribution of low to moderate degrees of hydrological stress within obligate phreatophytes across the study area.
- The vast majority of the field work required for the Robe River riparian vegetation mapping project was successfully completed and reported upon herein. However; some of the planned outer reaches of Robe River and Jimmawarrada Creek remain to be assessed with the methodology adopted in this study. Only those information requirements needed in the short term have been completed and included in this Stage 1 report. This includes the complete differentiation and mapping of some of the Floodplain/Terrace communities which lie in the outer riparian zones of the Robe River. Further to this; a 25 cm pixel aerial photo was requested for the complete study area in October of 2016, but at the time of production of this report had not yet been flown and processed due to mechanical breakdowns and weather limitations. Given the species specific, and community specific identification advantages of this orthophoto, it was planned to be used as an important tool in this project for providing the highest confidence mapping of OPV and FPV communities within the study area. This aerial photo is planned to be used once all additional field work is complete and the entire dataset can be validated using this tool as part of Stage 2.

Desktop and Field Data Acquisition Tools

- Size classes attributed to *M. argentea* populations are a visual estimate and potentially inaccurate in some cases.
- As previously experienced limitations in the correlation between NDVI cover anomalies and OPV were again apparent for the mature OPV woodland communities. This essentially determined that such communities (mainly the C1A and C1b vegetation type) were much harder to distinguish at a desktop level from that of more common mature *Eucalyptus* spp. FPV communities. In these instances; true colour aerial photo signatures and relatively comprehensive creek coverage was relied upon to minimise false negative recordings.

Ground Truthing and Vegetation Mapping Field Work

- The amount of standing water in the creek at the time of survey only restricted movement across creek in a few situations; consequently ground truthing traverse patterns were not hindered.

- Not all species of interest were in optimal condition at the time of the survey. However this did not significantly hinder the acquisition of field data and as mentioned above, for obligate phreatophytic species this enabled the collection of additional useful data. For the most part key eucalypt species were not regularly fruiting/flowering at the time of survey. This did hinder quick differentiation between riparian Eucalypts, however, given that the study area was >60 km in length, it was not feasible to differentiate between these species often enough in the field to provide meaningful differentiation at the scale of the mapping produced. As a result high resolution aerial photo signatures of *E. camaldulensis* and *E. victrix* was inevitably the key tool for mapping the distribution patterns of these two key riparian eucalypt species. However; some field data for ground-truthing aerial photo signatures was required, and where fruit was not available the following technique was used.
- Where riparian eucalypt fruit/flowers were not available, hand lenses were used to determine the identification of the resident eucalypts within a number of representative patches of vegetation via leaf anatomy. *E. camaldulensis* typically possesses true oil glands within the endoplasmic reticulum of its leaves, whereas *E. victrix* does not. Combined with the distinctive differences in lateral vein architecture of the two species (broad/sparse and wavy in *E. camaldulensis*, and tight/uniform and straight in *E. victrix*) ID's were considered accurate in all occasions rather than potentially inaccurate in certain conditions without hand lens techniques.
- Flora and vegetation data collected as part of this study came from a single phase of work and as such were not seasonally sampled.

Post Field Work Vegetation Mapping Process

- Data quantity and resolution was more than adequate for the scope of the targeted assessment.
- Coverage was more than adequate for the scope of the targeted assessment.

Mapping errors have been significantly minimised through extensive ground-truthing and 4-band aerial photo interpretations. The degree of ground-truthing effort conducted for the included groundwater dependent communities, and particularly the OPV communities, is such that the mapping is considered to be significantly more accurate than vegetation mapping typically undertaken within riparian areas.

4 RESULTS

4.1 VEGETATION MAPPING

Table 4-1 below presents the resultant vegetation types described as part of the GDE focused vegetation mapping process. A list of the associated species recorded in each is included in Appendix 2. Representative photos of the riparian vegetation types mapped as part of this study are presented in Appendix 3. For each vegetation type mapped, multiple photos are provided in Appendix 3 to provide some indication of the degree of variation which was observed in each. In an effort to provide a more simplified vegetation model which facilitates easier and broader comprehension of the distribution of groundwater dependent and mesic riparian communities within the study area, a number of the vegetation types presented in Table 4-1 were strategically amalgamated to produce the following riparian vegetation summary maps presented in Figures 4-1 to 4-4. Within Table 4-1, a column has been added to delineate which of the detailed vegetation types were amalgamated to form the summary map vegetation types presented in Figures 4-1 to 4-4. These figures are essentially for the purpose of viewing the distribution of potentially GDV at a larger scale and therefore over larger swathes of the river. These maps should be used when a simpler, broader scale perspective of riparian vegetation within the Robe River is preferred. Maps presenting the resultant vegetation mapping for the complete suite of Stage 1 vegetation types (i.e. without amalgamation of similar communities) are presented in Figures 4-5 to 4-13. These figures present the full degree of mapping detail resulting from stage 1 of the riparian mapping project within the Robe River. As a result Figures 4-5 to 4-13 are most appropriate when considering the distribution and extent of riparian vegetation at the finer scale.

4.1.1 Vegetation Coding

As detailed in the methods, the same coding regime as Rio Tinto (2015) was attributed to vegetation types identified in this study. To help equate the resultant vegetation types to the most recent and relevant local vegetation mapping in the sub-region, the equivalent Astron (2015/2016) veg code for each vegetation type in this study is provided in Table 4-1. The original codes and the hierarchy of significance which they were defined to convey in Rio Tinto (2015) have been maintained as much as possible while still allowing them to reflect the compositional findings and resultant vegetation structure identified in the study area. The most important differences between the coding of these two studies, while minor, relate to the C1AA end of the coding spectrum (communities with an overstorey dominated by obligate phreatophytes) and to the C4-C6 (differing shrublands) end of the coding spectrum. In addition; codes relating to *E. camaldulensis* dominated woodlands/open-forests were required to be integrated due to their delineation in this study and absence in Rio Tinto (2015).

4.2 GROUNDWATER DEPENDENT VEGETATION COMMUNITIES MAPPED

As part of the vegetation mapping process six key types of groundwater dependent vegetation were identified. Listed in order of relative hydrological sensitivity, these are:

1. OPV-A: Vegetation dominated by mature Obligate Phreatophytes

2. OPV-B: Vegetation co-dominated by mature Obligate Phreatophytes

3. OPV-C: Vegetation co-dominated by immature Obligate Phreatophytes
4. FPV-A: Vegetation dominated by *Eucalyptus camaldulensis* (the most hydrologically sensitive Local Facultative Phreatophyte) and at times supporting *Sesbania formosa*
5. FPV-B: Vegetation co-dominated by *Eucalyptus camaldulensis*
6. FPV-C: Vegetation dominated by *Eucalyptus victrix* (the second most hydrologically sensitive local Facultative phreatophyte)

These GDE types are generally relevant to the local Pilbara environment; however the structural concepts and physiological scales which they describe can be applied more widely. It should be noted that the applied differentiation (i.e. A, B, and C) within each accepted hydrological strategy (i.e. Obligate, Facultative etc.) is not widely known or accepted. However; the varying degrees of groundwater availability inferred by the degrees of phreatophyte structural dominance (and maturity) which they intend to classify, are entirely relevant and a useful way of classifying groundwater dependence.

Table 4-1: Vegetation descriptions and GDE summary info for all riparian vegetation types mapped in the study area.

Veg Code	GDE / Community Summary Info	GDE Type	Vegetation Description	Distribution	Condition	Equivalent Astron 2015 and 2016 Code
PO	Minimal Vegetation	Pool - GDE	**Tree Strata: N/A** **Shrub Strata: N/A** **Lower Strata:** Fringed by variable Sedgeland to open sedgeland of *Typha domingensis*, Cyperaceae spp., *Schoenoplectus* spp., *Schoenus* spp., along with *Stemodia grossa* and other small mesic shrubs	Uncommon but Scattered along the low flow channel and often spatially correlated with topographic pinch points along the river channel	Good to Poor	N/A
C1AAa	Mature MA dominated Closed Forest	OPV	**Tree Strata:** *Melaleuca argentea* closed forest **Shrub Strata:** *Petalostylis labicheoides*, *Acacia trachycarpa*, *Melaleuca glomerata* and *Acacia ampliceps* scattered shrubs **Lower Strata:** *Cyperus vaginatus* open sedgeland over *Stemodia grossa* scattered to low open shrubland, amongst scattered pools.	Scattered along low points in the river bed, where groundwater appeared shallow, often up against steep massive bank formations	Excellent to Very Good	Similar to EcMaCvCspp (Astron 2015) or MaEcCv (Astron 2016)
C1AAb	Mature MA dominated Open Forest	OPV	**Tree Strata:** *Melaleuca argentea* (plus scattered *Eucalyptus camaldulensis*) open forest (to closed forest in places). **Shrub Strata:** *Petalostylis labicheoides*, *Acacia trachycarpa*, and *Acacia ampliceps* scattered shrubs (to open shrubland in places) **Lower Strata:** *Cyperus vaginatus* very open sedgeland (to open sedgeland) over *Stemodia grossa* scattered low shrubs	Scattered along low points in the river bed, and near mesa features where groundwater appeared shallow	Excellent to Very Good	MaEcCv (Astron 2016) or Similar to EcMaCvCspp (Astron 2015)

Veg Code	GDE / Community Summary Info	GDE Type	Vegetation Description	Distribution	Condition	Equivalent Astron 2015 and 2016 Code
C1A	Mature MA and EC dominated Open forest to Low Woodland	OPV	**Tree Strata:** *Melaleuca argentea* & *Eucalyptus camaldulensis* subsp. *refulgens* (plus scattered *Sesbania formosa*) Low open forest (to woodland in places) **Shrub Strata:** *Melaleuca argentea*, *Petalostylis labicheoides*, *Acacia trachycarpa*, *Acacia ampliceps* and *Melaleuca glomerata* open shrubland (to shrubland in places) **Lower Strata:** Scattered sedges/shrubs of *Cyperus vaginatus*, *Stemodia grossa* and at times; **Cenchrus ciliaris*, **Cenchrus setiger*, **Setaria verticillata* very open tussock grassland	Consistently fringing low flow channels or scattered around permanent water features where groundwater appeared shallow	Excellent to Very Good	EcMaCvCspp (Astron 2015) or MaEcCv (Astron 2016)
C1b	Semi-Mature MA and EC dominated Low Woodland	OPV	**Tree Strata:** *Melaleuca argentea*, *Eucalyptus camaldulensis* subsp. *refulgens* variable low woodland (to low open woodland) (also includes low open forests of *M. argentea* & *E. camaldulensis* saplings fringing pools **Shrub Strata:** *Melaleuca argentea*, *Petalostylis labicheoides*, *Acacia trachycarpa*, and *Melaleuca glomerata* variable open shrubland to shrubland **Lower Strata:** *Cyperus vaginatus* scattered sedges, over *Stemodia grossa* scattered low shrubs.	Scattered along low flow or secondary channels of the main river bed, including some high flow channels	Excellent to Very Good	Similar to EcMaCvCspp (Astron 2015) or similar to MaEcCv (Astron 2016)
C2AA	Large Mesic EC dominated Open Forest representations	FPV-A	**Tree Strata:** *Eucalyptus camaldulensis* subsp. *refulgens* open forest (to low open forest with scattered *Eucalyptus victrix* and at times *Sesbania formosa*) **Shrub Strata:** *Petalostylis labicheoides*, *Acacia trachycarpa*, *Melaleuca glomerata* and *Acacia ampliceps* tall shrubland (to tall open shrubland in places) **Lower Strata:** *Cyperus vaginatus* scattered sedges and in places **Cenchrus ciliaris*, **Cenchrus setiger* (**Setaria verticillata*) very open tussock grassland	Scattered along secondary channels and banks of the main river bed, including some high flow channels	Very Good to Good	Similar to EcCv (Astron 2015) or EcEvAtrApyPlTw (Astron 2016)

Veg Code	GDE / Community Summary Info	GDE Type	Vegetation Description	Distribution	Condition	Equivalent Astron 2015 and 2016 Code
C2A	EC dominated Open Forest	FPV-A	**Tree Strata:** *Eucalyptus camaldulensis* subsp. *refulgens* open forest (to low open forest with scattered *Eucalyptus victrix* and at times *Sesbania formosa*) **Shrub Strata:** *Petalostylis labicheoides*, *Acacia trachycarpa*, *Melaleuca glomerata* and *Acacia ampliceps* tall shrubland (to tall open shrubland in places) **Lower Strata:** *Cyperus vaginatus* scattered sedges and in places **Cenchrus ciliaris*, **Cenchrus setiger*, **Setaria verticillata* very open tussock grassland	Consistently Scattered along low flow channels, secondary channels and banks of the main river bed	Very Good to Good	Similar to EcCv (Astron 2015) or EcEvAtrApyPlTw (Astron 2016)
C2B	EC & EV co-dominated Open Forest	FPV-B	**Tree Strata:** *Eucalyptus camaldulensis* subsp. *refulgens*, *E. victrix* open forest (to woodland in places) **Shrub Strata:** *Acacia trachycarpa*, *Petalostylis labicheoides* and *Melaleuca glomerata* tall open shrubland (to tall shrubland in places) **Lower Strata:** **Cenchrus ciliaris*, **Cenchrus setiger* (**Setaria verticillata*) very open (to open) tussock grassland with scattered sedges of *Cyperus vaginatus*	Scattered throughout the bed, but often along secondary channels and banks of the main river bed, including high flow channels.	Good to Poor	Similar to EcEvCspp (Astron 2015) or EcEvAtrApyPlTw (Astron 2016)
C2A-B	EC dominated Woodlands	FPV-A	**Tree Strata:** *Eucalyptus camaldulensis* subsp. *refulgens* woodland (to open forest in places) **Shrub Strata:** *Acacia trachycarpa*, *Petalostylis labicheoides* (*Acacia pyrifolia*, *Gossypium robinsonii*) tall open shrubland (plus *Melaleuca glomerata* in some areas) **Lower Strata:** **Cenchrus ciliaris*, **Cenchrus setiger* very open (to open) tussock grassland (plus scattered *Cyperus vaginatus* and *Stemodia grossa* and at times very open hummock grassland of *Triodia epactia* & *T. wiseana*)	Scattered throughout the bed, but often along secondary channels and banks of the main river bed, including high flow channels	Good	EcCv (Astron 2015) or EcEvAtrApyPlTw (Astron 2016)

4.3 SIGNIFICANCE OF THE RIPARIAN VEGETATION COMMUNITIES IN THE STUDY AREA

The extremely large distances traversed during the field survey enabled a relatively comprehensive understanding of the structure, composition and distribution of riparian communities throughout the study area. Through this process a thorough appreciation of the ecological values and significance held by vegetation communities within the Robe River was also attained. From this combined experience a number of communities of note, significance or elevated hydrological sensitivity were identified.

The permanent and semi-permanent pools of the Robe River are considered to be a restricted landform and habitat; in particular those with high species diversity and low disturbance from weed invasion, trampling and grazing. At the time of survey; the river was exceptionally dry and the remaining relatively permanent pools had been subject to greater than normal trampling and disturbance pressure from cattle. Vegetation surrounding these pools was typically dominated by dense *Melaleuca argentea* open forests, accompanied by scattered (and at times co-dominant) *Eucalyptus camaldulensis* subsp. *refulgens* over mixed sedge, grass and herbaceous species, and is described by vegetation associations C1AAa, C1AAb & C1A. This landform and associated vegetation often occurred on the edges of the Robe River, often close to breakaways and rock walls, where either adjacent (often porous) lithologies help maintain shallow water tables, or shallow water tables were coinciding with the main low-flow channel of the river. Patches of closed *Melaleuca argentea* forest (C1AAa) were often in association with such landforms. At the time of the survey; the more significant of these communities, namely the C1AAa & C1AAb vegetation types, were relatively dry, so the understorey appeared relatively devoid of the accompanying mesic species diversity thought to be normally supported.

The C1AAb and C1A communities were the most widespread of the more significant riparian OPV communities, with the C1AA vegetation types generally occurring where shallow water tables supported a wider more expansive lateral extent to the resident OPV communities. In areas where the zone of suitable conditions for OPV was much narrower and such vegetation was often more tightly restricted to low flow channel banks, the C1A community was common and relatively dominant.

Quite extensive, and relatively significant representations of the C1AA OPV vegetation types were mapped and noted to occur adjacent to and upstream of the East Deepdale deposits, adjacent to Yeera Bluff, immediately upstream and downstream of the confluence with Jimmawurrada creek, immediately upstream of the eastern tip of Mesa G, immediately upstream and downstream of the confluence with Mungarathoona creek (multiple occurrences), and immediately downstream of Mesa B. These areas were significant owing to the density and maturity of their canopies, the associated mesic species diversity, supported faunal assemblages, and mesic community diversity occupying the fringing ecotones (as a result of decreasing water availability).

The results of the field work and vegetation mapping exercise were used to contribute to an assessment of the significance of each of the communities mapped to occur within the study area. The significance value attributed to each community is derived from consideration of the factors deemed to be relevant when considering vegetation significance, and which are presented in Section 2.3. To do this in a relatively systematic qualitative manner the significance values attributed within this study followed a local significance framework developed in Rio Tinto 2015, adapted within this study and presented in Section 3.2.

This Framework incorporates an assessment of the ecological values provided, the distribution or degree to which it is represented in the environment (local, sub-regional, regional), the condition, and the sensitivity to change of each community mapped within the study area.

The resultant local significance framework attributed to each riparian vegetation unit is initially assigned to one of the following significance ratings (Table 4-3).

Table 4-2: Ten tier "Significance Rating" scale adapted for this study

(1) Very High	(2) Moderate
(3) High+	(4) Minor-Moderate
(5) High	(6) Minor +
(7) Moderate-High	(8) Minor
(9) Moderate+	(10) Low

It should be noted that this scale assumes the most common and widespread of the vegetation-types/habitats within a study area are considered to fall outside this scale such that the Low rating is attributed to vegetation of slightly elevated significance when compared to the remaining "common" vegetation units.

The results of the significance assessment are presented in Table 4-3 below. It should be noted that Table 4-3 does not provide an indication of conservation significance, rather provides a relative ranking in the locality for the context of this study.

Table 4-3: Significance ratings attributed to each community mapped in the study area and the associated factors contributing to assigned significance ratings.

Veg code	Broad Vegetation Type	GDE classification	Associated Ecological Values	Distribution/Representation/Rarity within the Pilbara Region.	Initial Local Significance	Condition	Sensitivity to relevant impacts	Resultant Local Significance Rating
C1AAa	Mature Melaleuca argentea dominated Closed Forest	OPV-A	Mature mesic Forest habitat, with a canopy dominated by Obligate Phreatophytes. Perennial groundwater availability, with scattered perennial pools also associated. High mesic flora species diversity. Cryptic and Conservation significant fauna habitat (likely to include the Pilbara olive python (POP), Northern Quoll (NQ), and potentially the Ghost Bat and Pilbara Leaf Nosed Bat (PLNB).	**Locally and Sub-regionally restricted and relatively rare/uncommon.** The rocky rangeland river variant of this community is genuinely uncommon and restricted within the Hamersley sub-region. Larger areal extent representations of this community are substantially restricted in the Hamersley sub-region. The unique substrates and adjacent rocky habitats which potentially support this community make it relatively unique when compared to riverine representations occurring in the wider Pilbara Bioregion **Potentially significant from Biological and cultural standpoints.** The representations present in the study area are at times relatively large and possess relatively wide lateral extents within the River Channel. Some degree of impact has already been suffered by these communities due to the construction of mining related infrastructure and minimal degrees of surplus water discharge.	**High**	**Excellent to Very Good**	**Very High**	**High (+)**
C1AAb	Mature Melaleuca argentea dominated Open Forest	OPV-A	Cryptic and conservation significant flora species habitat (e.g. Livistona alfredii). High subsurface aquatic invertebrate diversity. High local avifauna and bat species diversity. Some reduced value from direct impacts (e.g. rail line footings) and cumulative impact. Some vegetation augmentation from surplus water discharge (mainly in the Mesa J vicinity). Unique representation of a relatively upland positioned River System of the Pilbara.					
C1A	Mature M. argentea and *Eucalyptus camaldulensis* dominated Open Forest to Low Woodland	OPV-B	Relatively mature mesic woodland habitat Perennial groundwater availability, with some scattered semi-permanent pools also associated. Above average to High mesic flora species diversity. Cryptic and Conservation significant fauna habitat (likely to include the POP, NQ, and potentially the Ghost Bat, and PLNB). Cryptic and conservation significant flora species habitat (e.g. Livistona alfredii). High subsurface aquatic invertebrate diversity.	**Locally and somewhat Sub-regionally restricted and significant** The rocky rangeland river variant of this community is uncommon and relatively restricted within the Hamersley sub-region. Larger areal extent representations of this community are restricted in the Hamersley sub-region. The unique substrates and adjacent rocky habitats which potentially support this community make it relatively unique when compared to riverine representations occurring in the wider Pilbara Bioregion	**Moderate-high**	**Excellent to Very Good**	**High**	**High**

Veg code	Broad Vegetation Type	GDE classification	Associated Ecological Values	Distribution/Representation/Rarity within the Pilbara Region.	Initial Local Significance	Condition	Sensitivity to relevant impacts	Resultant Local Significance Rating
C1A (continued)			High local avifauna and bat species diversity. Some reduced value from direct and indirect impacts. Some reduced value from direct impacts (e.g. tracks & rail line footings) and cumulative impact. Some vegetation augmentation from surplus water discharge (mainly in the Mesa J vicinity). Above average representation of the Major Creeklines of the Pilbara Ecosystem at Risk. Potential for elevated sedge diversity, and possibly including or conservation significant species.	**Potentially significant from Biological and cultural standpoints.** The representations present in the study area are at times relatively large and possess relatively wide lateral extents within the River Channel. Some degree of impact has already been suffered by these communities due to the construction of mining related infrastructure and minimal degrees of surplus water discharge.				
PO	Minimal Vegetation	Pool - GDE	Perennial water availability Above average mesic flora species diversity; particularly sedge and emergent macrophyte species Cryptic and Conservation significant fauna habitat (likely to include the POP, NQ, and potentially the Ghost Bat, and PNLB), particularly migratory bird species. Cryptic flora species habitat. Elevated sedge diversity, and possibly including cryptic and conservation significant sedge species grasses and herbs. High subsurface aquatic invertebrate diversity. High local avifauna diversity and important refuge habitat. High local and sub-regional aquatic fauna diversity (particularly fish assemblages). Some reduced value from direct impacts. supports highly productive algal communities linked to productivity of surrounding ecosystems.	**Locally to Sub-regionally restricted** **Habitat is considered significant from Both Biological, Cultural and Social standpoints** **The representations mapped and present in the study area are all considered relatively Permanent (to Semi-permanent) and at times relatively substantial in size.**	**Moderate-High**	**Good to Poor**	**High**	**High**
C1b	Young to Semi-Mature Melaleuca argentea and Eucalyptus camaldulensis dominated Low Woodland	OPV-C	Young to semi-mature mesic woodland habitat At least semi-permanent to permanent groundwater availability, with surface water expressions not uncommon. Relatively High mesic flora species diversity. At times relevant as cryptic and Conservation significant fauna habitat (potential to include the POP, NQ, and potentially the Ghost Bat, and PLNB). Cryptic flora species habitat, and some potential as habitat for conservation significant flora (e.g. Livistona alfredii). High subsurface aquatic invertebrate diversity.	**Locally restricted and somewhat uncommon** The rocky rangeland river variant of this community is somewhat uncommon and relatively restricted within the Hamersley sub-region. Larger areal extent representations of this community are restricted in the Hamersley sub-region. The unique substrates and adjacent rocky habitats which potentially support this community make it relatively unique when compared to riverine representations occurring in the wider Pilbara Bioregion.	**Moderate to High**	**Excellent to Very Good**	**Moderate to High** (Generally High, but due to likely transient nature; rating is reduced)	**Moderate** (At times: Moderate to High; due to close proximity to High sig'n communities)

Veg code	Broad Vegetation Type	GDE classification	Associated Ecological Values	Distribution/Representation/Rarity within the Pilbara Region.	Initial Local Significance	Condition	Sensitivity to relevant impacts	Resultant Local Significance Rating
C1b (continued)			Relatively High local avifauna and bat species diversity. Some reduced value from direct and indirect impacts. Some reduced value from direct impacts (e.g. tracks & rail line footings) and cumulative impact. Some reduced value due to the interpreted likely transient nature of this type of community within relevant zones of a Pilbara ephemeral river system.	The representations present in the study area are at times relatively large and possess relatively wide lateral extents within the river channel. Some degree of impact has already been suffered by these communities due to the construction of mining related infrastructure and minimal degrees of surplus water discharge.				
C2AA	Large Mesic Eucalyptus camaldulensis dominated Open Forest representations	FPV-A	Mature to Semi-Mature mesic open-forest habitat. Apparent; at least semi-permanent to permanent groundwater availability. Relatively high to Above average mesic flora species diversity. Cryptic and Mesic Fauna habitat (May include the POP). Cryptic flora species habitat. Potentially possesses Above average subsurface aquatic invertebrate diversity. Above average local avifauna diversity. Some reduced value from direct and cumulative impacts. May represent a higher risk GDE due to Mesic indicators. Above average to high quality representation of Riverine Eucalypt forests.	**This community represents the more mesic and Larger areal extent representations of the C2A community. Given the size, structure and composition of this community, it is considered to be Locally and potentially sub-regionally restricted.** The rocky rangeland creek variant of this community is somewhat uncommon within the Hamersley sub-region, and relatively restricted to Larger River and creek systems.	**Moderate (+)** (Moderate to High for largest representations)	**Very Good to Good** (at times poor due to moisture attracting grazing disturbance)	**Moderate to High**	**Moderate (+)**
C2A	Eucalyptus camaldulensis dominated Open Forest	FPV-A	Mature to Semi-Mature mesic open-forest habitat. Apparent; at least semi-permanent groundwater availability. Above average mesic flora species diversity. Cryptic and Mesic Fauna habitat (May include the POP). Cryptic flora species habitat. Above average subsurface aquatic invertebrate diversity. Above average local avifauna diversity. Some reduced value from direct and cumulative impacts. Above average representation of Riverine Eucalypt forests.	**Somewhat locally restricted but not uncommon** The rocky rangeland creek variant of this community is somewhat restricted within the Hamersley sub-region, but is not considered uncommon.	**Moderate**	**Very Good to Good**	**Moderate to high**	**Moderate**

Veg code	Broad Vegetation Type	GDE classification	Associated Ecological Values	Distribution/Representation/Rarity within the Pilbara Region.	Initial Local Significance	Condition	Sensitivity to relevant impacts	Resultant Local Significance Rating
C2B	Eucalyptus camaldulensis & Eucalyptus victrix co-dominated Open Forest	FPV-B	Mature somewhat mesic woodland/open-forest habitat.	**Somewhat locally restricted but not uncommon**	**Minor-Moderate**	**Very Good to Good** (+ regularly Poor)	**Moderate (+)**	**Moderate**
			Apparent; at least semi-permanent groundwater availability.	The rocky rangeland river variant of this community is somewhat restricted within the Hamersley sub-region, but is not considered uncommon.				
			Elevated mesic flora species diversity.					
			Cryptic and Mesic Fauna habitat (Some potential for Conservation significant fauna).					
			Cryptic flora species habitat (may include Stylidium Weeli Wolli).					
			Above average subsurface aquatic invertebrate diversity.					
			Elevated local avifauna diversity.					
			Some reduced value from direct and cumulative impacts, particularly grazing and grazing related weed infestation.					
			Average representation of Riverine Eucalypt forests.					
C2A-B	Eucalyptus camaldulensis dominated Woodlands	FPV-A	Mature somewhat mesic woodland habitat.	**Relatively common but somewhat restricted locally.**	**Minor-Moderate**	**Very Good to Good** (+ regularly Poor)	**Moderate**	**Minor-Moderate**
			Apparent; at least semi-permanent to permanent groundwater proximity.					
			Elevated mesic flora species diversity.					
			Cryptic and Mesic Fauna habitat (Some potential for Conservation significant fauna).					
			Cryptic flora species habitat (may include Stylidium Weeli Wolli).					
			Above average subsurface aquatic invertebrate diversity.					
			Elevated local avifauna diversity.					
			Some reduced value from direct and cumulative impacts, particularly grazing and grazing related weed infestation.					
			Average representation of Riverine Eucalypt Woodland.					
C2B-B	Eucalyptus camaldulensis & Eucalyptus victrix co-dominated Woodland	FPV-B	Mature somewhat mesic woodland habitat.	**Relatively common but somewhat restricted locally.**	**Minor (+)**	**Good to Poor**	**Moderate**	**Minor-Moderate**
			Apparent; at least semi-permanent to permanent groundwater proximity.					
			Elevated mesic flora species diversity.					
			Cryptic and Mesic Fauna habitat (Some potential for Conservation significant fauna).					
			Cryptic flora species habitat (may include Stylidium Weeli Wolli).					
			Above average subsurface aquatic invertebrate diversity.					
			Elevated local avifauna diversity.					
			Significantly reduced value from direct and cumulative impacts, particularly grazing and grazing related weed infestation.					
			Average representation of Riverine Eucalypt Woodland.					

Veg code	Broad Vegetation Type	GDE classification	Associated Ecological Values	Distribution/Representation/Rarity within the Pilbara Region.	Initial Local Significance	Condition	Sensitivity to relevant impacts	Resultant Local Significance Rating
C2C	Eucalyptus victrix dominated Woodland	FPV-C	Mature somewhat mesic woodland habitat. Generally ephemeral water availability, with indications that groundwater may be accessed but accessibility is moderately variable. Elevated to average Mesic flora species diversity. Mesic Fauna habitat. Elevated subsurface aquatic invertebrate diversity. Elevated local avifauna diversity. Significantly reduced value from direct and cumulative impacts, particularly grazing and grazing related weed infestation. Average representation of Riverine Eucalypt Woodland.	**Relatively common but somewhat restricted locally.**	**Minor**	**Good to Poor**	**Low-Moderate**	**Minor**
C3A	Eucalyptus camaldulensis & Eucalyptus victrix co-dominated Open Woodland	FPV-B	Mature somewhat mesic open woodland habitat. Apparent; at least regular to intermittent groundwater proximity. Elevated subsurface aquatic invertebrate diversity. Mesic flora species present. Mesic Fauna habitat. Elevated local avifauna diversity. Significantly reduced value from direct and cumulative impacts, particularly grazing and grazing related weed infestation. Average representation of Riverine Eucalypt Woodland.	**Relatively common but somewhat restricted locally.**	**Minor (+)**	**Good to Poor**	**Low (+)**	**Minor (+)**
C3B	Eucalyptus victrix dominated Open Woodland	FPV-C	Mature open woodland habitat. Generally ephemeral water availability, with indications that groundwater may be accessed but accessibility is highly variable. Mesic flora species present. Mesic Fauna habitat. Elevated subsurface aquatic invertebrate diversity. Elevated local avifauna diversity. Significantly reduced value from direct and cumulative impacts, particularly grazing and grazing related weed infestation. Average representation of Riverine Eucalypt Woodland.	**Common and not locally restricted**	**Minor**	**Good**	**Low (+)**	**Minor**

Veg code	Broad Vegetation Type	GDE classification	Associated Ecological Values	Distribution/Representation/Rarity within the Pilbara Region.	Initial Local Significance	Condition	Sensitivity to relevant impacts	Resultant Local Significance Rating
C4	River bed Shrublands	Vadophytic with isolated facultative phreatophytes	Riparian habitat with ephemeral water availability. Mesic Fauna habitat. Elevated to average subsurface aquatic invertebrate diversity. Elevated local avifauna diversity. Some to at times significantly reduced value from direct and cumulative impacts, particularly grazing and grazing related weed infestation. Some increased value from discharge enhancement.	**Relatively common but somewhat restricted.** This community is relatively common within the western half of the Hamersley sub-region, but riparian representations are restricted to larger creek/river systems.	**Minor**	**Very Good to Good** (& regularly Poor)	**Low**	**Minor**
C5	Scoured Beds with minimal vegetation	Vadophytic with isolated facultative phreatophytes	Ephemeral water availability. Mesic Fauna habitat. Potentially elevated subsurface aquatic invertebrate diversity. Some reduced value from direct impacts. High potential for reversion to pre-impact condition due to fluvial processes in effect. Large repository of coarse alluvial sediments important for aquatic invertebrate habitats.	**Minimal vegetation; habitat relatively common but somewhat restricted.**	**Low**	**Excellent to Very Good**		**Low**
C6	Floodplain Shrublands	Vadophytic / Xerophytic	Ephemeral water availability (Perennial in some areas at present). Slightly elevated mesic flora species diversity. Mesic Fauna habitat. Elevated local avifauna diversity. At times significantly reduced value from direct and cumulative impacts, particularly grazing and grazing related weed infestation.	**Common and not locally restricted**	**Low**	**Very Good to Good (and regularly Poor)**	**Very Low**	**Low**

4.4 GDE SENSITIVITY AND RISK MAPPING

For the purpose of mapping the spatial distribution of risk within the study area each community mapped was attributed a risk rating. This process firstly involved providing an interpretation of the degree of sensitivity (or vulnerability) to hydrological change held by each community. Secondly; using this degree of sensitivity/vulnerability; produce a rating of the risk that "measurable" impact/change to a community could result from a significant degree of hydrological change. A significant degree of hydrological change may be in multiple forms, including;

- a 2-3m drop in the average groundwater height within the alluvial's immediately adjacent to features of value;
- a discernible (statistically significant) reduction in catchment reporting to the river, and
- a physical obstruction to river flow significantly changing flow patterns.

A "measurable" impact is defined as detectable (beyond natural variability) changes to the health, composition and structure of riparian communities, brought about by changes to groundwater access. Natural impacts to vegetation as a result of changing water availability are common in arid riparian habitats of the Pilbara region. Such arid habitats exhibit extremes in climate and therefore local vegetation inherently possess numerous adaptive traits to facilitate their persistence. As a result, significant impacts are best defined as those changes which are able to be distinguished from the natural variability in effect at the locality. For this reason it is important to be able to distinguish anthropogenic impacts from the inherent degree of natural variation and associated riparian changes. This baseline (or natural) riparian vegetation change is generally restricted to changes in health and at times structure, but less often leading to vegetation compositional changes. As a result "measurable" impact is restricted to that level of riparian change which includes both health changes as well as at least one of either compositional (loss or addition of dominant species) or structural change in resident vegetation.

Conceptually, a significant degree of hydrological change may be best viewed as a magnitude equal to or greater than that hydrological variability experienced naturally at least every 1 to 2 decades. However at this stage, the magnitude of hydrological change, or the definition of a "measurable" impact is not the important factor. What is most important to understand is that an interpretation of sensitivity has been combined with additional influential environmental factors to attribute a risk rating. Thus; once the magnitude of potential hydrological change can be measured the risk rating can be used as a factor by which to multiply the magnitude of hydrological change to in–turn give an idea of the potential size of the resulting ecological perturbation.

To interpret this sensitivity and therefore attribute a final risk rating; the following factors were considered:

(1) Water use strategy (i.e. obligate phreatophyte, facultative, etc.) and associated groundwater dependence associated;
(2) Obligate phreatophyte age structure (maturity);
(3) Obligate phreatophyte structural dominance;
(4) Distribution within the bed profile;
(5) Vegetation cover (i.e. stand density);
(6) Proximity to surface water; and
(7) Inherent Significance; broadly as a measure of degree of restriction, and magnitude of associated values.

Once all of these factors were considered a risk rating was attributed, and this rating was attributed from a 10 tier scale of risk rating such that the following ratings presented in Table 4-4 were

available. In situations where, almost no risk was perceived to be present, a rating of Negligible was determined as the relevant rating to be attributed.

Table 4-4: Ten tier "Risk Rating" scale adapted for this study

(1) Very High	(2) Moderate
(3) High+	(4) Low-Moderate
(5) High	(6) Low+
(7) Moderate-High	(8) Low
(9) Moderate+	(10) Very Low

The final Residual risk ratings (similar to "Importance" ratings applied in SKM (2001) attributed to each community are presented in Table 4-5 The spatial risk mapping created from this risk assessment process is presented in Figures 4-14 to 4-17.

Table 4-5: Risk ratings attributed to each community mapped in the study area and the associated GDE classification and sensitivity rating associated with each.

Veg Code	Broad Vegetation Type (MA= Melaleuca argentea, EC= Eucalyptus camaldulensis, EV= Eucalyptus victrix)	GDE Classification	Initial sensitivity rating	Residual Risk (or importance) Attributed
C1AAa	Mature MA dominated Closed Forest	OPV-A	Very High	Very High
C1AAb	Mature MA dominated Open Forest	OPV-A	Very High	
C1A	Mature MA and EC dominated Open forest to Low Woodland	OPV-B	High to High (+)	High
PO	Minimal Vegetation	Pool - GDE	High	
C1b	MA and EC dominated Low Woodland	OPV-C	High	Moderate-High
C2AA	Large Mesic EC dominated Open Forest representations	FPV-A	Moderate to High	
C2A	EC dominated Open Forest	FPV-A	Moderate to High	Moderate (+)
C2B	EC & EV co-dominated Open Forest	FPV-B	Moderate (+)	
C2A-B	EC dominated Woodlands	FPV-A	Moderate	
C2B-B	EC & EV co-dominated Woodland	FPV-B	Moderate	Moderate
C2C	EV Dominated Woodland	FPV-C	Low to Moderate	Low-Moderate
C3A	EC & EV co-dominated Open Woodland	FPV-B	Low (+)	
C3B	EV Dominated Open Woodland	FPV-C	Low (+)	Low
C4	Shrublands	Vadophytic	Low	
C5	Beds with minimal vegetation	Vadophytic	Negligible	Very Low
C6	Shrublands	Vadophytic / Xerophytic	Very Low

5 DISCUSSION

Within the study area; in general, GDV in the form of OPV was relatively common and somewhat consistently longitudinally (i.e. parallel to the river flow) distributed throughout. Local OPV is sensitive to hydrological change and has therefore been categorised as a High Risk type of GDE (as defined by the 10 tier risk rating scale presented in Table 4-4), as it possesses a core dominant species which is obligately dependent on groundwater access.

With regard to the more mature types of OPV identified; distributions were less consistent longitudinally, but such communities were still relatively common throughout the study area. Lateral (i.e. perpendicular to the river flow) distribution patterns of OPV (particularly the distribution of reaches possessing multiple large and laterally broad OPV representations) within the river profile did show stronger spatial correlation to various topographical, drainage and geological features in the landscape. Such features include; large structurally controlled formations (e.g. mesas) in close proximity to the river, river sections strongly confined by outcropping formations with cliffs / bluffs, and confluences with major creek systems. The distribution of mature OPV with tree strata solely dominated by obligate phreatophytes (*Melaleuca argentea*), and represented by vegetation types C1AAa & C1AAb were also more restricted and strongly correlated with such features. This observed association was considered to indicate that through these areas, groundwater was likely shallow and consistently accessible such that these areas also supported surface water expressions and OPV of much broader lateral extent.

Experience with large riparian systems elsewhere in the Pilbara suggests strong correlation between the distribution of mature OPV and alluvial bed intersection/interactions with underlying porous lithologies such as channel iron deposits. Despite this, it is not yet clear what is driving the distribution of clustering among larger, broader, and structurally mature OPV representations within the Robe River. It is plausible that the distribution of such communities may be significantly influenced by these landscape features, but their degree of influence and interaction with other sub-surface and local to catchment scale hydrological factors is highly variable and relatively unknown.

Based on the results, it was noted that occurrences of the mature C1A OPV community were regularly distributed throughout the study area, even occurring in areas where large and obvious landscape features (Mesas etc., with potential to influence groundwater proximity) were relatively absent. This is thought to be important, as it potentially provides evidence supporting the concept that the Robe River is representative of a River Base-flow System (RBS) type of GDE (Clifton and Evans 2001, Boulton and Hancock 2006), where resident communities are likely supported by a degree of groundwater base-flow throughout the local alluvial aquifer. While RBSs are generally perceived to be represented by rivers with perennial to near perennial surface flows, they can also be represented by sub-surface flow which maintain intermittent pools such as those present on the Robe River. Based on DoW gauging at Yarraloola; periods of zero flow along the Robe River occur less than 25% of the time (Streamtec 2016). In addition to this; pool velocity measurements conducted regularly as part of the long term ecological research project on the Robe River (Dobbs & Davies 2009) show that low flows (throughput) are often maintained in a significant proportion of the permanent pools every year. Other local evidence for a relatively sustained sub-surface groundwater flow within certain zones of the Robe is evident within the results of work conducted by Dobbs & Davies (2009), and includes:

- Abnormally low dry season turbidity levels within monitored permanent pools of the Robe River, suggesting relatively consistent sub-surface throughput is potentially reducing sediment loads;

- Observed relatively high levels of algal productivity, and likely nutrient enrichment within local river pools (ecologia & Streamtec 1992);

- Similar elevated nitrogen levels recorded in defined "ramp up" and "ramp down" periods (i.e. increasingly wet or increasingly dry periods) suggest nitrogen levels are less linked to rainfall induced flows and more likely to be a result of hyporheic exchanges and resultant nitrogen subsidies;

- The highest (while still relatively consistent) nitrogen levels are recorded in the largest, potentially most groundwater influenced pools; which could suggest that elevated nitrogen levels are likely to be subsidised by groundwater influx and associated hyporheic exchange processes (however may also be influenced by grazing inputs) .

- Monitored permanent pools commonly recorded as having a small flow velocity at 0.6m depth during dry season monitoring rounds thus indicating common throughput (i.e. supports the understanding that these are the result of base-flow).

Work conducted by Rio Tinto (2017) as part of the H3 Hydrogeological assessments for Mesa C and Mesa H, while not yet definitive, also indicates that base-flow through the alluvial aquifers is likely to have a significant influence on groundwater levels in the Robe River channel. This conclusion is also supported by work conducted by WRM (2016) and Aquaterra (2005).

In general, it is likely that GDEs which rely on river base-flow, have the potential to support more extensive OPV than GDEs that rely on more static type aquifers. Furthermore it is plausible that through continuing inputs; base-flow type GDEs are likely to be more resilient to the influence of changes experienced in "reach" to "local" scale aquifers due to "catchment" and "landscape" scale aquifer influences which are also being exerted on the base-flow delivered at the local and reach scales. Work by (Boulton and Hancock 2006) exploring the functional dependency of river base-flow systems on groundwater at the channel reach, catchment and landscape (regional) scales outlines how this upper catchment scale influence has the potential to minimise or even offset the influence of local scale changes.

In two key sections of the study area, the distribution of OPV showed sharp reductions in abundance, and at times only supported small scatterings of immature, more transient OPV (broadly represented by the C1b vegetation type). These two sections are located within the river reaches broadly running parallel and adjacent to Mesa G, and the reach located between the K and East Deepdale Mesas. For these reaches it is thought that sub-surface alluvial material depths and a reduced influence of sub-surface lithology is likely maintaining deeper groundwater and reduced water accessibility to biota. Importantly, the maintenance of at least minimal amounts of OPV in these reaches also potentially supports the inference that the system is likely base-flow driven.

As detailed above, there is evidence to suggest that rather that possessing more static primarily geomorphologically driven groundwater formations under the Robe River, the groundwater levels below are likely to also be significantly influenced by a catchment scale base-flow of groundwater.

Based on the results of the "H3 Hydrogeological Risk Assessment" for Mesa H (Rio Tinto 2017); the Robe River is considered an ephemeral river, which carries a significant underflow in its alluvial bed. In combination with the evidence sourced from work by Dobbs & Davies (2009), this suggests that; at least the vast majority of the river which falls within the current study area is likely to represent a river base flow type GDE which supports significant amounts of terrestrial GDV.

With the Robe River considered as likely to represent a river base flow type system; it is considered that the abundance and distribution of GDV mapped to occur within this system is largely dependent on the interaction of this base-flow and associated catchment scale inputs with local hydrogeology. Furthermore given the likely influence of base-flow; the influence of dewatering of adjacent local-scale aquifers (in some cases not considered to possess basement hydraulic connectivity with river alluvials) on groundwater proximity within the river channel, may be minimal or at least significantly reduced. However there are a number of unknowns; particularly in relation to basement hydraulic connectivity with alluvial's, and to a lesser degree in relation to the influence of base-flow.

6 CONCLUSIONS

With climatic influences broadly driving water levels in the Robe River to their lowest level in 26 years, and the potential for further anthropogenic changes to vegetation supported by the river a more holistic assessment of the significant riparian values of the Robe River was undertaken.

Broadly speaking the key aims of the study were to;

- Gather high confidence spatial data on the distribution structure, maturity/immaturity and temporal stability of resident OPVs (and to a lesser extent FPV) within the study area.

- Provide detailed mapping best positioned to assess significance and hydrological sensitivity of all potentially groundwater dependent vegetation throughout the study area (to support impact assessments and cumulative impact assessments)

- Provide spatial mapping of the interpreted risk associated with the significance and inherent sensitivity of these communities to potential hydrological change.

As a result of the degree of survey effort maintained throughout the study area, the field methodology employed, and the lack of significant limitations to the study outputs the study successfully achieved the key aims of the study. In addition, beyond the outputs presented herein; the level of detail recorded and the riparian knowledge accumulated through this study will directly continue to add significant additional value to the monitoring and management of significant riparian communities of the Robe Valley in the short to longer term. From these aims the following key learnings were made:

- GDEs in the form of OPV were relatively common and somewhat consistently longitudinally distributed throughout the study area.

- The more mature types of OPV (C1A vegetation type) were less consistent longitudinally, but still relatively common throughout the study area.

- Lateral distribution patterns of OPV, (particularly the distribution of reaches possessing multiple large and laterally broad representations) within the river profile, showed greater spatial correlation to geomorphological features in the landscape than longitudinal distributions.

- OPV with tree strata solely dominated by obligate phreatophytes (vegetation types C1AAa & C1AAb) and often more laterally broad in spatial extent; were relatively restricted and further correlated with larger geomorphological and geologically controlled features, demonstrating that in such areas, groundwater was quite shallow and consistently accessible.

From the resultant risk mapping produced as part of this study, it can inevitably be seen that the potential risk posed to GDEs in the study area by hydrological change in the alluvial aquifer is relatively extensive. However it is important to keep the risk mapping and attributed risk ratings in context. The risk attributed is not directly related to any proposed impacts related to current development proposal, but is rather a hypothetical risk if significant hydrological change were to eventuate for whatever reason. Furthermore; the Risk ratings were developed through a process of classifying dependence and inferred hydrological sensitivity on qualitative indicators (and some coarse quantitative indicators) of degrees of dependency on groundwater. In addition, it was recognised that the complexity of the natural environment determines that the potential for hydrological changes to be realised in the riparian zone is influenced by many overlapping factors. Factors which occur at the reach, catchment and regional scale, such that only a proportion of the predicted reach to local scale hydrological response may be realised.

While there is evidence to suggest that GDV present in the Robe River is to a degree likely supported by a sub-surface flow (consistent with a river base flow system), and as a result the influence of dewatering of smaller scale local aquifers, may be significantly reduced; at this stage there are still unknowns at a macro scale.

It is clear from the results of this study that a significant amount of groundwater dependent vegetation resides within the study area; importantly such communities are not restricted to those river reaches directly adjacent to mineral resources of the Robe Valley. In addition, there is a high potential that the influence of catchment scale base-flow has the ability to minimise low to moderate scale anthropogenic impacts on local hydrology/GDEs. Furthermore, in light of the magnitude of climatic influence inherently associated with and acting upon GDE's within arid Pilbara environments; the potential for broader scale anthropogenic impact on such communities is significantly reduced.

Vegetation Condition Scale*

E = Excellent (=Pristine of BushForever) Pristine or nearly so; no obvious signs of damage caused by the activities of European man.
VG = Very Good (= Excellent of BushForever) Some relatively slight signs of damage caused by the activities of European man. For example, some signs of damage to tree trunks caused by repeated fire, the presence of some relatively non-aggressive weeds such as **Sonchus oleraceus* or **Cucumis* spp., or occasional vehicle tracks.
G = Good (= Very Good of BushForever) More obvious signs of damage caused by the activities of European man, including some obvious impact on the vegetation structure such as that caused by low levels of grazing or by selective logging. Weeds as above, possibly plus some more aggressive ones such as **Cenchrus* spp.
P = Poor (= Good of BushForever) Still retains basic vegetation structure or ability to regenerate to it after very obvious impacts of activities of European man, such as grazing, partial clearing (chaining) or frequent fires. Weeds as above, probably plus some more aggressive ones such as **Cenchrus* spp.
VP = Very Poor (= Degraded of BushForever) Severely impacted by grazing, very frequent fires, clearing or a combination of these activities. Scope for some regeneration but not to a state approaching good condition without intensive management. Usually with a number of weed species including very aggressive species such as **Prosopis* spp.
D = Completely Degraded (= Completely Degraded of BushForever) Areas that are completely or almost completely without native species in the structure of their vegetation; ie. areas that are cleared or 'parkland cleared' with their flora comprising weed or crop species with isolated native trees or shrubs.

* Based on Trudgen M.E. (1988). A Report on the Flora and Vegetation of the Port Kennedy Area. Unpublished report prepared for Bowman Bishaw and Associates, West Perth.

1 INTRODUCTION

To provide information relevant to the proposed development of Mesa H, mapping of potentially groundwater dependent vegetation within the broader vicinity of Mesa H is required. In order to ensure that the mapping extended beyond the areas which may be affected by the proposal, the Riparian vegetation mapping work conducted along the Robe River was extended so as to cover approximately 21 km of Jimmawurrada Creek from its confluence with the Robe River.

The current report represents an addendum to the previous report "Assessment of Groundwater Dependent Vegetation Distribution on the Robe River, Targeted Riparian Vegetation Survey; Stage 1" (Rio Tinto 2017). The current report outlines additional details and results from the riparian vegetation mapping extended further along Jimmawurrada creek for the purpose of understanding any potential impacts which might occur due to potential groundwater level changes. Figure 1-1 shows the extent of the current study area and the boundaries of previous flora and vegetation surveys.

For all details relevant to the methodology and results not provided within this addendum, refer to Rio Tinto 2017 (Assessment of Groundwater Dependent Vegetation Distribution on the Robe River, Targeted Riparian Vegetation Survey; Stage 1).

The four key aims of this additional work are to:

1. Gather detailed and high confidence spatial information on the distribution of Groundwater Dependent Vegetation (**GDV**) along Jimmawurrada Creek, particularly those Obligate Phreatophytic Vegetation (**OPV**) communities.

2. Gather and incorporate information on the structure, age distribution, maturity and potential permanence/transience of resident OPV communities such that the resultant vegetation mapping is more strongly positioned to assess significance and groundwater dependence.

3. Describe and map all riparian communities throughout the study area, to a high level of detail, and in a manner prioritising the identification of all potentially groundwater dependent ecosystems and their distribution.

4. Based on the structure, maturity and distribution of mapped phreatophytic vegetation: provide an interpretation of the significance and inherent sensitivity of these communities to potential hydrological change in the form of interpreted risk mapping throughout the area of interest.

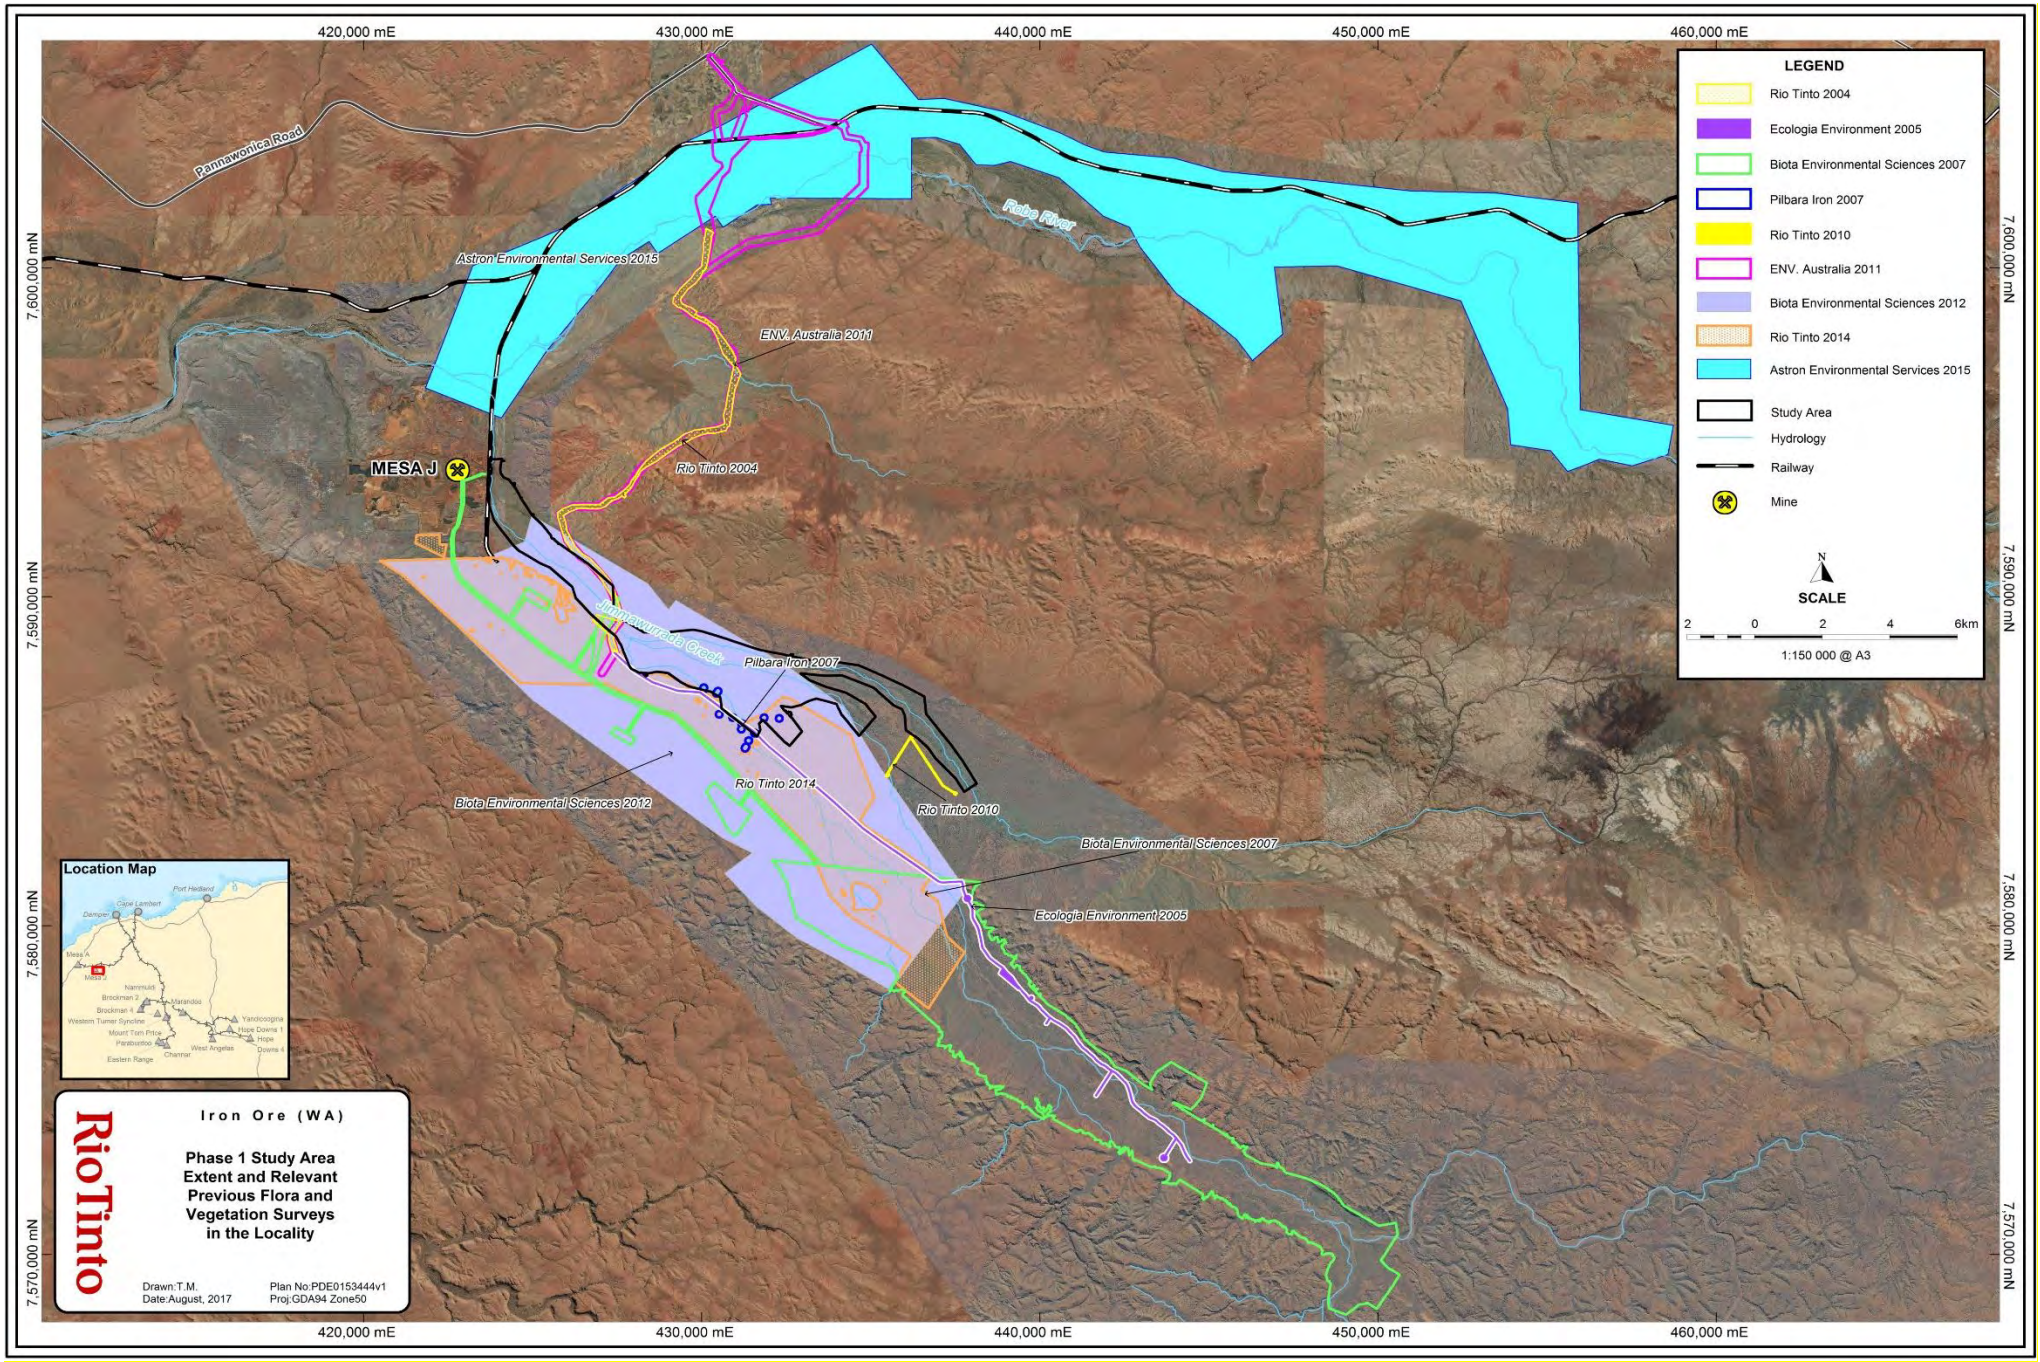

Figure 1-1: Extent of Jimmawurrada Creek covered by the Stage 1 Study Area; includes the study boundaries of key previous flora and vegetation surveys.

2 BACKGROUND

2.1 STUDY AREA

The study area focus of this addendum report incorporates an approximately 18 km stretch of Jimmawurrada Creek, which in combination with an approximate 3 km stretch covered by the main Robe River riparian report (Rio Tinto 2017a) provides an assessment of approximately 21 km of Jimmawurrada Creek (from the confluence with the Robe River). The stretch of Jimmawurrada Creek represented by the study area is wholly located within the Hamersley subregion of the Pilbara Bioregion (IBRA 7.1) (DoE 2014a).

The boundaries of this study area are presented in Figure 1-1 (and in more detail in Figure 3-1).

2.2 JIMMAWURRADA CREEK

Jimmawurrada Creek, and its adjoining member Bungaroo Creek, dissect a pair of broad, low-gradient valleys (forming the valley floor to rugged upland areas), which are prone to flooding after seasonal, tropical storms and cyclones. The creek valleys cut through the Buckland Hills and Mount Dempster areas, and are bounded to the south, and in some parts to the north by steep scarps, mostly formed of the resistant Dales Gorge member of the Brockman Iron formation (Rio Tinto 2011). The Bungaroo valley is approximately 0.5 km wide at the upstream end and 4 km wide where it confluences with Jimmawurrada Creek about 30 km downstream. The valley formed by Jimmawurrada Creek is approximately 9 km wide at the eastern end. Both valleys (particularly Bungaroo valley) contain numerous braided, dry creek beds that are prone to flooding during the wet season (Rio Tinto 2011).

The broader Bungaroo and Jimmawurrada Creek catchment provides approximately 1600 square kilometres of total catchment area. On its own, Jimmawurrada Creek has a catchment area of about 400 square kilometres, while the catchment for Bungaroo Creek is in the order of 1200 square kilometres.

2.3 PREVIOUS SURVEYS

A significant amount of survey work has been conducted in the Robe Valley locality since mining development began in the 1980's. Table 2-1 outlines the relevant flora and vegetation surveys which intersect Jimmawurrada Creek in the vicinity of the study area. The most relevant and recent studies have been conducted by Biota Environmental Sciences Pty Ltd (2012)(Table 2-1). This body of work has essentially sampled/surveyed a riparian environment which had already seen some degree of impact from pastoralism, groundwater drawdown and surplus dewater discharge from mining activities at Mesa J; and natural events (cyclones, flooding and fires). The survey boundaries of previous relevant flora and vegetation studies are presented in Figure 1-1 in relation to the boundary of the current study area.

Table 2-1: Summary of relevant vegetation and flora surveys intersecting the Jimmawurrada Creek study area.

Study (Reference)	Area Surveyed Within Study Area	Survey Description Survey Timing (Conditions for Plant Growth)	Available Data

2.3.1 Resultant Vegetation Mapping

Previous vegetation mapping covering the study area has been completed at a resolution commensurate with the environmental impact assessment (**EIA**) objectives for which it was commissioned. Generally, flora and vegetation surveys conducted for the purpose of EIAs are commissioned with the aim of sampling and documenting all the values present. As a result, sampling effort is spread widely and the level of detail attained is typically proportionate to the size of the area, number of landforms present, and the extent of areas of elevated ecological value.

The Greater Bungaroo Flora and Vegetation Survey conducted by Biota (2012) represents the most detailed and extensive of the vegetation models previously created on Jimmawurrada Creek. This mapping provides an important platform for the current study; however the objectives of the current study determined that mapping with much greater spatial confidence and at a finer resolution was required. Improving the spatial confidence and detail of riparian vegetation mapping would help increase knowledge in the riparian zone and increase the understanding of the local environmental values (and their distribution), and hence increase the effectiveness of environmental management.

3 METHODOLOGY

3.1 RIPARIAN VEGETATION MAPPING WITH A FOCUS ON GDE CHARACTERISTICS AND DISTRIBUTION

To achieve the vegetation mapping aims of this study; a "Targeted Survey" was conducted as defined under the EPA Technical Guidance; Flora and Vegetation Surveys for Environmental Impact Assessment (EPA 2016b).

The survey work conducted for the Jimmawurrada component, involved 3.5 days field work for two Botanists from the 21-24th of May 2017. The field component was conducted by Jeremy Naaykens (Rio Tinto Botanical Specialist), and Pierre-Louis De-Kock (Botanist; Biota Environmental Sciences). This field work was combined with approximately 1 day of field work conducted within the first 3 km of Jimmawurrada Creek as part of the 2016/2017 Robe River mapping component.

The vegetation mapping conducted as part of this study focused on gathering high confidence and relatively detailed information on the distribution and characteristics of GDEs within Jimmawurrada Creek. This was achieved by primarily focusing on gathering information about the maturity and distribution of Obligate Phreatophytic Vegetation (**OPV**)[1]. A secondary data focus was placed on gathering information on the distribution of Facultative Phreatophytic Vegetation (**FPV**)[2]; particularly the distribution patterns exhibited by *Eucalyptus camaldulensis* (River Red Gums). The primary focus on OPV is motivated by the fact that this vegetation incorporates species possessing the highest degree of sensitivity to surface and groundwater hydrological changes, potentially associated with mining. However, in the case of Jimmawurrada Creek, OPV communities were largely absent once away from the hydrological influence of the Robe River.

The field methodology used in the Jimmawurrada Creek Targeted Riparian Survey essentially followed the methodology outlined in Rio Tinto (2017a) (the Robe River component). However the methodology used did differ slightly due to the general absence of communities dominated/co-dominated by *Melaleuca argentea*. As a result the data collected in relation to OPV was very minimal, and instead individuals of this species were way-pointed when sighted, and the focus shifted to making sure *M. argentea* populations were not missed and collecting data on the distribution and abundance of other more intermediate mesic indicator species.

In addition to changes in focus, the much smaller width and significantly reduced spatial complexity of Groundwater Dependent Ecosystems (**GDEs**) along Jimmawurrada creek meant that lateral traverses were of reduced importance, and were therefore conducted less frequently.

The vegetation mapping process and the resultant field survey effort attributed to the study area was conducted on riparian units occurring within the major riparian habitats of the study area. As part of this process, a high degree of survey effort was afforded to the riparian units in the main incised channel zone of the creek compared to the outer fringing communities and the terrace and floodplain habitats. Mapping of the outer riparian habitats of a significant proportion the study area had already

[1] This label is addressed in Rio Tinto (2018b), and is not an accepted label, but is applied to help delineate between vegetation units dominated/co-dominated by one or more obligate phreatophytes.

[2] This label is addressed in Rio Tinto (2018b), and is not an accepted label, but is applied to help delineate between vegetation units dominated/co-dominated by one or more facultative phreatophytes.

been conducted by Biota (2012), and so mapping in these low risk areas (from a GDE sense) relied upon this previous mapping to increase the degree of community validation applied.

With respect to data collection methods; this survey noted the adequate amount of Quadrat/Relevé based data collection which has previously been conducted within various parts of the study area. This survey also observed that mapping traverses had previously been used to a lesser extent than quadrat/relevé based techniques in the riparian zone of the study area. Coupled with the GDE focus of the study, it was concluded that the degree of information on the associated floristic composition of riparian communities already captured within the Bungaroo valley area was sufficient to meet the objectives of this study. Mapping traverses were, therefore, considered to be the most effective method for targeted vegetation mapping in this study. Mapping traverses, generally comprise walking through the target area and regularly taking notes, photographic records, and spatial information on the apparent vegetation associations/sub-associations present, and the location and pattern of boundaries which separate them.

It should be noted that vegetation mapping is essentially a model, such that the spatial validity of boundaries and the vegetation associations depicted to lie within those boundaries, is only true a portion of the time. In general, the proportion of time which the model is correct is directly correlated to the amount of ground-truthing which is done per unit area of the model, and the scale of the community descriptions created. The third influencing factor is generally considered to be the complexity of environmental factors influencing vegetation ecology, but for the surveyor, this is an uncontrolled factor and is therefore not generally considered in detail.

For the vegetation mapping model presented as a part of this study, a key aim was to provide a high degree of accuracy in relation to the spatial location and distribution of resident OPV and FPV communities. As a result, the degree of ground-truthing effort conducted within the core riparian zone (particularly the incised channel zone) was high, such that the mapping is considered to be significantly more accurate than typical quadrat/relevé dominated sampling methodology and subsequent vegetation mapping undertaken in typical flora and vegetation surveys within WA.

All vegetation types mapped as part of this study, were described using Aplins' (1979) framework for "Vegetation Structural Classes" (Specht 1970). This framework is presented in Appendix 1, along with vegetation condition scale used in this study (Trudgen 1988). As such all communities (**Table 4-1**) established as part of this study are generally considered to represent sub-associations (equivalent to the NVIS classification). Community descriptions were created by identifying dominants (where present) for all relevant strata available, rather than restricted to the three traditional strata, such that they represent relatively detailed vegetation descriptions, approximately equivalent to level 5 mapping within the National Vegetation Information System (**NVIS**) (DoE 2014b).

Given the Stage 1 status of this study; some vegetation types mapped and described as part of this study are potentially more accurately classified as associations, or are lacking some of the structural/compositional differentiation which comes from sampling over multiple phases (as part of a detailed survey (EPA 2016b)). Furthermore; some of the non-core riparian communities of the high-flow and terrace riparian habitats are yet to be properly described and delineated throughout the study area. Given the focus of this study is on delineating groundwater dependent ecosystems the reduced level of detail provided for such communities is considered relatively inconsequential and of low significance when considering potential impacts.

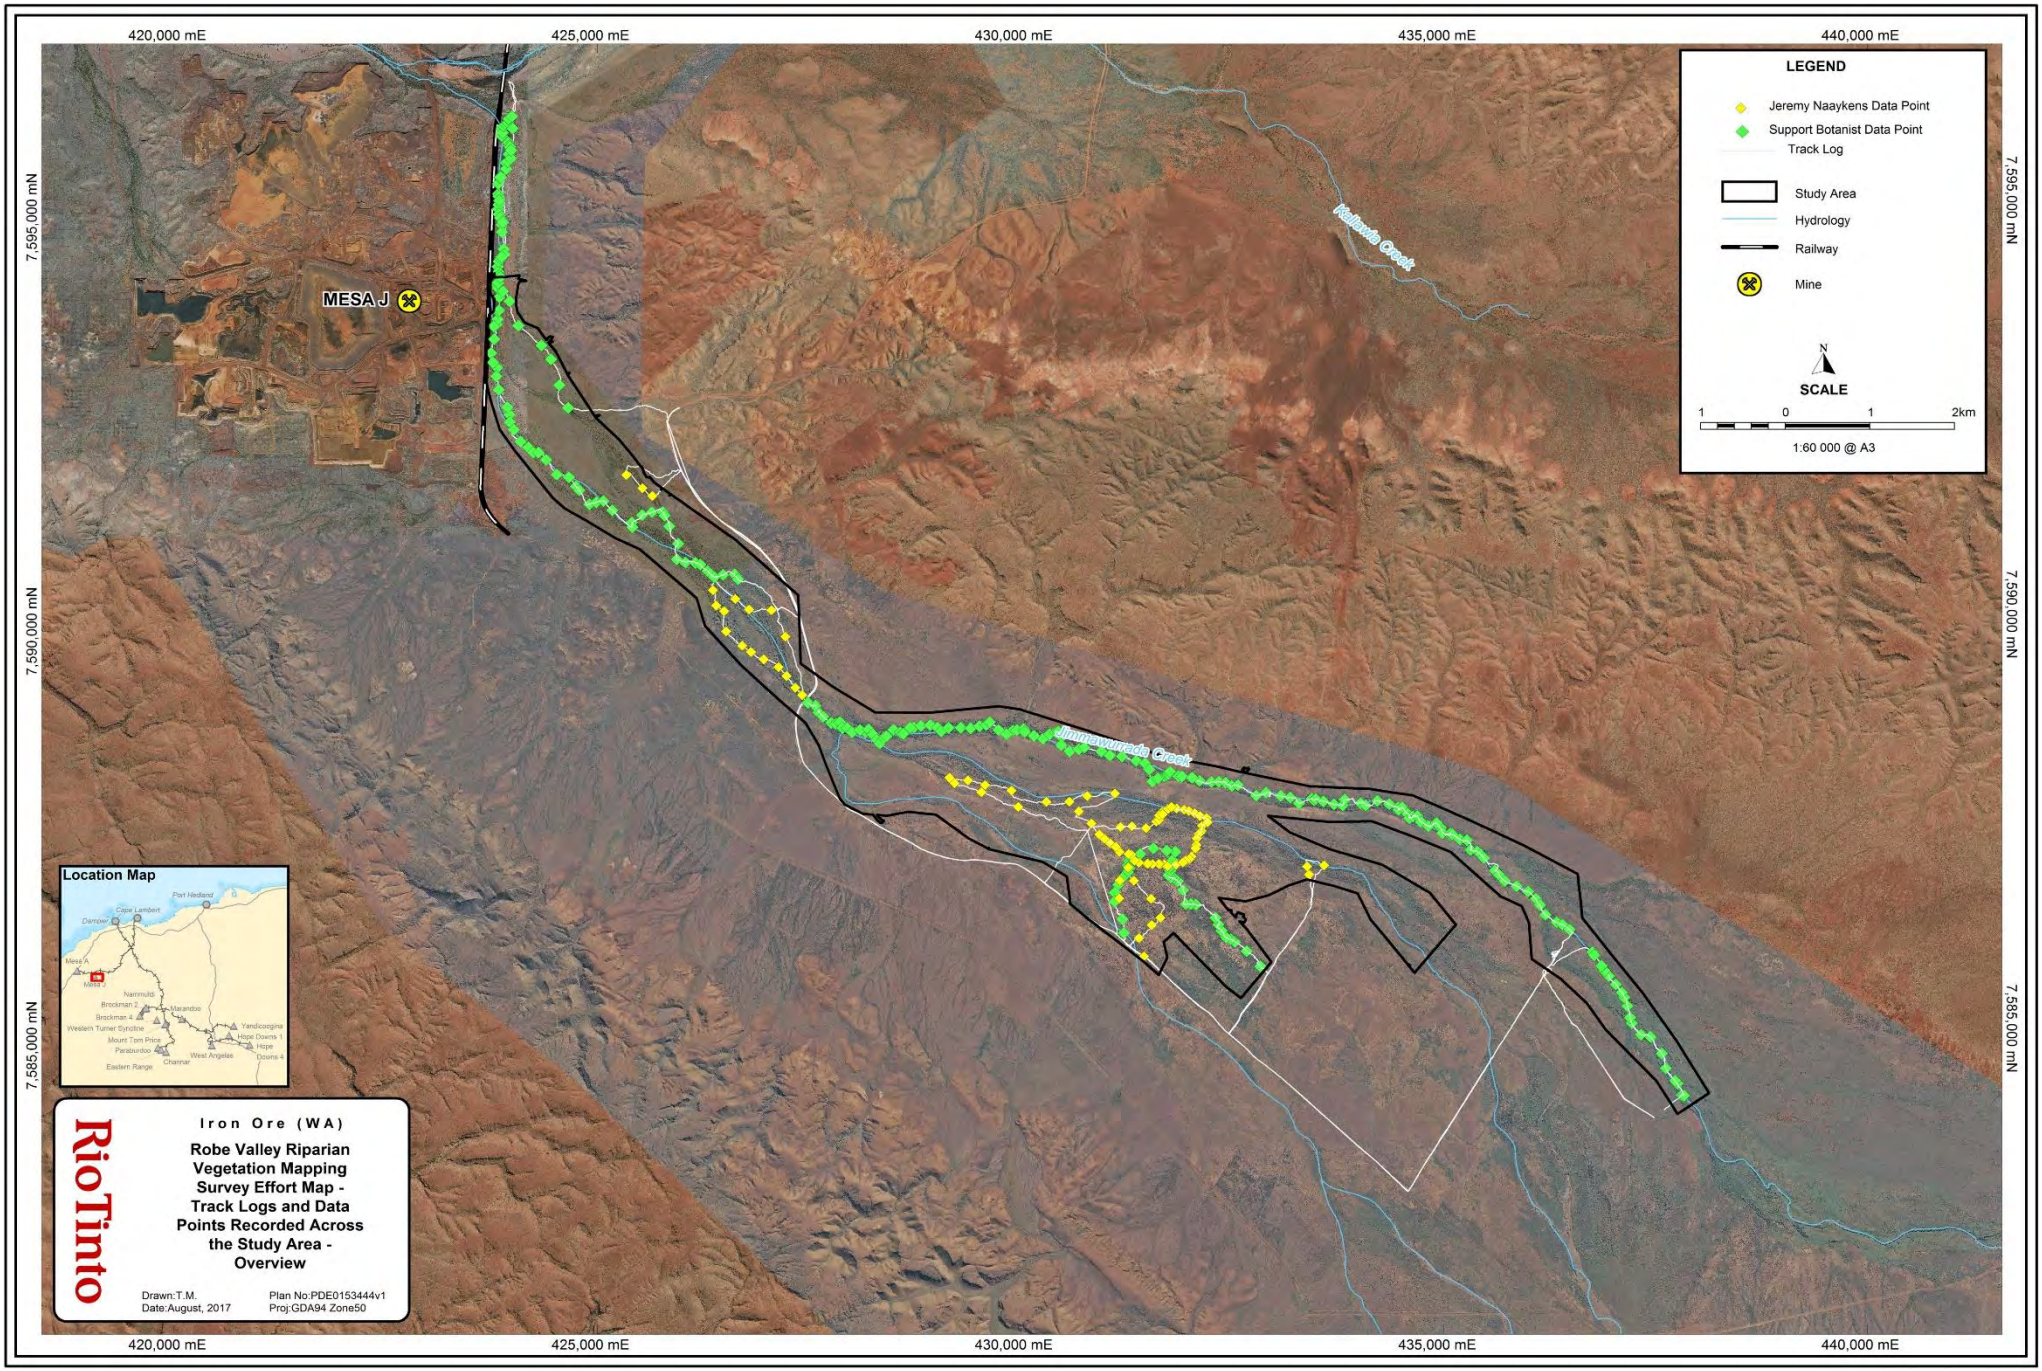

Figure 3-1: Survey Effort map, depicting the survey effort conducted within the study area by showing the track logs and data points collected throughout using a GPS.

3.2 SIGNIFICANCE FRAMEWORK USED TO ASSESS THE LOCAL SIGNIFICANCE OF RIPARIAN COMMUNITES MAPPED WITHIN THE STUDY AREA

For the purpose of incorporating a sense of "quantification" to the process of attributing significance to riparian communities within the study area, the following "framework for Significance" was developed in Rio Tinto (2015) and adapted in this study as a means of providing a more systematic qualitative assessment of significance. This Framework incorporates an assessment of the ecological values provided, the distribution or degree to which it is represented in the environment (local, sub-regional, regional), the condition, and the sensitivity to change of each community mapped within the study area.

Key steps for considering the relevant factors/attributes are:

1. Part one - consider the number and magnitude of ecological values associated with or provided by a biological feature.
2. Part two - determine the distribution and therefore degree to which it is restricted in the environment, the degree of representation (the degree to which a vegetation unit is represented by other communities outside of the study area), and potential rarity of this feature within local, sub-regional, and regional scales.
3. Part three – consider the condition of the biological feature, and its inherent resilience to perturbation.

Once determined, the combined consideration of parts one and two result in the determination of an initial significance rating. The inherent sensitivity or resilience of a feature to perturbation will tend to increase or decrease the likelihood of impact, as well as the consequences of the impact. In addition, the current condition of the feature at the time of consideration will have an influence on its significance. In order to incorporate sensitivity/resilience and locally known potential anthropogenic impacts into the resultant significance, it is proposed that for this study, a final "Resultant Local Significance rating" will be determined via part three of the framework and used to attribute an alternative and more locally measured significance to the biological features being assessed.

In addition to the considering physical and biological condition of a feature; this final significance will incorporate some consideration of the inherent risks and potential consequences of development on this feature into the attributed resultant significance. The result of this framework is that ultimately the final resultant local Significance will in turn provide a more measured guidance to management and mitigation as development is undertaken or continued.

The local significance framework attributed to each riparian vegetation unit is initially and finally assigned to one of the following significance ratings (Table 3-1).

Table 3-1: Ten tier "Significance Rating" scale adapted for this study

(1) Very High	(2) Moderate
(3) High+	(4) Minor-Moderate
(5) High	(6) Minor +
(7) Moderate-High	(8) Minor
(9) Moderate+	(10) Low

It should be noted that this scale assumes the most common and widespread of the vegetation-types/habitats within a study area are considered to fall outside this scale such that the Low rating is attributed to vegetation of slightly elevated significance when compared to the remaining "common" vegetation units.

3.3 GDE SENSITIVITY AND RISK MAPPING

For the purpose of mapping the spatial distribution of risk within the study area, each community is attributed a risk rating. This process firstly involves providing an interpretation of the degree of sensitivity (or vulnerability) to hydrological change held by each community. Secondly; using this degree of sensitivity/vulnerability; produce a rating of the risk that "measurable" impact/change to a community could result from a significant degree of hydrological change. A significant degree of hydrological change may be in multiple forms, including:

- a 2-5m drop (or more) in the average groundwater height within the alluvium immediately adjacent to features of value;
- a discernible (statistically significant) reduction in catchment reporting to the river, and
- a physical obstruction to river flow significantly changing flow patterns.

A "measurable" impact is defined as detectable (beyond natural variability) changes to the health, composition and structure of riparian communities, brought about by changes to groundwater access. Natural impacts to vegetation as a result of changing water availability are common in arid riparian habitats of the Pilbara region. Such arid habitats exhibit extremes in climate and therefore local vegetation inherently possess numerous adaptive traits to facilitate their persistence. As a result, significant impacts are best defined as those changes which are able to be distinguished from the natural variability in effect at the locality. For this reason it is important to be able to distinguish anthropogenic impacts from the inherent degree of natural variation and associated riparian changes. This baseline (or natural) riparian vegetation change is generally restricted to changes in health and at times structure, but less often leading to vegetation compositional changes. As a result "measurable" impact is restricted to that level of riparian change which includes both health changes as well as at least one of either compositional (loss or addition of dominant species) or structural change in resident vegetation.

Conceptually, a significant degree of hydrological change may be best viewed as a magnitude equal to or greater than that hydrological variability experienced naturally at least every 1 to 2 decades. However at this stage, the magnitude of hydrological change, or the definition of a "measurable" impact is not the important factor. What is most important to understand is that an interpretation of sensitivity has been combined with additional influential environmental factors to attribute a risk rating. Thus; once the magnitude of potential hydrological change can be measured, the risk rating can be used as a factor by which to multiply the magnitude of hydrological change to in–turn give an idea of the potential size of the resulting ecological perturbation.

To interpret this sensitivity and therefore attribute a final risk rating; the following factors are considered:

(1) Water use strategy (i.e. obligate phreatophyte, facultative, etc.) and associated groundwater dependence associated;
(2) Obligate phreatophyte age structure (maturity);
(3) Obligate phreatophyte structural dominance;
(4) Distribution within the bed profile;
(5) Vegetation cover (i.e. stand density);
(6) Proximity to surface water; and
(7) Inherent Significance; broadly as a measure of degree of restriction, and magnitude of associated values.

Once all of these factors are considered a risk rating is attributed. This rating is attributed from a 10 tier risk scale which is presented in Table 3-2. In situations where, almost no risk was perceived to be present, a rating of Negligible was determined as the relevant rating to be attributed.

Table 3-2: Ten tier "Risk Rating" scale adapted for this study

(1) Very High	(2) Moderate
(3) High+	(4) Low-Moderate
(5) High	(6) Low+
(7) Moderate-High	(8) Low
(9) Moderate+	(10) Very Low

The final step in the risk mapping process is to incorporate a consideration of the attributed significance rating of each community and also the determined condition of each, so that a final "Residual Risk Rating" which incorporates significance and condition can represent the overall perceived risk.

3.4 LIMITATIONS OF THIS STUDY

Overarching

- For the most part the study area was easily accessed.
- Despite the dry period which was felt in the Robe Valley from approximately 2010 climaxing in mid-2016, the 2016/2017 rainfall season (but including winter rainfall in 2016) was well above average. In fact; rainfall for the May 2016 to April 2017 period totalled approximately 830 mm, which is essentially twice the annual for that area (see Figure 3-2). While this 12 month period did include the significant winter rainfall received in 2016 (230 mm from May-July), the rainfall figures are still significant, and resulted in meaningful flows in both the Robe River and Jimmawurrada Creek. As a result of the good rainfall received in the area, seasonal conditions were optimal for observing the full suite of flora species likely to inhabit the local riparian habitats. Base flow in the Robe River was anecdotally much reduced preceding (for at least 1-2 years prior) and at the time of the first survey. Rainfall/seasonal conditions and flowering/fruiting conditions were sub-optimal. In addition; the recent dry period and remaining stress indicators in riparian canopies enabled collection of information on the spatial distribution of low to moderate degrees of recent hydrological stress within facultative phreatophytes across the study area.
- The vast majority of the field work required for mapping the extent and distribution of riparian communities within Jimmawurrada Creek was successfully completed and reported upon herein. However; some of the planned outer reaches of Robe River and parts of the primary and secondary channels associated with tributaries on the more upstream end of the current Jimmawurrada Creek study area remain to be assessed with the methodology adopted in this study. Only those information requirements needed in the short term have been completed and included in addendum to the Stage 1 report. Once all riparian areas of relevance to the robe Valley are assessed (Stage 2) they will be included into one report for the Robe Valley. This final report will utilise new high-resolution aerial photography to validate mapping boundaries within the complete study area.

Desktop and Field Data Acquisition Tools

- Size classes attributed to *M. argentea* populations are a visual estimate and potentially inaccurate in some cases.

- As previously experienced limitations in the correlation between NDVI cover anomalies and FPV & OPV were again apparent for the more mesic riparian communities. This essentially determined that such communities (mainly the C1A and C1b vegetation type) were much harder to distinguish at a desktop level from that of more common mature *Eucalyptus* spp. FPV communities. In these instances; true colour aerial photo signatures and relatively comprehensive creek coverage was relied upon to minimise false negative recordings.

Ground Truthing and Vegetation Mapping Field Work

- The amount of standing water in the creek at the time of survey only restricted movement across creek in 2 situations; consequently ground truthing traverse patterns were not hindered.
- Not all species of interest were in optimal condition at the time of the survey. For the most part key eucalypt species were not regularly fruiting/flowering at the time of survey. This did hinder quick differentiation between riparian eucalypts, however, given that the study area was large, it was not feasible to differentiate between these species often enough in the field to provide meaningful differentiation at the scale of the mapping produced. As a result high resolution aerial photo signatures of *E. camaldulensis* and *E. victrix* was inevitably the key tool for mapping the distribution patterns of these two key riparian eucalypt species. However; some field data for ground-truthing aerial photo signatures was required, and where fruit was not available the following technique was used.
- Where riparian eucalypt fruit/flowers were not available, hand lenses were used to determine the identification of the resident eucalypts within a number of representative patches of vegetation via leaf anatomy. *E. camaldulensis* typically possesses true oil glands within the endoplasmic reticulum of its leaves, whereas *E. victrix* does not. Combined with the distinctive differences in lateral vein architecture of the two species (broad/sparse and wavy in *E. camaldulensis*, and tight/uniform and straight in *E. victrix*) identifications were considered accurate on all occasions rather than potentially inaccurate in certain conditions without hand lens techniques.
- Flora and vegetation data collected as part of this study came from a single phase of work and as such were not seasonally sampled.

Post Field Work Vegetation Mapping Process

- Data quantity and resolution was more than adequate for the scope of the targeted assessment.
- Coverage was more than adequate for the scope of the targeted assessment.

Mapping errors have been significantly minimised through extensive ground-truthing and 4-band aerial photo interpretations. The degree of ground-truthing effort conducted for the included groundwater dependent communities, and particularly the OPV communities, is such that the mapping is considered to be significantly more accurate than vegetation mapping typically undertaken within riparian areas.

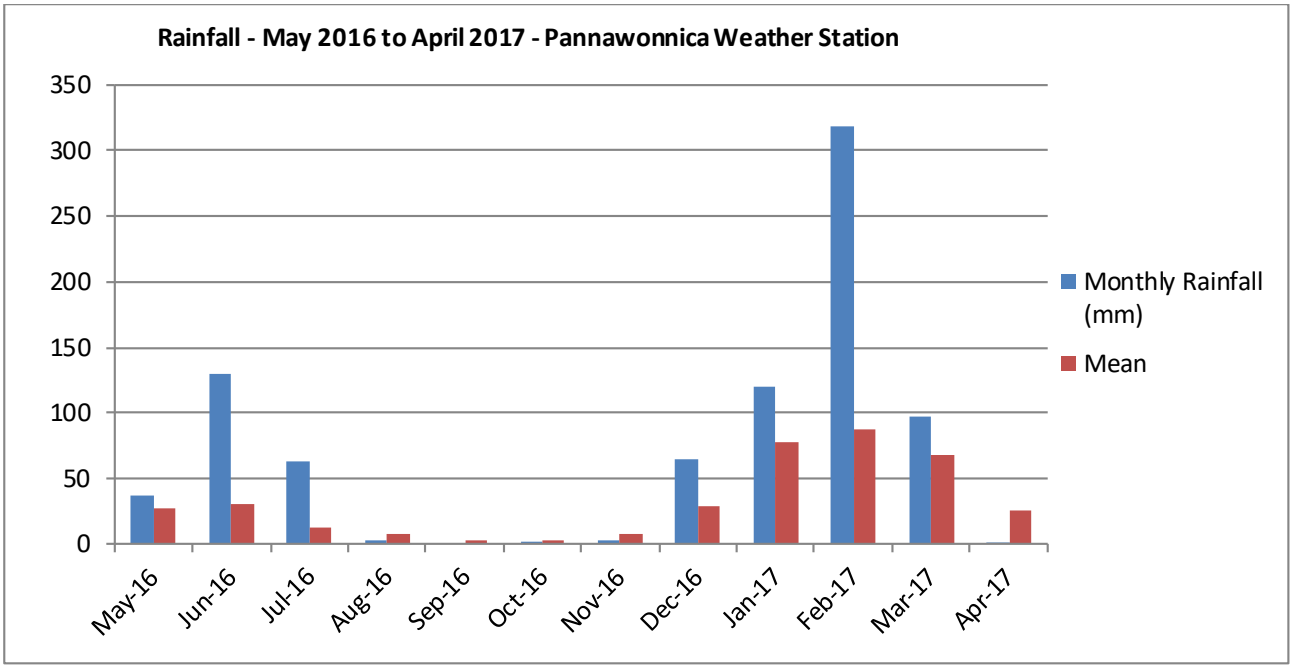

Figure 3-2: Monthly rainfall totals at Pannawonica weather station for the 12 months preceding the survey.

4 RESULTS

4.1 VEGETATION MAPPING

Table 4-1 below presents the resultant vegetation types described as part of the GDE focused vegetation mapping process. A list of the associated species recorded in each is included in Appendix 2. Representative photos of the riparian vegetation types mapped as part of this study are presented in Appendix 3. For each vegetation type mapped, multiple photos are provided in Appendix 3 to provide some indication of the degree of variation which was observed in each. Maps presenting the resultant vegetation mapping for the complete suite of Jimmawurrada Creek vegetation types are presented in Figures 4-1 to 4-4. These figures present the full degree of mapping detail resulting from stage 1 of the riparian mapping project within the Robe River and Jimmawurrada Creek.

4.1.1 Vegetation Coding

As detailed in the methods, the same coding regime as Rio Tinto (2015) was attributed to vegetation types identified in this study. To help equate the resultant vegetation types to the most recent and relevant vegetation mapping in the Sub-region, the equivalent Astron (2015, 2016) and Biota (2012) vegetation code for each vegetation type in this addendum study is provided in Table 4-1. The original codes and the hierarchy of significance which they were defined to convey in Rio Tinto (2015) have been maintained as much as possible while still allowing them to reflect the compositional findings and resultant vegetation structure identified in the study area. The most important differences between the coding of these two studies, while minor, relate to the C1AA end of the coding spectrum (communities with an overstorey dominated by obligate phreatophytes) and to the C4-C6 (differing shrublands) end of the coding spectrum. In addition; codes relating to *E. camaldulensis* dominated woodlands/open-forests were required to be integrated due to their delineation in this study and absence in Rio Tinto (2015).

4.2 GROUNDWATER DEPENDENT VEGETATION COMMUNITIES MAPPED

Broadly speaking; as you move upstream within Jimmawurrada creek, and away from the Robe River confluence, while minimal and laterally restricted, the first 2 km of Jimmawurrada creek (the majority of the topographically confined stretch of the creek) still possesses the lower significance, C1b coded OPV community of the Robe River (along with some C1A coded OPV at the mouth). By the 2.5 km mark, OPV communities are essentially absent, and while the *E. camaldulensis* and *E. victrix* dominated Woodland/Open forest communities of the Robe River still remain, they are less substantial in extent and becoming more ephemeral in nature as Jimmawurrada creek enters Bungaroo valley. As Jimmawurrada creek enters the valley, it also leaves the topographical confinement of the Mesa J range where it dissects finer valley sediments and is dominated by much smaller scale FPV riparian communities, less mesic alluvial conditions and apparently intensified grazing regimes. From the ~3 km mark the eucalypt dominated FPV communities of the Robe River transition to smaller but similar *Eucalyptus* spp.(*E. camaldulensis* and *E. victrix*) dominated communities with less mesic understorey assemblages reflective of the more ephemeral flow regimes, local grazing pressures and finer sediments. This story is replicated as you continue upstream through areas where the creek switches, in stretches, from more braided profiles to a relatively confined single channel, but where the riparian vegetation continues to be dominated by smaller scale eucalypt dominated creekline communities.

As part of the vegetation mapping process, six key types of groundwater dependent vegetation were identified. Listed in order of relative hydrological sensitivity, these are:

1. OPV-A: Vegetation dominated by mature Obligate Phreatophytes
2. OPV-B: Vegetation co-dominated by mature Obligate Phreatophytes
3. OPV-C: Vegetation co-dominated by immature Obligate Phreatophytes
4. FPV-A: Vegetation dominated by *Eucalyptus camaldulensis* (the most hydrologically sensitive local Facultative Phreatophyte) and at times supporting *Sesbania formosa*
5. FPV-B: Vegetation co-dominated by *Eucalyptus camaldulensis*
6. FPV-C: Vegetation dominated by *Eucalyptus victrix* (the second most hydrologically sensitive local Facultative phreatophyte)

These GDE types are conceptual and generally relevant to the local Pilbara environment; however the structural concepts and physiological scales which they describe can be applied more widely. It should be noted that the applied differentiation (i.e. A, B, and C) within each accepted hydrological strategy (i.e. Obligate, Facultative etc.), nor the application of water use strategy terminology to vegetation assemblages is not widely known or accepted. However; the varying degrees of groundwater availability inferred by the degrees of phreatophyte structural dominance (and maturity) which they intend to classify, are entirely relevant and a useful way of classifying groundwater dependence among vegetation types.

Table 4-1: Vegetation descriptions and GDE summary info for all riparian vegetation types mapped in the study area.

Veg Code	GDE / Community Summary Info	GDE Type	Vegetation Description	Distribution	Condition	Equivalent Astron 2015 and 2016, and Biota 2012 Code
C1A (only present at the confluence with the Robe)	Mature MA and EC dominated Open forest to Low Woodland	**OPV-B**	**Tree Strata:** *Melaleuca argentea* and *Eucalyptus camaldulensis* subsp. *refulgens* (plus scattered *Sesbania formosa*) Low open forest (to woodland in places), over **Shrub Strata:** *Melaleuca argentea*, *Petalostylis labicheoides*, *Acacia trachycarpa*, *Acacia ampliceps* and *Melaleuca glomerata* open shrubland (to shrubland in places), over **Lower Strata:** Scattered sedges/shrubs of *Cyperus vaginatus*, *Stemodia grossa* and at times; **Cenchrus ciliaris*, **Cenchrus setiger*, **Setaria verticillata* very open tussock grassland.	Consistently fringing low flow channels or scattered around moist alluvial features where groundwater appeared shallow	Excellent to Very Good	Similar to: EcMaCvCspp (Astron 2015) **or** MaEcCv (Astron 2016)
C1b	Semi-Mature MA and EC dominated Low Woodland Discharge established community within Jimmawurrada creek	**OPV-C**	**Tree Strata:** *Melaleuca argentea*, *Eucalyptus camaldulensis* subsp. *refulgens* variable low woodland (to low open woodland) (also includes low open forests of *M. argentea* & *E. camaldulensis* saplings fringing pools and channels), over; **Shrub Strata:** *Melaleuca argentea*, *Petalostylis labicheoides*, *Acacia trachycarpa*, and *Melaleuca glomerata* variable open shrubland to shrubland, over; **Lower Strata:** *Cyperus vaginatus* scattered sedges, over *Stemodia grossa* scattered low shrubs.	Scattered along low flow or secondary channels of Jimmawurrada Creek, including some high flow channels	Very Good	Similar to: EcMaCvCspp (Astron 2015) **or** similar to MaEcCv (Astron 2016)
C1bb	Semi-Mature MA and EC dominated Low Woodland Baseline community; some discharge influence	**OPV-C**	**Veg description equal to C1b (above)**	Located along a small stretch of the low flow channel at the mouth of Jimmawurrada creek with its confluence with the Robe River	Very Good	Similar to: EcMaCvCspp (Astron 2015) **or** similar to MaEcCv (Astron 2016)

Veg Code	GDE / Community Summary Info	GDE Type	Vegetation Description	Distribution	Condition	Equivalent Astron 2015 and 2016, and Biota 2012 Code
C2A	EC dominated Open Forest	**FPV-A**	**Tree Strata:** *Eucalyptus camaldulensis* subsp. *refulgens* open forest (to low open forest with scattered *Eucalyptus victrix* and at times *Sesbania formosa*), over; **Shrub Strata:** *Petalostylis labicheoides*, *Acacia trachycarpa*, *Melaleuca glomerata* and *Acacia ampliceps* tall shrubland (to tall open shrubland in places), over; **Lower Strata:** *Cyperus vaginatus* scattered sedges and in places **Cenchrus ciliaris*, **Cenchrus setiger*, **Setaria verticillata* very open tussock grassland.	Consistently scattered along low flow channels, secondary channels and terrace features of the terminal (downstream) stretches of Jimmawurrada creek	Very Good to Good	Similar to: EcCv (Astron 2015) **or** EcEvAtrApyPlTw (Astron 2016)
C2A-Cr	**C2AA-Cr**	EC dominated woodland to open forest - Creek	**FPV-A**	**Tree Strata:** *E. camaldulensis* woodland to open forest (with scattered to isolated *Sesbania formosa* low trees in mesic areas), over; **Shrub Strata:** Mixed tall open shrubland (to shrubland in places) of *Acacia trachycarpa*, *Melaleuca glomerata*, *M. bracteata*, and *Gossypium robinsonii* (with scattered *Ficus aculeata*, *Phyllanthus baccatus* and *Phoenix dactylifera* in more mesic zones; outer areas often dominated by *Acacia colei*), over; **Lower Strata:** Variable understorey of *C. vaginatus* open sedgeland, patchy **Cenchrus ciliaris* & **C. setiger* open tussock grassland, over *Triodia epactia/T. longiceps/T. angusta* scattered hummock grasses, (with low lying wet areas typically dominated by *Typha domingensis* and other emergent macrophytes).	Scattered along low flow channels, secondary channels and terrace features of Jimmawurrada Creek in the moister reaches of Jimmawurrada Creek	Poor	Similar to: EcEvMgCYPvCEc (Biota 2012)
	C2A-Cr	EC dominated woodland to open forest - Creek	**FPV-A**	**Tree Strata:** *E. camaldulensis* woodland to open forest, over; **Shrub Strata:** Mixed tall open shrubland (to shrubland in places) of *Acacia trachycarpa*, *Melaleuca glomerata*, *A. bivenosa*, and *Gossypium robinsonii* (with outer patches often dominated by *A. colei*), over; **Lower Strata:** Variable understorey of *Cyperus vaginatus* very open sedgeland, over patchy **Cenchrus ciliaris* & **C. setiger* open tussock grassland, over *Triodia epactia/T. longiceps/T. angusta* scattered hummock grasses.	Consistently scattered along low flow channels, secondary channels and terrace features of Jimmawurrada Creek	Poor	Similar to: EcEvMgCYPvCEc (Biota 2012)

4.3 SIGNIFICANCE OF THE RIPARIAN VEGETATION COMMUNITIES IN THE STUDY AREA

The large distances traversed during the field survey enabled a relatively comprehensive understanding of the structure, composition and distribution of key riparian communities throughout the study area. Through this process a thorough appreciation of the ecological values and significance held by vegetation communities within Jimmawurrada Creek was also attained. From this combined experience a number of communities of note, significance or elevated hydrological sensitivity were identified.

While some stretches of Jimmawurrada Creek were observed to possess a series of ephemeral pools with increased persistence, these intermittent pools were very small scale features and were observed upstream and beyond the modelled influence of the Mesa H proposal; from the 12km (from the Robe River Confluence) mark onwards upstream. Due to the fact that strictly intermittent, ephemeral pools (no permanent or semi-permanent pools), have been identified along the 12 km section of Jimmawurrada Creek nearest to Mesa J, the predicted drawdown will not have a direct impact to these intermittent pools; these pools are broadly surface water driven. Furthermore; ephemeral pool representations present on Jimmawurrada creek were observed to be substantially degraded due to grazing pressures present in the broader valley. While similar grazing pressures may be present on the Robe River, the abundance of semi-permanent (and permanent) water features on the Robe River in combination with the River's broader extent and gravel dominated substrates determines that pool habitats on the Robe River maintain significantly better condition. While small-scale, potentially semi-permanent water features were noted and recorded in upstream parts of the study area; subsequent visits later in the year (as part of other work) confirmed they had dried up, and so were not noted as part of the riparian vegetation mapping process. In all cases such areas were deemed unlikely to consistently hold water and were suffering from reduced mesic species diversity, weed infestation, minor erosion, and the general effects of significant trampling and grazing. For these reasons, unlike the pool features mapped on the Robe River, the mesic areas on Jimmawurrada creek were not deemed to be relevant for or significant enough to be mapped. At the time of survey and generally as a result of the well above average wet season of 2016/2017; Jimmawurrada Creek was showing good signs of recovery (mainly in the canopies of riparian trees) from the significant dry period noted within the Robe River mapping component (Rio Tinto 2018b) to culminate in 2016. Despite this observed canopy recovery; drought-induced canopy decline evidence in the form of overstorey sections maintaining substantial numbers of dead branches were still evident among the new growth.

The physical characteristics of the study area in comparison to the Robe River (creekline as opposed to riverine habitats), changed significantly once Jimmawurrada creek was no longer confined by the range features (forming a gorge like feature adjacent to Mesa J) which also constrict the Robe River in this locality. Despite this, the first 3-4 km of Jimmawurrada creek (extending from the confluence) is still tightly confined by these features and as such many of the vegetation units mapped within the Robe River continued through this area. Once within Bungaroo valley, the substrates of Jimmawurrada Creek are instead dominated by fine sediments, and as a result the supported shrub and understorey assemblages changed as well. As a result new creekline vegetation units were mapped for similar overstorey structures and assemblages mapped along the Robe. These units tried to follow the coding of the Robe River units but in this case with the "Cr" (creekline) tag added. For this reason the "Cr" coded units generally possessed a similar significance rating as their broadly equivalent Robe river relatives. However in the case of the creekline units, the relevant significance of each was diminished due to the significant grazing pressures they exhibited. Of the Creekline units the most significant were represented by the C2AA-Cr

unit which was attributed a "Moderate" significance rating. The majority of the more structurally dense riparian communities on Jimmawurrada Creek were attributed a Minor-Moderate significance rating.

A Sump/Wetland type mosaic of communities was recorded in the south east of the study area and relevant units associated with this community were attributed the "SW" coding tag. This area possesses a mosaic of several vegetation sub-associations restricted to a large soak type feature which lies approximately 7 km south east of the Mesa H development envelope. The area possesses various combinations of open *Eucalyptus victrix*/*E. camaldulensis* forest/woodland, *Melaleuca bracteata*/*M. glomerata* and *Acacia ampliceps*/*A. sclerosperma* tall shrubland to tall open scrub and *Triodia longiceps* and *T. angusta* hummock grasslands.

Five separate communities were mapped in relation to Sump/Wetland area. The C7-SW (scrub community) and C2A-SW (woodland/open-forest community) were both attributed a Moderate-High significance rating due to the highly restricted nature of such habitats and associations within the Pilbara. Of particular note was the C7-SW Open-scrub community dominated by mesic shrub species such as *Melaleuca bracteata* and *Acacia ampliceps*. This community is unusual and very rare outside of riverine/creekline environments. The communities present in this Sump/wetland area suggest that either the broader groundwater table, or a perched aquifer on a clay lens is providing consistently shallow groundwater access in this area.

While some representations of the significant C1B coded community (attributed a Moderate-High significance rating) was mapped to occur in the first 2-3 km of Jimmawurrada Creek, it seems reasonably clear from surveys conducted by Trudgen (1991) (pre-discharge at Mesa J) that these communities have established as a result of the surplus water discharge (augmenting resident phreatophytic vegetation) which has been introduced to this section of Jimmawurrada Creek for approximately 15 years. Prior to surplus mine water discharge and the construction of the Mesa J rail line (which intersects the original confluence point of Jimmawurrada Creek with the Robe River), a baseline flora and vegetation survey was conducted by Trudgen (1991). This survey stated that with respect to the flowlines of Jimmawurrada Creek, near the Robe River there was a woodland of *Eucalyptus camaldulensis* with occasional *Melaleuca argentea* scattered within, but that the remainder was free of obligate phreatophytes.

Data gathered within the vegetation on Jimmawurrada Creek along the first 2 km suggested that the age structure within Obligate Phreatophytic Species (**OPS**) populations in the area were quite even, and in general "semi-mature" in nature, with populations at the northern end near the confluence approaching or at times becoming "mature" with respect to their diameter at Breast height (DBH). *Melaleuca argentea* has been proven as a very fast growing species (Rio Tinto 2015), and data suggests that semi-mature individuals are able to establish in approximately 10+ years from a sapling. As a result it is suggested that those individuals recorded in Jimmawurrada Creek as currently equivalent to or bordering upon being "mature" (in DBH) are likely to represent those scattered individuals which were present pre-discharge; with the remainder having established since mining and discharge has begun. For this reason OPV near the mouth of Jimmawurrada Creek and recently recorded as possessing populations bordering on that equivalent to the C1A community have instead been mapped as the C1bb community, and described as being apparently representative of a baseline C1b community with discharge influence. In addition; the remainder of OPV within Jimmawurrada Creek has been mapped as C1b coded vegetation and described as a discharge established community due to its apparent absence pre-discharge. The key justification for this is that there is enough evidence to suggest that the structure, density and maturity levels of baseline communities in this section of Jimmawurrada Creek would at best have been consistent with C1b coded OPV and current day age structure and maturity levels are not clearly representative of the C1A

community unit especially in light of its general absence pre-discharge. Regardless of the mapping decisions made, a substantial proportion of the significance associated with these communities is associated with the perennial groundwater availability in such areas. As a result, the maintenance of intermittent discharge in this area should help maintain these values and the associated communities which appear to have established under the influence of mining and elevated rainfall conditions.

The results of the field work and vegetation mapping exercise were used to contribute to an assessment of the significance of each of the communities mapped to occur within the study area. The significance value attributed to each community is derived from consideration of the factors deemed to be relevant when considering vegetation significance, and which are presented in Section 2.3. To do this in a relatively systematic qualitative manner the significance values attributed within this study followed a local significance framework developed in Rio Tinto 2015, adapted within this study and presented in Section 3.2.

This Framework incorporates an assessment of the ecological values provided, the distribution or degree to which it is represented in the environment (local, sub-regional, regional), the condition, and the sensitivity to change of each community mapped within the study area.

The results of the significance assessment are presented in Table 4-3 below. It should be noted that Table 4-3 does not provide an indication of conservation significance, rather provides a relative ranking in the locality for the context of this study.

Table 4-2: Significance ratings attributed to each community mapped in the study area and the associated factors contributing to assigned significance ratings.

Vegetation Code	Broad Vegetation Type	GDE Classification	Associated Ecological Values	Distribution/Representation/Rarity & Presence in the Pilbara environment	Initial Local Significance	Condition	Sensitivity to Relevant Impacts	Resultant Significance Rating
C1A	Mature *Melaleuca argentea* and *Eucalyptus camaldulensis* dominated Open forest to Low Woodland	OPV-B	Relatively mature mesic woodland habitat.	**Locally and somewhat sub-regionally restricted and significant.**	**Moderate-high**	**Excellent to Very Good**	**High**	**High**
			Perennial groundwater availability, with some scattered semi-permanent pools also associated.	The rocky rangeland river variant of this community is uncommon and relatively restricted within the Hamersley sub-region. Larger areal extent representations of this community are restricted in the Hamersley sub-region. The unique substrates and adjacent rocky habitats which potentially support this community make it relatively unique when compared to riverine representations occurring in the wider Pilbara Bioregion.				
			Above average to High mesic flora species diversity.					
			Cryptic and conservation significant fauna habitat (likely to include the Pilbara olive python, Northern Quoll, and potentially the Ghost Bat, and Pilbara leaf nosed bat).					
			Cryptic and conservation significant flora species habitat (e.g. *Livistona alfredii*).					
			High subsurface aquatic invertebrate diversity.					
			High local avifauna and bat species diversity.	**Potentially significant from biological and cultural standpoints.**				
			Some reduced value from direct and indirect impacts.					
			Some reduced value from direct impacts (e.g. tracks & rail line footings) and cumulative impact. Some vegetation augmentation from surplus water discharge (mainly in the Mesa J vicinity).	The representations present in the study area are at times relatively large and possess relatively wide lateral extents within the River Channel. Some degree of impact has already been suffered by these communities due to the construction of mining related infrastructure and minimal degrees of surplus water discharge.				
			Above average representation of the Major Creeklines of the Pilbara Ecosystem at Risk.					
			Potential for elevated sedge diversity, possibly including conservation significant species such as *Fuirena ciliaris* and *Eleocharis geniculata*, as well as a suite of habitat specific sedges, grasses and herbs (Note: *Fuirena ciliaris* has not been detected in previous surveys in the area; *Eleocharis geniculata* was recorded once in 2004).					
C1b on Jimmawurrada Creek	Young to Semi-Mature *Melaleuca argentea* and *Eucalyptus camaldulensis* dominated Low Woodland. **Discharge Established**	OPV-C	Young to semi-mature mesic woodland habitat	**Locally restricted and somewhat significant.**	**Moderate to High**	**Very Good**	**Moderate to High**	**Moderate**
			At least semi-permanent to permanent groundwater availability, with surface water expressions common (discharge related).					
			Relatively high mesic flora species diversity.	The rocky rangeland river variant of this community is somewhat uncommon and relatively restricted within the Hamersley sub-region. The unique substrates and adjacent rocky habitats which potentially support this community make it somewhat unique when compared to riverine representations occurring in the wider Pilbara Bioregion.				
			At times relevant as cryptic and conservation significant fauna habitat (potential to include the Pilbara olive python, Northern Quoll, and potentially the Ghost Bat, and Pilbara leaf nosed bat).					
			Cryptic flora species habitat and some potential as habitat for conservation significant flora (e.g. *Livistona alfredii*).					
			High subsurface aquatic invertebrate diversity.					

Vegetation Code	Broad Vegetation Type	GDE Classification	Associated Ecological Values	Distribution/Representation/Rarity & Presence in the Pilbara environment	Initial Local Significance	Condition	Sensitivity to Relevant Impacts	Resultant Significance Rating
C1b on Jimmawurrada Creek (Continued)			Relatively high local avifauna and bat species diversity. Significant reduction in value from direct and indirect impacts. Some reduced value due to the interpreted likely transient nature of this type of community within relevant zones of a Pilbara ephemeral river system.	The representations present in the study area are considered to be discharge established and thus a product of augmentation. Some degree of impact has already been suffered by these communities due to the construction of infrastructure and surplus water discharge.			(Generally High, but due to likely transient nature; rating is reduced)	Community established through anthropogenic influence (discharge)
C1bb	Young to Semi-Mature (+) *Melaleuca argentea* and *Eucalyptus camaldulensis* dominated Low Woodland **Discharge augmented**	OPV-C	Young to semi-mature mesic woodland habitat At least semi-permanent to permanent groundwater availability, with surface water expressions common (discharge related). Relatively high mesic flora species diversity. At times relevant as cryptic and conservation significant fauna habitat (potential to include the Pilbara olive python, Northern Quoll, and potentially the Ghost Bat, and Pilbara leaf nosed bat). Cryptic flora species habitat and some potential as habitat for conservation significant flora (e.g. *Livistona alfredii*). High subsurface aquatic invertebrate diversity. Relatively high local avifauna and bat species diversity. Some reduced value due to discharge augmentation and the interpreted likely transient nature of this type of community.	**Locally restricted and significant.** The rocky rangeland river variant of this community is somewhat uncommon and relatively restricted within the Hamersley sub-region. The unique substrates and adjacent rocky habitats which potentially support this community make it somewhat unique when compared to riverine representations occurring in the wider Pilbara Bioregion This community is interpreted as a baseline representation of the C1b OPV, but having undergone augmentation from anthropogenic discharge. Impact has already been suffered by this community from infrastructure construction and surplus water discharge.	Moderate to High	Very Good	High (Generally High, but due to likely transient nature; rating is reduced)	Moderate to High (Maintained due to close proximity to High significance communities)
C2A	*Eucalyptus camaldulensis* dominated Open Forest	FPV-A	Mature to semi-mature mesic open-forest habitat. Apparent; at least semi-permanent groundwater availability. Above average mesic flora species diversity. Cryptic and mesic fauna habitat (May include the Pilbara olive python). Cryptic flora species habitat (may include *Stylidium weeliwolli*). Above average subsurface aquatic invertebrate diversity. Above average local avifauna diversity. Some reduced value from direct and cumulative impacts. Above average representation of Riverine Eucalypt forests.	**Somewhat locally restricted but not uncommon.** The rocky rangeland River variant of this community is somewhat restricted within the Hamersley sub-region, but is not considered uncommon.	Moderate	Very Good to Good	Moderate to high	Moderate

Vegetation Code		Broad Vegetation Type	GDE Classification	Associated Ecological Values	Distribution/Representation/Rarity & Presence in the Pilbara environment	Initial Local Significance	Condition	Sensitivity to Relevant Impacts	Resultant Significance Rating
C2A-Cr	C2AA-Cr	EC dominated woodland to open forest - Creek	FPV-A	Mature to semi-mature mesic riparian woodland to open-forest (habitat).	**Somewhat locally and Sub-regionally restricted but not overly uncommon.**	Moderate (+)	Poor	Medium (+) (to High in places)	Moderate
				Floristic composition suggests at least semi-permanent groundwater availability (within proximity of surface).	The more mesic rocky rangeland creek variant of this riparian community is somewhat restricted within the Hamersley sub-region, but is not considered uncommon.				
				Above average mesic flora species diversity. Isolated *Melaleuca argentea* recorded.					
				Cryptic and mesic fauna habitat (May include the Pilbara olive python - recorded on survey).					
				Cryptic flora species habitat (may include *Stylidium weeliwolli*; *Gymnanthera cunninghamii* recorded on survey).					
				Likely above average subsurface aquatic invertebrate diversity.

4.4 GDE SENSITIVITY AND RISK MAPPING

For the purpose of mapping the spatial distribution of risk within the study area, each community was attributed a risk rating. This process firstly involved providing an interpretation of the degree of sensitivity (or vulnerability) to hydrological change held by each community. From this a rating of the risk that "measurable" impact/change to a community could result from a significant degree of hydrological change was interpreted. This risk rating involved an initial consideration of 7 different factors to produce a rating. Then a residual risk rating was attributed through consideration of the significance and condition of the relevant community being considered. The steps, methods and definitions involved in this process are outlined in Section 3.3.

The final Residual risk ratings (similar to "Importance" ratings applied in SKM (2001)) attributed to each community are presented in Table 4-5. The spatial risk mapping created from this risk assessment process is presented in Figures 4-5 to 4-8.

Table 4-3: Risk ratings attributed to each community mapped in the study area and the associated GDE classification and sensitivity rating.

Vegetation Code	Broad Vegetation Type (MA = *Melaleuca argentea*, EC = *Eucalyptus camaldulensis*, EV = *Eucalyptus victrix*)	GDE Classification	Initial Sensitivity Rating

5 DISCUSSION

Jimmawurrada Creek Riparian Vegetation

Within the study area; in general, GDV in the form of OPV was relatively uncommon. Despite this, within the first 2-3 km stretch of Jimmawurrada Creek (from the confluence with the Robe River) the C1b community is relatively common (including a small stretch of C1bb) and consistently distributed along the low flow channel and some sections of the secondary or high flow channel. This distribution appears tightly aligned with the attenuation of Jimmawurrada Creek by the range (Hamersley Range) feature constricting the creek in this area, but also coincides with the local stretch of creek which receives discharge from the Mesa J mining operations. The consistent distribution of strips of *Melaleuca argentea* co-dominated vegetation (C1b), with quite narrow (uneven frequency distribution) and "semi-mature" age distributions, appears to be an indication that they have since established here, or were at least significantly augmented by the intermittent discharge which has occurred in this area for the last 15 years. Recent work (Rio Tinto 2015) suggests that the time period of discharge in this area is more than capable of accounting for the size distributions of *M. argentea* trees present in this area (generally less than 40cm DBH). Furthermore, the proximity to the Robe River and continuation of the Robe River alluvial aquifer into the Jimmawurrada Creek alluvium, in at least the first part of this stretch, (along with groundwater discharge from the Bungaroo valley, and proximity to the Mesa J pisolite aquifers) may also help account for the communities present.

The survey work conducted by Trudgen (1991) in this area (pre-discharge) indicated that only a small stretch of Jimmawurrada Creek near the confluence possessed occasional *Melaleuca argentea* individuals. Trudgen (1991) describes the remainder of woodlands within Jimmawurrada Creek as being dominated by riparian eucalypts (and being absent of *M. argentea*). In combination with present day observations of age structure, pre-discharge survey work has helped to conclude that baseline *Melaleuca argentea* populations and thus potential OPV distribution in Jimmawurrada Creek was most likely restricted to the first 500 m (but potentially as far as 800 m) along the creek. Groundwater modelling through this initial stretch of Jimmawurrada Creek suggests up to 10 m of drawdown (1-4 m in the first 200m and 4-10 m in the following 500 m) could potentially occur by 2030. However, while uncertainty remains, connectivity between the underlying formations and alluvium through this area is assumed to be low, and as such this degree of drawdown needs to be considered in light of such assumptions. Furthermore surface water influence on soil water and aquifer recharge along with groundwater influence from the Robe River alluvial aquifer and the Bungaroo valley aquifer mean that significant degrees of annual (or multiple times per year) recovery in groundwater heights have previously occurred (under influence from the Southern Cutback Borefield (**SCB**)) and are predicted to continue to occur (Rio Tinto 2018a) within the aquifers underlying Jimmawurrada Creek. Irrespective of the mitigating influence of such factors, modelled hydrological changes under Jimmawurrada Creek are likely to impact the more sensitive communities present in this stretch of the creek. However, the timing (and magnitude) of such groundwater changes in relation to seasonal water stress cycles and the potential onset of extended drought conditions will be the most influential factor determining whether significant impacts to OPV communities are realised. With intermittent discharge likely to continue within this stretch; demonstrated local cycles of groundwater recovery (driven by surface/groundwater flows from the Bungaroo Valley and Robe River) mean that more favourable growth conditions should regularly return to Jimmawurrada Creek. Cyclical restoration of more

favourable conditions should in-turn ensure that ongoing impacts will also regularly see some degree of amelioration which will likely ensure that continued and compounding hydrological stress and related changes is broadly absent in this zone of Jimmawurrada Creek.

While some pools were observed along parts of the Jimmawurrada Creek study area, the vast majority were confidently believed to be intermittent. Unlike the Robe River, relatively consistent and shallow groundwater base-flow within the alluvium is not believed to be present within Jimmawurrada Creek. While some permanent pools are known to occur further upstream in the Bungaroo Valley (such as the Old Yalleen Pool), no other similarly persistent pools were found or are considered likely to occur within the study area. In general permanent pools tend to be flanked by populations of Obligate Phreatophytic Species (**OPS**) whose presence generally corroborates with the consistency of water availability. Apart from the first 3 km stretch of Jimmawurrada Creek, the presence of *Melaleuca argentea* along Jimmawurrada creek was represented by a handful of recordings of no more than a couple young to semi-mature individuals. Interestingly, young to semi-mature populations of *M. argentea* are known from some of the relatively minor reticulating flowlines directly to the south (and outside of the study area) of the soak/wetland feature mapped in this study (see Plate 5-1 for the location of the *M. argentea* individual recorded south of the soak). The presence of obligate phreatophytes on almost plain like habitats within the valley floor, with no distinct drainage channel present and without a dense accompanying riparian community, is very unusual and potentially an indication of a shallow zone within the broader Bungaroo aquifer (or smaller independent, shallow aquifers). While more substantial and consistent populations of *Sesbania formosa* (and in some areas **Phoenix dactylifera*) were encountered on Jimmawurrada Creek from approximately 8.5-14 km upstream, their presence is not a reliable indicator of water permanence, but is instead a good indication of increasingly high water availability and surface water input; especially in the absence of *M. argentea* populations. Two pools were recorded in the upper parts of the study area as potentially being semi-permanent (located approximately 17 km and 18 km upstream from the confluence). This determination was based on a number of factors, including: the presence of single records of *M. argentea*, abnormally deep incisions of the channel into the local alluvium, and above average grazing disturbance indicating that such areas are consistently visited and that cattle-based erosion may also be helping maintain depth in the water hole. In these areas, high levels of in-pool cattle disturbance meant that the presence of semi-permanent, water-indicating macrophytes was unable to be interpreted. Visits by other surveyors to these locations late in 2017, anecdotally suggested that these pools were dry at this time of year. Despite this, the presence of relatively fine-sediment derived banks in such stretches of Jimmawurrada Creek increases the water holding capacity of the channel and thus the likelihood that some of the pools are at times, more consistently present. Beyond values for terrestrial fauna, the value of such pools for flora is difficult to define, due to the intense cattle activity and vegetation trampling.

The distribution of certain mesic indicator species within specific zones of Jimmawurrada Creek could be used as evidence to suggest that baseline moisture conditions through such zones were elevated in comparison to other areas. The mesic indicator species considered important in the locality include: *Melaleuca argentea, *Phoenix dactylifera, Sesbania formosa, Melaleuca bracteata, Phyllanthus baccatus, Ficus aculeata, *Passiflora foetida, Lobelia arnhemica*, and *Typha domingensis* (*T. domingensis* only relevant where consistent larger scale formations are present). Distribution of these species could be attributed to multiple factors, including:

- shallow groundwater (for whatever reason)
- intermittent disconnected surficial/alluvial aquifers;
- basement rock outcropping within the creek bed;
- incised channels and confinement of the fluvial system into a narrow corridor;
- fine sediment substrates and increased water holding capacity; and
- perched small scale aquifers linked to shallow basement material, or clay lenses.

Plate 5-1 displays the basic distribution of mesic indicator species within the Jimmawurrada Creek study area, where **Phoenix dactylifera*, *Sesbania formosa*, *Melaleuca bracteata* and *Melaleuca argentea* represent key mesic indicator species.

The presence of scattered (and clustered, mature) **Phoenix dactylifera* palms and consistently scattered *Sesbania formosa* through the central red polygon of Plate 1 suggests increasing water availability in this zone. While this type of mesic species distribution may partially be explained by generally shallow groundwater (baseline (pre-mining) groundwater levels in this zone were estimated at approximately 4-5 m), at the finer scale; confinement/incision of the channel along with seasonally intermittent (but likely disconnected) alluvial aquifers/through-flow is likely to also be playing a role in the establishment of vegetation associations recorded through this area. Furthermore; these same factors and potentially some influence from small scale perched aquifers (likely perched on clay lenses) could also explain the presence of isolated *Melaleuca argentea* individuals in the eastern orange polygon of Plate 5-1. Also of relevance were the observations that within this stretch of Jimmawurrada Creek; the low flow channel was relatively incised, bedrock was at times outcropping in and adjacent to the creek bed, surface water expressions were consistently intermittent, and mesic indicator species were relatively common.

Another area where mesic indicator species were prevalent and often formed a co-dominant component of vegetation, but which wasn't associated with a known drainage channel or fluvial system was the Soak/Wetland feature previously recorded in the south east of the study area. The vegetation associations in this area not only suggested quite shallow groundwater, or very consistent water availability, but also represented quite rare associations, especially in light of the landforms they were recorded on. The area, at over 200 ha seems to represent a large soak, which at times becomes part of the floodplain of the Bungaroo Creek arm of Jimmawurrada Creek; thus receiving and storing pooled water as a result of peak creek flows. While the presence of *Eucalyptus camaldulensis* woodlands over mesic shrublands on floodplain like features (C2A-SW), is quite rare in the Pilbara, the tall open scrub of *Melaleuca bracteata* and *Acacia ampliceps* (and *Melaleuca glomerata* and *Acacia sclerosperma*) over open hummock grasslands of *Triodia longiceps* and *Triodia angusta* (C7-SW) are extremely rare on similar landforms. With the dominant and co-dominant species present in this area suggesting a high degree of water availability, and with substantial surface water input events into this area likely to be uncommon, it is thought that either the broader groundwater table is quite locally shallow, or that clay lenses below it are facilitating the formation of a small perched aquifer in the area. Such factors suggest that this community is relatively sensitive to hydrological change. The highly restricted distribution of these communities (particularly C2A-SW, C7-SW, but also to a lesser degree C2C-SW1, C2C-SW2 & CL-SW) in combination with the likely hydrological sensitivity of vegetation in the soak/wetland area determines that their significance is likely to be relatively high.

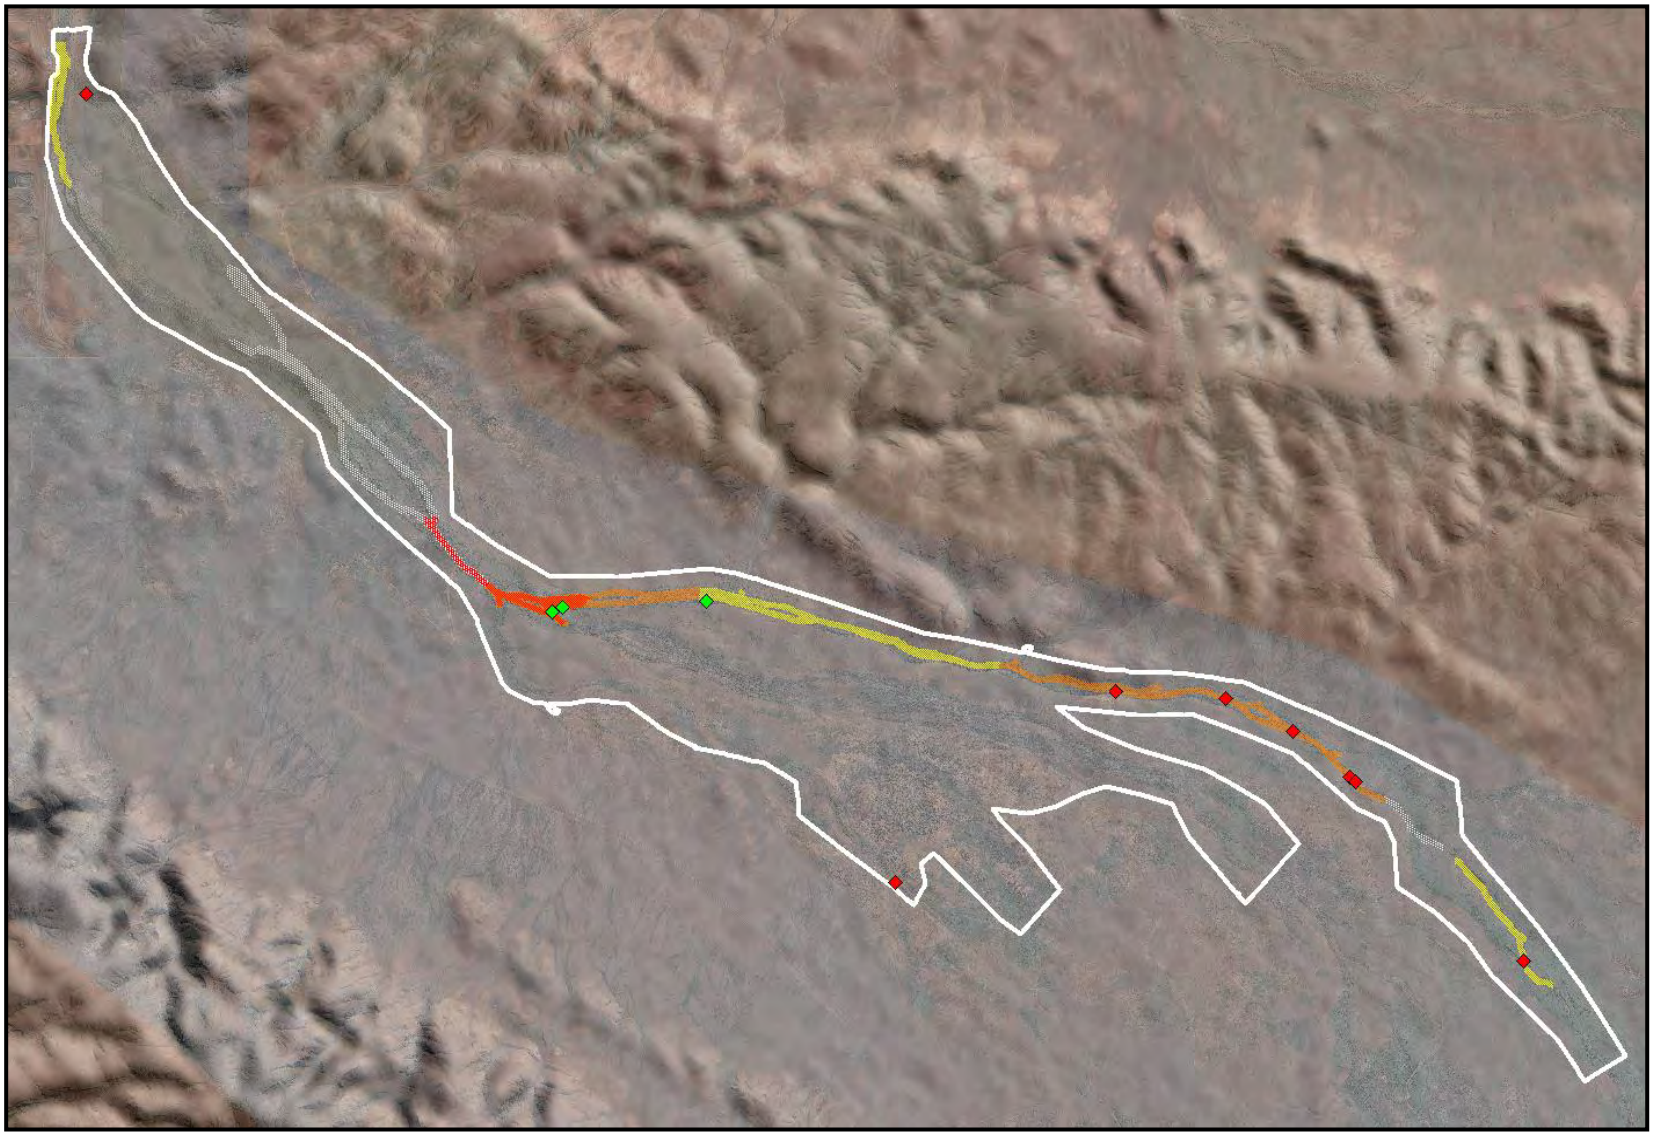

Plate 5-1: Basic distribution of mesic indicator species within the Jimmawurrada Creek study area (white outlined polygon).

Red polygon indicates where populations of nearly all mesic indicator species were recorded (except *Melaleuca argentea*), Orange polygns indicate where 3 key species were regularly recorded, Yellow indicates where 2 key species were regularly recorded, and white shaded polygons is where only one key mesic indicator species was regularly recorded. Green dots are where clusters of mature *Phoenix* palms were recorded, and Red dots are where 1-4 *Melaleuca argentea* individuals were recorded.

The vegetation communities within Jimmawurrada Creek, while generally representative of more typical mid to larger sized Pilbara creek systems, also possess some more mesic elements which are likely reflective of the substantial aquifer system which is present and discharging from the Bungaroo Valley towards the Jimmawurrada and the Robe River. From Jimmawurrada Creek at the confluence with the Robe River to the south eastern end of the study area; pre-mining groundwater levels in the first 2-3 km were in the vicinity of 2-3 meters below ground level (mbgl). From there groundwater depth increased to approximately 4-5 mbgl near the SCB and then fluctuated between 3 and 8 mbgl throughout the remainder. This suggests that groundwater has historically been somewhat shallow through parts of Jimmawurrada Creek. This is significant, given that groundwater modelling indicates that cumulative drawdown from Mesa J, H and the Coastal Water Supply Project will result in impacts to the aquifer underlying Jimmawurrada Creek riparian vegetation. Under such a scenario, factors affecting continued degrees of access to groundwater by resident vegetation will become important for determining the associated risk of impact to local GDV.

For Australian systems, evidence suggests that reliance on groundwater by terrestrial vegetation is greatly reduced in areas where the water table exceeds a threshold depth, likely to lie between 7 m and 12 m (Benyon, Theiveyanathan, and Doody 2006; Department of Water 2009; O'Grady, Carter, and Holland 2010; Zolfaghar et al. 2014), with 10 m suggested as a general threshold (Eamus, Froend, *et al*. 2006). However vegetation may potentially access groundwater when the water table is between 10 m and 20 m depth, although it is thought to be negligible in terms of contribution to total plant water use (Zencich *et al.* 2002). Beyond 20 m depth, the probability of groundwater as a water source for vegetation is regarded as being low. While meta-analyses by Canadell *et al.* (1996), Schenk & Jackson (2002) and Schenk & Jackson (2005), have shown maximum rooting depths across multiple biomes to extend 20-50m below ground, significant variation exists, and questions remain about the relative success of roots at this depth. Models of vertical root resource distribution (and water extraction) and field observations made by Schenk (2008), suggest that the percentage of root resources present below 10m is almost negligible, and likely to be less than 1% of all root resources available. A study by Kath *et al.* (2014) on groundwater decline and tree change in eastern Australian floodplain landscapes identified groundwater depth thresholds ranging from 12.1 m to 22.6 m for *Eucalyptus camaldulensis* (a dominant component of Jimmawurrada Creek vegetation); beyond which canopy condition declined abruptly. Statistical modelling conducted as part of this study indicated that 27% of variation was explained by survey year, 24% was explained by antecedent groundwater depths, 20% was explained by tree density, and 10% was explained by groundwater decline magnitude. It was hypothesised by Kath *et al.* (2014) that while maximum rooting depths in *E. camaldulensis* were unknown, critical groundwater depths identified in this study may represent a functional physiological limit to effective root growth and water extraction. In the Pilbara, the degrees of adaptation to aridity among local tree populations is thought to be higher (along with lower vegetation densities) and as such more importance tends to be placed on continued groundwater access beyond decline thresholds (associated with water table depths beyond 10 m). This continued access; while facilitating uptake of relatively negligible proportions of tree water use is considered highly important for the maintenance of turgor within trees and thus the avoidance of water stress induced mortality at key seasonal times.

Groundwater Modelling and Potential for Impacts Associated With Development of Mesa H

Modelled cumulative groundwater changes as a result of the ongoing operations at Mesa J (including the Southern Cutback Borefield) and the Coastal Water Project, combined with the development of Mesa H, are predicted to result in the initial 12 km stretch of Jimmawurrada Creek (from the confluence with the Robe River) experiencing significant groundwater height changes. Within the initial most sensitive stretch of Jimmawurrada Creek (approximately 3 km), this height change is modelled to be in the order of 1-8 m (increasing at distance from the confluence), with 4-10 m of groundwater drawdown experienced in the following 5 km stretch (i.e. from the vicinity of the corner of the creek closest to the SCB) (Rio Tinto 20189. Upstream of this stretch and away from discharge influence, modelled drawdown trends within the final approximate 4 km stretch of Jimmawurrada Creek are similar (4-8 m) depending on timing, with similar but generally greater drawdown than experienced in downstream reaches predicted for the year 2037. Beyond 2037, at the end of the Mesa H and Mesa J mine life and subsequent end of dewatering / water demand, groundwater levels in this area are expected to begin to recover. Plate 5-2 provides a spatial representation of some of the most relevant metrics from this groundwater modelling for local vegetation.

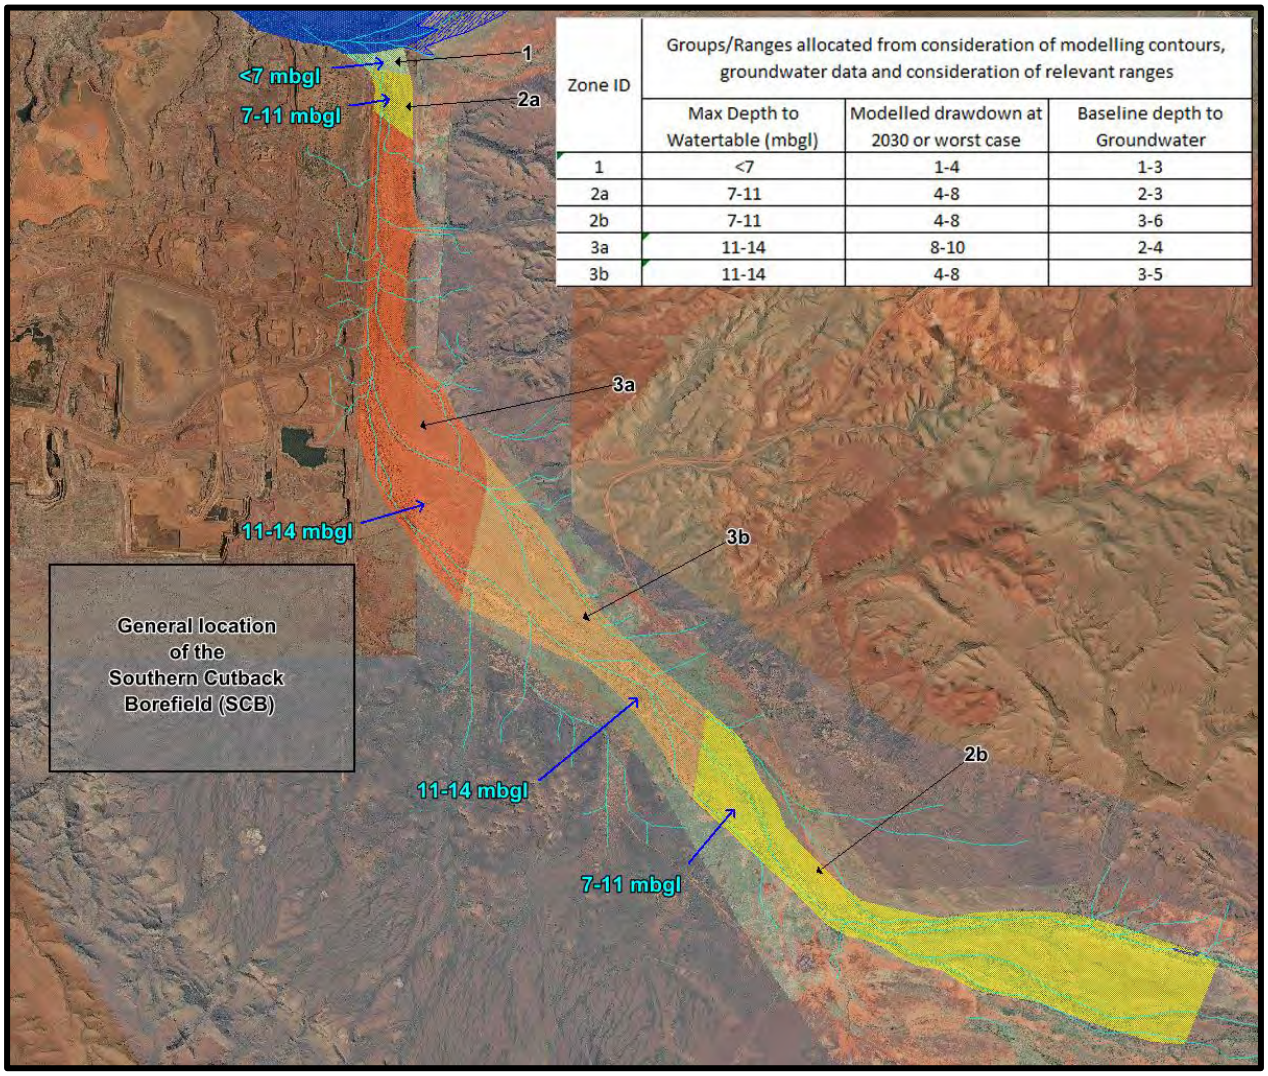
Based on current groundwater modelling (groundwater modelling from Rio Tinto 2019a), the first 0.2 km stretch of Jimmawurrada Creek from the confluence (represented by Zone 1 in Plate 5-2 and equating to approximately 2% of the modelled section of Jimmawurrada Creek), will experience a maximum depth to groundwater in 2030 of approximately <7 mbgl. Under such a scenario, groundwater should still be directly[3] and indirectly[4] accessible to overstorey vegetation, with some potential for indirect access by understorey constituents. However, some impacts are considered likely for smaller scale OPV communities present in this zone, irrespective of perceived degrees of groundwater access. See Plate 5-2 for approximate mapping of the maximum groundwater depth modelled to occur at 2030 (or the worst case scenario) within the relevant potential impact zones.

Approximately 43% of the modelled zone of Jimmawurrada Creek is represented by the following ~0.5 km creek stretch (0.2-0.7 km from the confluence) and the most upstream ~4.7 km stretch (7.3-12 km from the confluence) within the modelling area (Zone 2a & 2b in Plate 5-2). In this zone maximum depth to groundwater is modelled to be in the order of 7-11 mbgl at 2030. In addition, parts of the larger upstream stretch (7.3-12 km from the confluence) will also experience a similar depth to water later in the modelling period at 2037. Under such a scenario groundwater should still be directly and indirectly accessible to overstorey vegetation. Access for understorey vegetation is unclear, and while some understorey vegetation components may potentially maintain indirect access, this is dependent on multiple factors. Furthermore, the importance of the presence/absence of access to groundwater for understorey vegetation is not only very species dependent but is very dependent on antecedent conditions and generally this aspect of riparian ecology is poorly understood. In the case of Jimmawurrada Creek, it seems unlikely that groundwater access is a significant water source for understorey vegetation, but in some more mesic stretches it may play a role. Through the downstream

[3] Direct groundwater access is pertaining to roots directly in contact with the saturated zone of underlying aquifers.

[4] Indirect groundwater access is pertaining to roots being able to access water present in the soil profile but representing water sourced from the aquifer and forming the unsaturated zone directly above the underlying aquifer (including but not restricted to the capillary fringe) where varying degrees of capillary rise (or capillarity – forces influenced by matric and soil water potentials) can be present.

portion of this modelling group (0.2-0.7 km from the confluence) potential impacts are also likely for smaller scale OPV communities present in this area irrespective of perceived access.



Zone ID	Groups/Ranges allocated from consideration of modelling contours, groundwater data and consideration of relevant ranges		
	Max Depth to Watertable (mbgl)	Modelled drawdown at 2030 or worst case	Baseline depth to Groundwater
1	<7	1-4	1-3
2a	7-11	4-8	2-3
2b	7-11	4-8	3-6
3a	11-14	8-10	2-4
3b	11-14	4-8	3-5

Plate 5-2: Approximate mapping of the modelled maximum depth to groundwater groups (meters below ground (mbgl)) at 2030 (blue labels and arrows) for the relevant stretch of Jimmawurrada Creek*.

*** Includes delineation of the relevant potential impact zones (1-3) and table of other relevant hydrological modelling data for each zone such as; grouped maximum depth to water-table below ground level, groupings for modelled drawdown and groupings for approximate baseline (pre-mining) depth to water-table below ground level.**

Of the remainder of the drawdown modelled section of Jimmawurrada Creek (~55% or 6.6 km), and representing the central stretch, broadly located adjacent to Mesa J and the SCB (Zone 3; Plate 5-2), the maximum depth to water table is modelled as being between 11-14 mbgl at 2030. Under such a scenario, direct groundwater access is likely to be maintained by at least a portion (the more mature portion) of the overstorey riparian components. Furthermore indirect[5] access to groundwater should

[5] Indirect groundwater access is pertaining to roots being able to access water present in the soil profile but representing water sourced from the aquifer and forming the unsaturated zone directly above the underlying aquifer (including but not restricted to the capillary fringe) where varying degrees of capillary rise (or capillarity – forces influenced by matric and soil water potentials) and water delivery can be present.

be maintained by most riparian trees. However regardless of the maintenance of indirect or direct groundwater access; its acknowledged than where the water table is deeper than 10-12 mbgl, the relative contribution of groundwater to the environmental water requirements of overstorey phreatophytes is thought to be limited.

Limitations on groundwater access applied by the dimensions of local alluvial formations is also an important factor to consider in relation to the maintenance of groundwater access by GDV. At the deepest part of the Jimmawurrada Creek Alluvial Aquifer channel (the thalweg), alluvial depths are interpreted from borehole data, where available, to range from 28-40m deep. However; the denser riparian vegetation communities are not necessarily aligned with the thalweg of the alluvial aquifer channel. Based on available borehole data, the flanks of the alluvial formation ranges from 14-28m deep, and on the periphery of these outer zones, alluvial depths may be even shallower..

Based on the above observed ranges in alluvial depth, an ultimate depth to groundwater in the realm of 15m, while temporary, would broadly coincide with areas where alluvial formations extend deeper than the maximum water table depth. This means that vegetation should not experience a situation where their root systems no longer have access to groundwater saturated alluvials, notwithstanding the potential that root access to this depth may be constrained by other factors (i.e. lack of an inherent capability to or available stimuli to root that deep). Despite this; variability in channel morphology and vegetation distribution does determine that if modelled drawdown in this stretch is realised and does lead to groundwater levels extending as deep as 14 mbgl (or greater), stress associated with complete groundwater access removal from vegetation may occur in localised areas. However; this is considered unlikely based on the estimates of alluvium thickness. While this is a potential issue (but considered unlikely) for vegetation overlying some small stretches within approximately 8 km of the modelled zone, the remainder of the modelling area will not be exposed to this issue as it is also proven to have a greater alluvial sediment thickness than 15m on the creek flanks surrounding the thalweg. In addition to this; approximately 90 % of the alluvial layers in the modelled stretch of Jimmawurrada creek overlie a basement lithology of Channel Iron Deposit (**CID**), and as such, the degree of porosity, structural complexity, and inherent water holding capacity of both the lithology and sediments, may positively influence water availability at the alluvial-CID interface.

While there is limited information regarding the interface between the alluvial basement and the underlying formations, clay formations are known to be common in the area, and the potential for fine, moisture holding formations at the alluvial basement are elevated. Such formations may not only be important for holding water through dry periods, but may also be important for reducing the influence of aquifers in the underlying rock layers on those present in the alluvium. Dell et al., (1983) explored the role of root channels in deep soil profiles through coring and excavation methods in the jarrah forest of South West Western Australia. Fine Roots of *Eucalyptus marginata* were shown to penetrate the clay matrix and occupy the entire profile down to weathered basement at depths of up to 40 m. Such root channels were found to extend vertically from fissures and conduits in the shallow subsurface caprock layer deep in the clay subsoil. The channels are considered permanent features of the profile and are occupied by successive generations of trees (Dell *et al.* 1983). For roots to form channels this deep and into the fissures of basement lithologies and over successive generations, moisture sources (likely from fractured rock aquifers) in these zones must be important, and are potentially what is enticing roots down to such depths (rather than random establishment). It is for the same reason that potential moisture sources in the weathered bedrock interface between the alluvium and the porous CID layer in Jimmawurrada Creek may also represent relevant water source for trees if groundwater levels are significantly reduced.

Despite the potential for the formation of accessible fractured rock aquifers in the interface between the alluvial basement and weathered bedrock zone; information on such characteristics are minimal and thus unable to be considered as an important alternative water source. This is also compounded by the potential, in some small areas, for the groundwater table to recede down to the base of the local alluvial formations. In such situations, however spatially small they may be; the potential for impacts to overlying GDV increase substantially given that groundwater access may be removed altogether. Regardless of the presence of periods of negligible access, or degrees of groundwater access removal, the overriding factor of importance is that at least partial recovery of groundwater tables has been shown to occur annually (and at times more frequently). As a consequence, cycles of exposure to water stress and return to more acceptable conditions, have been and will be (and will continue to be) facilitating some degree of hydraulic adaptation within local vegetation communities to periodic water stress.

In situations where groundwater contact with tree roots may be removed through the general drop of water tables below existing root systems (however deep they may range), the rate of drawdown is modelled to be slow enough (average < 1 m per year, but at times greater and accompanied by short term recovery cycles as shown in Figure 5-1) in order for roots to successfully follow groundwater as it declines. This process will increase the ability of trees (particularly young to semi-mature trees) to be able to slowly adapt and potentially establish larger root masses. The development of larger root masses than previously held will help increase the ability of trees to rely more heavily on sourcing water needs from the vadose zone and associated surface water driven replenishment events.

As addressed earlier; some understorey changes are likely as a result of changes predicted by the groundwater modelling. However it is important to point out that the majority of mesic understorey components within Jimmawurrada Creek are crowded around the low flow channels where surface water inputs are generally focused. The regular surface water inputs present in these zones (along with intermittent discharge in the downstream stretches) should therefore go some way to minimising changes within the more sensitive understorey components. Despite this; structural and potentially compositional changes in the understorey vegetation are possible in the historically mesic zones experiencing the higher degrees of aquifer drawdown.

General Responses of Riparian Vegetation in Jimmawurrada Creek through Anthropogenic and Climatic Influences

As is typical in the overstorey of any woodland community when groundwater access and thus water availability is reduced, assuming the rate and severity of change stay below certain thresholds; trees will typically respond[6] by reducing their Huber value (ratio of leaf area to sapwood area) in the form of reductions in canopy leaf area (Carter & White 2009). In various locations/cases this can ultimately lead to tree mortality as a result of spatial spikes in soil dryness and the resulting competition for water resources. While mechanisms surrounding water stress induced mortality are many and often hard to attribute, the distribution and extent of mortality linked to water stress are likely to come in two key forms (assuming more extended drought conditions are not in effect). Spatial clusters of elevated mortality occurring more sporadically and which depend on smaller scale edaphic

[6] Use of the term respond is used loosely here, as this may more accurately be described as a flow on effect from multiple feedback loops within the physiology of a plant. In the shorter term this may result in leaf drop, and reductions in LAI without obvious changes in sapwood resources.

characteristics interacting with areas of elevated competition for water resources. Such clusters are generally not very obvious, as they tend to be scattered among more average conditioned vegetation. Alternatively, in arid environments such as the Pilbara, mortality events are likely to eventuate as a result of increased amounts of dead wood in canopies (from cavitation and death of some branches), increasing the susceptibility of trees to succumb to fire. These mortality events tend to convert overall to reductions in basal area over certain communities as tree density (along with leaf area per hectare) transitions to a value which the new soil moisture regime can support in the short to long term.

Current modelling (Rio Tinto 2019) suggests that the greatest rate of change in groundwater height along the creek is predicted to occur between 2027 and 2030 with a cumulative drawdown rate of approximately 2.5 m/year. However, drawdown and aquifer recovery rates of 2m/year will happen frequently depending on duration of the dry season and the frequency of rainfall events (Figure 5-1). Between 2023 and 2036 the average linear rate of drawdown during this entire period is predicted to be approximately 0.2 m/year.

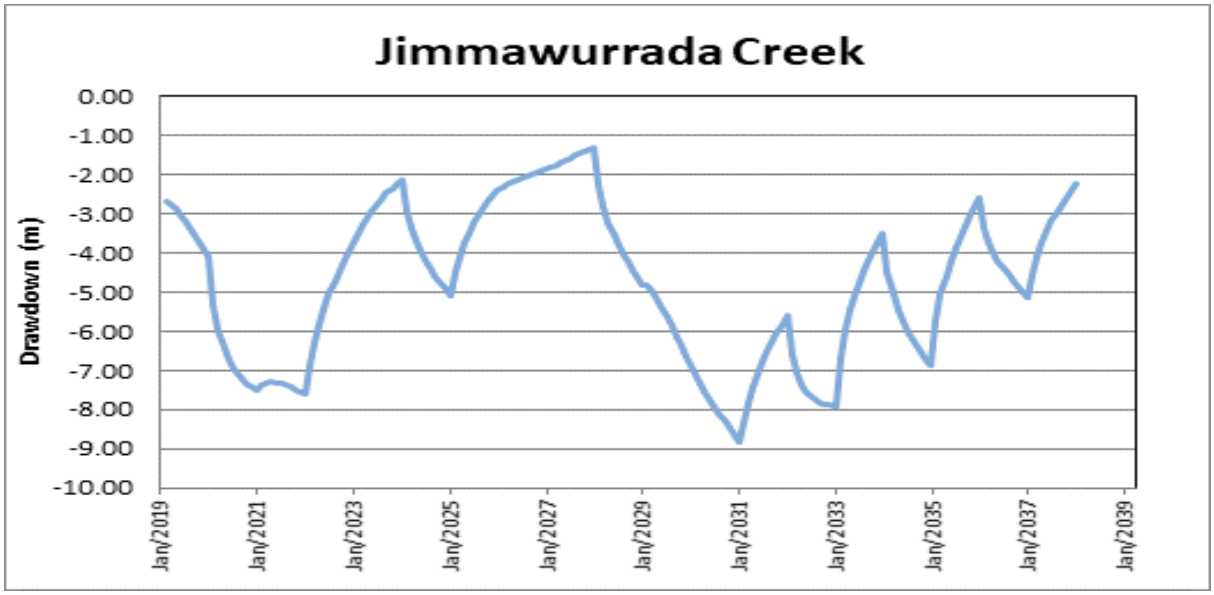


Figure 5-1: Graph showing the maximum rates of drawdown modelled to occur along the stretch of Jimmawurrada creek where groundwater heights are influenced by the Mesa H proposal.

The modelled degree of vertical change to groundwater levels is generally thought to be within ranges which local facultative phreatophytes can successfully adapt to (i.e. 1 cm per day which translates to more than 3 meters per year; Kranjcec, Mahoney and Rood 1998; Scott, Shafroth, and Auble 1999; Horton and Clark 2001; and Canham 2011). This suggests that, assuming an extreme drought does not temporally align with spikes in drawdown induced water stress; rates of change are unlikely to bring about significant threshold induced mortality events and extreme canopy decline. Furthermore, such rates of groundwater table decline are considered well within the range with which tree root growth is thought capable of tracking down through the alluvial profile in order to maintain contact and groundwater access. However, it is acknowledged that aquifer drawdown based on groundwater modelling does not accurately predict rates of drawdown at a smaller scale. Instead, as the degrees of drawdown predicted are realised in the environment, cycles of fluctuation in the water table (as depicted in Figure 5-1) will be likely and as such there will be periods of slower change and periods of accelerated change, often followed by some level of recovery in the shorter term. As a result and also through consideration of the historical groundwater levels in the area; small sections of

Jimmawurrada Creek such as the area adjacent to and further upstream of the SCB (see Plate 5-2; where drawdown of 4-8 and 8-9 m may be experienced), also have the potential to experience threshold-induced mortality events and significant canopy decline as a result of water stress. However, this same area is also where significant changes in groundwater height, in the order of that predicted to occur as a result of the proposal, have already been experienced (along with subsequent recovery) due to climatic changes and historical dewatering of local aquifers. Therefore, it is assumed that these riparian communities have already undergone some degree of adaptation to hydrological change and as such should possess increased resilience to future hydrological change of a similar magnitude.

So far, groundwater changes broadly linked to climatic shifts, but also partly attributable to local bore fields have seen canopy cover changes in the order of 10-40 % in communities surrounding the low flow channel (Rio Tinto 2018c). However; baseline monitoring in the area of interest along Jimmawurrada Creek is limited to 2017 onwards, and as a result, does not provide a full context with which to quantify the impact of recent hydrological changes experienced in the study area. This means that the following changes are summarised from a limited number of tree health sites (monitored back to 2012), some located near to, but all positioned upstream of the modelled influence of the SCB and Mesa H/J. In addition, some localised increases in mortality (patchy, and generally not coinciding spatially with monitoring sites), likely to be in the order of 1-5 % of local overstorey populations have also been observed, but not monitored.

Based on the hydrogeological modelling results, there is a risk that certain riparian zones within Jimmawurrada Creek may suffer impacts to overstorey and some understorey components. Such impacts are most likely to be a result of reduced access to groundwater in combination with increased competition for water. Increased competition for water is thought to be linked to elevated tree stand densities which appear to have established as a result of historical groundwater access, discharge and the climatically wet period appearing in the rainfall records between 1988 and 2011. However; certain local conditions may also determine that the riparian systems in the area possess an increased degree of resilience to changes in the broader groundwater table.

Sediments in the Jimmawurrada Creek area appear to be relatively fine, so the alluvial deposits below creek bed and bank communities are likely to possess relatively high soil matric potentials. Water in soil profiles typically moves from areas of high water potential to areas of low water potential (i.e. wet soil to dry soil), with such water potential gradients often formed by root zones drying the soil in their areas of influence (Hillel 1998). While the force of gravity generally restricts water moving too far along such gradients against this force (i.e. vertically up), soil matric potentials (broadly a product of soil particle sizes and surface characteristics) essentially influence the size of capillary forces and have the power to draw water up from saturated/unsaturated areas along water potential gradients (Hillel 1998). For this reason soil matric potentials and processes which set up soil water potential gradients in the soil, have an ability to influence the distance over which water can be transported vertically (up) from the saturated zones associated with local aquifers. As a result wetting and drying cycles in the soil profile down to average rooting depths have a tendency to create underlying gradients of soil water potential capable of drawing moisture up from the unsaturated zone above the broader water table through capillary rise (via the forces of capillarity (unsaturated soil water movement)). Where soil matric potentials are high and barriers to capillary rise are not present (such as clay lenses), capillary rise can be substantial, and potentially in the order of 2-6 m above the actual water table

height[7]. In arid climates the water delivered by transfer along such gradients is potentially as important as direct connection to the groundwater as it serves the same purpose of maintaining turgor within plant tissues through drought and seasonal water stress periods. As a result groundwater supplementation to the vadose zone along gradients of matric potential has the potential to prevent/diminish substantial decline/mortality events. The potential extent of this type of moisture supplementation to the vadose zone in riparian environments is clearly relatively unknown, but may also represent a key mechanism driving the resilience shown by established arid-zone riparian communities to recorded groundwater changes.

The Robe Valley has recently transitioned from a medium term period (approximately 15+ years) of above average rainfall to a five year period of average to slightly below average rainfall (from 2012) which appeared to be broken by an above average 2016/2017 wet season (See Figure 5-1). A significant drying trend was also noted to reach a peak in 2016 as part of long-term pool monitoring conducted within the Robe River (Streamtec 2017), and within riparian tree canopies monitored as part of a suite of tree health sites within Jimmawurrada Creek (Rio Tinto 2018c). In the section of Jimmawurrada Creek where a good number of bores are located relatively close to the creek (broadly equivalent to zones 2b & 3b in Plate 5-2), bore data has shown that groundwater has dropped between 2-6 m in various locations, with change in the order of 5m and greater located in the creek section closest to the southern cut back Borefield (Rio Tinto 2018d). While a significant component (probably the most substantial component) of the drying trend detected is likely attributable to the climatic influence recorded (and importantly a significant reduction in surface water flows within Jimmawurrada Creek prior to 2016), it is not yet clear how much of this trend is also associated with local anthropogenic groundwater pressures. What is clear is that in the zone where greatest recent groundwater height change has been experienced, beyond a general trend of canopy decline and some patchy clustering of more substantial canopy decline, no significant increases in tree mortality were noticed at the time of survey (and more generally by Rio Tinto monitoring staff). However it is important to note that similar levels of groundwater height change have not been confirmed in the alluvium of Jimmawurrada Creek due to a limited number of bores located directly in this zone. Despite this, it is assumed that a similar degree of change has also occurred in the alluvium. If not, this may be testament to the influence of local surface water regimes, the water holding capacity of alluvial formations in this area and the reduced potential for groundwater changes in the basement to transfer through to the potentially dense alluvial formations above.

When considered in light of the magnitude of hydrological change experienced through the 2014-2018 period (up to 6 m of groundwater drawdown in some areas); the magnitude of canopy decline and particularly mortality observed along key sections of Jimmawurrada Creek appears relatively low. If this is also considered in light of the 2017 canopy regrowth and some recovery within riparian vegetation through such areas; the evidence suggests that at least partial groundwater recovery events are regular, vegetation in the area is relatively robust, and a significant degree of adaptation to new hydrological conditions, particularly within the root-zone may have already occurred and will likely continue to occur.

[7] Estimated based on theoretical graphs provided in various literature, but not backed by good empirical data, rather a guide from theoretical models. This should be assumed to give some indication of hydraulic uplift could be achieved via such pathways rather than suggesting what's occurring in this situation.

Despite more positive rainfall and recharge conditions during the 2016/2017 wet season and some positive 2018 winter rainfall events, 2017/2018 rainfall has generally been below average, with similar trends seen in the creek flow data for Jimmawurrada Creek. This is an important trend given how important groundwater in the Bungaroo valley is, and how tightly linked aquifer recharge is to rainfall/stream-flow in the locality.

If an extended period of drought and a lack of cyclonic events (and associated stream flows) is experienced; natural recharge and thus recovery of the local Bungaroo aquifer and groundwater heights under Jimmawurrada creek; may be heavily reduced. Hydrogeological modelling based on a simulated 50% reduction of natural recharge (Uncertainty run 2; Rio Tinto 2019), suggested that the water table along the Jimmawurrada Creek could be reduced by a further 3m on top of current modelling. However; this does assume below average rainfall/cyclonic events occur and persist for an extended period, which while possible, is relatively unlikely under current short term climate change predictions. Importantly, the nature of the hydrogeological environment of the Bungaroo valley determines that recharge rates per unit area appear broadly high, when compared to other Pilbara aquifer systems. As a result, any decline in water levels brought about by such climatic changes, also have the potential to be ameliorated relatively rapidly under the influence of a cyclone or multiple large tropical rainfall events. However the modelling conducted in the H3 report (Rio Tinto 2019) generally suggests recovery rates of 2m/year will happen frequently depending on the duration of dry season and frequency of rainfall events. This is supported by airborne geophysical data interpretation which suggests that there is a fair degree of hydraulic connectivity between the Jimmawurrada Creek sediments and Bungaroo palaeochannel aquifer in the upper Jimmawurrada area (Rio Tinto 2019).

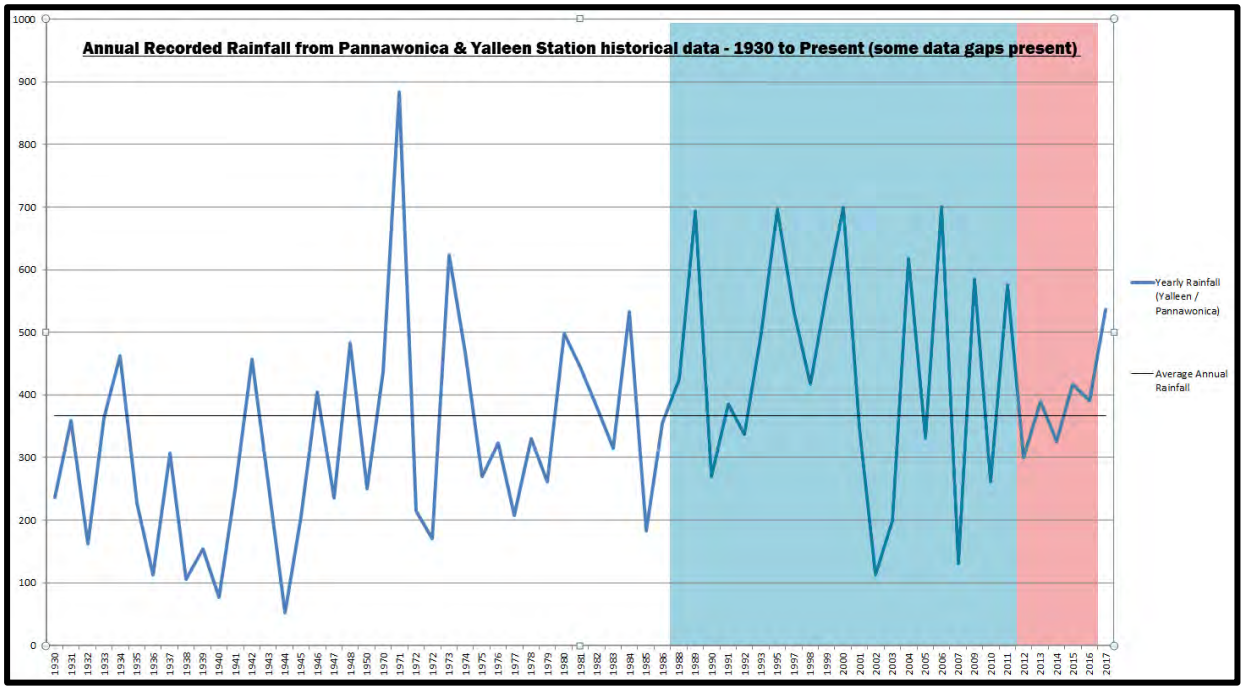

Figure 5-2: Graph of the long term annual rainfall records for Pannawonica and Yalleen Station combined*

*takes advantage of mid-late 1900's Yalleen station data and gaps in this data filled by the Pannawonica data.

6 CONCLUSIONS

Broadly speaking; vegetation communities mapped within the Jimmawurrada Creek study area and excluding communities in the sump/wetland, are relatively equivalent to typical medium to larger sized creekline communities which are well represented throughout the Pilbara. Despite the presence of some atypical mesic floristic components and associations within the upstream reaches of Jimmawurrada Creek (likely associated with hydrological influence form the Bungaroo valley aquifer, the high degree of grazing related disturbance and weed infestation led to the ultimate significance attributed to these communities being reduced. As a result, the key riparian communities which are distributed on and around the main low and high flow channels of the creek are estimated to possess a "Moderate" to "Minor" range of significance. In addition to this, some small areas of C1b/C1bb coded vegetation (OPV), where *Melaleuca argente*a forms a co-dominant component, are present at the Robe River end (Jimmawurrada Creek – Robe River confluence) of the study area. In addition to these areas being quite sensitive to hydrological change, they are also of elevated significance having been attributed a "Moderate-high" significance (where present at baseline) rating as part of this study.

Significant impacts to the more sensitive C1bb community (~0.5 ha interpreted present at baseline) within Jimmawurrada Creek are unlikely but possible given the inherent vulnerability of the resident obligate phreatophytes and the degree of consistency of water access they are likely accustomed to. Significant impacts/changes to the C1b community within Jimmawurrada Creek are likely based on groundwater modelling, but together with the mitigating influence of discharge, surface water inputs, and groundwater recovery cycles, such impacts if realised are unlikely to persist over short to medium time scales. Furthermore this community appears to have established under the influence of discharge and as a result, any transition to a more ephemeral type riparian community is potentially insignificant. Upstream of these communities where greater magnitude drawdown is likely; a slow transition to smaller canopies (i.e. reduced Leaf Area Index) and reduced tree densities (or basal areas) within communities currently accessing and relying upon groundwater is likely. The Facultative phreatophytic type vegetation communities present in such zones of the creek are generally known to be more resistant to hydrological change and much better at transitioning to utilising alternative water sources for the vast majority of their requirements. As a result, it is predicted that some level of change (minimal compositional changes (understorey) and potentially some structural change (reduced cover) in overstorey/understorey components) is likely within riparian vegetation communities within Zones 1 – 3 along Jimmawurrada Creek, but that there is potential for more pronounced change in certain zones (particularly Zone 3a (southern half), and 3b, and the western half of 2b south (Plate 5-2)), where elevated stand densities occur adjacent to the Mesa J SCB.

Within the Sump/Wetland area, communities were attributed a "Moderate-High" significance and were also determined to possess "Medium (+) to High" sensitivity to hydrological change. While the Sump/Wetland communities may be dependent on small perched aquifers and therefore potentially exist independent of the broader groundwater table, the cumulative drawdown modelled as part of the Mesa H Proposal is not predicted to have a detectable influence that far to the east.

Leeper). Melbourne.

Vegetation Condition Scale*

E = Excellent (=Pristine of BushForever) Pristine or nearly so; no obvious signs of damage caused by the activities of European man.
VG = Very Good (= Excellent of BushForever) Some relatively slight signs of damage caused by the activities of European man. For example, some signs of damage to tree trunks caused by repeated fire, the presence of some relatively non-aggressive weeds such as **Sonchus oleraceus* or **Cucumis* spp., or occasional vehicle tracks.
G = Good (= Very Good of BushForever) More obvious signs of damage caused by the activities of European man, including some obvious impact on the vegetation structure such as that caused by low levels of grazing or by selective logging. Weeds as above, possibly plus some more aggressive ones such as **Cenchrus* spp.
P = Poor (= Good of BushForever) Still retains basic vegetation structure or ability to regenerate to it after very obvious impacts of activities of European man, such as grazing, partial clearing (chaining) or frequent fires. Weeds as above, probably plus some more aggressive ones such as **Cenchrus* spp.
VP = Very Poor (= Degraded of BushForever) Severely impacted by grazing, very frequent fires, clearing or a combination of these activities. Scope for some regeneration but not to a state approaching good condition without intensive management. Usually with a number of weed species including very aggressive species such as **Prosopis* spp.
D = Completely Degraded (= Completely Degraded of BushForever) Areas that are completely or almost completely without native species in the structure of their vegetation; ie. areas that are cleared or 'parkland cleared' with their flora comprising weed or crop species with isolated native trees or shrubs.

* Based on Trudgen M.E. (1988). A Report on the Flora and Vegetation of the Port Kennedy Area. Unpublished report prepared for Bowman Bishaw and Associates, West Perth.

1.0 Project Summary

In accordance with the Rio Tinto scope of work, Table 1.1 presents a summary of survey and project information.

Table 1.1: Summary of project specifications and limitations.

Project Name	Mesas A and K Targeted Troglofauna Survey			
Level of Survey	Targeted survey			
Location	Approximately 38 km west of Pannawonica township			
Survey Area Size	Mesa A	20 km^2	Mesa K	6.3 km^2
Survey Timing	Surveys completed between December 2016 – March 2017			
Relevant Regulatory Guidance Documents and Applicable Legislation	• EPA Statement of Environmental Principles, Factors and Objectives (EPA 2016a); • Environmental Factor Guideline – Subterranean Fauna (EPA 2016b); • Technical Guidance - Subterranean fauna survey (EPA 2016c); and • Technical Guidance - Sampling methods for subterranean fauna (EPA 2016d).			
Key Survey Limitations	• Sampling for troglofauna in the Robe Valley and wider Pilbara region relies on the use of drill holes, which are almost always installed as part of exploration drilling and thus focus on geological units of economical importance. This creates a bias in availability of drill holes for troglofauna sampling, as sampling tends to not extend far beyond the footprint of the target ore body and is focussed on particular rock types. This places limitations on determining wider species distributions and whether there are potential barriers to dispersal. • For most taxa, only adult specimens have diagnostic morphological characteristics necessary to be identified to species level. As juvenile specimens are often collected, this limited the level to which many specimens could be identified. These specimens, as well as those too damaged to identify have been classified as indeterminate species (sp. 'indet'). Indeterminate species (e.g. *Paradraculoides* sp. 'indet' and Thysanura sp. 'indet'), while reported on for transparency within the results, were removed from the discussion analysis since these specimens may represent multiple species or may equate to a species already known elsewhere. • A relatively small number of sampling locations were available to investigate the subterranean fauna habitat questions considered by this study (only a single site in the case of the low grade waste dump at Mesa A). With the high degree of ecological sampling effects and intra-site variation inherent in troglofauna data sets, this limits the power of the sampling design and thereby the conclusiveness with which this study can resolve habitat utilisation.			

This page intentionally blank.

2.0 Executive Summary

Rio Tinto wishes to improve knowledge on the persistence of troglobitic communities within historically disturbed habitats at Mesa A and Mesa K. The target habitats in this respect include substrate beneath existing mine pits and habitat beneath or within waste dumps.

Biota Environmental Sciences (Biota) was commissioned to undertake targeted troglofauna sampling at Mesa A and K to build upon data from previous surveys in each area and investigate whether troglofauna communities still persist beneath the pit floors, the extent of these communities, and whether they have become established within, or still persist beneath, waste dumps.

Two phases of troglofauna sampling involving three field mobilisations were conducted at Mesa A and K between December 2016 and March 2017. A total of 19 drill holes were successfully sampled within the Mesa A and Mesa K survey areas (14 and 5 sites respectively). Fifteen sites were sampled in consecutive phases and four sites sampled once. A total of 86 troglofauna traps were installed with 79 traps recovered. The number of traps installed per site varied from 1 – 3 traps depending on hole depth. Haul net scraping was completed for 16 of the 19 sites during Phase 1. No haul net scraping was conducted during Phase 2.

A total of 383 specimens, representing 44 taxa across 11 orders were documented for the Mesa A search area during the desktop review. Of these, 22 taxa could not be identified to species level. Six of the remaining 22 taxa represent formally described species and the remaining 16 taxa are undescribed. The most commonly collected species was the schizomid *Paradraculoides anachoretus*, representing over 32% of specimens. This species, as well as four pseudoscorpion species, *Lagynochthonius asema*, *Tyrannochthonius* sp. 'Mesa A', *Ideoblothrus linnaei* and *Ideoblothrus* sp. 'Mesa A', are all listed as conservation significant.

The Mesa K desktop review yielded 363 past specimen records representing 29 taxa across 14 orders. Seven taxa were unable to be identified to species level and four taxa aligned with formally described species. The remaining 18 taxa are currently undescribed. The schizomid species *Paradraculoides kryptus* was most commonly recorded, representing over 38% of Mesa K collections. This species is the only listed conservation significant fauna species identified from the desktop review for Mesa K.

During the current survey, four schizomid specimens were recorded from drillhole RC16MEA004 at Mesa A, all of which were recorded during Phase 2. Genetic analysis of the collected Schizomida determined the presence of two distinct lineages, equating to two species for the purpose of this report, *Paradraculoides anachoretus* and *Paradraculoides* sp. 'SCH034'.

Paradraculoides anachoretus has been widely recorded from Mesa A in the past and is considered to be endemic to the mesa. *Paradraculoides* sp. 'SCH034' was recorded from RC16MEA004 during the current sampling, which is located within the pit and drilled through a low-grade waste dump, and has previously been recorded from two sites within the Mesa A Mining Exclusion Zone (MEZ).

No troglomorphic specimens were collected from Mesa K during the current survey, and no additional information on habitat utilisation by troglofauna at this site is therefore available.

Currently, insufficient data exist to allow for a robust analysis comparing results of sampling in-pit at Mesa A with the results of sampling within the MEZ and prior to mining operations, but both schizomid species recorded in-pit have been demonstrated to also occur within the MEZ. Most sampling effort since operations commenced has focused on reference area sampling. However some observations can still be made from the results of the in-pit sampling. From the very limited data available, it is possible troglofauna may be utilising the low-grade waste dump at Mesa A as habitat. However, information provided by Rio Tinto indicates that the sampled drill hole

(RC16MEA004) was also drilled beyond the base of the waste dump and into intact troglofauna habitat below. This introduces the possibility that the troglobites recorded from this site may have entered the drillhole from intact habitat at depth, rather than truly utilising the waste dump as habitat.

3.0 Introduction

Rio Tinto wishes to improve knowledge on the persistence of troglobitic communities within historically disturbed habitats at Mesa A and Mesa K (Figure 3.1). The target habitats in this respect include substrate beneath existing mine pits and habitat beneath or within waste dumps.

Previous studies in the vicinity of Mesa A and elsewhere in the Robe Valley have documented troglofauna species that are isolated to individual mesas, demonstrating extreme short-range endemism, which has implications for environmental impact assessment (EIA). Biota Environmental Sciences (Biota) was commissioned to undertake troglofauna sampling at Mesa A and K, as part of prefeasibility studies to further inform EIA. The purpose of this work is to build upon previous surveys in each study area and investigate whether troglofauna communities still persist beneath the pit floors and waste dumps, the nature and extent of these communities, and whether they have also become established within waste dumps.

3.1 Project Background

Biota conducted sampling for stygobitic fauna at Mesa A in 2003 and recorded four troglobitic taxa within the voids in the pisolitic mesa (Biota 2004). Prior to this, troglofauna had not been recorded from the Pilbara region (Biota 2004). Since this discovery, further sampling has demonstrated that troglofauna are widely distributed within the Robe Valley (Biota 2006a, 2007, 2011a, 2017) and elsewhere in the Pilbara (Biota 2016). However, previous sampling within the Robe Valley mesas has demonstrated that each mesa provides habitat for a unique assemblage of troglofauna (Biota 2006a, 2007, 2011a, 2017). A total of 10 phases of sampling has been completed at Mesa A and 12 phases at Mesa K.

3.2 Objectives and Scope

The scope of this study was two-fold:

- to undertake troglofauna sampling at Mesas A and K to build upon the knowledge gathered during previous surveys in the Robe Valley area; and
- to investigate whether a troglofauna community is present within previously disturbed parts of Mesa A and K.

The key objectives of this study were to:

1. conduct a two-phase targeted troglofauna survey at Mesas A and K;
2. document the recorded fauna to the lowest level of identification possible, including alignment and comparison with previously collected taxa;
3. complete molecular analysis of troglobitic specimens that are not able to be adequately identified morphologically;
4. discuss the distribution of taxa recorded during this survey;
5. discuss the conservation significance of the species recorded during the survey in both a local and regional context; and
6. compare the troglofauna community recorded during this targeted survey with the communities recorded previously at Mesas A and K, and elsewhere in the Robe Valley.

The study was planned and implemented as close as practicable in accordance with:

- EPA Statement of Environmental Principles, Factors and Objectives (EPA 2016a);
- Environmental Factor Guideline – Subterranean Fauna (EPA 2016b);
- Technical Guidance - Subterranean fauna survey (EPA 2016c); and
- Technical Guidance - Sampling methods for subterranean fauna (EPA 2016d).

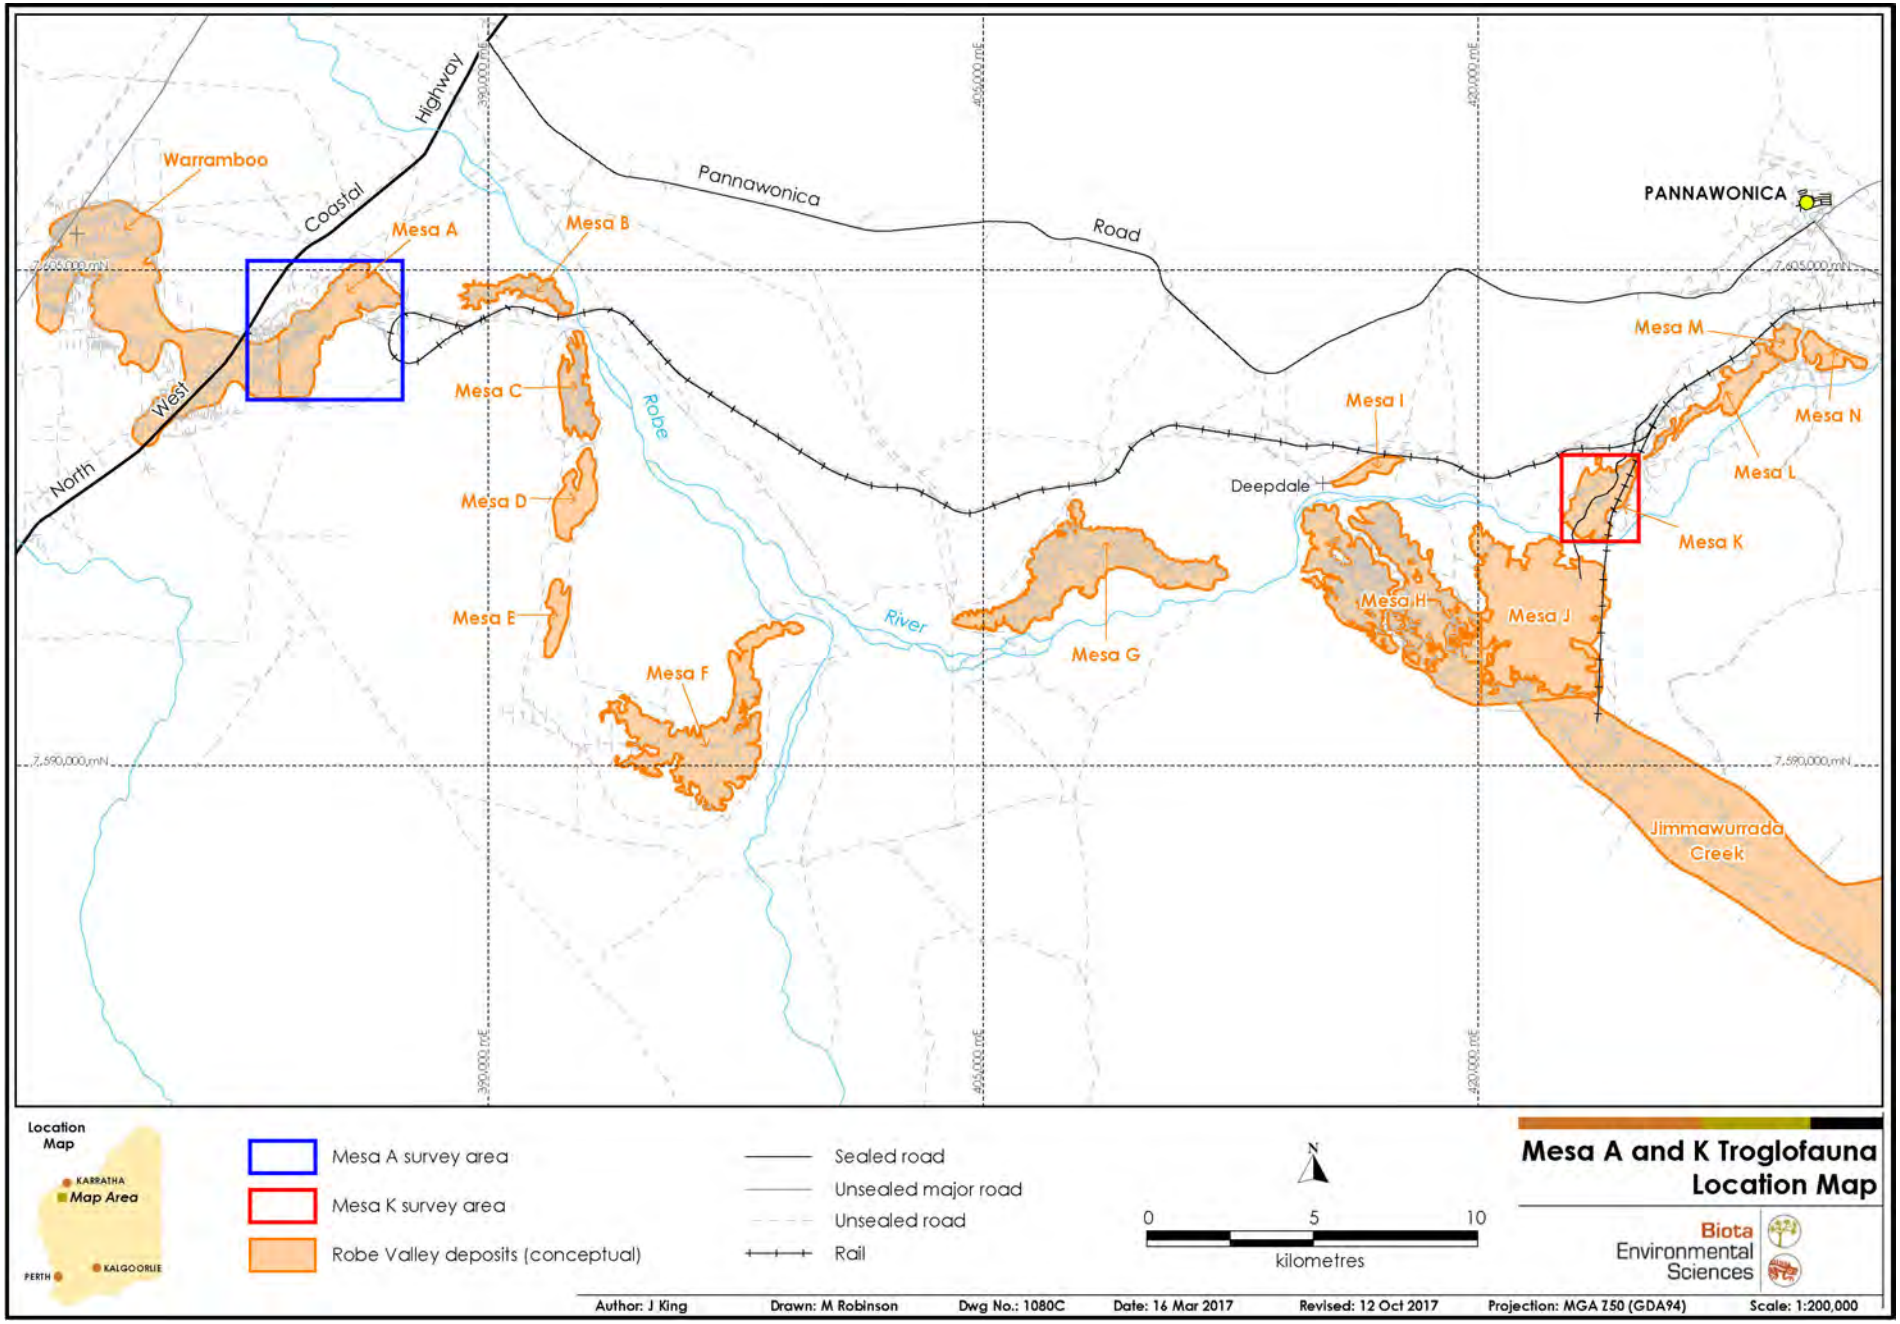

Figure 3.1: Location of the Mesa A and Mesa K survey areas.

3.3 Terminology

For the purpose of this report, the following terms are used as defined below:

Survey area – Refers to the extents of Mesa A and Mesa K that were surveyed as part of the current scope (Figure 3.1).

MEZ – Mining Exclusion Zone; Refers to the avoidance areas set aside at Mesa A where mining is prohibited under current Ministerial approval.

Survey – Refers to the two phases of sampling undertaken for the current scope of work.

3.4 Subterranean Fauna Overview

Until relatively recently, Australia was thought to lack habitat suitable for subterranean fauna. However, recent research (mostly with an emphasis on impact assessment) has revealed Australia to be highly diverse in subterranean fauna, with numerous areas of interest throughout the continent (Guzik et al. 2010). In Western Australia these zones of subterranean biodiversity can be found at Cape Range, Barrow Island, the Pilbara bioregion, the Yilgarn and the Nullarbor (Humphreys 2001, Page et al. 2008, Guzik et al. 2010).

Relatively recent surveys in the Pilbara have collected subterranean fauna from a range of geological units such as pisolitic iron formations, channel iron deposits, unconsolidated alluvium and sedimentary basalt (Marmonier et al. 1993, Biota 2004, 2006a, 2010, 2011b, 2013). This indicates that the suitability of a formation as habitat for subterranean fauna is mostly a function of the availability of habitable space (Marmonier et al. 1993, Humphreys 1999, Biota 2006a), rather than a specific geology unit.

Subterranean fauna habitats are characterised by shared physical parameters that include a lack of light, stable temperature, limited nutrient infiltration from surface environments and a constant humidity (Juberthie 2000, Romero 2009). These habitat characteristics have resulted in convergence in body morphology evolution amongst many subterranean fauna. Morphological characteristics common to most subterranean fauna include reduced or lack of pigmentation, reduced or lack of eyes, and elongate body morphology and appendages adapted for sensory movement (Culver and Pipan 2009, Romero 2009).

Subterranean fauna can be categorised into two distinct ecological groups based on habitat: troglofauna and stygofauna. Troglofauna are a suite of fauna that survive only in air-filled cavities and interstices between the surface and the water table. Stygofauna comprise aquatic taxa occurring in groundwater aquifers and subterranean water bodies. Troglobites and stygobites are obligatory subterranean habitat dwellers, and while they may occur close to surface environments, are strongly adapted to subterranean environments. This makes such fauna unable or highly unlikely to survive surface conditions. A range of similarly adapted fauna known as troglophiles, trogloxenes and edaphobites also occur; these fauna use subterranean habitats opportunistically but are able to survive outside these stable environments. Studies from the Pilbara bioregion have demonstrated that these suites of fauna are not similarly restricted in range and are therefore unlikely to be impacted by small-scale developments (Biota and Helix 2012, Helix 2012).

Troglofauna in semi-arid Australia are thought to be relictual rainforest fauna; fauna adapted to humid environments, which retreated underground to cave systems during the aridification of Australia (In the late Miocene; Humphreys 1993). This is inferred from affinities of the taxonomic groups represented amongst the troglofauna with other extant taxa in tropical climates. Some invertebrate groups with troglobitic representatives include the Arachnida (e.g. Schizomida, Pseudoscorpiones and Araneae), Chilopoda (e.g. Scolopendrida), Diplopoda (e.g. Polydesmida and Haplodesmida), and Insecta (e.g. Diplura, Thysanura, Coleoptera and Blattodea). A single troglobitic vertebrate species of blind snake (*Anilios longissimus*) is known from Australia, collected from Barrow Island (Aplin 1998, Humphreys et al. 2013).

Due to their dependence on constant humidity, the dispersal and distribution of troglobitic fauna species tends to remain limited to individual blocks of inter-connected habitat, leading to long periods of population isolation and speciation. As a result, troglobitic fauna are considered to be of conservation significance, given that species often display extreme short-range endemism and may therefore be affected by relatively small-scale developments such as mining and construction.

4.0 Methodology

4.1 Desktop Review and Database Searches

4.1.1 Review of Previous Relevant Studies

A literature review was completed to identify previous relevant surveys conducted within the survey area. This included searches of Biota's library database, GoogleScholar[1] and the EPA's website, in addition to the identification of previous surveys via database specimen records (Section 4.1.2). Reports and data supplied by Rio Tinto were also collated with the results of the literature search and reviewed.

4.1.2 Database Searches

The following databases were searched to assist with compilation of a list of potential species for the survey area:

1. NatureMap: a collaboration between the Department of Parks and Wildlife and the Western Australian Museum (WAM). This database represents the most comprehensive source of information on the distribution of Western Australia's fauna, comprising records from the Fauna Survey Returns database and WA Threatened Fauna Database (both maintained by the Department of Parks and Wildlife) and the WAM Specimen Database.
2. WAM's Arachnid, Myriapod and Crustacea database.
3. Biota Internal Database: This database includes all of the subterranean fauna data collected by Biota within Western Australia, which includes the majority of the historical records recorded from the Robe River valley.

Details of database searches conducted are summarised in Table 4.1.

Table 4.1: Summary and location of database searches completed

Database	Date	Search Target	Bounding Coordinates	
			Eastings (m E)	Northings (m N)
Biota, NatureMap	17/03/2017	Mesa A	384970	7603500
		Mesa K	423685	7598092
WAM	14/03/2017	Arachnida, Myriapoda and Crustacea	405138	7607948
			435642	7582695

4.2 Sampling Methodology

Troglobitic fauna sampling was completed under "Licence to Take Fauna for Scientific Purposes" No. 08-000238-1 issued to Penny Brooshooft (Appendix 1). Methodology and approach were consistent with those outlined in Technical Guidance; Subterranean Fauna Survey (EPA 2016c) and Technical Guidance; Sampling Methods for Subterranean Fauna (EPA 2016d). Similar methodologies have been used in previous Robe Valley subterranean fauna assessments (Biota 2006a, 2009a, 2011a). Troglobitic fauna were sampled using two methods; baited colonisation traps and drillhole scraping.

4.2.1 Colonisation Trapping

Custom-built litter colonisation traps were suspended at intervals within drillholes located within the study area. Traps were constructed from 60 mm internal diameter PVC irrigation pipe cut to a length of 180 mm. Each trap had a series of 20 mm holes drilled into the side, and traps remained open at the upper end. Up to three traps were installed such that they were in contact with the interior of the sampled drillhole, facilitating fauna entry into the trap.

[1] https://scholar.google.co.uk

Leaf litter was gathered locally from the ground surface in the study area, particularly from the bases of *Acacia* shrubs. The collected litter was soaked in water and irradiated in a microwave oven for two minutes on maximum power setting. The microwave acted to kill any surface invertebrates present and assisted in the breakdown of organic matter. Wet leaf litter was added to the traps, which were kept in sealed containers until immediately prior to insertion into the drillholes to avoid desiccation of the litter. After the installation of traps, the opening of each drillhole was sealed to maintain humidity and to avoid entry of surface fauna.

Traps were recovered from each drillhole after a minimum of six weeks, as per EPA guidance, and stored in labelled zip-lock bags in order to maintain humidity and prevent desiccation of potential troglofauna specimens during transportation to Perth.

Fauna specimens were recovered from the traps using specially designed Tullgren funnel units. The leaf litter from each trap was placed in a sieve under an aluminium lamp containing a 25-watt globe. This created a temperature of approximately 30°C at the surface of the leaf litter. A funnel situated below the leaf litter collected the fauna as they fell, directing them into an attached vial of 100% ethanol. Leaf litter was left in the Tullgren funnels for a period of 24 hours, or until dry, after which time the bulked invertebrate sample was removed.

4.2.2 Haul Net Scraping

Troglofauna were also sampled using reinforced haul nets. These nets were constructed from 70 µm plankton mesh and had 100 mm apertures attached to a weighted catch jar. Sampling took place by lowering the net to the bottom of the site before being hauled slowly to the surface whilst scraping the edge of the drillhole. This dislodged any fauna on the vertical surface of the drillhole interior. Each site was scraped a minimum of four times, scraping each side of the drillhole. On completion, fauna specimens were preserved in-situ in 100% ethanol and individually labelled. The contents of the net, which included dry soil and root matter, were emptied into a uniquely labelled container. The container was then filled with 100% ethanol to preserve any specimens that may have been in the soil and root matter for later sorting in the field laboratory.

4.2.3 Data Management

Preliminary identification of subterranean fauna involved identification of specimens to order level, where possible, or separation of specimens into distinct morphotypes. Sorting was completed in Perth using dissecting microscopes (Olympus SZ40 and SZ61, magnification up to 40x). Morphotypes were then assigned a unique number based on drill hole name, date and method of collection. Specimens were preserved in 100% ethanol once separated out into morphotypes, which allows for both morphological and molecular analyses.

4.3 Molecular Analysis

Molecular analysis of collected schizomida was completed to inform determinations of the number of species present, and compare the results with those obtained during previous surveys in the Robe Valley and wider Pilbara region. Yvette Hitchen of Helix Molecular Solutions (Helix) completed the molecular sequencing. Specimens were sequenced for variation at the mitochondrial cytochrome oxidase subunit I gene (CO1; Appendix 2).

Dr Terrie Finston (of Helix) provided analysis and interpretation of the molecular data (Appendix 2). The molecular analysis used was a preliminary neighbour-joining approach using representative sequences from regional context data sets, followed by a phylogenetic analysis using the sequence data from this study (Appendix 2). This resulted in specimens from the current survey being placed into genetic lineages, which also included specimens from collections elsewhere in the region. Determination of putative species was then inferred from these genetic lineages based on the level of divergence between lineages of the same group (such as order or family), giving consideration to the variation within each lineage.

It should be noted that detailed morphological analysis was not completed for most specimens and the phylogenetic analysis was based on sequence data from a single gene. Therefore, all species arrived at by this approach should be considered putative unless previously described and fully determined by taxonomic specialists. Lineages with a divergence of less than 4.0% were considered a single species, whereas lineages with a divergence greater than 6.0% were considered separate distinct species for the purpose of this report, unless advised otherwise by Helix based on other data for the relevant taxonomic group. Lineages with intermediate divergences ranging from 4.0–6.0% were resolved to a preliminary level for the purposes of this report, with further input from Helix, and consideration to collection proximity, habitat characteristics and geology.

4.4 Categories of Conservation Significance

For the purpose of this report, the conservation significance of the fauna collected during this study, or records collated during the desktop review, was categorised as per Table 4.2.

Table 4.2: Conservation classification used within this report.

Category	Description
Conservation Significant species	Species listed as Priority, Schedule or Vulnerable at State or Federal levels.
Confirmed Short-range endemic (SRE) species *	Species where sufficient taxonomic expertise is available, and with adequate representation in WAM collections or genetic databases, that are known to be limited in distribution based on geological characteristics.
Potential SRE species *	Species where there is insufficient taxonomic knowledge or too limited a number of collections to determine SRE status. Habitat, morphology, molecular or taxonomic data deficient, but belonging to groups that may display short-range endemism.
Widespread (not an SRE) species *	Well-collected species that are typically taxonomically well resolved. Species are not confined by geological barriers.

* Category based on WAM SRE guidelines (WAM 2014).

4.5 Survey Design

4.5.1 Survey Timing and Personnel

Two phases of troglofauna sampling involving three field mobilisations were conducted at Mesa A and K between December 2016 and March 2017 (Table 4.3).

Table 4.3: Summary of field mobilisations completed for the Mesa A and K troglofauna survey.

Mobilisation	Dates	Phase	Purpose	Personnel
1	6th – 11th December, 2016	1	Troglofauna scraping Installation of troglofauna traps	Nicola Watson, Jacinta King
2	30th January – 2nd February, 2017	1	Troglofauna trap recovery	Jason Alexander
		2	Installation of troglofauna traps	
3	21st – 23rd March, 2017	2	Troglofauna trap recovery	Jason Alexander

Jason Alexander managed the study, with directional input from Garth Humphreys. Preliminary sorting of collected subterranean fauna was completed by Nicola Watson, Penny Brooshooft and Jacinta King. All personnel involved in the project were from Biota and collectively hold several decades of experience in subterranean fauna surveys.

4.5.2 Weather

Temperature and rainfall data were obtained from Mesa J mining operations approximately 38.6 km east-southeast of Mesa A, and 4 km southwest of Mesa K. Long-term climatological reference data (rainfall from 1971 – 2014, temperature data from 1971 – 2005) were obtained from the Bureau of Meteorological (BOM) weather station in Pannawonica (station number 5069, approximately 44.1 km east of Mesa A.

Sampling occurred during the 2016-17 wet season. No major rainfall events occurred in the three months prior to sampling (Figure 4.1). During the sampling period, however, conditions varied between Mesas A and K: A total of 110 mm of rain fell at Mesa A between January and March 2017 (December data not available), while Mesa K received 408 mm of rain between December 2016 and the end of the sampling period in March 2017, with over double the long-term average rainfall amount received in February (Figure 4.1).

The findings from previous surveys in the Robe valley and elsewhere suggest that dry conditions preceding installation of troglofauna traps may create less than ideal conditions for capturing troglofauna (Biota 2006a). There is also evidence that significant rain events during sampling (while traps remain in the ground) may result in a reduced colonisation of traps due to surface soil being washed into the traps and leaf litter being washed out of the traps.

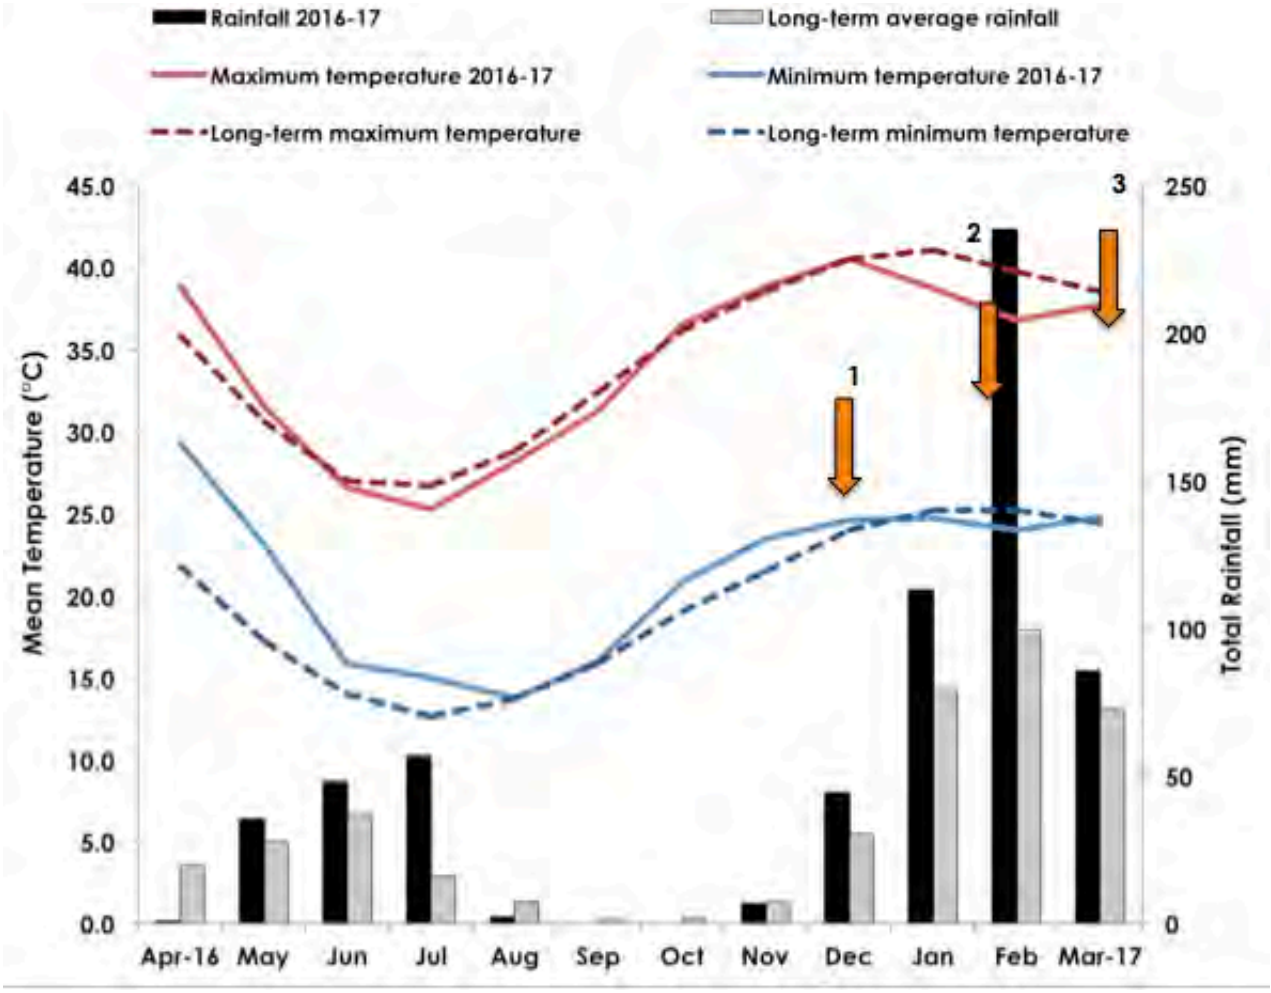

Figure 4.1: Climate and weather graph depicting long-term and monthly averages for the year preceding the final field mobilisation.

Long-term temperature data 1971-2005, rainfall data 1971-2014; arrows indicate field mobilisation timing as per Table 4.3.

4.5.3 Sampling Effort

A total of 19 drill holes were sampled within the Mesa A and Mesa K survey areas (14 and 5 sites respectively) (Table 4.4). On both phases two sites were unable to be accessed for installation or recovery of traps. As such a total of 17 sites were successfully sampled during Phase 1 and Phase 2, with 15 sites being sampled twice and four sites sampled once (Table 4.4). A total of 79 troglofauna traps were recovered from across both phases.

Haul net scraping was completed for 16 of the 19 sites prior to the installation of troglofauna traps. No haul net scraping was conducted during Phase 2 (Table 4.4).

Table 4.4: Troglofauna sampling sites within the Mesa A and Mesa K survey area.

4.6 Limitations

Several limitations apply to this study, some of which are common functions of working on subterranean fauna, rather than functions of this specific study. These limitations include:

1. Sampling for troglofauna in the Robe Valley and wider Pilbara region relies on the use of drill holes, which are almost always installed as part of exploration drilling and thus focus on geological units of economical importance. This creates a bias in availability of drill holes for troglofauna sampling, as sampling tends to not extend far beyond the footprint of the target ore body and is focussed on particular rock types. This places limitations on determining wider species distributions and whether there are potential barriers to dispersal.
2. For most taxa, only adult specimens have diagnostic morphological characteristics necessary to be identified to species level. As juvenile specimens are often collected, this limited the level to which many specimens could be identified. These specimens, as well as those too damaged to identify have been classified as indeterminate species (sp. 'indet'). Indeterminate species (e.g. *Paradraculoides* sp. 'indet' and Thysanura sp. 'indet'), while reported on for transparency within the results, were removed from the discussion analysis. These specimens may represent multiple species or may equate to a species already known elsewhere.
3. A relatively small number of sampling locations were available to investigate the subterranean fauna habitat questions considered by this study (only a single site in the case of the low grade waste dump at Mesa A). With the high degree of ecological sampling effects and intra-site variation inherent in troglofauna data sets, this limits the power of the sampling design and thereby the conclusiveness with which this study can resolve habitat utilisation.

5.0 Results

5.1 Desktop Review

5.1.1 Priority and Threatened Ecological Communities

Threatened Ecological Communities (TECs) are described by the Department of Parks and Wildlife as biological assemblages occurring in a particular habitat, which are under threat of modification or destruction from various processes (DEC 2013). Priority Ecological Communities (PECs) are biological (flora or fauna) communities that are recognised to be of significance, but do not meet the criteria for a TEC.

Two Priority Ecological Communities of relevance to the current study overlap both Mesas A and K (Table 5.1 and Figure 5.1). Both PECs are categorised as Priority One; Poorly-known ecological community. This category is defined as:

"*Ecological communities that are known from very few occurrences with a very restricted distribution (generally ≤5 occurrences or a total area of ≤ 100ha). Occurrences are believed to be under threat either due to limited extent, or being on lands under immediate threat (e.g. within agricultural or pastoral lands, urban areas, active mineral leases) or for which current threats exist. May include communities with occurrences on protected lands. Communities may be included if they are comparatively well-known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under immediate threat from known threatening processes across their range*"(DEC 2013).

Table 5.1: Description of relevant PECs overlapping the survey area.

Community	Proximity to Survey Area
Subterranean invertebrate community of pisolitic hills in the Pilbara "Subterranean invertebrate communities of a series of isolated pisolitic mesas in the Robe Valley near Pannawonica in the Shire of Ashburton in the State's Pilbara Region. Includes Mesa A, B, C, G and K and mesas not yet surveyed. The mesas are remnants of old valley infill deposits of the palaeo Robe River. Mesas are flat topped hills with a hard laterised goethite cap (Biota 2006a). The cap is underlain by pisolite, which is made up of spherical accretions of iron minerals called pisoliths (the iron ore source), which often have small caverns and spaces between them. These interstices can be large enough to accommodate troglobitic fauna (Biota 2009b). It is assumed that the other ironstone hills also provide a similar habitat for troglobitic fauna that were located in these hills by Biota (Biota 2006a)."	Overlaps Mesa A < 5 kms south-east of Mesa K
Subterranean invertebrate communities of mesas in the Robe Valley region "Troglobitic faunal communities occur in extremely specialised habitats and appear to require the particular structure and hydrogeology associated with mesas (but also apparently with other ironstone hills in the Robe Valley Region; Biota 2006a) to provide a suitable humid habitat (EPA 2007). Specifically, the habitat is the humidified pisolitic strata (small round accretionary masses of rock). These troglobitic communities are believed to be relics of the late Miocene (23 to 5.3 million years BP), having arisen from tropical faunal lineages that descended into subterranean environments during the aridification of Australia (Biota 2006a). Short range endemism is common in these fauna (Biota 2006a). Eleven fauna taxa located in Mesa A, for example, was not located in any other mesa sampled. This high level of endemicity was the general pattern of distribution noted by Biota (Biota 2006a) for mesas and other hills in the Robe Valley that were thought to be likely habitat for troglofauna."	Overlaps Mesa A and Mesa K

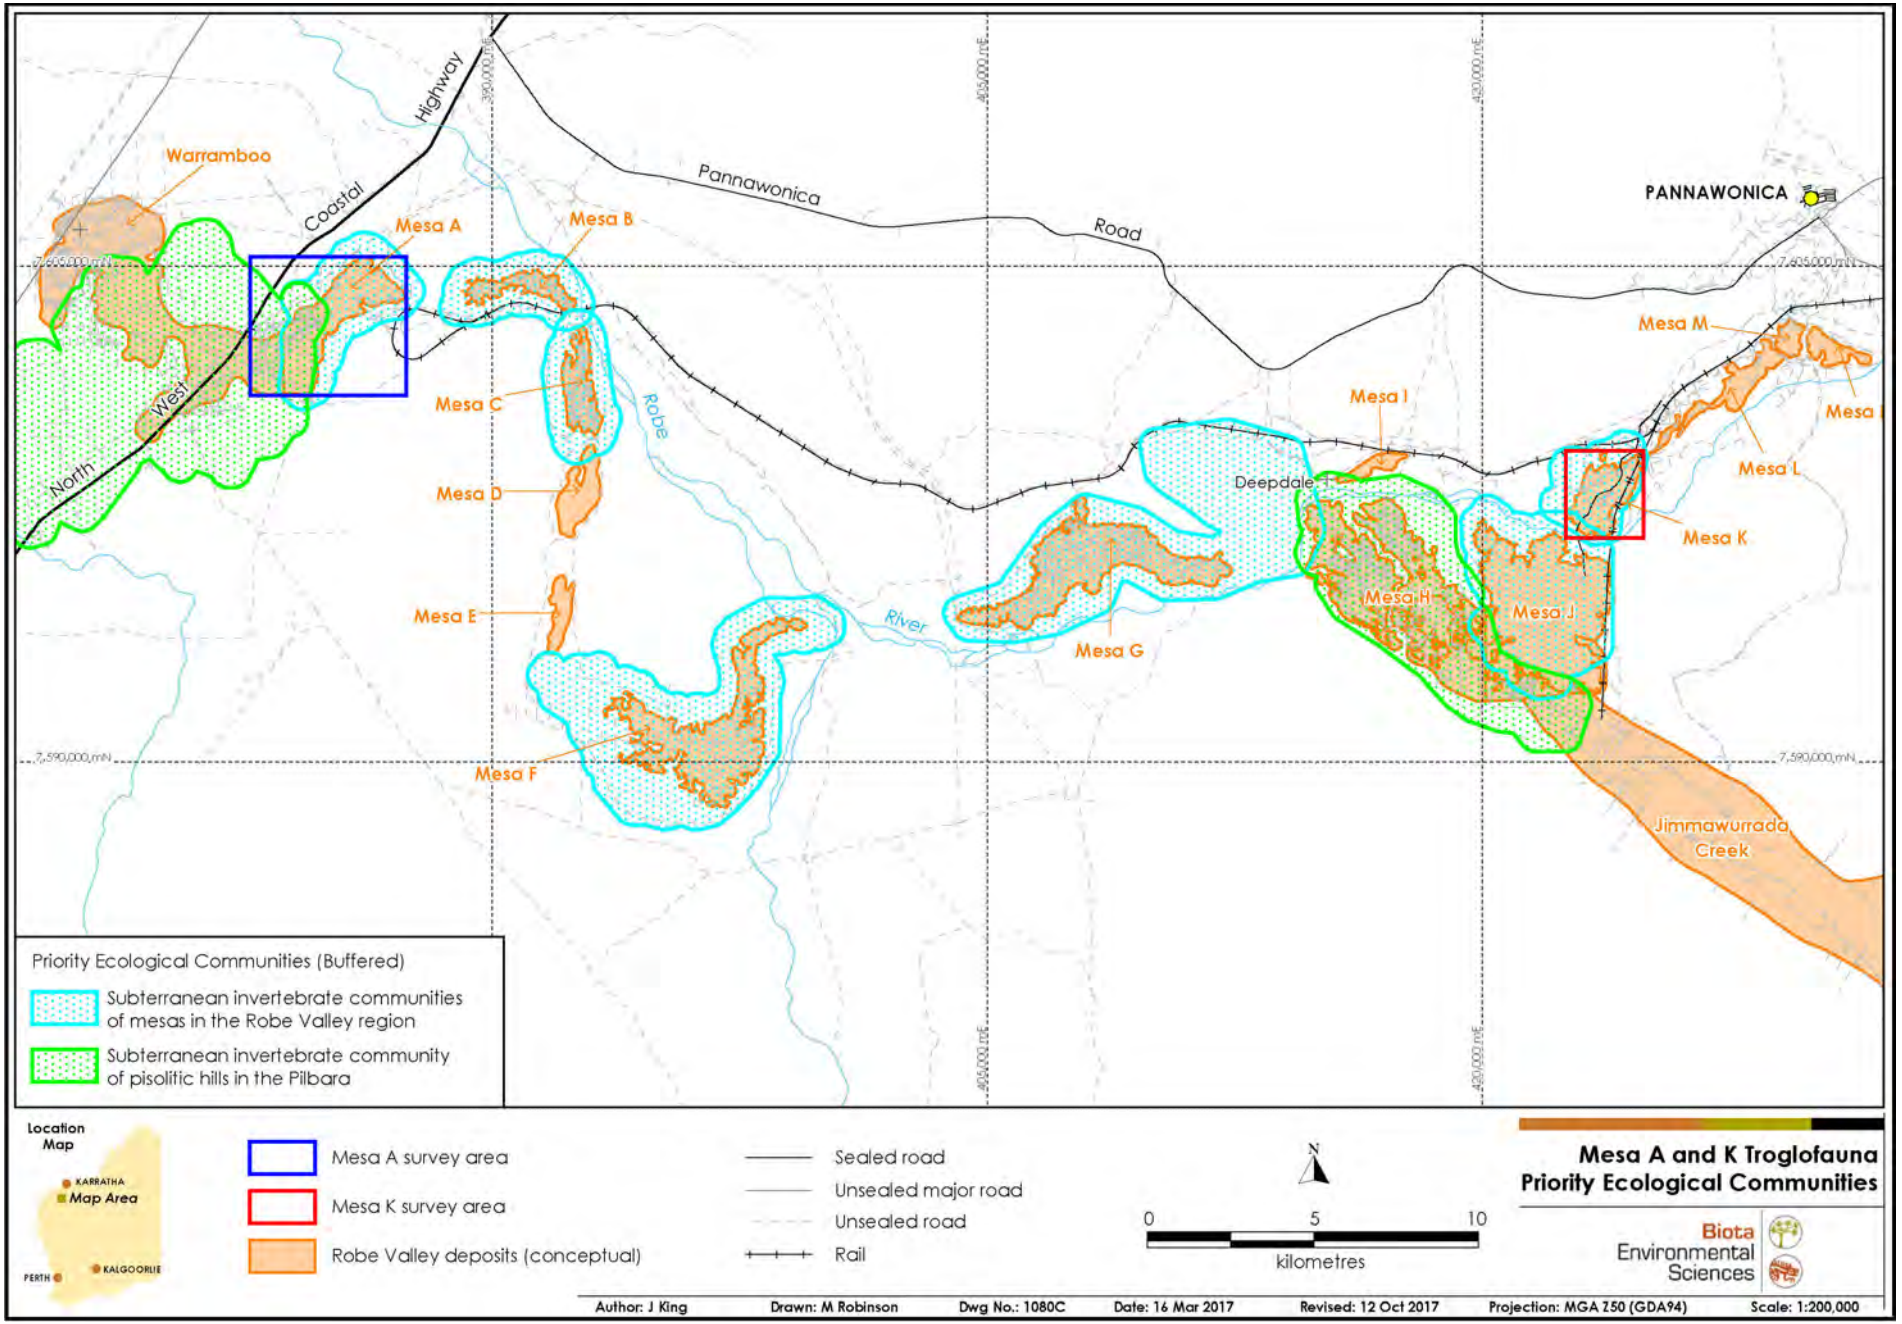

Figure 5.1: Relevant Priority Ecological Communities in the vicinity of the survey area.

5.1.2 Previous Relevant Surveys

Extensive subterranean fauna sampling has been conducted within the Robe Valley, including within the survey area. The focus of these surveys has included baseline studies, assessments and more recently, compliance monitoring. Five reports as listed below summarise the troglofauna sampling conducted at Mesa A. Eight reports as listed below summarise the sampling conducted at Mesa K:

5.1.2.1 Mesa A

- Mesa A Troglofauna Survey; Compilation of Sampling Results (Biota 2006b);
- Mesa A Troglobitic Fauna Compliance Monitoring 2012 (Biota 2012b);
- Mesa A Troglofauna Biennial Compliance Monitoring 2014 (MWH 2014a);
- Mesa A and Mesa B Annual Compliance Troglofauna Survey 2016 (Bennelongia 2017a); and
- Mesa A In-pit sampling July 2016 (Bennelongia 2017b).

5.1.2.2 Mesa K

- Mesa K Remnant Mining Project Troglobitic Fauna Survey (Biota 2007);
- Mesa K Troglobitic Fauna Compliance Monitoring 2010 (Biota 2011c);
- Mesa K Troglobitic Fauna Compliance Monitoring 2011 (Biota 2012a);
- Mesa K Troglobitic Fauna Compliance Monitoring 2012 (Biota 2012c);
- Mesa K Troglofauna Annual Compliance Monitoring 2013 (Outback Ecology 2014);
- Mesa K Troglofauna Annual Compliance Monitoring 2014 (MWH 2014b);
- Mesa K Remnant Mining Project: Troglofauna Compliance Report 2015 (Bennelongia 2015); and
- Mesa K Remnant Mining Project: Troglofauna Compliance Report 2016 (Bennelongia 2017c).

Collectively these sampling programmes represent 10 phases of sampling at Mesa A and 12 phases at Mesa K. These surveys have been reviewed and a summary of relevant information is presented in Table 5.2 and Table 5.3 for Mesa A and K, respectively. The location of previous surveys conducted within Mesas A and K is presented in Figure 5.2 and Figure 5.3.

A summary of the findings from these previous studies and a comparison with the current study is provided in Appendix 3.

5.1.3 Previously Recorded Fauna

5.1.3.1 Mesa A

A total of 383 specimens were documented from Mesa A from past surveys (Table 5.4 and Figure 5.4). Of these, 198 specimens could not be identified to species level, and are therefore not considered further. These indeterminate records are typically unable to be determined to species levels as they represent juvenile or damaged specimens, or a lack of taxonomic expertise exists for the respective groups. The remaining 185 specimens were identified as belonging to 24 species, of which six have been formally described. Eighteen species are undescribed. Complete details of all previous records are displayed in Appendix 3.

The most commonly collected species was the schizomid *Paradraculoides anachoretus*, representing 65.9% of identified records. This species, as well as four pseudoscorpion species, *Lagynochthonius asema*, *Tyrannochthonius* sp. 'Mesa A', *Ideoblothrus linnaei* and *Ideoblothrus* sp. 'Mesa A' are all listed as conservation significant. These are discussed further in Section 6.1.

Specimens belonging to the orders Polyxenida and Blattodea, and the pseudoscorpion species *Tyrannochthonius aridus* have been documented as having widespread spatial distributions throughout the Pilbara. These specimens are likely troglophilic or epigean and therefore not directly relevant to this troglofauna assessment.

5.1.3.2 Mesa K

The Mesa K desktop review yielded 363 specimens (Table 5.5 and Figure 5.5). Sixty-five specimens were unable to be identified to species level and are therefore not considered further. The remaining 298 specimens were identified as belonging to 22 species. Four species have previously been formally described, and the remaining 18 taxa are currently undescribed. Complete details of all previous records are displayed in Appendix 3.

The schizomid species *Paradraculoides kryptus* was most commonly recorded, representing 50.5% of identified Mesa K records. This species is the only listed conservation significant fauna identified from the desktop review for Mesa K.

The geophilid centipede *Ballophilus australiae*, which has been recorded from Mesa K, is widespread throughout Australia and is epigean. Specimens from the order Polyxenida (corresponding to the species *Lophoturus madecassus*) were also documented from Mesa K. As with the Mesa A results, these taxa are widespread and are likely troglophilic or edaphobitic.

Table 5.4: Previously recorded troglofauna from Mesa A.

5.2 Survey Results

5.2.1 Mesa A

A complete account of all specimens recorded, including surface and edaphobitic specimens, is presented in Appendix 4. Only troglomorphic fauna records from the survey area will be discussed further.

5.2.1.1 Schizomida

Four schizomid specimens were recorded from drillhole RC16MEA004 at Mesa A (Table 5.6), all of which were recorded during Phase 2. Genetic analysis of collected Schizomida determined the presence of two distinct lineages, with divergence levels indicating they represent distinct species (Table 5.6, Plate 5.1, Plate 5.2, Figure 5.7).

Table 5.6: Schizomida records from Mesa A.

Family	Genetic Lineage	Species Name	Number Recorded	Drillhole
Hubbardiidae	Schizomida SCH034	*Paradraculoides* sp. 'SCH034'	3	RC16MEA004
	Schizomida SCH063	*Paradraculoides anachoretus*	1	RC16MEA004

Plate 5.1: *Paradraculoides* sp. 'SCH034' .

Plate 5.2: *Paradraculoides anachoretus* .

Paradraculoides sp. 'SCH034' differs from *Paradraculoides anachoretus* by between 5.6% and 6.3% genetic divergence, and from their next closest related reference species, *Paradraculoides* sp. 'SCH003' (Warramboo) and *Paradraculoides bythius* (Mesa B), by 7.7% and 8.4% genetic divergence respectively.

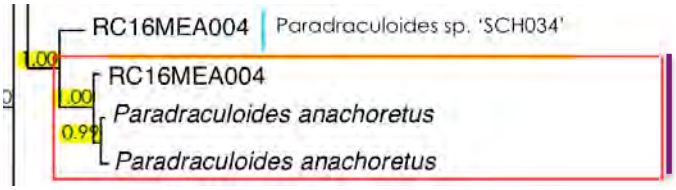

Figure 5.6: Excerpt of the Helix Bayesian analysis of CO1 haplotypes of the family Hubbardiidae collected from Mesa A.
(Numbers on major nodes correspond to posterior probabilities; values <50% are not shown. Coloured blocks indicate specimens belonging to a single species.)

Paradraculoides anachoretus has been widely recorded from Mesa A and is considered to be endemic to the mesa. *Paradraculoides* sp. 'SCH034' was recorded from RC16MEA004, which intercepts both the low grade waste dump and strata beneath the pit floor. This species is also known from two other sites within the MEZ. Sequencing of the schizomids recorded from Mesa A during the current study also included a juvenile specimen recorded from Mesa A by Bennelongia (2017b).

This specimen was originally only identified to genus level based on morphology, but genetic analysis undertaken in the current study has determined that it too belongs to *Paradraculoides* sp. 'SCH034', and was recorded from the same drillhole, RC16MEA004 (Appendix 2).

5.2.2 Mesa K

No troglomorphic specimens were collected from Mesa K.

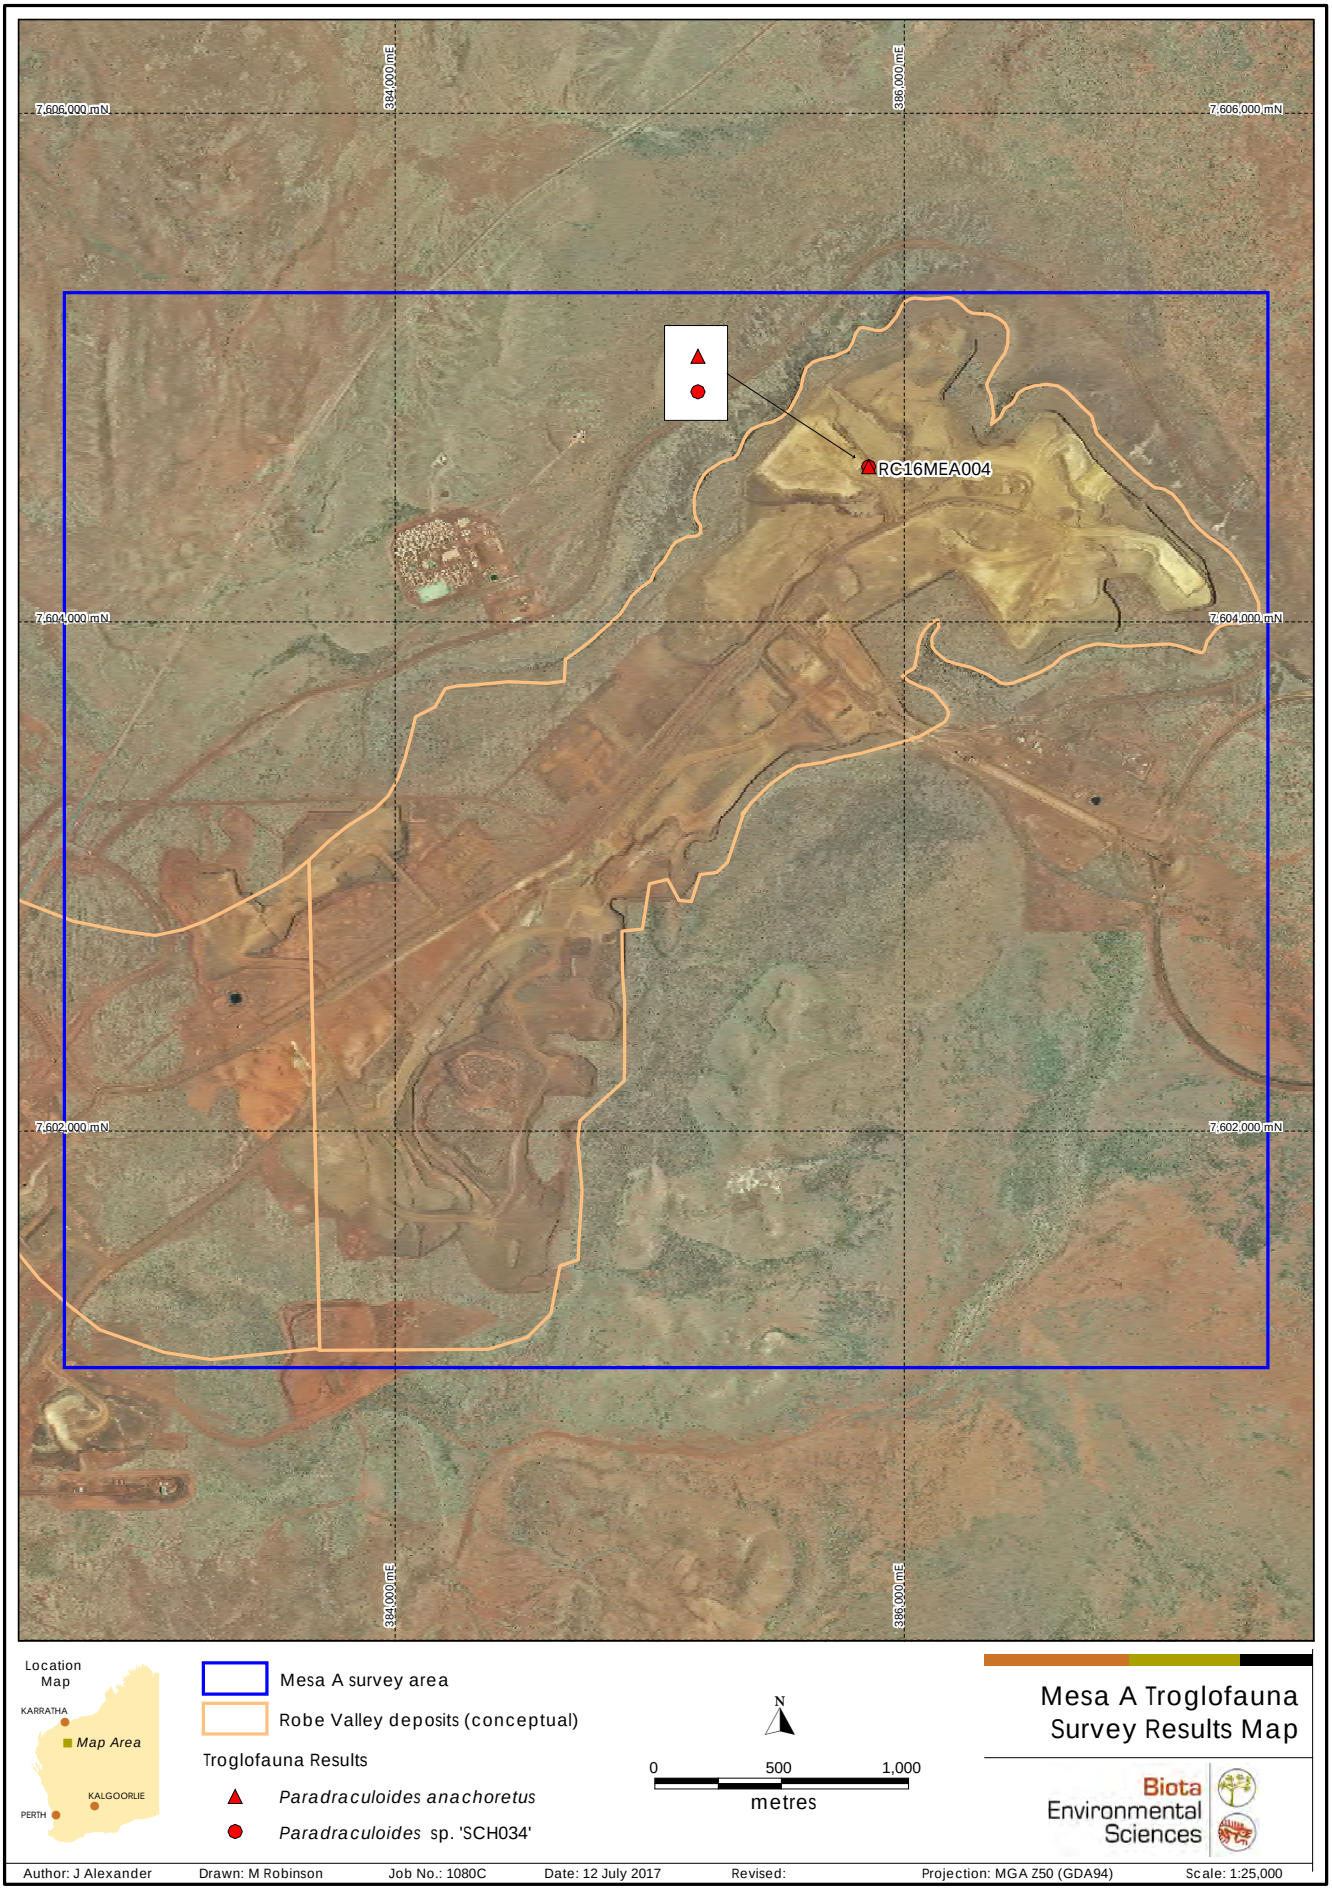

Figure 5.7: Location of schizomid records collected from Mesa A during current survey.

6.0 Discussion

6.1 Conservation Significance and Distribution of In-pit Records

6.1.1 Mesa A

A total of 22 taxa identified to species level have been recorded from the Mesa A deposit. Five of these (one schizomid and four pseudoscorpion taxa) represent species that are of conservation significance:

1. *Paradraculoides anachoretus* (Schedule 3): Over 120 specimens known only from Mesa A.
2. *Ideoblothrus linnaei* (Priority 1): Four specimens known only from Mesa A.
3. *Ideoblothrus* sp. 'Mesa A' (Priority 1): Six specimens known only from Mesa A.
4. *Lagynochthonius asema* (Priority 1): Eight specimens known only from Mesa A.
5. *Tyrannochthonius* sp. 'Mesa A' (Priority 1): One specimen known only from Mesa A.

Of these five conservation significant species, one was recorded from in-pit sampling at Mesa A during the current survey, with a single *Paradraculoides anachoretus* specimen collected from RC16MEA004. This species is well represented and commonly recorded throughout Mesa A, with more than 120 records confirmed (Table 5.4). A separate species, *Paradraculoides* sp. 'SCH034', was collected from the same drillhole, RC16MEA004, during the current survey. The presence of two species of schizomid within the Mesa A landform is notable, as previous sampling has indicated the presence of only one species per mesa landform (Harvey et al. 2008). The collection of *Paradraculoides anachoretus* from the same drillhole indicates that the two species occur in sympatry, though the possibility exists that the habitats of the two species are vertically separated and thus effectively precluding sympatry. Six specimens from the specied *Paradraculoides* sp. 'SCH034' have been recorded, including the specimen collected by Rio Tinto during a previous survey at Mesa A (Bennelongia 2017b).

A summary of schizomid species recorded from Mesa A during the current survey, including their conservation status and known distribution is presented in Table 6.1. All Schizomida from the Robe Valley mesas are considered strongly obligate troglofauna, and as such *Paradraculoides* sp. 'SCH034' is unlikely to have a distribution greater than the Mesa A landform. *Paradraculoides* sp. 'SCH034' therefore currently represents a potential SRE species (Table 6.1). The distribution of previously recorded conservation significant and potential SRE troglofauna species recorded at Mesa A (including those from the current study) is presented in Figure 6.1.

Table 6.1: Summary of species recorded from Mesa A for the current Scope of Work, including their conservation status and distribution.

(Coordinates in GDA94, Zone 50; A summary of the WAM SRE categories is located in Appendix 4).

Species Name	Distribution (km^2)	Collection Representation*	New Species	Singleton Record ∞	SRE Sub-Categories ^	Notes
Conservation Significant Species						
Paradraculoides anachoretus	5.7	Good	-	-	-	Listed as Schedule 3. Over 120 specimens known from Mesa A distribution.
Potential SRE Species						
Paradraculoides sp. 'SCH034'	0.24	Fair	X	X	A. Data Deficient D. Molecular evidence	Multiple specimens from single location.

* Poor: <5 specimens, Fair: 5 – 15, Good: >15.

∞ includes multiple specimens collected from single site.

^ A. Data Deficient, B. Habitat Indicators, C. Morphology indicators, D. Molecular Evidence, E. Research and Expertise (more detail in Appendix 5).

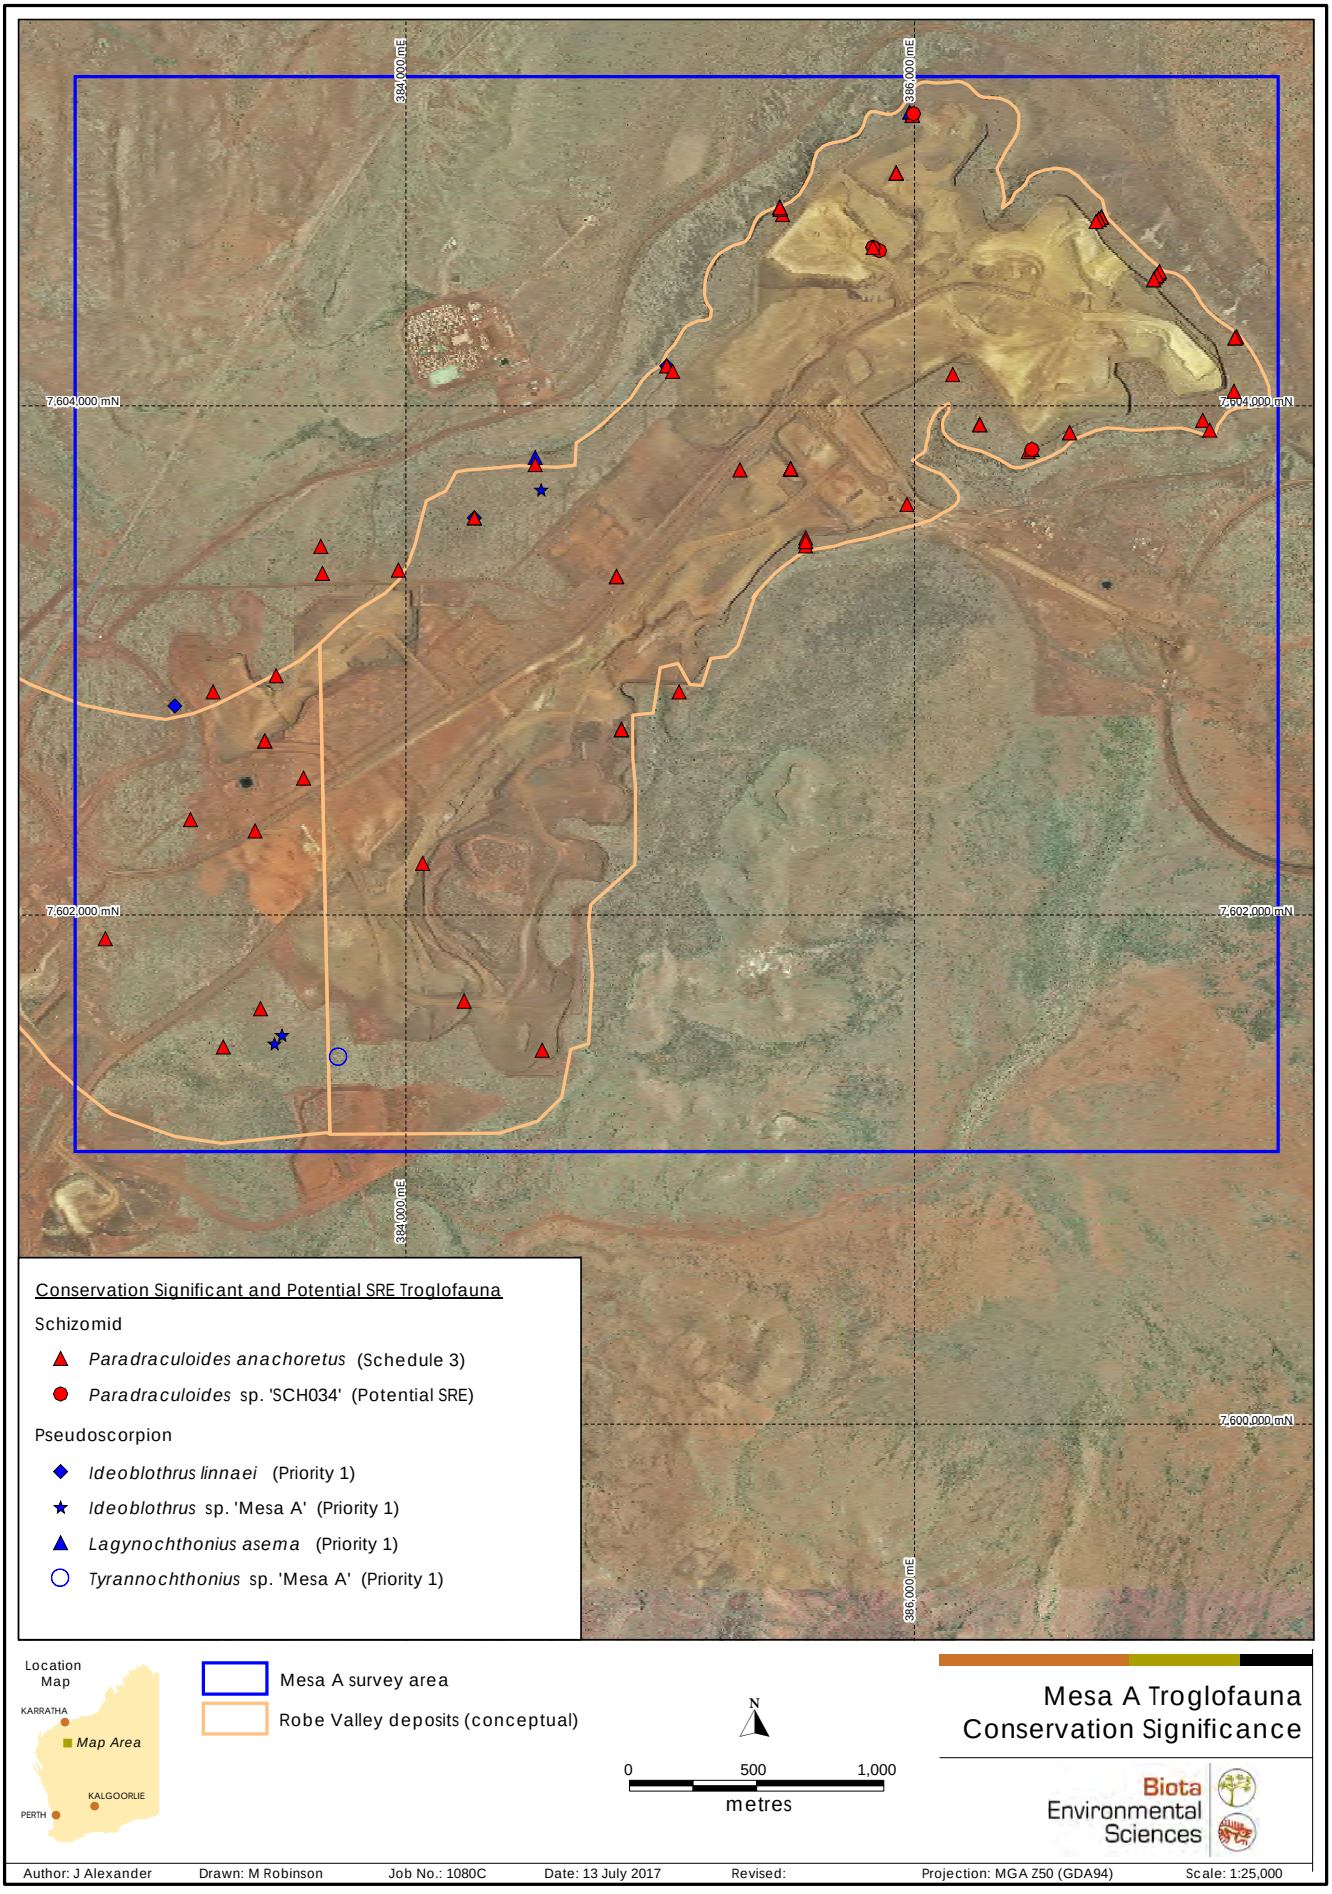

Figure 6.1: Distribution of conservation significant and potential SRE troglofauna species at Mesa A.

6.1.2 Mesa K

A total of 22 species have been recorded from the Mesa K deposit. The current survey did not add any further records to this total. Of the recorded taxa, only one species, the schizomid *Paradraculoides kryptus* is listed as being of conservation significance. This species is listed as Schedule 3 fauna, with 120 specimens recorded solely from Mesa K (Table 5.5). The distribution of this species at Mesa K is presented in Figure 6.2.

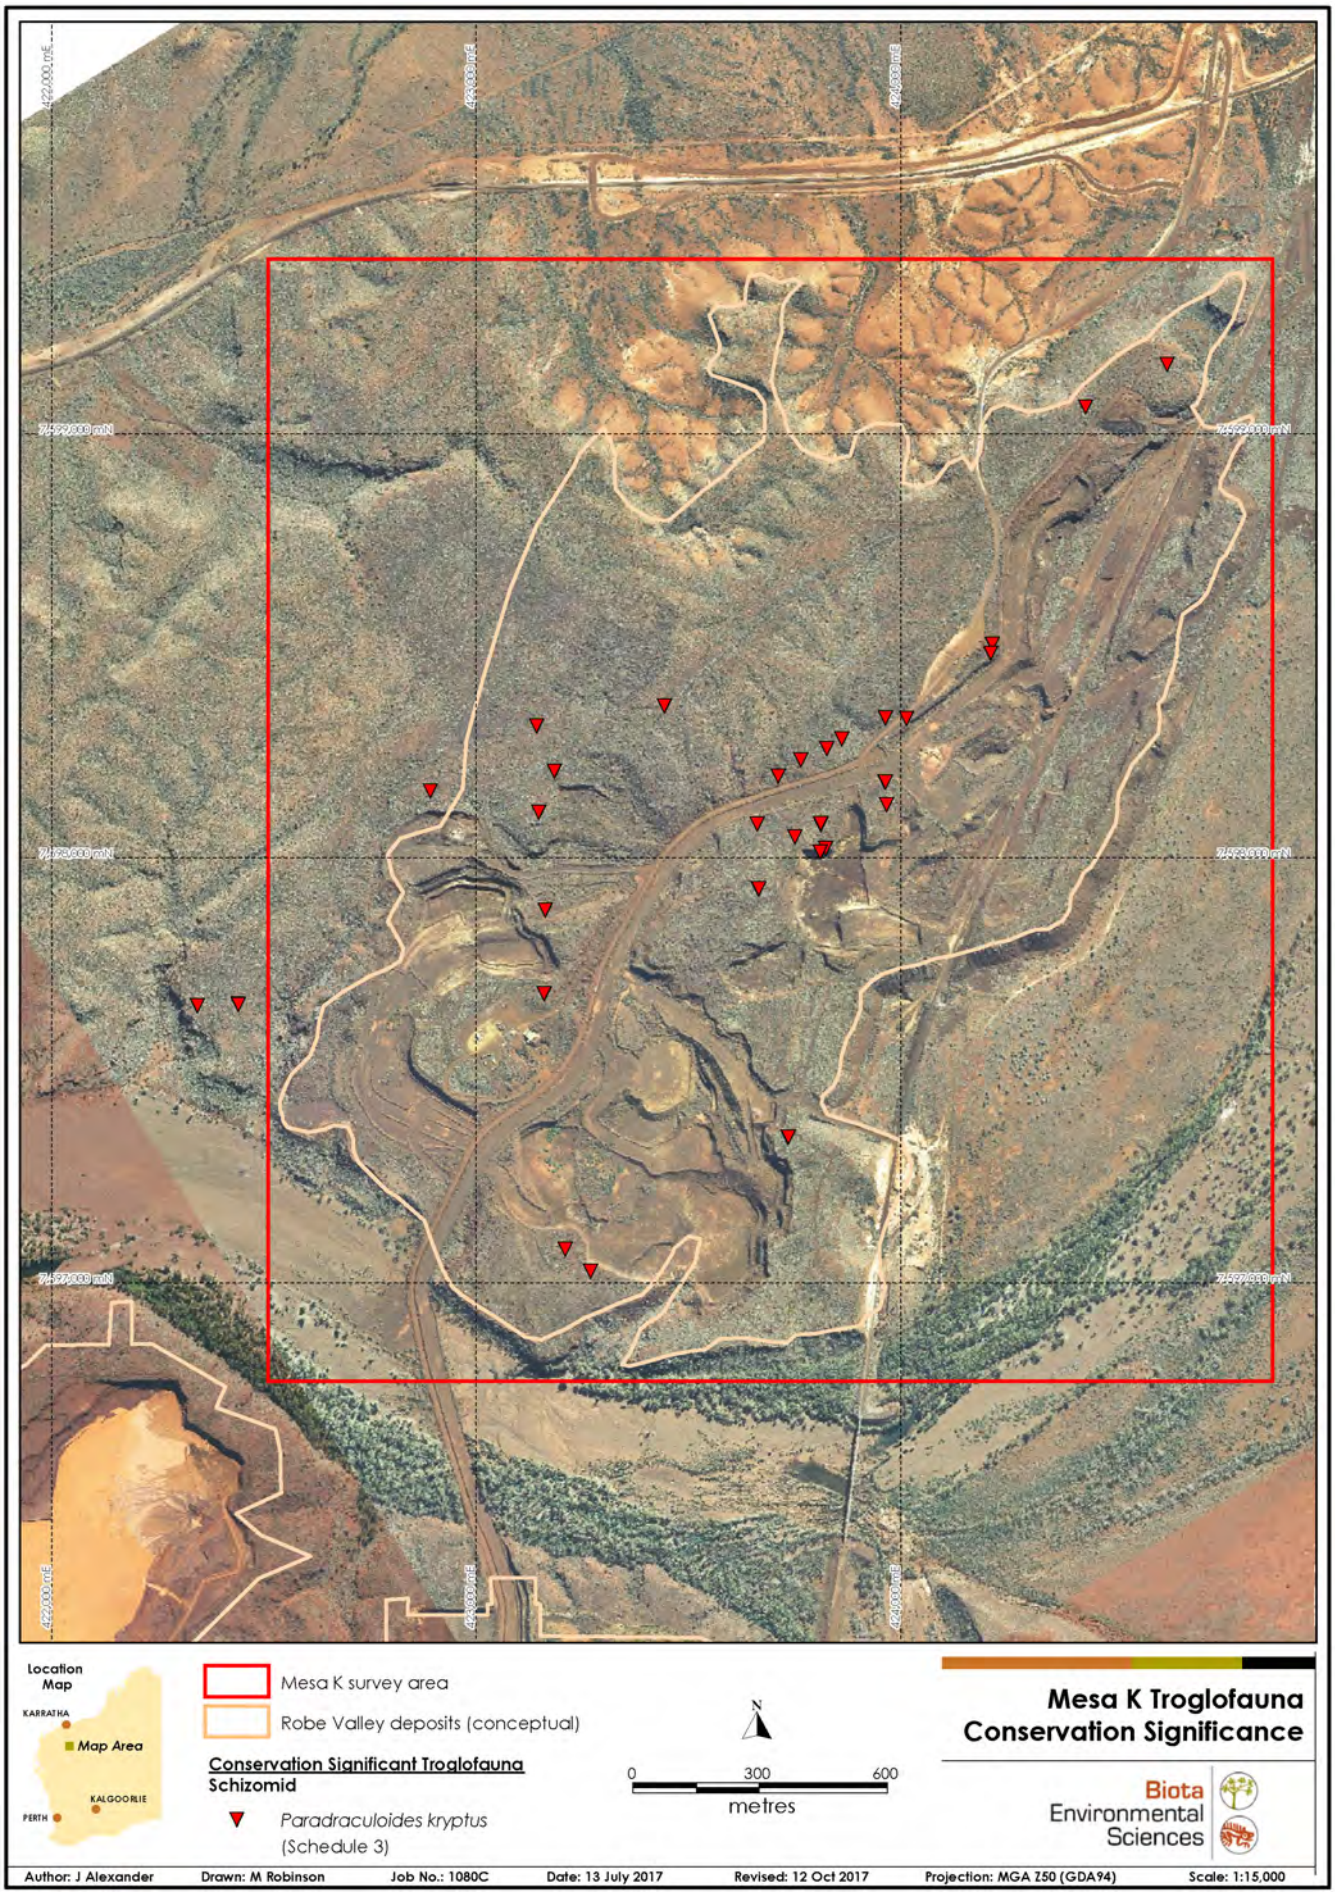

Figure 6.2: Distribution of conservation significant troglofauna species at Mesa K.

6.2 Troglofauna Communities of In-pit Habitats

Currently, insufficient data exist to allow for a robust analysis comparing the results of in-pit sampling at Mesa A with the results of sampling within the MEZ and prior to mining operations, but as a minimum, this study has confirmed that both schizomid species recorded in-pit also occur within the MEZ. Most sampling effort since operations commenced has focused on reference area sampling, creating a biased data set.

Some observations can be made from the results of the in-pit sampling. From the very limited data available, it is possible troglofauna may be utilising the low-grade waste dump at Mesa A as habitat. However, information provided by Rio Tinto indicates that the sampled drill hole was also drilled beyond the base of the waste dump and into intact troglofauna habitat below. This introduces the more likely possibility that the troglobites recorded from this site may have entered the drillhole from intact habitat at depth, rather than truly utilising the waste dump as habitat.

7.0 Glossary

Edaphobite	Deep soil inhabitant.
Endemic	Native to or confined to a certain region.
EPA	Environmental Protection Authority of Western Australia.
Epigean	Fauna from above the soil level.
Karst	Soluble-rock landscape; terrain with distinctive hydrology and landforms arising from a combination of high rock solubility and well-developed secondary porosity.
Mesocaverns	Underground voids in the size range 0.1 – 20cm, especially in karst and volcanic substrates.
Pisolite	Rock composed of pisoliths.
Short-Range Endemic (SRE)	A species that has a naturally small distribution and is often characterised by having poor dispersal capabilities, confinement to disjunct habitats and low fecundity. WAM guidelines for determining SRE status in Appendix 5.
Species Complex	A group of closely related species currently placed within a single species name.
Stygobite / Stygofauna	Fauna inhabiting the various types of groundwater.
Sympatry	The occurrence of populations in overlapping geographical areas, but without interbreeding.
Troglobite / Troglofauna	Species that do not exist outside caves. They may, however, occur in the superficial underground compartment or in the upper hypogean zone.
Troglophile / Troglophilic	Species that utilise, but are not restricted to, subterranean environments. Able to use surface environments for dispersal.

Wildlife Conservation Act 1950

REGULATION 17

Regulation 17 – Licence to take fauna for scientific purposes (Regulation 17 - Standard)

The undermentioned person may take fauna for research or other scientific purposes and where authorised, keep it in captivity, subject to the following and attached conditions, which may be added to, suspended or otherwise varied as considered fit.

Director General

Conditions

1 The licensee shall comply with the provisions of the Wildlife Conservation Act 1950, Wildlife Conservation Regulations 1970 and any Notices in force under this legislation.

2 The licensee shall take fauna only in the manner stated on the endorsed Regulation 17 licence application form and endorsed related correspondence.

3 Unless specifically authorised in the conditions of this Licence or otherwise in writing by the Director General, species of fauna declared as likely to become extinct, rare or otherwise in need of special protection shall not be taken.

4 Any by-catch of fauna, which is declared to be rare, likely to become extinct, or otherwise in need of special protection shall be released immediately at the point of capture. Where such fauna taken under this licence is injured or deceased, the licensee shall contact the Department's Wildlife Licensing Section for advice on disposal. Records must be kept of any such fauna so captured and details are to be included in the report required under further condition below.

5 Any interaction involving Gazetted Threatened Fauna that may be harmful to the fauna and/or invasive may require approval from the Commonwealth Department of the Environment ph 02 6274 1111. Interaction with such species is controlled by the Commonwealth Environment Protection and Biodiversity Conservation Act 1999 and Environment Protection and Biodiversity Conservation Regulations 2000 as well as the Wildlife Conservation Act 1950 and Wildlife Conservation Regulations 1970.

6 No fauna shall be taken in areas where it would impinge on pre-existing scientific research programs.

7 Except in the case of approved lethal traps, the licensee shall ensure that measures are taken in the capture and handling of fauna to prevent injury or mortality resulting from that capture or handling. Where traps or other mechanical means or devices are used to capture fauna these shall be deployed so as to prevent exposure of trapped animals to ants and debilitating weather conditions and inspected at regular intervals throughout each day of their use. At the conclusion of research all markers used, and signs and structures erected by the licensee shall be removed and the environment returned to its original condition.

8 Not more than ten specimens of any one protected species of fauna shall be taken and removed from any location less than 20km apart. Where exceptional circumstances make it necessary to take a larger number of specimens from a particular location in order to obtain adequate statistical data, the collector must proceed with circumspection and justify their actions to the Director General in advance.

9 The licensee shall not release any fauna or their progeny in any area where it does not naturally occur, nor hand such fauna over to any other person or authority unless approved by the Director General, nor dispose of the remains of such fauna in any manner likely to confuse the natural or present day distribution of the species.

10 Bioprospecting involving the removal of sample aquatic and terrestrial organisms for chemical extraction and bioactivity screening shall not be conducted without specific written approval by the Director General.

11 No fauna shall be taken from any CALM land, as defined in the Conservation and Land Management Regulations 2002, without prior written approval of the Director General. No fauna shall be taken from any public land without the prior written approval of the Government Authority managing that land.

12 The licensee shall not enter upon any private property or pastoral lease for the purposes of this licence, nor take any fauna from any private land or pastoral lease without the prior consent in writing of the owner or occupier. Similarly, in the case of Aboriginal lands, the licensee must not enter upon or take fauna from such lands without the written approval of the Department of Aboriginal Affairs and/or the relevant native title holders or applicants.

13 Copies of this licence and any written approval or consent required by conditions of this licence must be carried by the licensee and any person/s authorised under the licence at all times when conducting activities relevant to the licence

and must be presented to an authorised officer of the Department upon request.

14 All holotypes and syntypes and a half share of paratypes of species or subspecies permitted to be permanently taken under this licence shall be donated to the Western Australian Museum. Duplicates (one pair in each case) of any species collected, which represents a significant extension of geographic range shall upon request be donated to the Western Australian Museum.

15 To prevent any unnecessary collecting in this State, all specimens and material taken and retained under the authority of this license shall, upon request, be loaned to the Western Australian Museum. Any unused portion or portions of any specimen collected under the authority of this license shall be offered to the Western Australian Museum for inclusion in its collection or made available to other scientific workers if so required.

16 Within one month of the expiration of this licence, the holder shall submit an electronic return into the department's Wildlife Licensing System, detailing the locality, site, geocode, date and number of each species of fauna captured, sighted or vouchered during the currency of the licence. A copy of any paper, report or thesis resulting from the research shall upon completion be lodged with the Director General.

Purpose

Troglofauna and Stygofauna survey for environmental impact assessment via plankton net hauls, PVC leaf-litter traps and net haul scrapings in accordance with EPA guidance statement 54a

Locations

Warramboo, Mesa A, Mesa C, Mesa K

Re. Report on the molecular systematics of troglofauna from Warramboo, and Mesas A, C and K (Biota 1080c)

Dear Jason,

Following is a summary of the results of the troglofauna study we have completed for six taxonomic groups (Araneae, Coleoptera, Diplura, Pseudoscorpiones, Schizomida, Thysanura) from Mesas A, C, K and Warramboo. Nine distinct genetic lineages were detected in the collections, five of which have been detected previously in the Pilbara.

Thanks once again for collaborating on this project with Helix. We hope we can continue to provide you with useful information, and feel free to contact us if you have any questions or would like to discuss the results in detail.

Sincerely,

Dr. Terrie Finston, Yvette Hitchen and Dr. Oliver Berry
Helix Molecular Solutions

Background and Objective

Seventeen specimens of troglofauna from six taxonomic groups (Araneae, Coleoptera, Diplura, Pseudoscorpiones, Schizomida, Thysanura) were collected from Mesas A, C, K and Warramboo and sequenced for variation at the mitochondrial COI gene, with the exception of the Thysanura, which was sequenced for 12s. The molecular data were assessed in order to determine the number of species present and compare the results to those obtained during previous surveys in the Pilbara.

Executive summary

- Seventeen specimens of troglofauna from Mesas A, C, K and Warramboo were sequenced for variation at the COI or 12s gene.
- Nine distinct genetic lineages from were detected among the 17 specimens.
- Five of the lineages have been detected previously in the Pilbara, during previous surveys at Mesa B and C.
- Four of the lineages appear to be new, based on the material available for comparison.

Methods

Seventeen specimens of troglofauna from six taxonomic groups (Araneae, Coleoptera, Diplura, Pseudoscorpiones, Schizomida, Thysanura) were sequenced for variation at the mitochondrial cytochrome oxidase subunit I gene (COI) using primers LCOI/HCO2, with one exception. The Thysanura was sequenced for the 12s gene, using primers 12sai/12sbi (Simon et al., 1994).

Sequences were edited using GENEIOUS software (Drummond *et al.* 2011). Alignment was performed with CLUSTAL W (Thompson *et al*. 1994) using default parameters. Genetic distances between unique genetic sequences (haplotypes) were measured using uncorrected p-distances (total percentage of nucleotide differences between sequences).

MODELTEST software (Posada and Crandall, 1998) was used to determine the model of sequence evolution that best fitted the data for each taxonomic group. Bayesian analysis was used to construct the phylogenetic trees, incorporating the model as identified in MODELTEST for each taxonomic group. The phylogeny, branch lengths and posterior probabilities were obtained by running two trees simultaneously, each running four simultaneous MCMC chains. The number of cycles needed was determined by the standard deviation of the split frequencies of the two trees. The analysis was paused after every 1 x 10^6 generations and when the standard deviation fell below 0.01, the analysis was stopped. A majority rule consensus tree was constructed after discarding the "burn-in" trees in both analyses. The burn-in value was determined by plotting the posterior probabilities obtained after every generation and identifying the point at which the values reach stationarity (= the asymptote). Trees produced prior to stationarity were discarded.

For the purposes of this report, lineages were defined as haplotypes or groups of haplotypes differing from other such groups by >3% sequence divergence. This cut-off was selected based on bar-coding data, which indicates that intra-specific variation rarely exceeds 2-3% (Hebert et al., 2003b).

Results

Araneae

A single specimen of Araneae from Mesa C was sequenced for COI (Table 6). The sequence was compared to sequences of Araneae in the Helix and GenBank databases. The specimen was most similar to specimens of Gnaphosidae (85% similarity to a Genbank specimen of *Zelanda*), however a subset of reference specimens that differed by ≤15% from the Mesa B and C specimens from all phases were selected to include in the phylogenetic analysis, including 33 specimens of Araneae from the Pilbara, eight of which were collected during previous surveys at Mesas B and C, as well as eight GenBank reference specimens as follows: Gnaphosidae: *Zeland* sp. (Genbank accession # KY017738) Aranidae: *Arachnura scorpiooides*, (GenBank accession #KJ957946 and *Gea theridoides* (Genbank accession #KJ959766), Oonopidae: *Ischnothyreus auritus* (Genbank accession# KR864743) Theridiidae: *Theridion ohlerti* (Genbank accession #GU684645), *Robertus neglectus* (GenBank accession #AY231053), *Theridion boesonbergi* (Genbank accession #KX537094) and *Coleosoma acutiventer* (Genbank

accession # EF050286). Two specimens of Mygalomorphae, *Missulena* sp. WAM T97637 (Genbank accession # KC708097) and *Missulena* sp. WAM T113626 (Genbank accession # KC708079) were used as outgroups.

Phylogenetic analysis
The phylogenetic analysis, which included the new specimen from Mesa C, in addition to 41 reference specimens, placed the Mesa C specimen in a single genetically distinct lineage (Figure 4). The lineage was placed in a clade containing a Genbank reference specimen of Gnaphosidae and four specimens from Jirrpalpur, Opthalmia and Wheelarra Hill, and thus was assigned to the new lineage AG003 (Figure 4). The specimens of Araneae from previous sampling phases at Mesas B and C were placed in clades containing Theridae/Symphytognathidae, Aranidae and Oonopidae (Figure 4).

Differentiation within and between lineages
The new specimen from Mesa C (lineage AG003) differed from the reference specimens by between 15.0 and 27.7% sequence divergence (Table 7).

Coleoptera
Reference specimens and outgroups
Two specimens of Coleoptera from Mesa B were sequenced for COI (Table 6). In order to reduce analysis time and to simplify the presentation of results, a preliminary neighbour-joining (NJ) analysis was conducted on the Mesa B specimens and analysed with 123 reference sequences of Coleoptera, including 23 provided by the WAM, to identify a manageable and relevant reference data set. The specimens were most closely related to reference specimens of Curculionidae, so the final dataset consisted of a Genbank voucher sequence (Curculionidae sp. 8, Genbank accession #KU519717) and 29 reference specimens of Curculionidae from the Pilbara, including 15 sequences provided by the WAM, representing eight species and ten from previous surveys at Mesas B and C. Two specimens of Coleoptera from the family Dermestidae, *Dermestes maculatus* (Genbank accession # HM909035) and *Dermestes frischii* (Genbank accession # KM578824) were used as outgroups.

Phylogenetic analysis
The phylogenetic analysis, which included the two specimens from Mesa B, in addition to 30 reference specimens, placed the Mesa B specimens in a single lineage, which also contained five reference specimens of Curculionidae from previous surveys at Mesas B and C in the Robe Valley (Figure 5). Thus the new Mesa B specimens were assigned to the existing lineage CCU012 (Figure 5). The lineage was placed in a well-supported clade containing two WAM reference specimens of Curculionidae sp. 8 (Figure 5). The specimens of Coleoptera from previous sampling phases at Mesas B and C were all placed in the Curculionidae (Figure 5).

Differentiation within and between lineages
The two specimens of Curculionidae from Mesa B differed from one another by 0.9% sequence divergence (Table 8).

The Mesa B specimens differed from the reference specimens by between 0 and 23.0% sequence divergence (Table 8). In particular, the Mesa B specimens differed from five reference specimens from previous surveys at Mesas B and C by between 0 and 0.9% sequence divergence and from the reference specimens in clade Curculionidae sp. 8 by between 2.7 and 3.4% sequence divergence (Table 8).

Diplura
Reference specimens and outgroups
One specimen of Diplura from Mesa C was sequenced for COI (Table 6). Comparisons to Genbank and Helix databases showed that the specimen was most closely related to the family Japygidae, however, the specimen was analysed with 36 specimens of Diplura from the Pilbara belonging to three families, in order to include specimens from previous surveys at Mesas B and C: Campodeidae, Japygidae, and Parajapygidae, as well as five Genbank voucher specimens, Diplura sp., which is most similar to Genbank specimens of Campodeidae (Genbank accession #HQ943342), *Campodea tillyardi* (Genbank accession # AF370844) and *Lepiodocampa weberi* (Genbank accession #HQ882832) from the family Campodeidae,

Parajapyx pauliani (Genbank accession #JQ692327) from the family Parajapygidae and *Japyx solifugus* (Genbank accession #AY771989) from the family Japygidae. The planthopper *Lycorma delicatula* (Genbank accession # FJ456942) and a specimen of Fulgoridae (Hemiptera sp.; Genbank accession #GU671563) were used as outgroups.

Phylogenetic analysis
The phylogenetic analysis, which included the new specimen of Diplura from Mesa C, in addition to 36 reference specimens, placed the Mesa C specimen in a distinct genetic lineage that did not contain any reference specimens (Figure 6). The specimen was placed in a clade containing lineages of Japygidae, and was assigned to the new lineage DJA011 (Figure 6). The specimens of Diplura from previous sampling phases at Mesas B and C were placed in the Parajapygidae and Campodeidae (Figure 6).

Differentiation within and between lineages
The specimen of Japygidae from Mesa C differed from the nearest reference specimen (JU01) by 15.0% sequence divergence (Table 9).

Thysanura
Reference specimens and outgroups
One specimen of Thysanura from Mesa C was sequenced for 12s (Table 6). A search of similar sequences on Genbank and in the Helix database indicated that the specimen most closely matched database specimens of the subfamily Nicoletiinae. Based on those results, GenBank voucher sequences were included as reference sequences of Nicoletiinae (two specimens) as follows: *Trinemura callawa* and *T. cundalin* (GenBank accession #JQ282164 and JQ282165). In addition, as local references, 33 specimens of Nicoletiinae, including five from previous surveys at Mesa B/C, were included in the analysis. A specimen of Atelurinae was used as an outgroup: *Atelura formicaria* (Genbank accession # EU084035).

Phylogenetic analyses
The phylogenetic analysis, which included the new specimen from Mesa C, in addition to 35 reference specimens, placed the Mesa C specimen in a single distinct genetic lineage, which also contained two reference specimens from a previous survey at Mesa B/C, thus was assigned to the existing lineage TN010 (Figure 7). The specimens of Thysanura from previous sampling phases at Mesas B and C were all placed in the subfamily Nicoletiinae (Figure 7).

Differentiation within and between lineages
The lineage of Nicoletiinae differed from nearest reference specimens IV333 and IV227 by 0.5 and 2.8% sequence divergence, respectively and from the remaining reference specimens by >9% (Table 10).

Pseudoscorpions

Reference sequences and outgroups
Three pseudoscorpions were sequenced from Mesa C and K (Table 6). A search of similar sequences on Genbank and in the Helix database indicated that all of the specimens most closely matched the family Chthoniidae. Based on those results, a reference dataset of 81 Genbank and Pilbara specimens was reduced to a more manageable and relevant dataset by selecting only the 41 reference specimens that occurred in the same clades as the Mesa C and K specimens, based on a preliminary neighbour joining analysis. Two Genbank voucher sequences of Chthoniidae were included in the analysis as follows: *Paraliochthonius* sp JM 2008 (Genbank accession #EU5595505) and *Tyrannochthonius aridus* (GenBank accession # KJ659959 from Western Australia). In addition, as local references, 39 specimens of Chthoniidae from previous surveys in the Pilbara, were included in the analysis, including 16 from previous surveys at Mesas B and C. Sequences of the scorpion *Pandinus imperator* (Genbank accession # AY1565821) and harvestman spider *Siro rubens* (Genbank accession # DQ5131111) were used as outgroups.

Phylogenetic analysis
The phylogenetic analysis of the Chthoniidae, which included the three Chthoniidae specimens from Mesa C and K, in addition to 41 reference specimens, placed the Mesa C and K specimens in two distinct genetic lineages (Figure 8). Neither lineage contained reference

specimens and the two were therefore assigned to the new lineages PC058 and PC059 (Figure 8). However the lineages showed significant although distant relationships with some reference specimens (Figure 8). Specifically, specimen LI31/lineage PC058 formed a well-supported clade with specimens of lineage PC047 (IV261, KD66, KD67 and KD69) from Mesas B and C (Figure 10). Similarly, specimens LI34 and LI35/lineage PC059 formed well-supported clades with specimens IV212/IV226 and IV269, respectively, from previous surveys in the Robe Valley (Figure 8). The specimens of Pseudoscorpiones from previous sampling phases at Mesas B and C were placed in the Chthoniidae (Figure 8) and the Hyiidae (not shown).

Differentiation within and between lineages

The three specimens of Chthoniidae from Mesa C and K differed from one another by between 0.0 and 20.2% sequence divergence and from the reference lineages by > 6.0% sequence divergence (Table 11). Specifically, specimen LI31 (lineage PC058) differed from the nearest reference specimens, IV261, KD66, KD67 and KD69 (lineage PC057) by between 6.1 and 6.3% sequence divergence (Table 11). Specimens LI34 and LI35 (lineage PC059) differed from the nearest reference specimens, IV212, IV226 and KD24 (lineages PC009, PC010 and PC053, respectively) by between 7.6 and 10.2% sequence divergence (Table 11).

Schizomids

Preliminary analysis - Reference sequences and outgroups

Eleven schizomids were sequenced from Mesas A and C (Table 6). In order to assemble a relevant reference data set, a preliminary neighbour-joining (NJ) analysis was conducted on the 11 Mesa A and C specimens, to identify the number of genetic lineages present. A representative from each was compared to Helix and Genbank sequence databases, representing >500 reference sequences of schizomids from previous surveys in the Pilbara. The reference sequences were selected based on the criteria that they showed ≤ 15% sequence divergence from at least one of Mesa A and C lineages.

Three distinct genetic lineages were detected and the number of individuals within each lineage ranged from one to four (Figure 9). All three showed the highest genetic similarity to reference specimens of *Paradraculoides*. A representative from each was analysed in a model-based phylogenetic analysis with 27 reference specimens of *Paradraculoides*, including five Genbank voucher specimens of *Paradraculoides*: *P. anachoretus* (GenBank accession # EU272701), *P. bythius* (GenBank accession # EU272715), *P. gnophicola* (GenBank accession # EU272716) *P. kryptus* (GenBank accession # EU272723), and *Paradraculoides* sp (GenBank accession # EU272697). As local references, 22 specimens from previous surveys in the Pilbara were included in the analysis, including 11 from previous surveys at Mesas B and C. Two specimens of *Draculoides*, *D. julianeae* (GenBank accession # EU272696) and *D. vinei* (GenBank accession # EU272690) were used as outgroups.

Phylogenetic analysis

The phylogenetic analysis, which included the three Mesa A and C specimens, in addition to 27 reference specimens of *Paradraculoides*, placed the Mesa A and C specimens in three distinct lineages, all three of which (SCH001 (*P. bythius)*, SCH034 and SCH036 (*P. anachoretus*) also contained reference specimens from previous surveys at Mesa B and C (Figure 10). Lineages SCH034 and SCH036 formed a well-supported clade, with the lineages separated by relatively short branch lengths (Figure 10). The specimens of Schizomida from previous sampling phases at Mesas B and C were placed in the genus *Paradraculoides* (Figure 10) and a new genus, perhaps closely related to *Bamazomus* (not shown).

Differentiation within and between lineages

The three lineages of *Paradraculoides* detected at Mesa A and C differed from one another by between 5.6 and 9.4% mean sequence divergence (Table 12). Individuals within each of the three lineages differed from one another by 0.1% mean sequence divergence (Table 13).

The three lineages (SCH001, SCH034 and SCH036) differed from the closest reference lineages by ≤1% sequence divergence (Table 14).

Conclusions

COI is widely considered to show suitable variation to distinguish species (Hebert et al., 2003a). In a comparison of COI sequences for over 13,000 pairs of taxa, Hebert et al (2003b) found a mean of 11.1% sequence divergence between distinct species. Nearly 80% of the comparisons showed that species pairs differed from one another by greater than 8% sequence divergence. However, a taxon by taxon approach, examining the amount of phylogenetic variation within and between species is the most widely accepted method of defining species.

Araneae

A single genetically distinct lineage of Araneae was detected at Mesa C (AG003), representing a single distinct species, owing to the high level of sequence divergence between it and the reference lineages. The lineage differed from the reference lineages by >15%, indicating that it is likely to be a new species, based on the material available for comparison. The species is likely to belong to the family Gnaphosidae (ground spiders), based on its phylogenetic placement and similarity to a reference specimen of *Zelanda* from New Zealand. The family is widespread in Australia, and two troglobitic species are known from Barrow Island (Humphreys et al., 2013). Previous specimens of Araneae collected at Mesa B/C were putatively assigned to the families Theridae/Symphytognathidae, Aranidae and Oonopidae.

Gnaphosidae (putative)
AG001 = new lineage and species

Coleoptera

A single genetic lineage of Coleoptera was detected at Mesa B. The lineage differed from specimens of the nearest reference lineage CCU012 by < 1%, indicating that the specimen represents a lineage and species of Curculionidae that has been detected previously.
The Mesa B specimen was placed in a clade containing reference specimens from the WAM, assigned to the species Curculionidae sp. 8. Differentiation within the clade ranged from 2.7-3.3% sequence divergence, suggesting that the species from Mesa C belongs to Curculionidae sp. 8. For comparison, differentiation within the four WAM species for which there are multiple sequences (species 1, 3, 4, 8) ranges from a mean of 0.1% (species 1) to 5.2% (species 4). Previous specimens of Coleoptera collected at Mesa B/C were also assigned to the family Curculionidae.

Curculionidae
CCU012 = lineage and species detected previously at Mesas B and C in the Robe Valley

Diplura

A single distinct genetic lineage of Diplura was detected at Mesa C. The lineage was placed with the Japygidae (lineage DJA011). The lineage differed from the reference lineages by >15% sequence divergence, indicating that it is likely to represent a new species, which has so far not been detected in the Pilbara, based on the material available for comparison. Previous specimens of Diplura collected at Mesa B/C were putatively assigned to the families Parajapygidae and Campodeidae.

Japygidae
DJA011 = new lineage and species

Thysanura

The mitochondrial gene 12S is widely used in insect systematics (Simon et al., 1996; Caterino et al., 2000), although in contrast to the mitochondrial gene COI, fewer broadscale comparative studies are available to provide a basis for species discrimination. Nonetheless, 12S has proven useful for establishing phylogenetic relationships in many insect groups (Caterino et al., 2000). The 12S gene evolves approximately 1.5 times (Mueller, 2006) more slowly than COI. Hence we would expect that the threshold for species discrimination using 12S would be, by inference, lower than COI.

A single distinct lineage of Thysanura was detected at Mesa C, Nicoletiinae TN010. It differed from the nearest reference specimens by between 0.5 and 2.8% sequence divergence.

Using a conversion factor of 1.5 x to account for the slower 12s rate of evolution, this value might correspond to approximately 0.8 to 4.2% of COI divergence. For comparison, the six specimens of *Trimenura callawa* differ by a mean of 0.4% sequence divergence (range = 0 to -0.9% at 12s may correspond to up to approximately 1.4% at COI). Given the relatively low value between specimens of TN010, but keeping in mind that these are estimates based on current understanding of 12s and COI evolution rates, it is likely that lineage TN010 represents a single species, showing some genetic divergence among drillholes. Previous specimens of Thysanura collected at Mesa B/C were also assigned to the sub-family Nicoletiinae.

Nicoletiinae
TN010 = lineage and species that has been detected previously at Mesa B/C.

Pseudoscorpiones

Two distinct genetic lineages of pseudoscorpions were detected at Mesa C and K, both likely belonging to the family Chthoniidae. The two lineages of Chthoniidae differed from one another by approximately 20% sequence divergence, thus each is likely to represent a distinct species. Further, both Chthoniidae lineages from Mesa C and K differed from the nearest reference specimens by ≥6%, indicating that the two are likely to be new species that have so far not been detected in the Pilbara, based on the material available for comparison. Previous specimens of Pseudoscorpiones collected at Mesa B/C were assigned to the families Chthoniidae and Hyiidae.

Chthoniidae
PC058 = new lineage, new species
PC059 = new lineage, new species

Schizomida
Previous analyses of genetic variation between morphologically distinct species of Schizomida can be used as a genetic 'yardstick' to interpret the current data set. The five described species of *Paradraculoides* (Harvey et al, 2008) differ from one another by between 8.4 to 12.1% sequence divergence (uncorrected p-distances; calculated by us from the Harvey et al., 2008 data). Similarly, the four described species of *Draculoides* differ from one another by between 4.5 to 13.7% sequence divergence (uncorrected p-distances calculated by us from Harvey et al., 2008).

Three genetically distinct lineages of schizomids were detected at Mesa A and C. The three lineages correspond to three species, all of which were assigned to existing lineages and species. Specifically, one specimen was assigned to *Paradraculoides bythius* (lineage SCH001) and four specimens were assigned to *Paradraculoides anachoretus* (lineage SCH036), differing from these reference lineages by <3%. Finally, x specimens were assigned to the existing lineage SCH034, as it differed from the reference specimens of that lineage by >1%. Lineages SCH034 and SCH036 formed a well-supported clade and differed by a moderately low level of sequence divergence (5.6 to 6.3% sequence divergence). This variation is greater than would be expected within a single species, and given that both lineages were detected in the same drillhole (RC16MEA004), indicates that that the two lineages are reproductively isolated. Previous specimens of Schizomida collected at Mesa B/C were assigned to the genus *Paradraculoides* and a new genus, putatively related to *Bamzomus*.

Paradracucloides
SCH001 = previously detected lineage and species (*Paradraculoides bythius*)
SCH034 = previously detected lineage and species
SCH036 = previously detected lineage and species (*Paradraculoides anachoretus*)

1. Tamura K., Stecher G., Peterson D., Filipski A., and Kumar S. (2013). MEGA6: Molecular Evolutionary Genetics Analysis version 6.0. Molecular Biology and Evolution30: 2725-2729.

The number of base differences per site from between sequences are shown. Standard error estimate(s) are shown above the diagonal. The analysis involved 42 nucleotide sequences. Codon positions included were 1st+2nd+3rd+Noncoding. All ambiguous positions were removed for each sequence pair. There were a total of 495 positions in the final dataset. Evolutionary analyses were conducted in MEGA6 [1].

1. Tamura K., Stecher G., Peterson D., Filipski A., and Kumar S. (2013). MEGA6: Molecular Evolutionary Genetics Analysis version 6.0. Molecular Biology and Evolution30: 2725-2729.

The number of base differences per site from between sequences are shown. Standard error estimate(s) are shown above the diagonal. The analysis involved 42 nucleotide sequences. Codon positions included were 1st+2nd+3rd+Noncoding. All ambiguous positions were removed for each sequence pair. There were a total of 495 positions in the final dataset. Evolutionary analyses were conducted in MEGA6 [1].

1. Tamura K., Stecher G., Peterson D., Filipski A., and Kumar S. (2013). MEGA6: Molecular Evolutionary Genetics Analysis version 6.0. Molecular Biology and Evolution30: 2725-2729.

The number of base differences per site from between sequences are shown. Standard error estimate(s) are shown above the diagonal. The analysis involved 42 nucleotide sequences. Codon positions included were 1st+2nd+3rd+Noncoding. All ambiguous positions were removed for each sequence pair. There were a total of 495 positions in the final dataset. Evolutionary analyses were conducted in MEGA6 [1].

Disclaimer: Although utmost care has been taken to ensure the correctness of the caption, the caption text is provided "as is" without any warranty of any kind. Authors advise the user to carefully check the caption prior to its use for any purpose and report any errors or problems to the authors immediately (www.megasoftware.net). In no event shall the authors and their employers be liable for any damages, including but not limited to special, consequential, or other damages. Authors specifically disclaim all other warranties expressed or implied, including but not limited to the determination of suitability of this caption text for a specific purpose, use, or application.

1. Tamura K., Stecher G., Peterson D., Filipski A., and Kumar S. (2013). MEGA6: Molecular Evolutionary Genetics Analysis version 6.0. Molecular Biology and Evolution30: 2725-2729.

The number of base differences per site from between sequences are shown. Standard error estimate(s) are shown above the diagonal. The analysis involved 42 nucleotide sequences. Codon positions included were 1st+2nd+3rd+Noncoding. All ambiguous positions were removed for each sequence pair. There were a total of 495 positions in the final dataset. Evolutionary analyses were conducted in MEGA6 [1].

1. Tamura K., Stecher G., Peterson D., Filipski A., and Kumar S. (2013). MEGA6: Molecular Evolutionary Genetics Analysis version 6.0. Molecular Biology and Evolution30: 2725-2729.

The number of base differences per site from between sequences are shown. Standard error estimate(s) are shown above the diagonal. The analysis involved 42 nucleotide sequences. Codon positions included were 1st+2nd+3rd+Noncoding. All ambiguous positions were removed for each sequence pair. There were a total of 495 positions in the final dataset.
Evolutionary analyses were conducted in MEGA6 [1].

1. Tamura K., Stecher G., Peterson D., Filipski A., and Kumar S. (2013). MEGA6: Molecular Evolutionary Genetics Analysis version 6.0. Molecular Biology and Evolution30: 2725-2729.

The number of base differences per site from between sequences are shown. Standard error estimate(s) are shown above the diagonal. The analysis involved 42 nucleotide sequences. Codon positions included were 1st+2nd+3rd+Noncoding. All ambiguous positions were removed for each sequence pair. There were a total of 495 positions in the final dataset. Evolutionary analyses were conducted in MEGA6 [1].

Appendix 5

WAM Short Range Endemic Categories Guidelines

WAM SHORT-RANGE ENDEMIC CATEGORIES

	Taxonomic Certainty	Taxonomic Uncertainty
Distribution < 10 000km^2	**Confirmed SRE** • *A known distribution of < 10 000km².* • *The taxonomy is well known.* • *The group is well represented in collections and/ or via comprehensive sampling.*	**Potential SRE** • *Patchy sampling has resulted in incomplete knowledge of the geographic distribution of the group.* • *We have incomplete taxonomic knowledge.* • *The group is not well represented in collections.* • *This category is most applicable to situations where there are gaps in our knowledge of the taxon.* **Sub-categories for this SRE designation are outlined below**
Distribution > 10 000km^2	**Widespread (not an SRE)** • *A known distribution of > 10 000km².* • *The taxonomy is well known.* • *The group is well represented in collections and/ or via comprehensive sampling.*	

SRE SUB-CATEGORIES

If a taxon is determined to be a "Potential SRE", the following sub-categories will further elucidate this status.

A. *Data Deficient:*
- There is insufficient data available to determine SRE status.
- Factors that fall under this category include:
  - New species.
  - Lack of geographic information.
  - Lack of taxonomic information.
  - The group may be poorly represented in collections.
  - The individuals sampled (e.g. juveniles) may prevent identification to species level.

B. *Habitat Indicators:*
- It is becoming increasingly clear that habitat data can elucidate SRE status.
- Where habitat is known to be associated with SRE taxa and vice versa, it will be noted here.

C. *Morphology Indicators:*
- A suite of morphological characters are characteristic of SRE taxa.
- Where morphological characters are known to be associated with SRE taxa and vice-versa, it will be noted here.

D. *Molecular Evidence:*
- If molecular work has been done on this taxon (or a close relative), it may reveal patterns congruent or incongruent with SRE status.

E. *Research & Expertise:*
- Previous research and/ or WAM expertise elucidates taxon SRE status.
- This category takes into account the expert knowledge held within the WAM.

Mesa H Subterranean Fauna Assessment

Contents

1.0 Executive Summary 9

2.0 Introduction 11

2.1 Project Background 11
2.2 Terminology 11
2.3 Objectives and Scope 11
2.4 Purpose of this Report 13
2.5 Subterranean Fauna Overview 13

3.0 Methodology 15

3.1 Desktop Review and Database Searches 15
3.2 Survey Timing and Personnel 15
3.3 Stygofauna Sampling 18
3.4 eDNA Sampling 18
3.5 Troglofauna Sampling 18
3.6 Morphological Identifications 19
3.7 Specimen Molecular Analysis 19
3.8 eDNA Sample Analysis 20
3.9 Categories of Conservation Significance 20
3.10 Sampling Effort 21
3.11 Study Limitations 30

4.0 Desktop Review 31

4.1 Priority and Threatened Ecological Communities 31
4.2 Surface Geology 31
4.3 Previous Relevant Surveys 35
4.4 Desktop Review Results 38

5.0 Survey Results 47

5.1 Stygofauna 47
5.2 eDNA 55
5.3 Troglofauna 57

6.0 Discussion 69

6.1 Known Subterranean Assemblage 69
6.2 Conservation Significant Fauna 69
6.3 Potential SRE Fauna 70

7.0 Glossary 79

8.0 References 81

1.0 Executive Summary

Rio Tinto is evaluating the potential development of a number of iron ore deposits within the Robe Valley in the Pilbara region of Western Australia. This includes the development of the Mesa H deposit (15 km southwest of Pannawonica). The development has the potential to impact subterranean fauna, including both troglofauna (air-breathing subterranean fauna living above the water table) and stygofauna (aquatic fauna of the groundwater). Biota Environmental Sciences was therefore commissioned to conduct a detailed subterranean fauna survey at Mesa H. While the location of the proposed mine pits and other infrastructure, and the extent of the dewatering needed for the project to access below water table ore, are considered here, their use in this report is limited to a framework to categorise the subterranean fauna records arising from the survey.

A total of six phases of troglofauna sampling and five phases of stygofauna sampling were undertaken through nine field mobilisations occurring between October 2015 and December 2017. Stygofauna were sampled using modified plankton haul nets, and troglobitic fauna were sampled using two methods: baited colonisation traps and haul net scraping. A total of 53 sites were sampled for stygofauna across five phases and 136 sites were sampled for troglofauna using colonisation traps across six phases, with 57 sites sampled for troglofauna with haul nets. Environmental DNA (eDNA) sampling was also conducted at 16 sites in December 2017, with groundwater samples collected to target the specially protected Blind Cave Eel (*Ophisternon candidum*), which is not readily detectable with conventional sampling methods.

Molecular analysis was conducted to determine the number of species present, and to compare the results with data from elsewhere in the Pilbara. Morphological identifications of specimens were undertaken where mature, intact specimens and suitable taxonomic frameworks were available.

A total of 855 stygofauna specimens were recorded over the five phases of sampling, comprising at least 43 species-level taxa. As is typical of the Pilbara bioregion, the fauna recorded was numerically dominated by the Crustacea, which accounted for 98% of the specimens.

With the survey results, and the additional species previously known from desktop records, 46 stygofauna species are known from the immediate locality of Mesa H and the stygofauna of the drawdown extent itself currently stands at a total of 32 species, with half of these taxa recorded occur more widely in the locality or the bioregion. Thirteen of the species within the drawdown extent were identified as potential Short-range Endemic (SRE) fauna and six of these are restricted to the Mesa H drawdown extent based on the currently available data (the snail Hydrobiidae sp. 2, the ostracod Candoninae sp. 'BOS541', the copepod *Parastenocaris* sp. 'B28', the isopod *Haptolana* sp. 'B01', and the amphipod species Paramelitidae sp. 'AMP003' and Paramelitidae sp. 'AMP037').

Three stygofauna species of conservation significance have been recorded within the Mesa H groundwater drawdown extent during previous surveys: the Blind Cave Eel *Ophisternon candidum* (Vulnerable; Schedule 3), and the Schedule 3 amphipod species *Nedsia hurlberti* and *Nedsia sculptilis*. No additional records of the latter two species were obtained during the current survey, but further sampling targeting this species during the current study resulted in the detection of *Ophisternon* DNA at five locations, both along Jimmawurruda Creek and the Robe River, including at two sites within the drawdown extent and three outside of the drawdown extent along the Robe River. An additional specimen was also collected during surface water alluvium sampling along the Robe River, bringing the number of locations outside of the drawdown extent that the species has been recorded at to five (including Cape Range). The significantly improved distributional data indicate that the species occurs more widely in the locality, probably in association with the major alluvial aquifers of the Bungaroo-Jimmawurruda-Robe system.

A total of 150 troglobitic fauna specimens were collected across the six phases of sampling, representing five classes, nine orders and at least 32 species-level taxa. The orders Coleoptera and Schizomida were the greatest contributors to troglofaunal composition, accounting for 33% and 25% of the specimens collected, respectively. One other troglobitic taxon was previously known from the development envelope, bring the current known troglofauna assemblage to 33 species.

No troglofauna of conservation significance (i.e. listed as Priority, Schedule or Vulnerable at State or Federal levels) were recorded during the survey at Mesa H. A total of 27 troglofauna taxa classified as potential SREs are now known solely from within the Mesa H development envelope and do not currently have wider documented distributions (26 species from the current survey and one from historical records).

Twenty of these potential SRE taxa were represented by singleton records (single specimen records), making determination of their true distributions difficult. This overall pattern of short-range endemism is consistent with the findings of previous comprehensive surveys of the troglofauna of pisolitic mesas elsewhere within the Robe River valley.

2.0 Introduction

2.1 Project Background

Rio Tinto is evaluating the potential development of a number of iron ore deposits within the Robe River valley, in the Pilbara region of Western Australia. This includes the development of the Mesa H deposit (15 km southwest of Pannawonica) (Figure 2.1).

Previous studies have documented the occurrence of troglobitic and stygobitic fauna communities within the Robe River valley, with many of the documented troglofauna species isolated to individual mesa formations (Biota 2006a, Harvey et al. 2008). Troglofauna, in particular, demonstrate extreme short-range endemism as a result of geological barriers, and are therefore of significance to the environmental impact assessment (EIA) of any proposed developments affecting their habitat.

The development of the Mesa H deposit has the potential to impact subterranean fauna, and Rio Tinto therefore wishes to improve knowledge of these communities at Mesa H by collating existing data, determining information gaps and completing additional phases of sampling. Rio Tinto commissioned Biota Environmental Sciences (Biota) to complete the required subterranean fauna surveys to achieve this.

2.2 Terminology

This report primarily addresses the outcomes of the subterranean fauna surveys, with the assessment of impacts on subterranean fauna species, communities and habitats considered in a separate report (Biota 2018). While the location of the proposed mine pits and other infrastructure, and the extent of the dewatering needed for the project to access below water table ore, are considered here, their use in this report is limited to a framework to categorise subterranean fauna occurrence. For the purposes of this report then, the following terms are used as defined below:

- Development envelope – The Mesa H project boundary, which will accommodate the full extent of the physical components of the project (Figure 2.1);
- Drawdown extent – the spatial extent of the maximum groundwater dewatering influence for the Mesa H project, which extends beyond the development envelope to the east and southeast, and is primarily of relevance to stygofauna from an EIA perspective (Biota 2018) (Figure 2.1);
- Survey area – The area surveyed for subterranean fauna, including the development envelope and reference sites outside of the development envelope at the Pannawonica bore field and Pannawonica Road (Figure 2.1); and
- Desktop review area – An area encompassing the development envelope and a 15 km square around it to include previous surveys undertaken adjacent to Mesa H (Figure 2.1).

2.3 Objectives and Scope

The overall scope of this study was to document the subterranean fauna from the proposed Mesa H development envelope, consolidating the data with existing records from the locality, and placing the findings into wider regional context and assessing conservation status, where possible.

The specific objectives of this study were to:

1. conduct molecular analyses of troglobitic fauna specimens previously collected in the vicinity of Mesa H;
2. conduct a multiple phase sampling programme to document troglofauna and stygofauna present within the survey area; and
3. place the recorded fauna into a regional context and discuss their potential conservation significance.

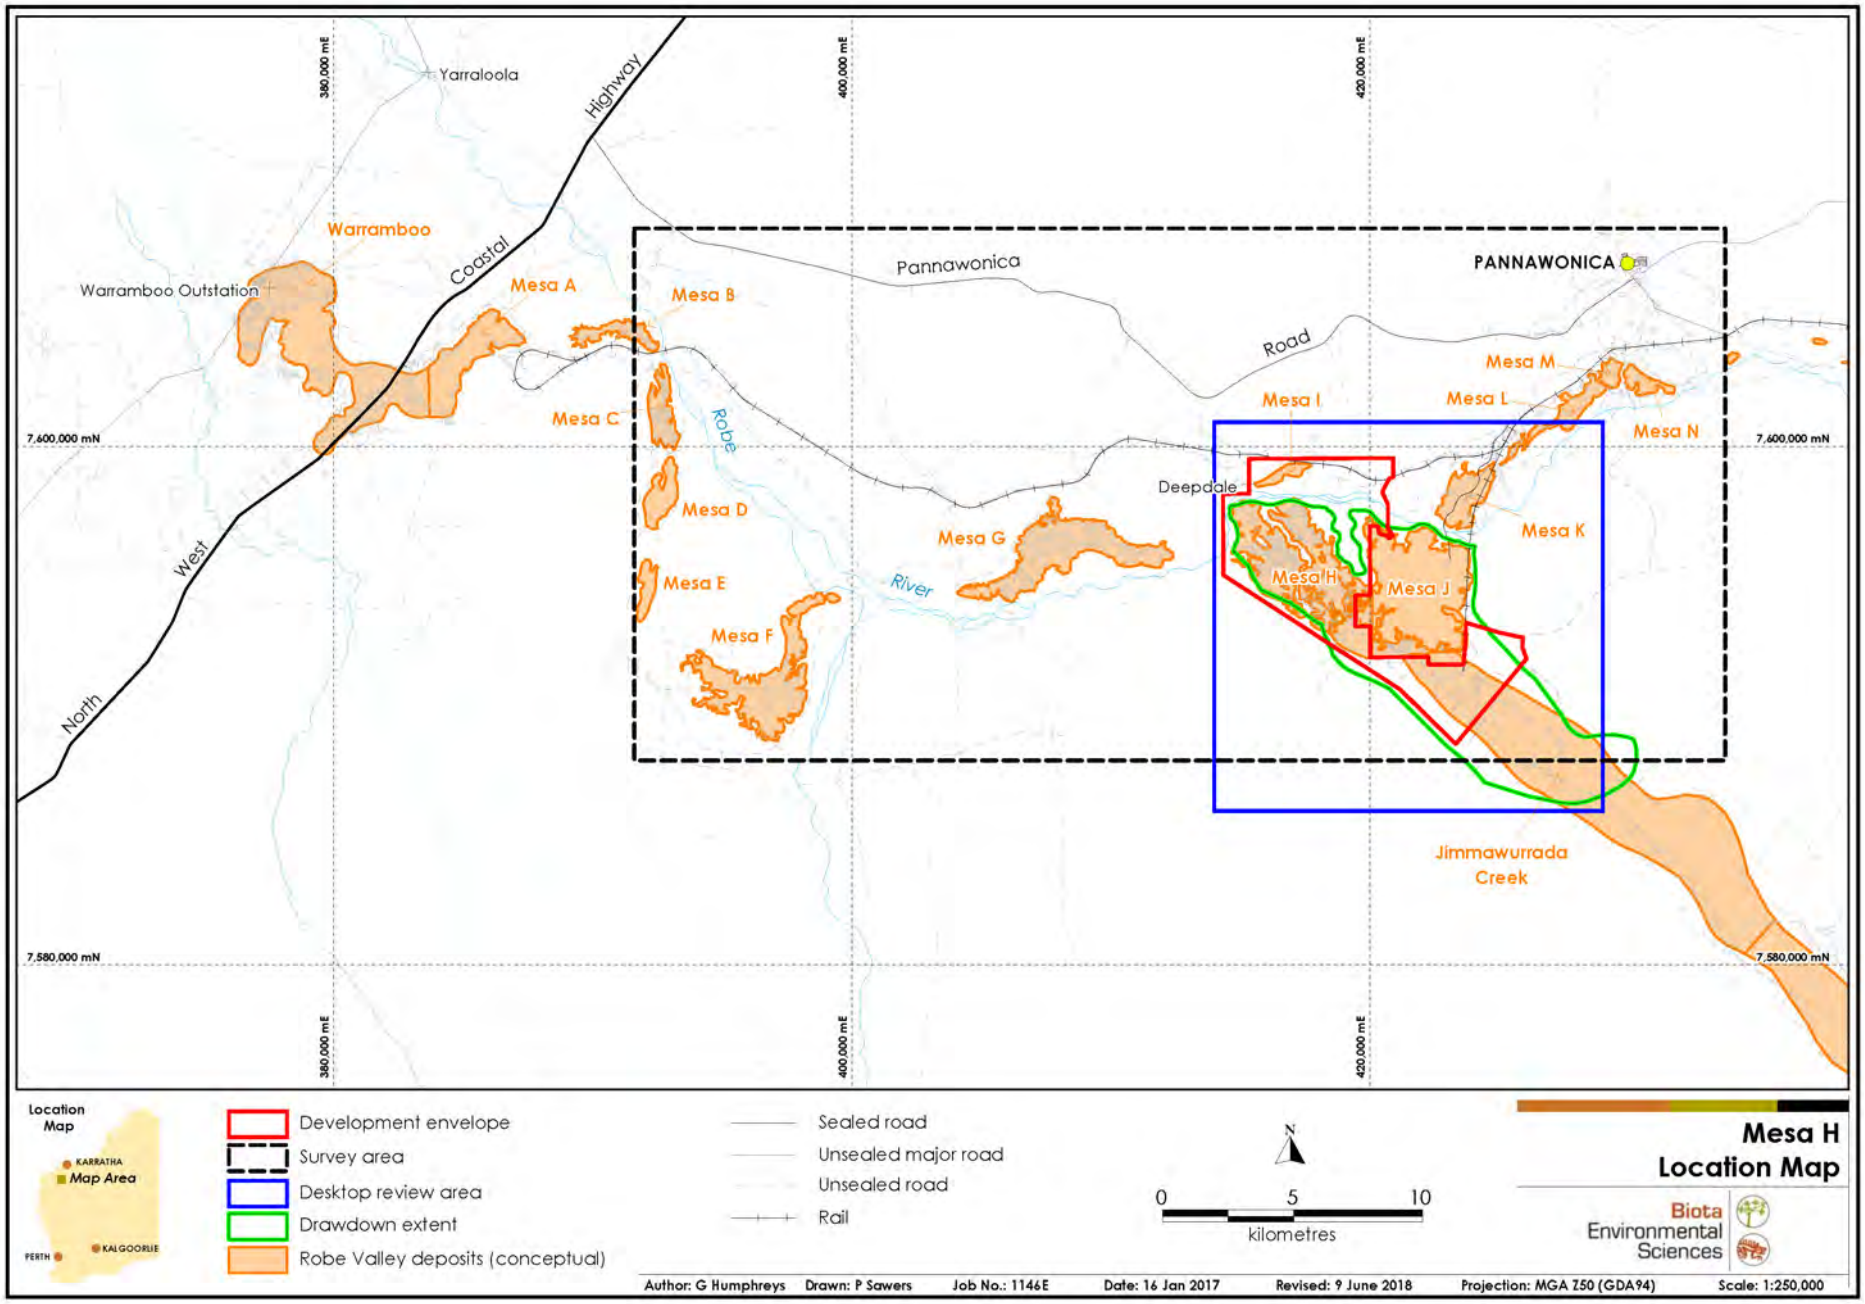

Figure 2.1: Location map of the Mesa H survey area.

The study was planned and implemented as far as practicable in accordance with the following:

- EPA Statement of Environmental Principles, Factors and Objectives (EPA 2016a);
- Environmental Factor Guideline – Subterranean Fauna (EPA 2016b);
- Technical Guidance - Subterranean fauna survey (EPA 2016c); and
- Technical Guidance - Sampling methods for subterranean fauna (EPA 2016d).

2.4 Purpose of this Report

The purpose of this report is to provide consolidated baseline survey information to inform the EIA of proposed mining activities within the development envelope.

This report documents the methodology, sampling effort and results of the subterranean fauna sampling programme completed within the survey area. Both the field sampling and report are subject to specific limitations that are discussed in Section 3.11.

2.5 Subterranean Fauna Overview

Until recently, Australia was thought to lack habitat suitable for subterranean fauna. However, recent research (mostly with an emphasis on impact assessment) has revealed Australia to be highly diverse in subterranean fauna, with numerous areas of interest throughout the continent (Guzik et al. 2010). In Western Australia these zones of subterranean biodiversity can be found at Cape Range, Barrow Island, the Pilbara bioregion, the Yilgarn and the Nullarbor (Humphreys 2001a, Page et al. 2008, Guzik et al. 2010).

Recent surveys in the Pilbara have collected subterranean fauna from a range of geological units such as pisolitic iron formations, channel iron deposits, unconsolidated alluvium and sedimentary basalt (Marmonier et al. 1993, Biota 2004, 2006a, 2010a, 2011a, 2013). This indicates that the suitability of a formation as habitat for subterranean fauna is mostly a function of the availability of habitable space (Marmonier et al. 1993, Humphreys 1999, Biota 2006a), rather than a specific geological unit.

Subterranean fauna habitats are characterised by shared physical parameters that include a lack of light, stable temperature, limited nutrient infiltration from surface environments and a constant humidity (Juberthie 2000, Romero 2009). These habitat characteristics have resulted in convergence in body morphology evolution amongst many subterranean fauna. Morphological characteristics common to most subterranean fauna include reduced or lack of pigmentation, reduced or lack of eyes, and elongate body morphology and appendages adapted for sensory movement (Culver and Pipan 2009, Romero 2009).

Subterranean fauna can be categorised into two distinct ecological groups based on habitat: troglofauna and stygofauna. Troglofauna are a suite of fauna that survive only in air-filled cavities and interstices between the surface and the water table. Stygofauna comprise aquatic taxa occurring in groundwater aquifers and subterranean water bodies. Troglobites and stygobites are obligatory subterranean habitat dwellers, and while they may occur close to surface environments, are strongly adapted to subterranean environments. This makes such fauna unable or highly unlikely to survive surface conditions. A range of similarly adapted fauna known as troglophiles, trogloxenes and edaphobites also occur; these fauna use subterranean habitats opportunistically but are able to survive outside these stable environments. Studies from the Pilbara bioregion have demonstrated that these suites of fauna are not similarly restricted in range and are therefore unlikely to be impacted by small-scale developments (Biota and Helix 2012, Helix 2012).

2.5.1 Troglofauna

Troglofauna in semi-arid Australia are thought to be relictual rainforest fauna; fauna adapted to humid environments, which retreated underground to cave systems during the aridification of

Australia (In the late Miocene; Humphreys 1993). This is inferred from affinities of the taxonomic groups represented amongst the troglofauna with other extant taxa in tropical climates. Some invertebrate groups with troglobitic representatives include the Arachnida (e.g. Schizomida, Pseudoscorpiones and Araneae), Chilopoda (e.g. Scolopendrida), Diplopoda (e.g. Polydesmida and Haplodesmida), and Insecta (e.g. Diplura, Zygentoma, Coleoptera and Blattodea). A single troglobitic vertebrate species of blind snake (*Anilios longissimus*) is known from Australia, collected from Barrow Island (Aplin 1998, Humphreys et al. 2013).

Due to their dependence on constant humidity, the dispersal and distribution of troglobitic fauna species tends to remain limited to individual blocks of inter-connected habitat, leading to long periods of population isolation and speciation. As a result, troglobitic fauna are considered to be of conservation significance, given that species often display extreme short-range endemism and may therefore be affected by relatively small-scale developments such as mining and construction.

2.5.2 Stygofauna

Stygal communities in Western Australia are predominantly Crustacean (e.g. Amphipoda, Isopoda, Decapoda, Syncarida, Ostracoda and Copepoda), however Annelida (e.g. Oligochaeta), Arachnida (e.g. Hydracarina) and Platyhelminthes are also commonly collected. Three species of stygal vertebrates have been recorded from Australia. This includes two species of blind gudgeon (*Milyeringa veritas* and *M. justitia*) as well as a blind cave eel, *Ophisternon candidum* (Humphreys 2001b, DSEWPaC 2008, Foster and Humphreys 2011, Larson et al. 2013).

3.0 Methodology

3.1 Desktop Review and Database Searches

3.1.1 Desktop Review

A desktop review of relevant existing information was undertaken in order to provide context to the assessment of subterranean fauna at Mesa H. The review considered:

1. previous relevant studies conducted within 40 km of the development envelope;
2. Threatened Ecological Communities (TECs) and Priority Ecological Communities (PECs) listed by the Department of Biodiversity, Conservation and Attractions (DBCA) that are of relevance to subterranean fauna and within 40 km of the development envelope; and
3. assessment of the surface geology of the development envelope in a local context.

3.1.2 Database Searches

The following databases were searched to assist with compilation of a list of potential species for the development envelope:

1. NatureMap: a collaboration between DBCA and the Western Australian Museum (WAM). This database represents the most comprehensive source of information on the distribution of Western Australia's fauna, comprising records from the Fauna Survey Returns database and Western Australian Threatened Fauna Database (both maintained by the Department of Biodiversity, Conservation and Attractions) and the WAM Specimen Database. The search was conducted 06/02/2017 within a 20 km radius of a central point (421372 m E, 7597354 m S).
2. Atlas of Living Australia (ALA): a collaborative project between academic collecting institutions, private individual collectors and community groups. The atlas contains occurrence records, environmental data, images and the conservation status of species throughout Australia. The search was conducted 06/02/2017 within a 10 km radius of a central point (421372 m E, 7597354 m S).
3. WAM's Arachnida, Myriapoda, Crustacea and Mollusca databases: The search request was submitted 14/03/2017 using the following bounding co-ordinates: 405138 m E, 7607948 m S (top left corner), 435642 m E, 7582695 m S (bottom right corner).
4. Biota Internal Database: This database includes all of the subterranean fauna data collected by Biota within Western Australia, which includes the majority of the past records from the Robe River valley. The search was conducted 06/02/2017 within 15 km from a central point in the development envelope (421490 m E, 7593430 m S).

3.2 Survey Timing and Personnel

A total of six phases of troglofauna sampling and five phases of stygofauna sampling were undertaken over the course of nine field mobilisations occurring between October 2015 and December 2017.

The field work was completed under "Regulation 17: Licence to Take Fauna for Scientific Purposes", licence numbers SF010536 (30/09/2015 – 30/06/2016) and SF010915 (22/07/2016 – 30/06/2017), both issued to Mr Chris Cole of Biota (Appendix 1). Phases 4- 6 were completed under "Licence to Take Fauna for Scientific Purposes" No. 08-001539-1 issued to Jason Alexander (Appendix 1).

A summary of survey timing, survey components and survey personnel is presented in Table 3.1.

Table 3.1: Summary of field sampling undertaken during the survey.

Sampling Dates	Survey Component	Survey Personnel
23 - 29 October 2015	Phase 1 trap installation Phase 1 stygofauna sampling	David Keirle and Chris Cole
9 -12 December 2015	Phase 1 trap retrieval Phase 2 trap installation	David Keirle, Tim Sachse
18 – 21 January 2016	Phase 2 trap retrieval Phase 2 stygofauna sampling	Penny Brooshooft, Scott Werner
3 – 7 May 2016	Phase 3 trap installation Phase 3 stygofauna sampling	Chris Cole, Nicola Watson
27 – 28 June 2016	Phase 3 trap retrieval	Chris Cole, Nicola Watson
9 – 14 September 2016	Phase 4 trap installation Phase 4 stygofauna sampling	Nicola Watson, Penny Brooshooft
25 – 27 October 2016	Phase 4 trap retrieval Phase 5 trap installation	Penny Brooshooft, Jason Alexander
12 – 14 December 2016	Phase 5 trap retrieval Phase 6 trap installation	Nicola Watson, Jacinta King
30 -31 January 2017	Phase 6 trap retrieval	Jason Alexander, Greg Richter (Rio Tinto)
11-15 December 2017	eDNA and Phase 5 stygofauna sampling (reference areas)	Jason Alexander, Jacinta King, Michael Greenham

3.2.1 Weather Conditions

Temperature and rainfall data were obtained from the Mesa J mining operations adjacent to the east end of Mesa H (Figure 2.1). Long-term climate data (rainfall from 1971 – 2014, temperature data from 1971 – 2005) were obtained from the Bureau of Meteorological (BOM) weather station in Pannawonica (station number 5069), approximately 15 km northeast of Mesa H.

The phases of sampling within the development envelope occurred between October 2015 and the end of January 2017. Several major rainfall events occurred throughout that sampling period (Figure 3.1). Past observations suggest the approximate timing of sampling after significant rainfall creates suitable conditions for sampling for troglofauna (Biota 2006a). Weather data from Pannawonica show that no rainfall was recorded during the three months preceding the Phase 5 reference area stygofauna sampling in December 2017.

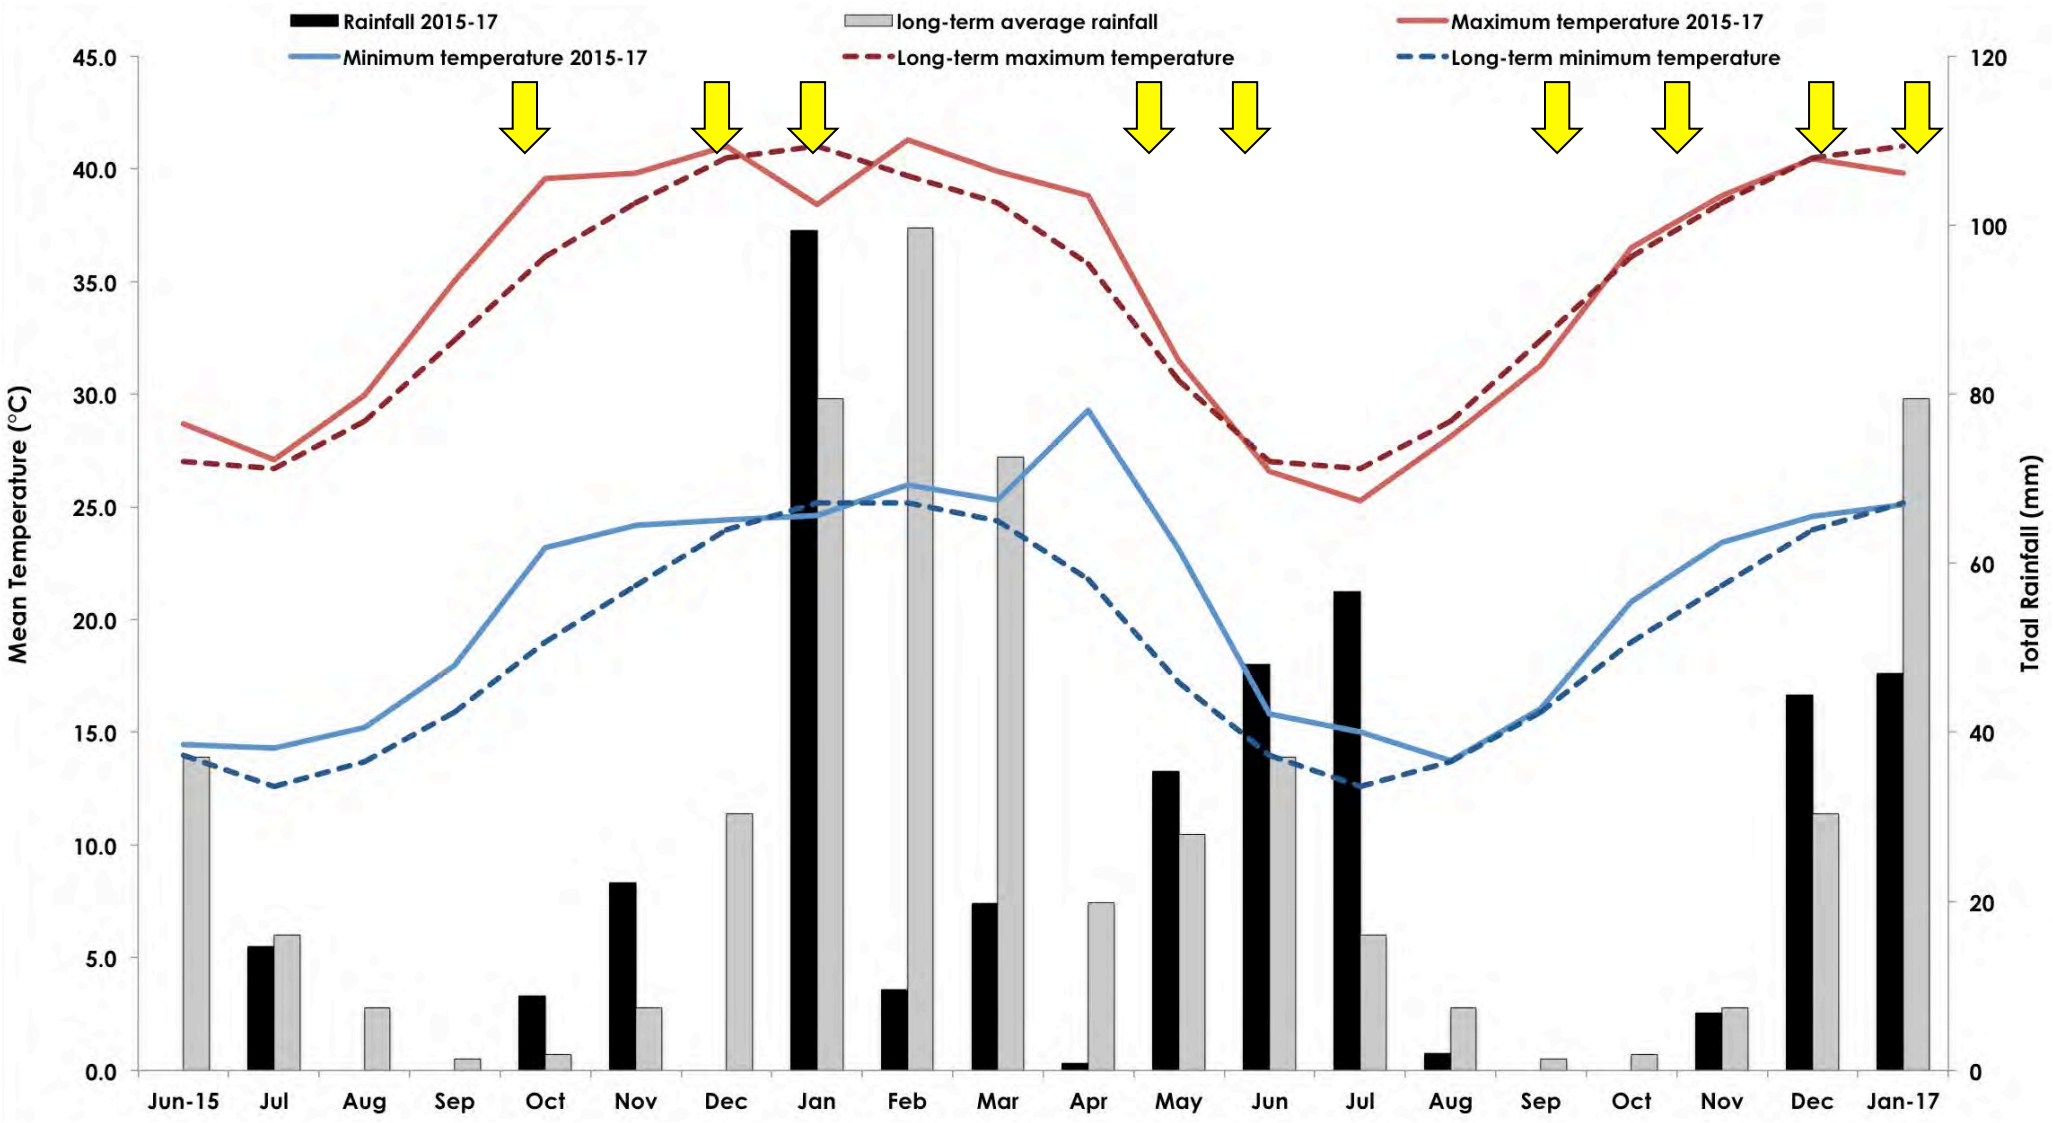

Figure 3.1: Climate and weather graph depicting long-term and monthly averages for 6 months preceding and during subterranean fauna sampling. Long-term temperature data 1971-2005, rainfall data 1971-2014; arrows indicate field mobilisation timing.

3.3 Stygofauna Sampling

Stygofauna were sampled using modified plankton haul nets, constructed from 70 μm plankton mesh, with 50 mm and 100 mm apertures attached to a stainless steel catch cylinder. Nets were lowered to the bottom of water bores and drill holes before being hauled slowly through the water column to the surface, where the contents of the cylinder were flushed into a uniquely labelled container. Each monitoring site was sampled in this way a minimum of five times. On the final haul, the net was agitated gently to stir the benthos layer and mobilise any fauna present for more effective specimen collection. Specimens were stored in a shaded esky in order to keep the samples cool prior to sorting and identification.

Following sampling of each monitoring site, the nets were thoroughly rinsed with water, inspected and (where possible) left to dry before using on another site. This prevented cross-contamination of specimens between sampling sites.

3.4 eDNA Sampling

Environmental DNA (eDNA) sampling took place on completion of stygofauna haul net sampling during Phase 5 in December 2017 (Table 3.1). The environmental samples were collected to target the Blind Cave Eel (*Ophisternon candidum*) (Section 4.4.1.1), which is not readily detectable with conventional sampling methods (Biota and Helix 2014).

This sampling initially included agitation of the benthos at the base of the borehole, to mobilise DNA molecules and fragments of tissues within the water column. Then, wearing nitrile gloves, a 1 L bailer, attached to the same line used for haul net sampling at that specific site, was lowered into the bore until approximately 1 m from the bottom of the hole. The bailer was then removed from the bore and the contents of the bailer emptied into a brand new and uniquely labeled 1 L container. This step was repeated twice more. The line was then discarded after bailing to prevent contamination of eDNA between sites.

A further two 1 L containers were filled using a specialised downhole pump (a GEOsub 12 V purging pump) attached to brand new HDPE tubing. The pump was lowered to approximately 1 m from the benthos and activated. The pump was allowed to run for three minutes, which acts to purge the bore and draw in groundwater, and potential eDNA, from the surrounding aquifer. After this, the remaining two labeled containers were filled in the same fashion. All filled containers were stored in the field an ice-filled esky until arrival at the on-site laboratory in Pannawonica.

3.5 Troglofauna Sampling

Troglobitic fauna were sampled using two methods; baited colonisation traps and haul net scraping.

3.5.1 Colonisation Trapping

Custom-built litter colonisation traps were suspended at intervals within drillholes located within the survey area. Traps were constructed from 60 mm internal diameter PVC irrigation pipe cut to a length of 180 mm. Each trap had a series of 20 mm holes drilled into the side, and traps remained open at the upper end. Up to three traps were installed such that they were in contact with the interior of the sampled drillhole, facilitating fauna entry into the trap.

Leaf litter was gathered locally from the ground surface in the survey area, particularly from the bases of *Acacia* shrubs. The collected litter was soaked in water and irradiated in a microwave oven for two minutes on maximum power setting. The microwave acted to kill any surface invertebrates present and assisted in the breakdown of organic matter. Microwaved leaf litter was added to the traps, which were kept in sealed containers until immediately prior to insertion into the drillholes to avoid desiccation of the litter. After the installation of traps, the opening of each drillhole was sealed to maintain humidity and to avoid entry of surface fauna.

Traps were recovered from each drillhole after a minimum of six weeks and stored in labelled zip-lock bags in order to maintain humidity and prevent desiccation of potential troglofauna specimens during transportation to Perth.

Fauna specimens were recovered from the traps using specially designed Tullgren funnel units. The leaf litter from each trap was placed in a sieve under an aluminium lamp containing a 25-watt globe. This created a temperature of approximately 30°C at the surface of the leaf litter. A funnel situated below the leaf litter collected the fauna as they fell, directing them into an attached vial of 100% ethanol. Leaf litter was left in the Tullgren funnels for a period of 24 hours, or until dry, after which time the bulked invertebrate sample was removed.

3.5.2 Troglofauna Scraping

Troglofauna were also sampled using reinforced stygofauna haul nets. These nets were constructed from 70 µm plankton mesh and had 100 mm apertures attached to a weighted catch jar. Sampling took place by lowering the net to the bottom of the site before being hauled slowly to the surface whilst scraping the edge of the drillhole. This dislodged any fauna on the vertical surface of the drillhole interior. Each site was scraped a minimum of four times, scraping each side of the drillhole. On completion, fauna specimens were preserved in-situ in 100% ethanol and individually labelled. The contents of the net, which included dry soil and root matter, were emptied into a uniquely labelled container. The container was then filled with 100% ethanol to preserve any specimens that may have been in the soil and root matter for later sorting in the field laboratory.

3.6 Morphological Identifications

Preliminary identification of subterranean fauna involved identification of specimens to order level, where possible, or separation of specimens into distinct morphotypes. Sorting was completed using dissecting microscopes (Olympus SZ40 and SZ61, magnification up to 40x). Specimens were preserved in 100% ethanol once separated out into morphotypes, which allows for both morphological and molecular analyses. Specialist morphological identifications of copepods, ostracods and isopods were undertaken by Jane McRae and Stuart Halse of Bennelongia Environmental Consultants (Appendix 2).

3.7 Specimen Molecular Analysis

Molecular analysis of selected groups was conducted to determine the number of species present, and to compare the results with data from elsewhere in the Pilbara. These were taxonomic groups for which past studies have shown morphological identifications to species level are generally not possible or reliable for most specimens, where inadequate taxonomic expertise is readily available for the groups in question, and/or where well established phylogenetic frameworks exist to more adequately place the specimens into regional context. Yvette Hitchen of Helix Molecular Solutions (Helix) completed DNA sequencing of the collected Amphipoda, Schizomida, Diplura, Thysanura, Isopoda and Pseudoscorpiones. Terrie Finston (Helix) and Rachael King (South Australian Museum) provided analysis and interpretation of the molecular data.

The collected specimens were sequenced for variation at the mitochondrial cytochrome oxidase subunit 1 gene (CO1). Where larger numbers of specimens of the same morphotype (i.e. more than five) were recorded from the same sampling site, a subsample of five specimens was typically taken for sequencing. Schizomid specimens recorded during previous surveys at Mesa J (Biota 2009) were also sequenced as part of the current study to improve local context. A complete account of the molecular analysis methodology is provided in Appendix 3.

On the basis of existing literature and past molecular studies of Pilbara troglofauna (Hebert et al. 2003a, 2003b, Harvey et al. 2008), lineages with a divergence of less than 4.0% were considered a single species, whereas lineages with a divergence greater than 6.0% were considered separate distinct species for the purpose of this report, subject to a review of the relative variation within each putative species, unless advised otherwise by Helix based on other data for the relevant taxonomic group. Lineages with intermediate divergences ranging from 4.0 – 6.0% were resolved to a preliminary level for the purposes of this report, with further input from Helix, and consideration to collection proximity, habitat, geology and past results from the same taxonomic groups.

3.8 eDNA Sample Analysis

3.8.1 Sample Processing

Groundwater samples collected for eDNA analysis were filtered through 0.45 μm sterile filter membranes, using both Sentino Microbiology Pumps and manually using specialised Nalgene Filter Flasks and a hand pump. One container of groundwater (1 L) was processed per membrane and on completion of this process, the membrane was folded in half then cut vertically. These halves were placed in separate sterile storage bags and frozen with the remaining filters for that site depending on which lab the membrane would be despatched to for further analysis (Section 3.8.2). All laboratory equipment was sterilised between samples using a bleach solution.

3.8.2 Sample Analysis

eDNA sample filters were analysed by two different molecular methods, each of which was undertaken independently by two separate laboratories. The objectives of both methods were to detect residual DNA from the Blind Cave Eel (*Ophisternon candidum*) (Section 4.4.1.1) in the environmental samples.

3.8.2.1 qPCR

Helix Molecular Solutions analysed half of the replicate membranes from each sample site using a real-time qPCR method developed previously for the Blind Cave Eel (Biota and Helix 2014). Sequence data from past collections of *Ophisternon* from the Jimmawurrada and Bungaroo Creek locality was used to design a species-specific probe using the Integrated DNA Technology (IDT) design tool PrimerQuest and further edited using Oligo Primer analysis software version 6 (Molecular Biology Insights, Cascade, USA). The resulting assay amplified a diagnostic 80 bp fragment of the mitochondrial cytochrome c oxidase subunit I gene (COI) (Biota and Helix 2014).

Samples were extracted using the QIAGEN Blood and Tissue Kit (QIAGEN, Hilden, Germany) and as with previous studies all starting volumes were doubled to ensure that the filter membrane was covered during incubation. All samples had two elutes of 50 μl each.

The specifically designed qPCR assay was then used to detect the presence of *Ophisternon* DNA. Quantitative real-time PCR assays were performed using the Applied Biosystems StepOne Plus real-time PCR system and software (Biota and Helix 2014). The assay identifies the presence of the target species by the unique fluorescent signal produced during the polymerase chain reaction when both the species-specific primers as well as species-specific probes match DNA present in the sample. The fluorescent response can be visualised in real time as amplification proceeds. Only samples that showed a positive CT value (the number of cycles required for the fluorescent signal to exceed the background level of fluorescence) and amplification plot were considered to test positive for the target *Ophisternon* DNA.

3.8.2.2 Next Generation Sequencing Metabarcoding

The matching halves of the filters from each site were despatched to the Trace and Environmental DNA laboratory at Curtin University. The molecular analysis undertaken by Curtin University also involved a QIAGEN Blood and Tissue Kit to extract eDNA from the samples, and then utilised a metabarcoding to simultaneously sequence the resultant environmental DNA. A fish 16S assay as used amplified using PCR followed by sequencing to obtain data relevant to *Ophisternon* (Appendix 4). This was then subsequently refined using specific assays developed for the purposes of this study (Appendix 4).

The sequence data were then analysed against both publicly available reference sequence data on GenBank and other sources, in addition to comparisons with sequences obtained from *Ophisternon* specimens collected previously from the locality (Appendix 4).

3.9 Categories of Conservation Significance

For the purpose of this report, the conservation significance of the fauna collected during this study, or records collated during the desktop review, was categorised as follows:

- Confirmed short-range endemic (SRE) species: Species where sufficient taxonomic expertise is available, and with adequate representation in WAM collections or genetic databases, that are known to be limited in distribution.
- Potential SRE species: Species where there is insufficient taxonomic knowledge or too limited a number of collections to determine SRE status. Habitat, morphology, molecular or taxonomic data deficient, but belonging to groups that may display short-range endemism.
- Widespread species (Not an SRE): Well-collected species, that are typically taxonomically well resolved.

SRE categories are based on WAM SRE guidelines (see Appendix 4 for more detail).

3.10 Sampling Effort

3.10.1 Stygofauna

A total of 53 sites were sampled for stygofauna across the five phases (Table 3.2, Figure 3.2 and Figure 3.3). The majority of sites (n=39) were sampled on at least two separate phases. Fourteen sites were sampled only once, 10 sites were sampled across three phases and one site (WB13MEJ003) was sampled across four of the five phases (Table 3.2). Eighteen of the 53 sites were located outside of the development envelope (denoted by an asterisk in Table 3.2) (Figure 3.2; Figure 3.3).

Table 3.2: Stygofauna sampling sites at Mesa H (*site outside of the drawdown extent).

Sixteen of the bores sampled for fauna were also sampled for eDNA during the December 2017 Phase 5 stygofauna sampling (Table 3.3; Figure 3.2; Figure 3.3). These were selected primarily on the basis of having been past confirmed eel record sites (Section 4.4.1.1) or being situated in equivalent hydrogeological settings along Bungaroo Creek, Jimmawurrada Creek and the Robe River (Table 3.3). In addition, a 3 L sample of surface water as taken as a Control sample from standing water within a pool along the Robe River (Table 3.3; Figure 3.2). The majority of the eDNA sampling sites were outside of the drawdown extent, within five located within (Table 3.3; Figure 3.3).

Table 3.3: eDNA sites sampled during December 2017 (*site outside of the drawdown extent).

3.10.2 Troglofauna

A total of 136 sites were sampled for troglofauna across six phases (Table 3.4, Figure 3.4). Two thirds of the sites were sampled were sampled at least twice (n=86), with the remaining 50 sampled once (Table 3.4). A total of 57 sites had additional haul net sampling completed (denoted by 'S' in Table 3.4), with nine sites being scraped with haul nets twice.

Table 3.4: Troglofauna sampling sites at Mesa H.

3.11 Study Limitations

A number of limitations apply to this study that are not necessarily functions of this specific survey, but rather relate to work on subterranean fauna in general. These limitations include:

- There is a lack of adequate taxonomic framework and specialist expertise for some faunal groups, both within Australia and internationally. This often limits the conclusiveness of some of the findings in regards to both taxonomic placement and ecological status.
- Sampling points are often limited to locations of interest for geological exploration: as most drill holes have been sited in areas of mining interest, there is often a lack of sampling points in neighbouring geological units, which may limit interpretations of available subterranean fauna habitat.
- Conservation significance could not be assigned to many taxa which could not be identified to species level, as these specimens may correspond to taxa already known from elsewhere and/or may represent species complexes. The records for these indeterminate specimens are still presented from both desktop and field survey sources, but they are excluded from final tallies of taxa for stygofauna or troglofauna.
- All genetic analysis was completed using the CO1 gene only. This gene was used because it has proved to be relatively fast evolving across many taxonomic groups and a typically reliable indicator of likely species boundaries (Hebert et al. 2003b). Recent studies, however, have indicated that using specific genes for different taxa, or using multiple genes, may provide for more informative results.
- Detailed morphological analysis was not completed for the specimens subject to molecular analysis, and the phylogenetic analysis was based on sequence data from a single mitochondrial gene. Therefore, all species arrived at by this approach should be considered putative unless previously described and fully determined by taxonomic specialists.

Despite these limitations, the survey meets current EPA guidance and is adequate to inform the forthcoming EIA for the Mesa H proposal.

4.0 Desktop Review

4.1 Priority and Threatened Ecological Communities

Threatened Ecological Communities (TECs) are described by DBCA as biological assemblages occurring in a particular habitat, which are under threat of modification or destruction from various processes (DEC 2013). Priority Ecological Communities (PECs) are biological (flora or fauna) communities that are recognised to be of significance, but do not meet the criteria for a TEC.

A total of seven PECs occur within 50 km of the Mesa H development envelope, of which three are relevant to subterranean fauna; all of which overlap the development envelope (Figure 2.1, Table 4.1). No TECs are known within 50 km of the development envelope.

Table 4.1: Priority Ecological Communities within 50 km of the development envelope relevant to subterranean fauna.

Community	Priority
Subterranean invertebrate community of pisolitic hills in the Pilbara A series of isolated low undulating hills occur in the state's Pilbara region. The troglofauna are being identified as having very short range distributions. Threats include mining" (Department of Parks and Wildlife 2016).	Priority 1
Subterranean invertebrate communities of mesas in the Robe Valley region "A series of isolated mesas occur in the Robe Valley in the state's Pilbara Region. The mesas are remnants of old valley infill deposits of the paleo Robe River. The troglobitic faunal communities occur in an extremely specialised habitat and appear to require the particular structure and hydrogeology associated with mesas to provide a suitable humid habitat. Short range endemism is common in the fauna. The habitat is the humidified pisolitic strata. Threats include mining" (Department of Parks and Wildlife 2016).	Priority 1
Stygofaunal Community of the Bungaroo Aquifer "A unique assemblage of aquatic subterranean fauna including eels, snails and other stygofauna. Threats include groundwater drawdown and mining" (Department of Parks and Wildlife 2016).	Priority 1

All three PECs are classified as Priority One, "Poorly-known ecological communities", defined as: "*Ecological communities that are known from very few occurrences with a very restricted distribution (generally ≤5 occurrences or a total area of ≤ 100ha). Occurrences are believed to be under threat either due to limited extent, or being on lands under immediate threat (e.g. within agricultural or pastoral lands, urban areas, active mineral leases) or for which current threats exist. May include communities with occurrences on protected lands. Communities may be included if they are comparatively well-known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under immediate threat from known threatening processes across their range"* (DEC 2013).

4.2 Surface Geology

Mesa H is one of several channel iron deposits (CID), which form the Robe Pisolite Formation, a series of paleodrainage channels that meanders through the Robe River valley. CIDs are often preserved in an inverted topography as remnant mesas in the centre of the palaeochannels (Ramanaidou et al. 2003).

The Mesa H development envelope comprises 13 surface geological units (Table 4.2). By area, the majority of the development envelope is accounted for by just two surface geological units: colluvium, covering 34%, and Robe Pisolite Formation, covering 32%. Both of these geological units have been shown to represent suitable habitat for subterranean fauna in the Robe valley and the wider Pilbara region, with Robe Pisolite in particular recognised as core habitat for troglofauna. A more detailed review of the subterranean fauna habitats is presented in Biota (2018).

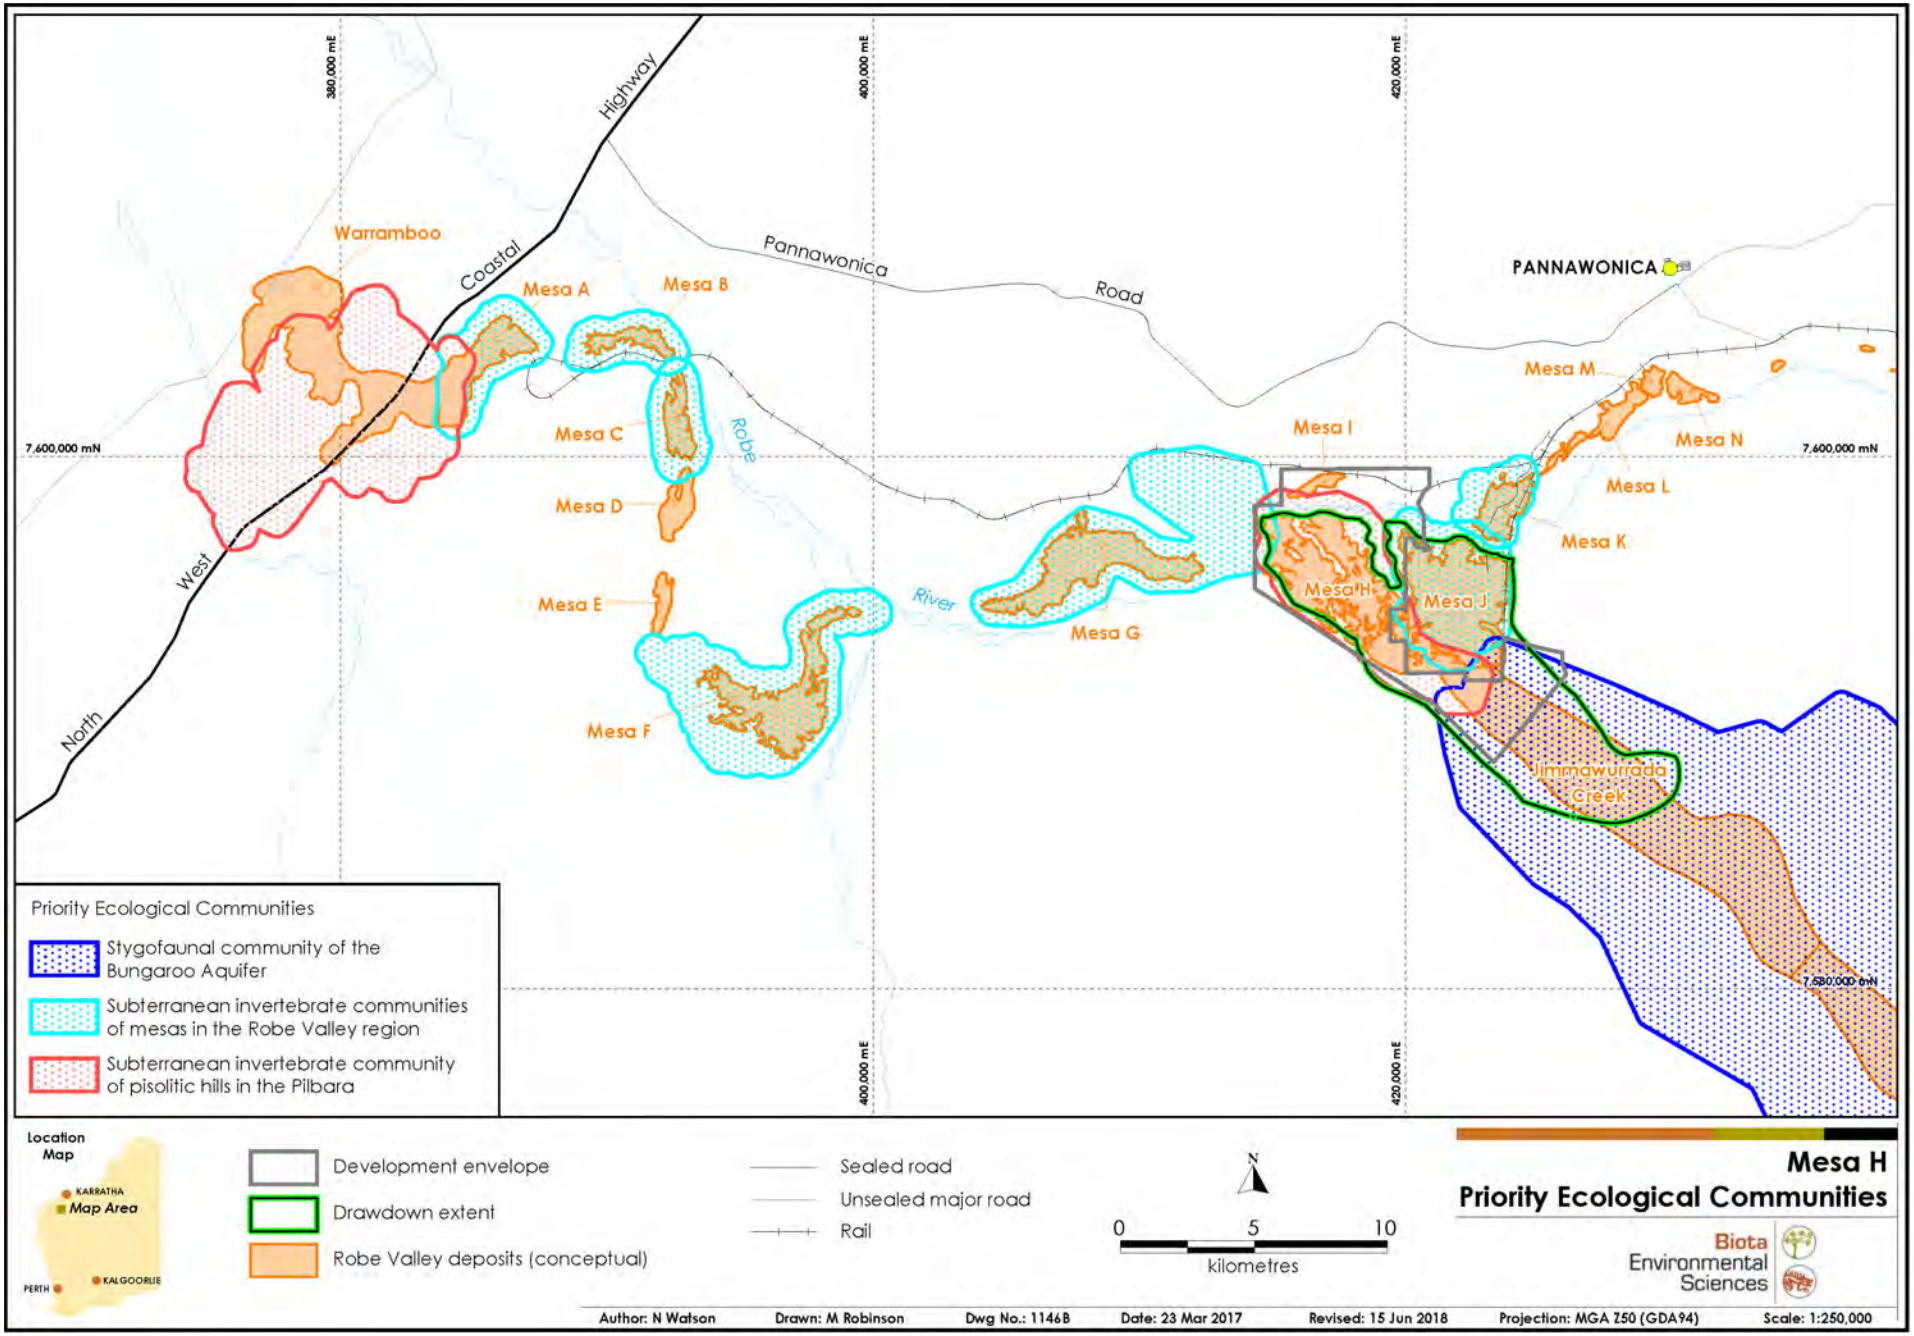

Figure 4.1: PECs relevant to subterranean fauna within 50 km of the Mesa H development envelope.

Table 4.2: Surface geology units of the development envelope and representative sampling effort (units previously identified as subterranean fauna habitat highlighted in yellow).

Eon	Era	Unit code	Description	Surface area (ha)	Proportion of development envelope (%)	Number of stygofauna sites	Number of troglofauna sites
Precambrian	Archaean	Hm	Marra Mamba Iron Formation: Chert, ferruginous chert and banded iron with minor shale; jaspilite with pronounced 'pinch and swell' structures, small occurrences of manganese.	302.1	7.1	-	-
	Proterozoic	Hb	Brockman Iron Formation: Banded jaspilite and chert with some shale dolomitic with riebeckite and crocidolite at Wittenoom Gorge and Dales Gorge. Contains stromatolites.	85.2	2.0	-	-
		Hd	Wittenoom Dolomite Formation: Thin to medium-bedded grey crystalline dolomite, intercalations of chert, dolomitic shale, and metatuff in upper part.	39.4	0.9	-	1
		Hr	Mt Mcrae Shale Formation: Shale, siltstone and dolomitic shale some and some chert.	44.4	1.0	-	-
		Hw	Woongarra Volcanics Formation: rhyolitic and dacitic volcanics, commonly porphyritic, some tuff. Some phases are intrusive.	21.1	0.5	-	-
	-	Wa	Ashburton Formation: wacke, mudstone, ferruginous mudstone interbedded with sandstone and dolomite intruded by doleritic sills.	98.1	2.4	1	6
Phanerozoic	Mesozoic	Kny	Yarraloola Conglomerate: Poorly sorted conglomerate with shale, claystone lenses and interbedded sandstone.	4.1	0.1	-	-
	Cenozoic	Czc	Colluvium: Partly consolidated valley-fill deposits.	51.6	1.2	1	6
		Czd	Duricrust: Indurated crust on older rocks; relict texture and structure preserved in some places	10.1	0.2	-	-
		Qg	Colluvium: Unconsolidated to loosely consolidated slope deposits.	1,471.6	34.5	20	55
		Ql	Lacustrine deposits: Clay, silt; saline in part, flood deposits. Unconsolidated fluviatile and sheet - flood deposits in levees and river terraces.	351.8	8.3	4	2
		Qr	Alluvium: Unconsolidated fluviatile deposits, mostly sand.	382.0	8.9	2	-
		Tp	Robe Pisolite Formation: Pisolitic limonite deposits. Occurs along old river channels.	1,403.3	32.9	13	66
			Total	4,264.8	100	41	136

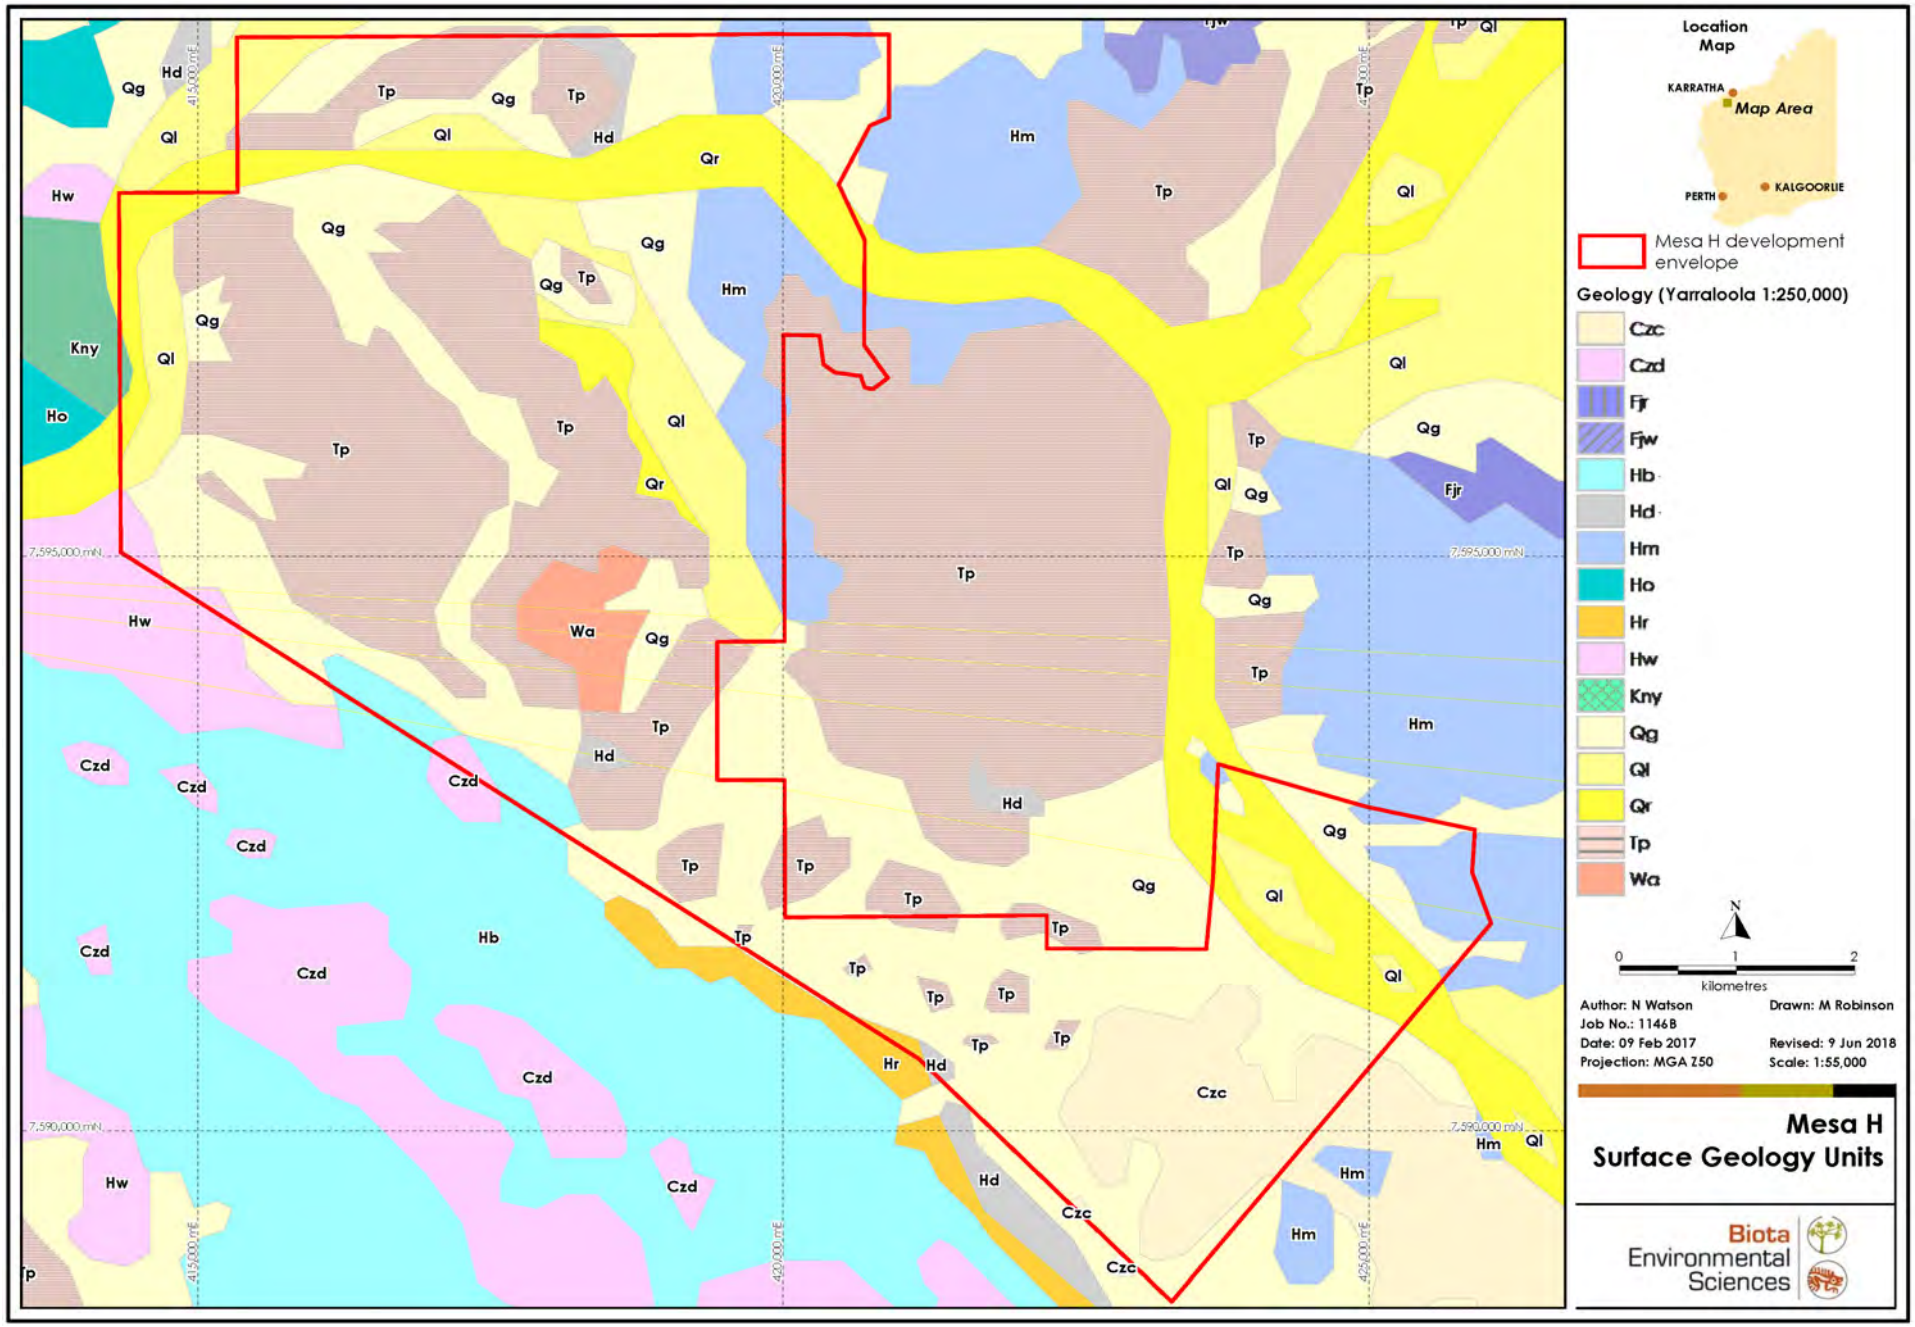

Figure 4.2: Surface geology mapping of the Mesa H development envelope.

4.3 Previous Relevant Surveys

Extensive sampling for troglofauna and stygofauna has been undertaken in areas of proposed development throughout the Robe River valley. Multiple-phase sampling programmes have been undertaken on tenements neighbouring Mesa H, including at Bungaroo (Biota 2010b), Mesa K (Biota 2007) and on Australian Premium Iron's West Pilbara Iron Ore Project (Biota 2010c, 2010d).

Due to the highly localised distributions of subterranean fauna and often mesa-specific species distributions, searches for past survey records were limited to within a desktop review area of a 15 km square around a central point in the development envelope (see Figure 2.1).

A total of seven troglobitic and eight stygobitic fauna surveys have been conducted within the search area (Table 4.3; Figure 4.3; Figure 4.4). The fauna recorded from these surveys within the desktop review area were reviewed and collated and are presented in Section 4.4.

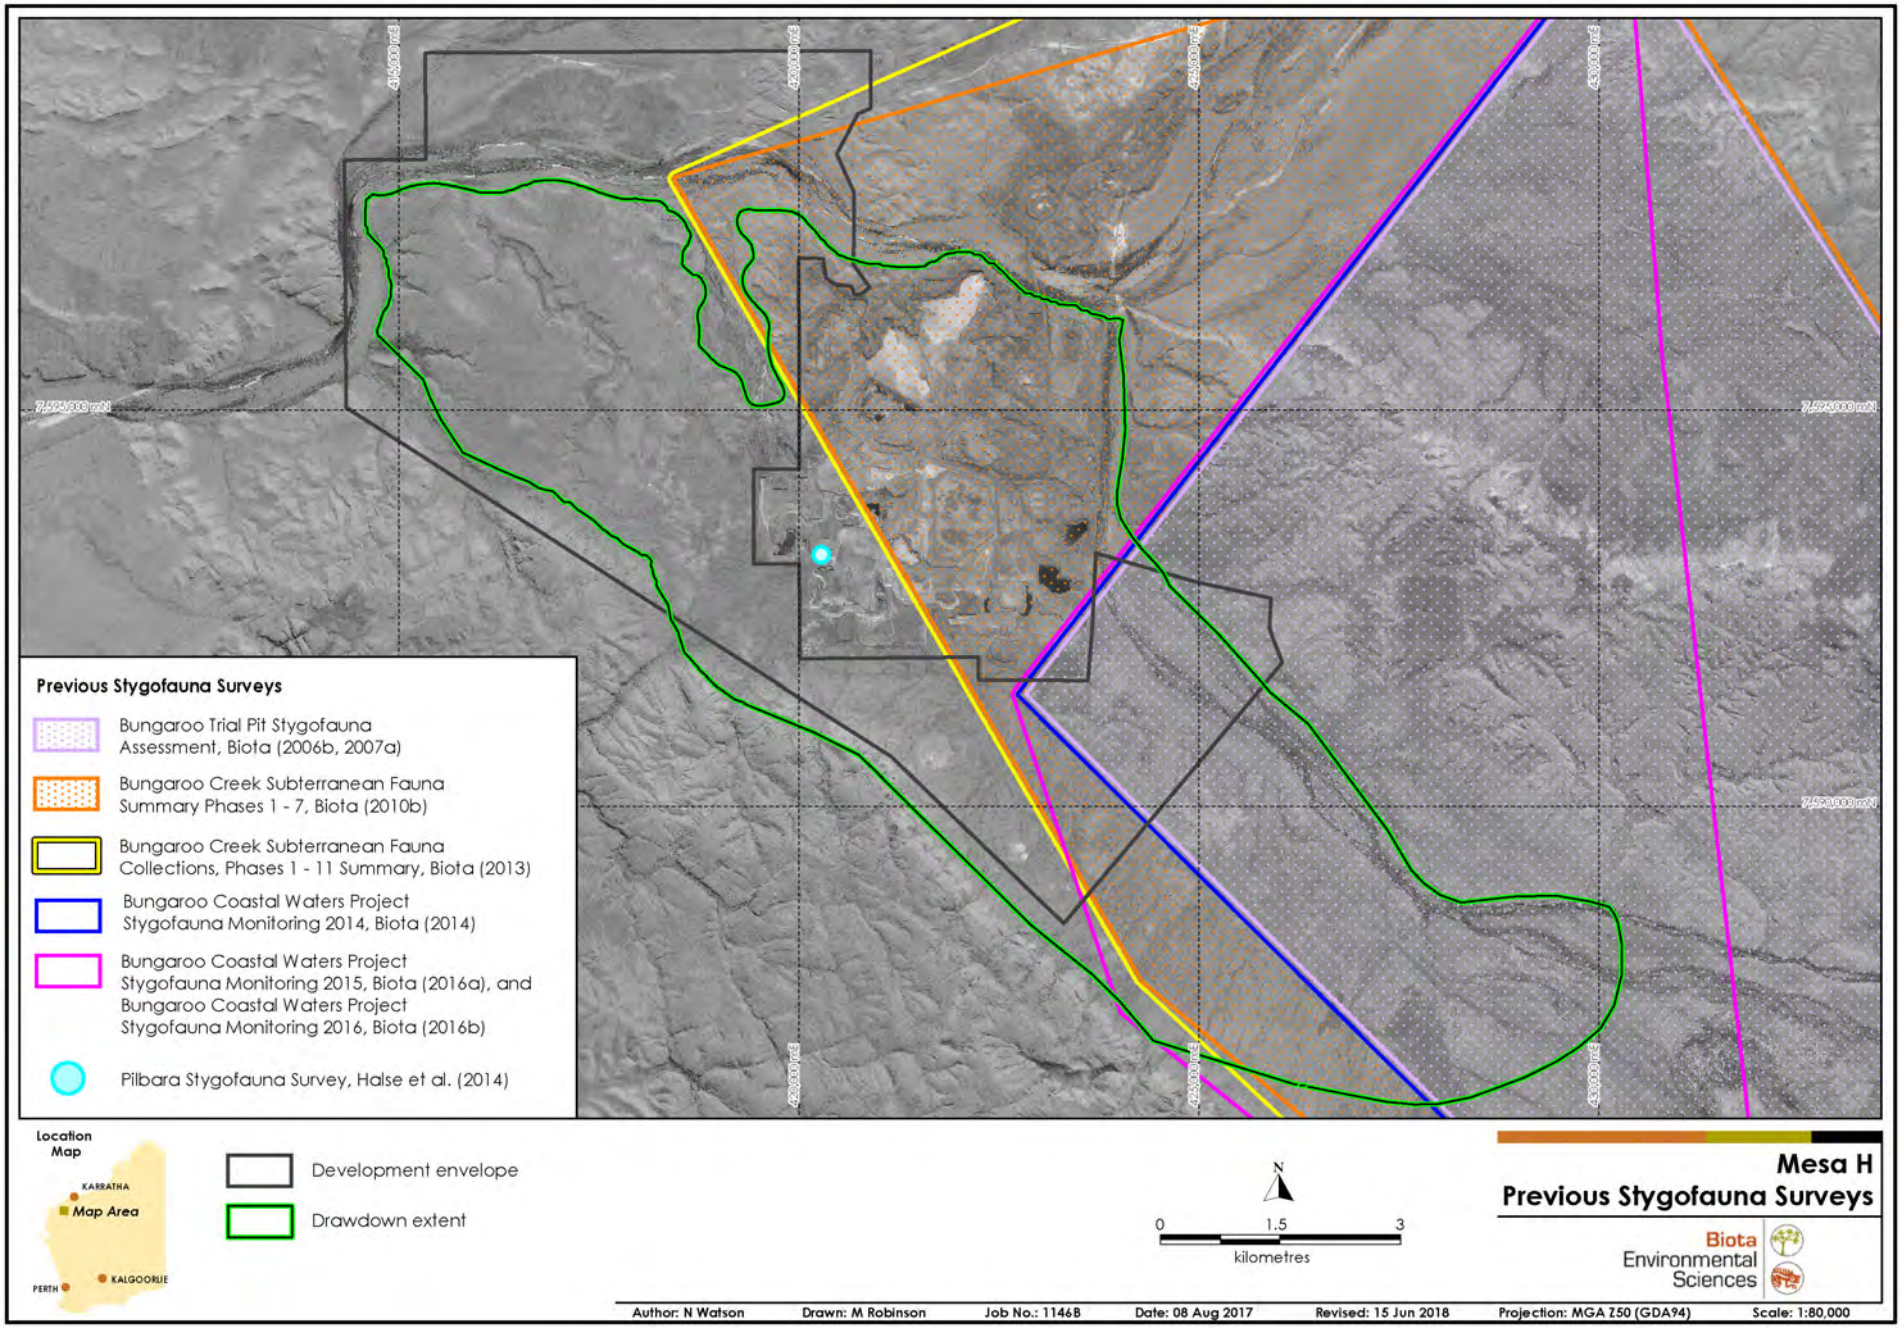

Figure 4.4: Previous stygofauna surveys within 15 km of the Mesa H development envelope.

4.4 Desktop Review Results

4.4.1 Stygofauna

A total of 15 orders were represented amongst the past stygofauna specimens recorded from within the desktop review area, the majority of which were recorded during stygofauna surveys at Bungaroo (Table 4.4; Figure 4.5).

Excluding indeterminate specimens, a total of 22 species-level taxa have been recorded during previous surveys occur within the Mesa H drawdown extent. This included three stygofauna species of conservation significance:

- Blind Cave Eel, *Ophisternon candidum* – Vulnerable; Schedule 3 (see Section 4.4.1.1);
- the amphipod species *Nedsia hurlberti* – Schedule 3; and
- the amphipod species *Nedsia sculptilis* – Schedule 3 (Table 4.4; Figure 4.5).

Five of the remaining 19 taxa are considered to represent potential SRE species (Neoniphargidae sp. 'B02', *Parastenocaris* sp. 'B28', *Haptolana* sp. 'B01', Candoninae sp. 'BOS541' and Hydrobiidae sp. 2; Table 4.4). These taxa have been included in the assessment of taxa recorded from within the drawdown extent in Table 6.1 (see Section 6.2).

4.4.1.1 Blind Cave Eel

The Blind Cave Eel (*Ophisternon candidum*) is a de-pigmented, subterranean fish growing up to 40 cm in length, with a long slender body, no eyes, and a thin rayless membrane around the tip of the tail (DSEWPaC 2008). The Blind Cave Eel is the world's longest cave fish and one of only three vertebrate animals known from Australia that are restricted to subterranean waters (Humphreys 2001b). The species is specially protected under legislation at both State (Schedule 3) and Commonwealth (Vulnerable) levels.

The Blind Cave Eel inhabits groundwater systems in subterranean caves, transmissive geological formations, fissures and wells (Humphreys 2001b). On Cape Range, the Blind Cave Eel is known to utilise cave floor pool sediments characteristic of crustacean-rich cave habitats. It also occurs within the karst aquifers of Barrow Island, though it remains to be confirmed if this record represents the same species as present on Cape Range (Humphreys et al. 2013).

The Blind Cave Eel has also been previously collected from three sites in the Jimawurrada-Bungaroo Creek system, within the current study area. The first specimen was recorded in 2009 at Bungaroo Creek from borehole BC186, 5.6 km southeast of the development envelope and just outside of the current desktop review boundary (Figure 2.1) (Biota 2010e), with subsequent records coming from JW023 (1 km southeast of the development envelope) (Biota 2016b) and the immediately adjacent JW024 in 2017 (C. O'Neill, Rio Tinto, pers. comm. 2017). Tissue from the Bungaroo specimens has been sequenced at both the CO1 mitochondrial DNA and 16S ribosomal RNA markers, showing that the Bungaroo records are less than 1% divergent from the Cape Range specimens, indicating that they are the same species (Foster and Humphreys 2011).

The species is considered likely to be associated with the regional aquifer of the Robe River (Biota and Helix 2014) and it is probable that it occurs within at least the southeast portion of the development envelope in association with the alluvial aquifer of Jimawurrada Creek. Environmental DNA sampling was undertaken as part of the current study in an attempt to better understand the distribution of the species in the locality (Section 3.4).

4.4.2 Troglofauna

Eleven orders were represented amongst the troglofauna taxa previously been recorded within the desktop review area (Table 4.4; Figure 4.6; Figure 4.7; Figure 4.8). One species is of conservation significance; the schizomid species *Paradraculoides kryptus* (Schedule 3). This species is restricted to Mesa K and is very unlikely to occur at Mesa H.

Excluding indeterminate records, four taxa have been recorded from sites within the Mesa H development envelope and two of these are true troglobites considered to represent potential SRE fauna: the isopod species *Troglarmadillo* sp. 1 and the schizomid species *Paradraculoides* sp. nov. 'Mesa H' (Table 4.4; Figure 4.6).

Table 4.4: Stygofauna taxa and abundance (n) recorded from the desktop review (records highlighted in bold were recorded within the drawdown extent).

5.0 Survey Results

5.1 Stygofauna

A total of 855 stygofauna specimens were recorded over five phases of sampling, comprising at least 43 species-level taxa (excluding indeterminate specimens that could not be resolved to species level). The fauna was dominated by the Crustacea, which was represented by seven orders, with the Maxillopoda (copepods) and Amphipoda (amphipods) accounting for the most specimens (48% and 37% of total specimens respectively; Table 5.1). The least commonly recorded groups were the oligochaete and nematode worms (n=1 and 2 respectively), isopods (n=4), water mites (order Tombidiformes; n=4) and snails (order Hypsogastropoda; n=2) (Table 5.1).

Table 5.1: Summary of stygofauna recorded during the current survey (n= number of specimens).

Taxonomy				n	Number of Sites
Phylum	Subphylum	Class	Order		
Annelida	-	Oligochaeta	Tubificida	1	1
Platyhelminthes	-	-	-	9	2
Nematoda	-	-	-	2	2
Mollusca	-	Gastropoda	Hypsogastropoda	2	1
Arthropoda	Chelicerata	Arachnida	Trombidiformes	4	3
	Crustacea	Ostracoda	Podocopida	83	9
		Maxillopoda	Calanoida	236	20
			Cyclopoida	138	17
			Harpacticoida	36	3
		Malacostraca	Thermosbaenacea	20	3
			Isopoda	4	2
			Amphipoda	320	24
			Total	855	

A detailed account of the fauna recorded, including the results of genetic analysis, follows in Sections 5.1.10 to 5.1.3. Record locations for the lower abundance groups are shown in Figure 5.1, with the numerically dominant Maxillopoda in Figure 5.2 and Amphipoda in Figure 5.3.

5.1.1 Class Oligochaeta (Earthworms)

A single oligochaete was recorded from site BC186, on the margin of the drawdown extent (Figure 5.1). The specimen was identified as *Enchytraeus* sp. 'AP PSS1', which has previously been recorded during the Pilbara Biodiversity Survey from approximately 39 km to the west (Halse et al. 2014).

5.1.2 Phylum Platyhelminthes (Flatworms)

A total of nine platyhelminth specimens were recorded from sites 31 and 32, both of which were outside of the drawdown extent (Figure 5.1). These specimens are unable to be identified below phylum level due to a lack of taxonomic framework for this group.

5.1.3 Phylum Nematoda (Nematode Worms)

Two nematode specimens were recorded from two sites within the drawdown extent during the survey (DD13MEH0007 and RC12JIM0019; Figure 5.1). These specimens are unable to be identified below phylum level due to a lack of taxonomic framework for this group.

5.1.4 Class Gastropoda (Aquatic Snails)

Eight specimens of hydrobiid snails were recorded from site MB17MEH0007 to the north of the drawdown extent during the Phase 5 sampling (Figure 5.1). The specimens were identified to morphotype level as Hydrobiidae sp. 'B09', which appears to be distinct from other hydrobiid snail forms collected previously from the adjacent Bungaroo valley (Biota 2015a).

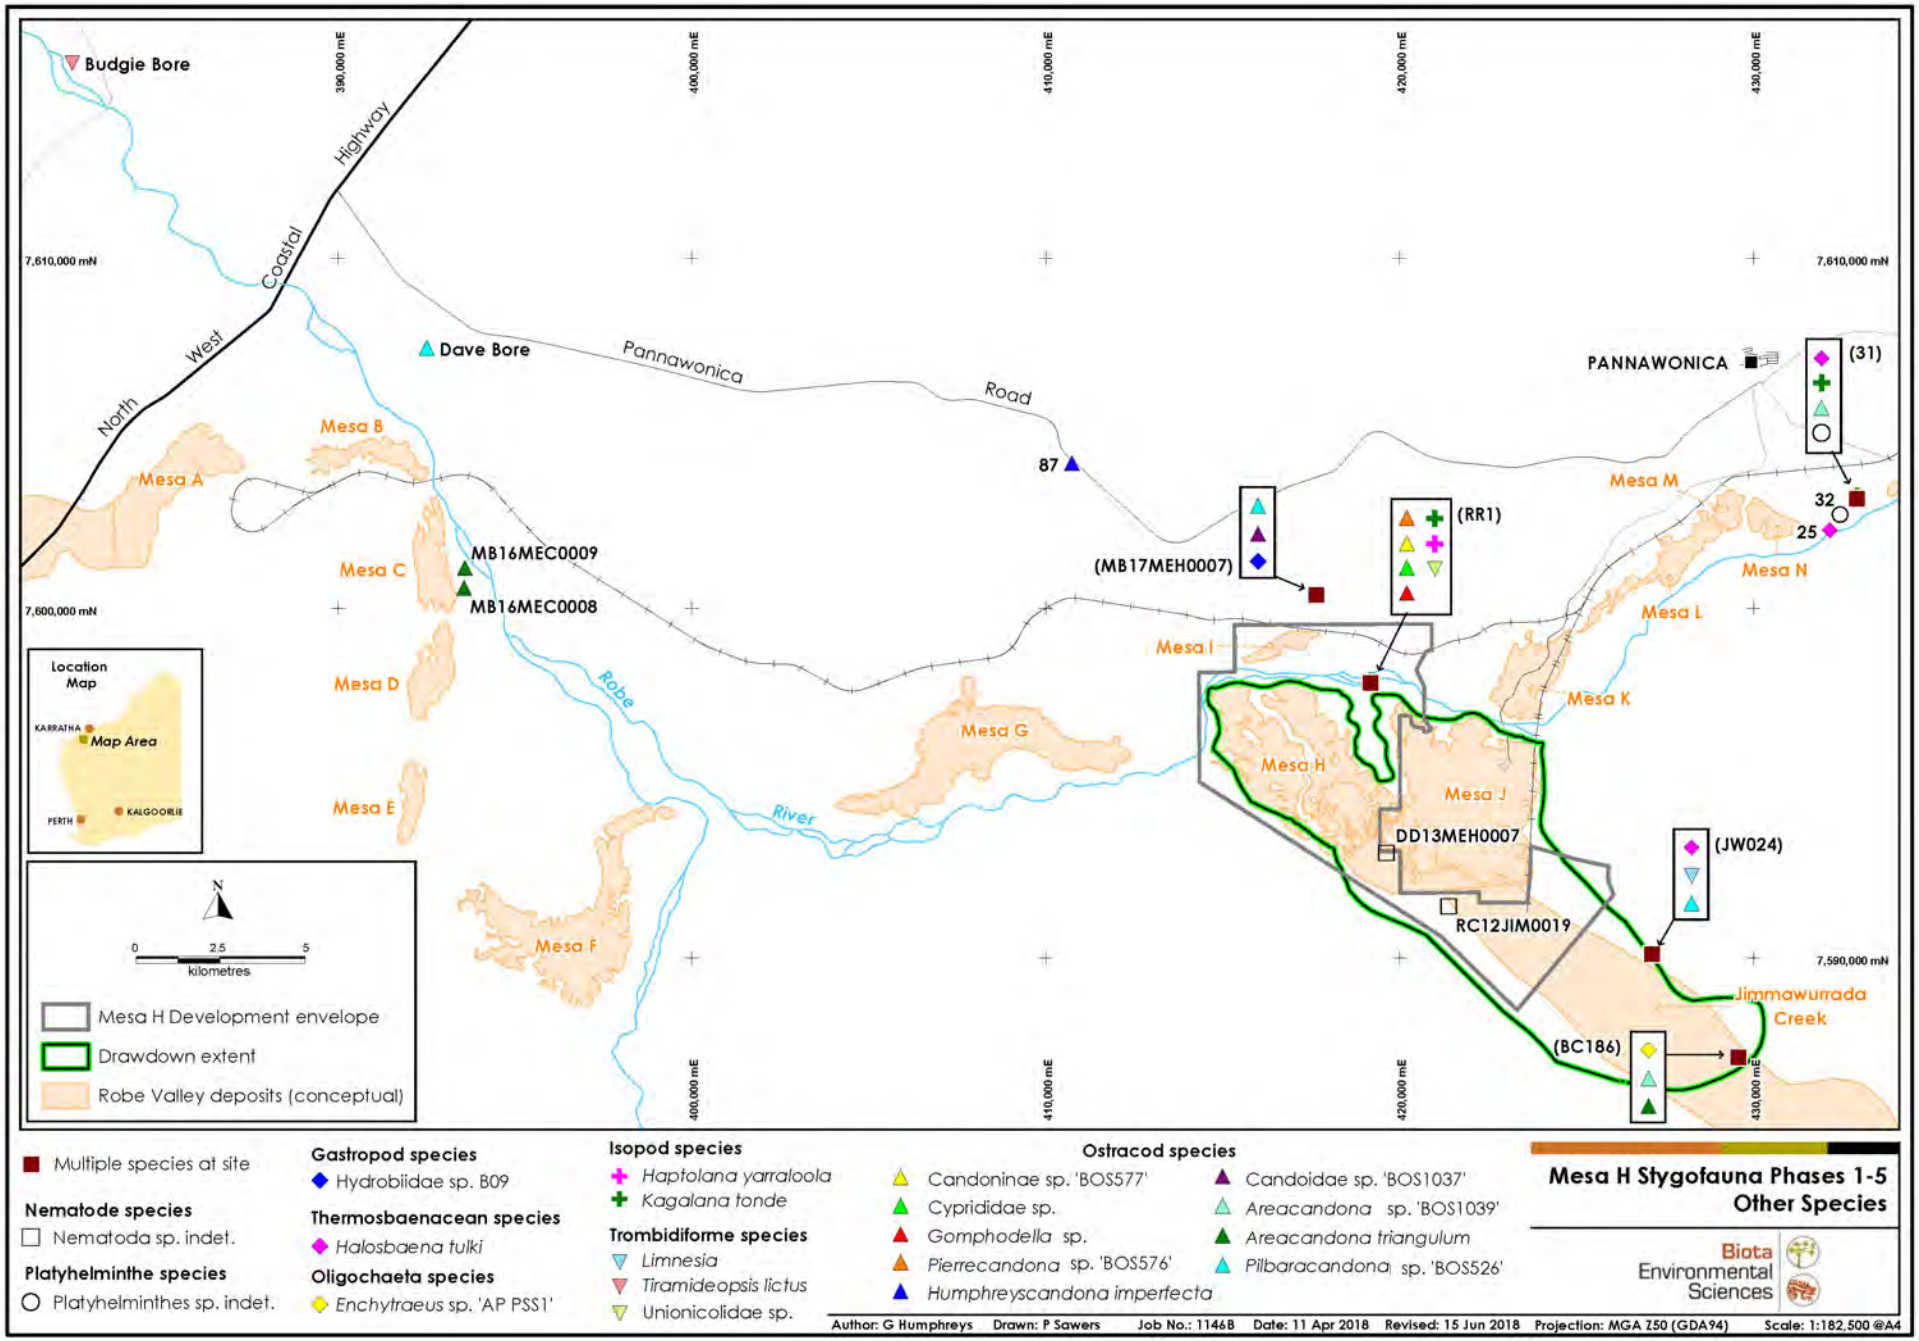

Figure 5.1: Lower abundance stygofauna taxa recorded from Mesa H during the current survey.

5.1.5 Order Trombidiformes (Water Mites)

Three water mite taxa were recorded during the survey, all during the Phase 5 sampling (Appendix 5; Table 5.2). Two of the taxa, Unionicolidae sp. indet and *Tiramideopsis lictus*, were recorded from sites outside of the drawdown extent (Figure 5.1).

Table 5.2: Summary of water mite taxa recorded from the current survey (*denotes sites outside of the drawdown extent).

Family	Species	Site	Number
Limnesiidae	*Limnesia* sp. indet.	JW024	1
Mideopsidae	*Tiramideopsis lictus*	Budgie Bore*	2
Unionicolidae	Unionicolidae sp. indet.	RR1*	1
		Total	4

5.1.6 Order Ostracoda (Ostracods)

Eighty-three ostracod specimens were recorded during the Mesa H survey (Table 5.3; Figure 5.1), with one specimen from site RR1 unable to be resolved below family level (Cyprididae sp.). Two taxa represented were previously known species (*Humphreyscandona imperfecta* and *Areacandona triangulum*) were recorded (Table 5.3), which are both originally described from elsewhere in the Pilbara (Karanovic 2005).

Gomphodella sp. from site RR1 was the sole representative of the Limnocytheridae (Table 5.3), and all of the five remaining ostracod taxa belong to the family Candonidae and are currently undescribed. Two of these, *Pilbaracandona* sp. 'BOS526' and *Pierrecandona* sp. 'BOS576', have been recorded previously from Warramboo (Biota 2017) and Bungaroo (Biota 2016b), respectively. None of the ostracod taxa are known only from the drawdown extent (Table 5.3).

Table 5.3: Summary of ostracod taxa recorded from the current survey (*denotes sites outside of the drawdown extent).

Family	Species	Site	Number
Cyprididae	Cyprididae sp.	RR1*	1
Limnocytheridae	*Gomphodella* sp.	RR1*	3
Candonidae	Candoninae sp. 'BOS577'	RR1*	3
	Humphreyscandona imperfecta	87*	3
	Pierrecandona sp. 'BOS576'	RR1*	2
	Pilbaracandona sp. 'BOS526'	Dave Bore*, MB17MEH0007*, JW024	10
	Areacandona sp. 'BOS1039'	BC186, 31*	9
	Areacandona triangulum	MB16MEC0008*, MB16MEC0009*, BC186	27
	Candonidae sp. 'BOS1037'	MB17MEH0007*	25
		Total	83

5.1.7 Subclass Copepoda (Copepods)

Nine species of copepod were identified from amongst the 410 specimens collected during the survey, representing four families (Figure 5.2; Table 5.4). Seventeen juvenile specimens could only be morphologically determined to genus level (*Diacyclops* sp.; Table 5.4). All of the described species recorded are widespread and previously known from outside the survey area (Biota 2016b).

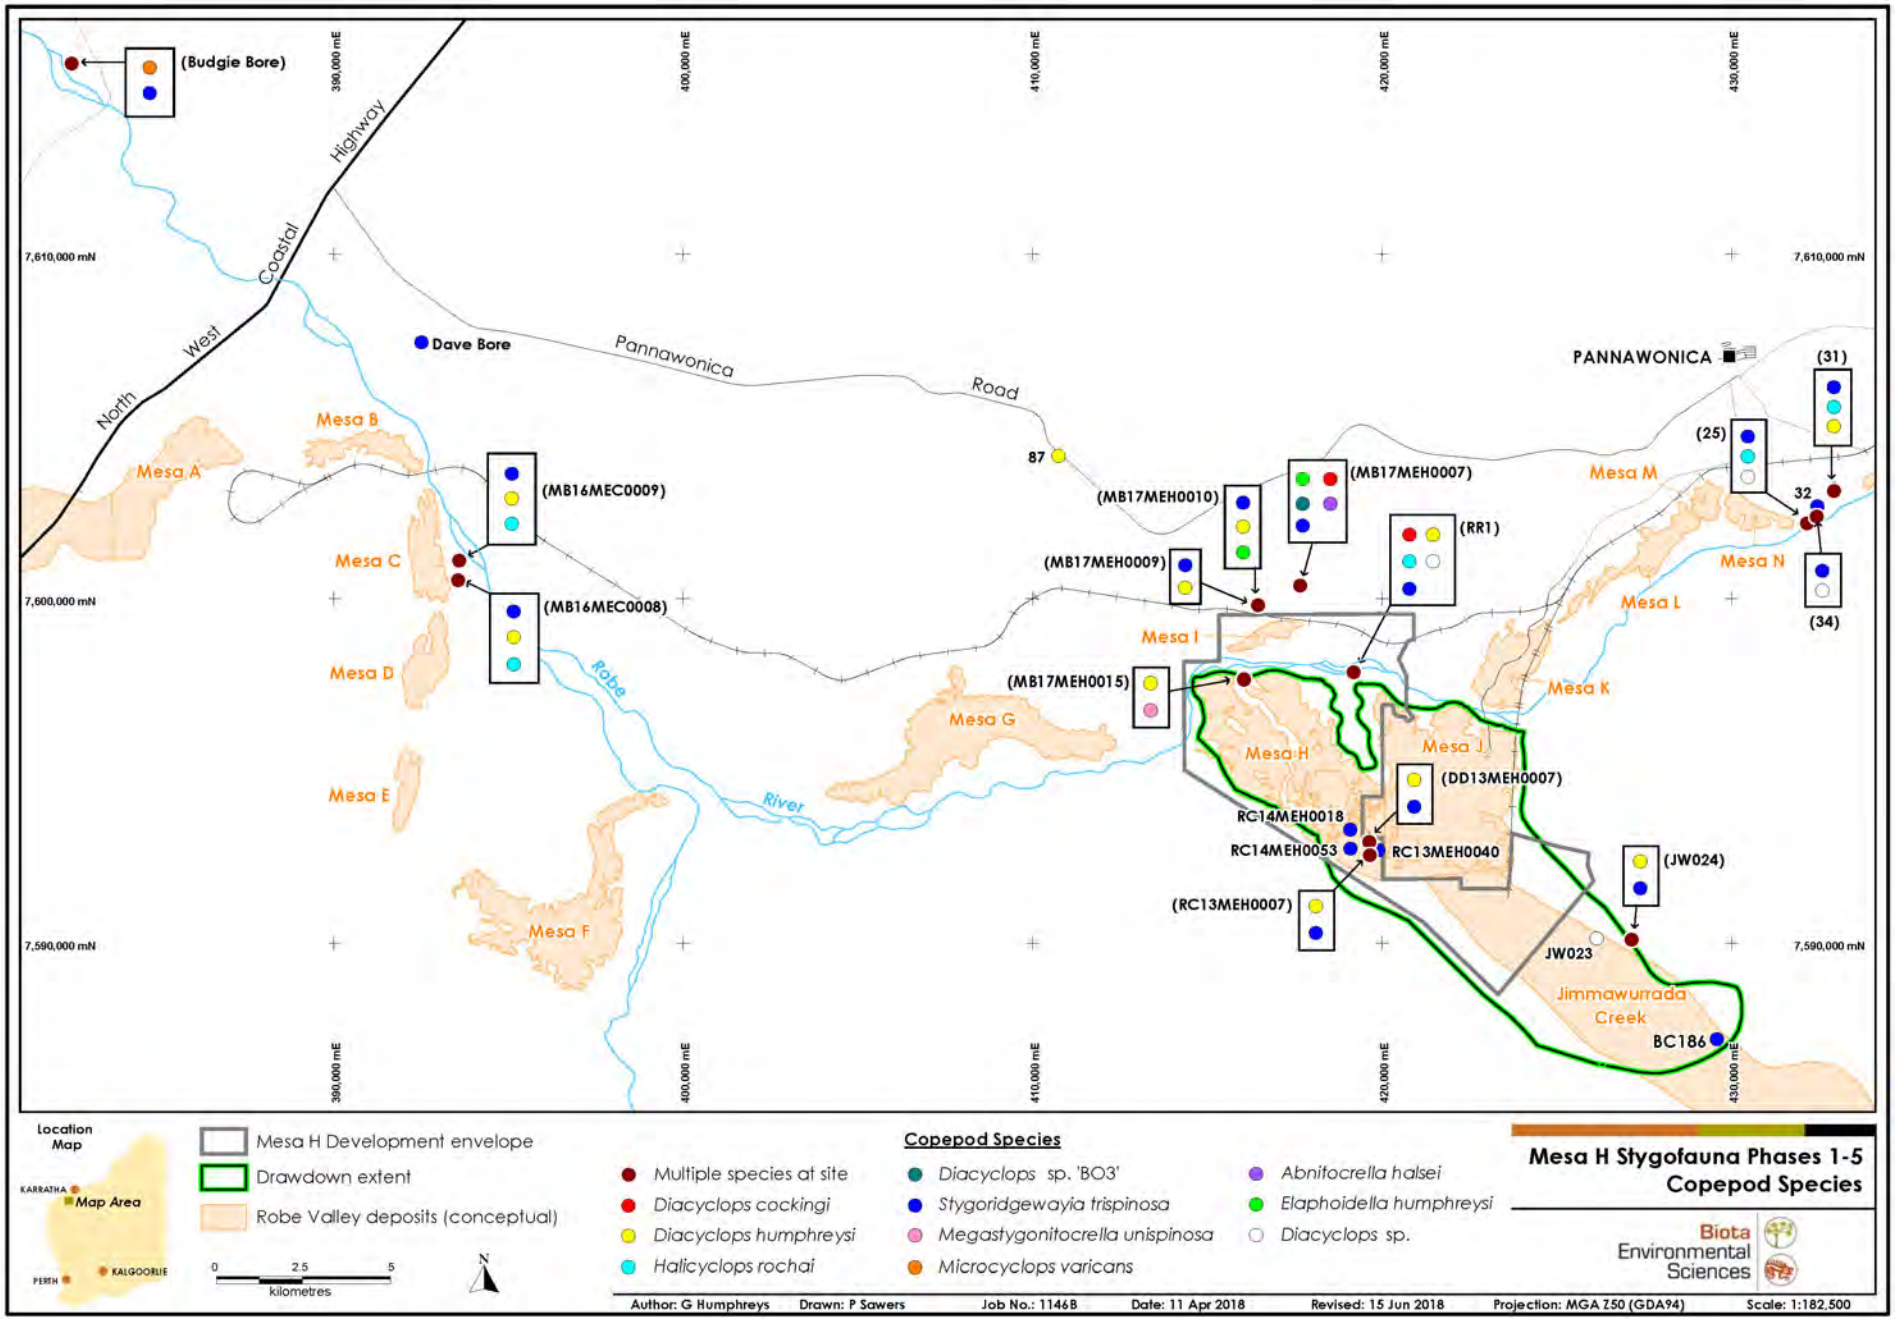

Figure 5.2: Copepod taxa recorded from Mesa H during the current survey.

Table 5.4: Summary of copepod taxa recorded from the current survey (*denotes sites outside of the drawdown extent).

Family	Species	Site	Number
Ridgewayiidae	*Stygoridgewayia trispinosa*	25*, 31*, 32*, 34*, Dave Bore*, Budgie Bore*, RR1*, MB16MEC0008*, MB16MEC0009*, MB17MEH0007*, MB17MEH0009*, MB17MEH0010*, BC186, DD13MEH0007, JW024, RC13MEH0007, RC13MEH0040, RC14MEH0018, RC14MMEH0053	236
Cyclopidae	*Diacyclops cockingi*	RR1*, MB17MEH0007*	24
	Diacyclops humphreysi humphreysi	31*, 87*, JW024*, RR1*, MB16MEC0008*, MB16MEC0009*, MB17MEH0007*, MB17MEH0009*, MB17MEH0010*, DD13MEH0007, RC13MEH0007, MB17MEH0015	68
	Diacyclops sp. 'BO3'	MB17MEH0007*	1
	Halicyclops rochai	25*, 31*, RR1*, MB16MEC0008*, MB16MEC0009*, Budgie Bore*	20
	Microcyclops varicans	Budgie Bore*	8

	Megastygonitocrella unispinosa	MB17MEH0015	2
Canthocamptidae	*Elaphoidella humphreysi*	MB17MEH0007*	33
		Total	410

5.1.8 Order Thermosbaenacea (Thermosbaenaceans)

Twenty specimens of *Halosbeana tulki* were recorded from three sites; JW024, 25 and 31, the latter two of which are outside of the drawdown extent (Table 5.5; Figure 5.1). *H. tulki* is widespread and has been collected commonly from the Bungaroo Valley (Biota 2016b) as well as from locations around Cape Range, Barrow Island and Warramboo (Humphreys 1989, Humphreys et al. 2013, Biota 2017). Recent molecular work has indicated that this taxon may actually represent a species complex containing at least five separate species that reflect local geography (Page et al. 2016). Records of *H. tulki* from the Robe River would belong to the Pilbara high elevation species.

Table 5.5: Summary of thermosbaenaceans recorded from the current survey (*denotes sites outside of the drawdown extent).

Family	Species	Site	Number
Thermosbaenacidae	*Halosbaena tulki*	25*, 31*, JW024	20

5.1.9 Order Isopoda (Isopods)

Four stygal isopods belonging to two described species were recorded from site 31 and RR1, both of which are outside the drawdown extent (Table 5.6; Figure 5.1). *Haptolana yarraloola* was originally described from records from Yarraloola station (Bruce 2008) and has also been recorded from the Warramboo area (Biota 2017). *Kagalana tonde* is widespread in the west Pilbara (Biota 2010c) and has been recorded adjacent to the Mesa H survey area from Bungaroo (Biota 2016b).

Table 5.6: Summary of stygal isopod taxa recorded from the current survey (*denotes sites outside of the drawdown extent).

Family	Species	Site	Number
Cirolanidae	*Haptolana yarraloola*	RR1*	1
	Kagalana tonde	RR1*, 31*	3
		Total	4

5.1.10 Order Amphipoda (Amphipods)

A total of 320 amphipod specimens were recorded, comprising 19 taxa from three families (Table 5.7; Figure 5.3). Eighty-four specimens that were unable to be identified to species level remained as Amphipoda sp. indet (Table 5.7). These specimens were unable to be determined due to either a failure to sequence or where large numbers of specimens of the same morphotype were recorded from the same site (only a subsample of the specimens from such sites were sequenced; Section 3.7).

A total of 148 specimens recorded across 16 sites were assigned to lineage AMM001 (Table 5.7). This lineage was placed into a well-supported group which has been assigned the putative species name of *Nedsia* sp. 'AMM001' (family Eriopisidae), which is part of a species complex containing multiple other closely-related (<5% mean sequence divergence) lineages from the locality (Helix 2017a). This species complex has been recorded at multiple locations throughout the Robe River valley including from Warramboo, Budgie Bore and Camp Bore (Biota 2017, Helix 2017a) (Appendix 3).

An additional taxon belonging to family Eriopisidae, *Nedsia* sp. 'AMM031' was also recorded from a single site outside of the drawdown extent (Dave Bore; Table 5.7; Figure 5.3). This lineage was originally included within the *Nedsia* sp. 'AMM001' species complex but discussion with genetic and taxonomic specialists at Helix, WAM and the South Australian Museum have conservatively determined that *Nedsia* sp. 'AMM031' is likely to be a distinct species, though additional specimens and further analysis would be needed to more fully confirm this. This species has also been recorded from Dave Bore, Budgie Bore and Mesa A (Biota 2017, Helix 2017a) (Table 5.7).

Six other taxa from the family Eriopisidae, *Nedsia* sp. 'AMM004', sp. 'AMM06', sp. 'AMM022', sp. 'AMM031', sp. 'AMM032' and sp. 'AMM033', were also recorded during the survey, but none of these were detected within the drawdown extent (Table 5.7; Figure 5.3). Three of these taxa, *Nedsia* sp. 'AMM004', sp. 'AMM032' and sp. 'AMM033', represent new species not previously recorded in the Pilbara (Helix 2017a) (Appendix 3). The final erioposid taxon, Nedsia sp. 'AMM026' was recorded from within the drawdown extent, but also occurs outside (at site 31; Table 5.7; Figure 5.3).

Five species of Neoniphargidae amphipods were recorded from the survey area (Table 5.7), consisting of one species that has been recorded elsewhere in the Robe River valley; Neoniphargidae sp. 'AMN008' (Biota 2017), and three new species that had not previously been recorded in the region: Neoniphargidae sp. 'AMN002', sp. 'AMN003' and *Wesniphargus* sp. 'AMN004' (Helix 2017a) (Appendix 3). Additional sequencing of historical survey specimens by the WAM found that records of both Neoniphargidae sp. 'AMN003' and *Wesniphargus* sp. 'AMN004', had previously gone unrecognised as such from sampling at Bungaroo (Cullen and Harvey 2017). *Wesniphargus* sp. 'AMN004' was the only neoniphargid taxa to be recorded from the drawdown extent, but was also recorded from reference site 25 (Table 5.7), in addition to the earlier Bungaroo record. The fifth species, Neoniphargidae sp. 'B02', was recorded from site 32 on the basis of morphology. This species has also been recorded from a site within the Mesa H development envelope during a previous survey at Bungaroo (Biota 2013) (see Section 4.4.1).

The final family, Paramelitidae, was represented by six species, with three recorded from within the drawdown extent: Paramelitidae sp. 'AMP003' sp., 'AMP035' (Plate 5.1) and 'AMP037', two of which were collected as singletons (Table 5.7), and appear to represent new taxa not previously detected in the region (Helix 2017a) (Appendix 3).

Plate 5.1: Paramelitidae sp. 'AMP035' from drillhole RC13MEH0007.

Table 5.7: Summary of amphipod taxa recorded from the current survey (*denotes sites outside of the drawdown extent).

Family	Lineage	Species	Site	Number

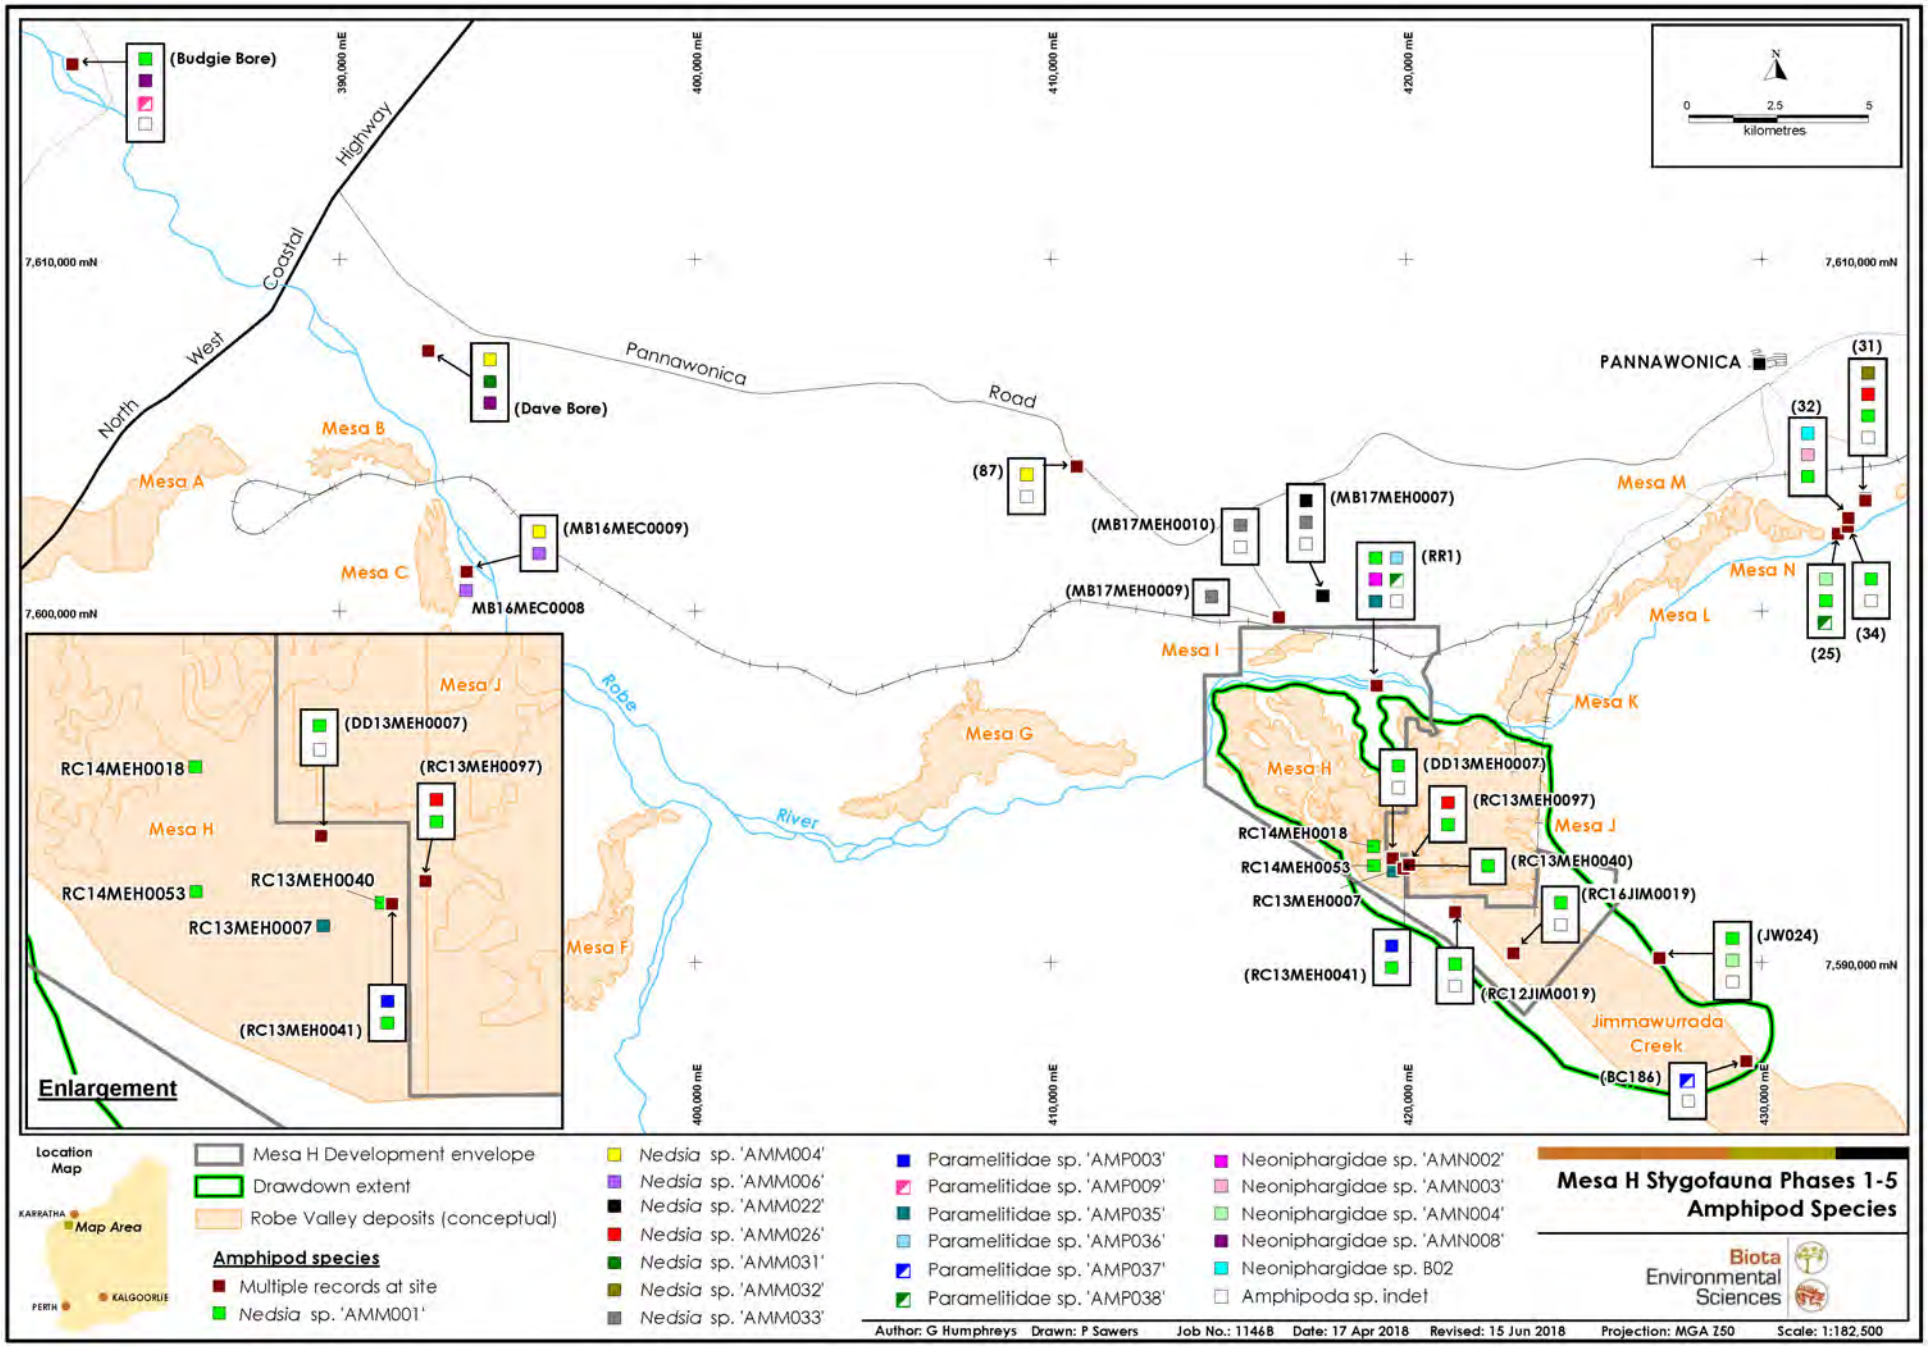

Figure 5.3: Amphipoda taxa recorded from Mesa H during the current survey.

5.2 eDNA

Replicated samples from the 16 sites where groundwater was sampled for eDNA were analysed by two different molecular methods in an attempt to detect residual DNA from the Blind Cave Eel (*Ophisternon candidum*) (Section 3.4).

Six of the 16 eDNA sampling sites yielded positive results for *Ophisternon* DNA by at least one method (Figure 5.4; Table 5.8), with the results from sites 25, MB17MEH0015 and the Control site having an even higher degree of confidence being independently detected by both laboratories (Table 5.8). An additional site, JW021, which was previously sampled for groundwater as part of previous work (Figure 5.4; Table 5.8), also yielded a positive detection during the preliminary metabarcoding analysis undertaken by Curtin University (Appendix 4).

Table 5.8: Results of eDNA analysis of environmental samples ('Y' = positive detection of *Ophisternon* DNA; *denotes sites outside of the drawdown extent; †denotes detection only after refinement of metabarcoding methods (latter section of Appendix 4)).

			Ophisternon DNA Detected?		
Site	Easting (m E)	Northing (m N)	Helix qPCR Assay	Curtin Metabarcoding	Notes
Control*	424478	7597147	Y	Y	Surface pool site

JW021	424138	7589754	Not sampled	Y	Sampled previously

The qPCR assay is a targeted molecular method that will only identify the presence of target DNA in an environmental sample when both the species-specific primer and the specific-specific probe match the DNA present in the sample (Biota and Helix 2014). This means the positive results from the qPCR assay from sites 25, MB17MEH0015 and the Control sample can all be regarded with confidence as containing *Ophisternon candidum* DNA (Table 5.8) (Helix 2018).

The metabarcoding approach uses a high throughput approach to amplify DNA and in the case of this study the 16S gene was specifically targeted during amplification to compare against reference sequence data. The findings from the preliminary Curtin University analysis were that possible *Ophisternon* DNA was detected from site 25 and RR1, as well as site JW021 (Table 5.8; Figure 5.4). The sequences from the JW021 site were a 100% match for the known *O. candidum* sequences from JW024, and those from sites 25 and RR1 were a 97% match. Subsequent additional work using an assay specifically developed for *Ophisternon* resulted in further detections at three other sites, including MB17MEH0015; where the qPCR assay had independently detected eDNA belonging to the species (Table 5.8).

In addition to the desktop review records, a specimen was recently recorded from the phreatic zone of the Robe River during aquatic fauna sampling in a surface pool in the river (Biota 2018) (site RRD2; Figure 5.4). Considered in total then, the eDNA positive sites and specimen collection locations to date comprise five sites within the drawdown extent and four sites outside (Figure 5.4).

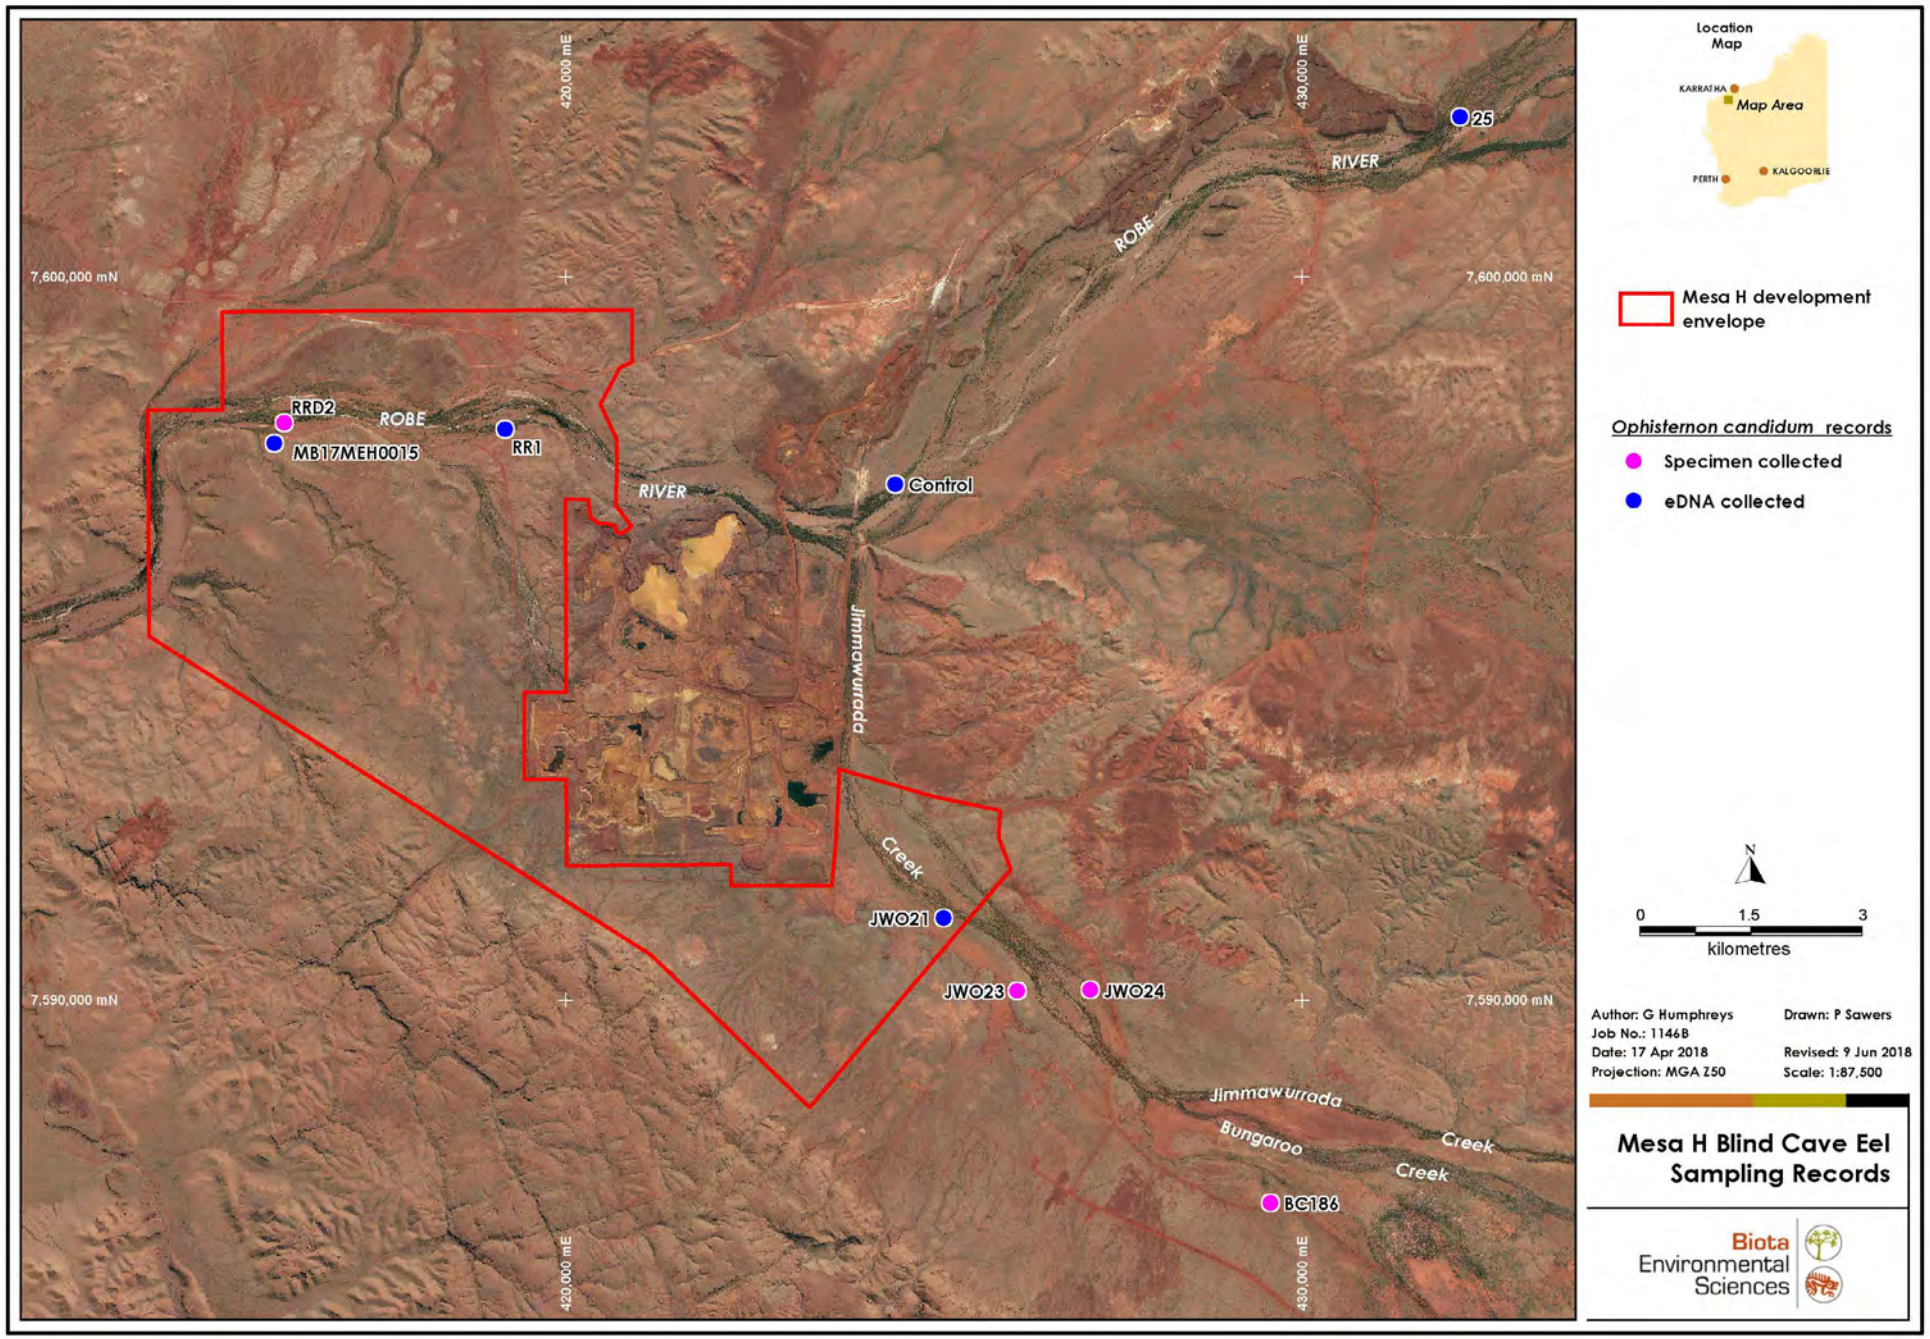

Figure 5.4: Locations where positive eDNA results were recorded for *Ophisternon* DNA detection, in context with confirmed *Ophisternon* specimen collection locations.

5.3 Troglofauna

A total of 150 troglobitic specimens were collected across the six phases of sampling of the Mesa H survey area (Table 5.9). The specimens represented five classes and nine orders and 32 taxa (Appendix 5). A total of 150 troglobitic specimens were collected across the six phases of sampling of the Mesa H survey area (Table 5.9). The specimens represented five classes and nine orders and 32 taxa (Appendix 5). The orders Coleoptera and Schizomida were the greatest contributors to faunal composition, accounting for 33% and 25% of the specimens, respectively.

Table 5.9: Summary of troglobitic fauna recorded from Mesa H during the current survey (n= number of specimens collected).

Taxonomy				n	Number of Sites
Phylum	Subphylum	Class	Order		
Arthropoda	Chelicerata	Arachnida	Araneae (Spiders)	2	2
			Pseudoscorpiones (Pseudoscorpions)	14	12
			Schizomida (Schizomids)	37	22
	Hexapoda	Entognatha	Diplura (Bristletails)	12	11
		Insecta	Blattodea (Cockroaches)	2	2
			Coleoptera (Beetles)	50	5
			Zygentoma (Silverfish)	2	2
	Crustacea	Malacostraca	Isopoda (Slaters)	30	4
	Myriapoda	Chilopoda	Scolopendromorpha (Centipedes)	1	1
			Total	150	

As is common during troglofauna surveys, a large number of edaphobitic (deep soil adapted fauna) and epigean (surface) specimens were also collected. These specimens are not troglobitic and are therefore not discussed further in this report.

A detailed account of the troglobitic fauna recorded, including discussion of the results of genetic analysis, follows in Sections 5.3.1 to 5.3.6. Record locations are presented in Figure 5.16.

5.3.1 Order Diplura (Diplurans)

Twelve dipluran specimens were recorded and assigned to nine lineages based on molecular analysis (Helix 2017b) (Table 5.10; Figure 5.16). Two specimens failed to sequence and were therefore indeterminate (Diplura sp. indet.), while three lineages were closely related (3.5 % sequence divergence) and were combined into one species; Projapygidae sp. 'DPR008/009/011'. The remaining six lineages identified correspond to six new species (Helix 2017b) (Figure 5.5).

Table 5.10: Summary of dipluran taxa recorded from the current survey.

Family	Lineage	Species	Site	Number
Parajapygidae	DPA001	Parajapygidae sp. 'DPA001' (Plate 5.2).	RC14MEH0308	1
	DPA009	Parajapygidae sp. 'DPA009'	MEHRD0758	1
Projapygidae	DPR008	Projapygidae sp. 'DPR008/DPR009/DPR011'	RC15MEH0166, RC15MEH0175, RC15MEH0261, RC16JIM0005	4
	DPR009			
	DPR011

			Total	12

Plate 5.2: Parajapygidae sp. 'DPA001' from drillhole RC14MEH0308.

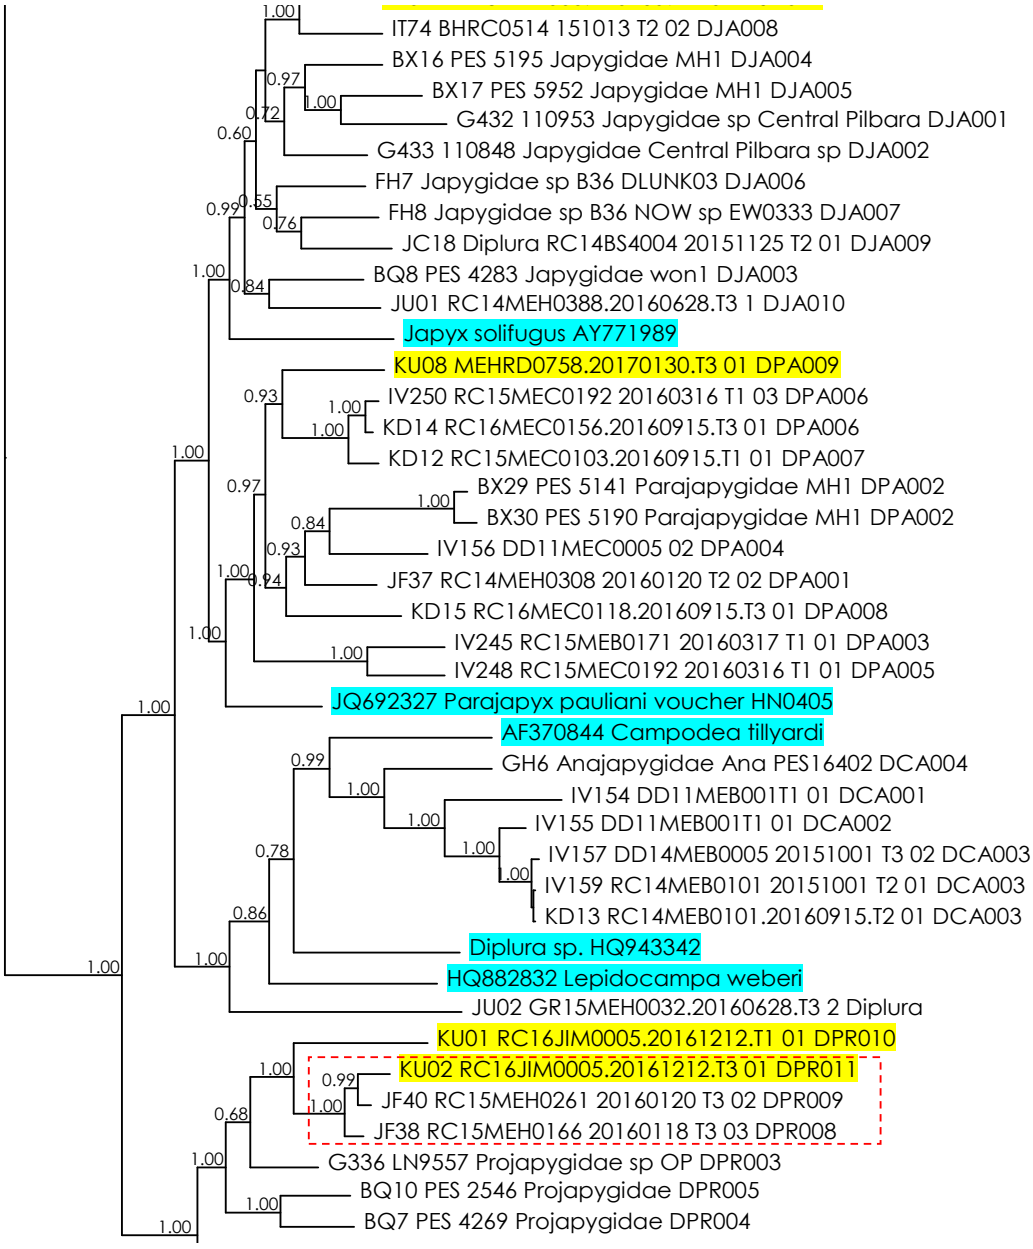

Figure 5.5: Bayesian analysis of CO1 haplotypes of Diplura recorded from the Mesa H survey area. (Numbers on major nodes correspond to posterior probabilities; values <50% are not shown. Specimens from the current study are highlighted in yellow; GenBank specimens are highlighted in turquoise. Red boxes enclose species with high confidence. Red boxes with dashed lines indicate lineages combined to form single species for the purposes of this assessment.

5.3.2 Order Isopoda (Slaters)

A total of 30 troglomorphic isopod specimens were recorded from the survey area, 27 of which were sequenced. Ten of these specimens failed to yield a sequence and therefore remained indeterminate as Isopoda sp. indet., along with three specimens that were not sequenced as large numbers of specimens of the same morphotype were recorded from the same site (Table 5.11). The remaining 17 specimens were assigned to four lineages belonging to two families; Philosciidae and Armadillidae (Table 5.11; Figure 5.16).

All four collected lineages are new, however the two philosciid lineages (Philosciidae. sp. 'ISP047' and 'ISP055') are closely related (5.1 % sequence divergence) (Figure 5.6) and may represent the same species, but confirming this requires further investigation using morphological analysis of adult specimens or sequencing of additional genes (Helix 2017b). In the interests of a conservative assessment, the two taxa are maintained as distinct species in the current report (Table 5.11).

Of the two armadillid lineages, Lineage ISA046 was assigned to the species *Troglarmadillo* sp. 'ISA046' and differed by 18.5% to its mostly closely related lineage (ISA054 from Mesa C) (Figure 5.7). The second armadillid Lineage, ISA057, was closely related (4.5 % sequence divergence) to a lineage previously recorded from Mesa C (lineage 'ISA056') (Figure 5.8) (Helix 2017b), and the two lineages were grouped to form a single putative species, Armadillidae sp. 'ISA056/ISA057' (Table 5.11).

Table 5.11: Summary of isopod taxa recorded from the current survey.

Family	Lineage	Species	Site	Number
Philosciidae	ISP047	Philosciidae sp. 'ISP047'	RC15MEH0382	6
	ISP055	Philosciidae sp. 'ISP055'	RC15MEH0427	1
Armadillidae	ISA046	*Troglarmadillo* sp. 'ISA046'	RC15MEH0382	1
	ISA057	Armadillidae sp. 'ISA056/ISA057'	MEHRD0577, MEHRD0834	9
Indeterminate	Failed to sequence	Isopoda sp. indet.	MEHRD0577, MEHRD0834	13
			Total	30

(Numbers on major nodes correspond to posterior probabilities; values <50% are not shown. Specimens from the current study are highlighted in yellow; GenBank specimens are highlighted in turquoise. Red boxes enclose species with high confidence. Red boxes with dashed lines indicate groups requiring further investigation.

5.3.3 Order Pseudoscorpiones (Pseudoscorpions)

Fourteen pseudoscorpion specimens were recorded from the survey area. Molecular analysis placed the specimens into 10 lineages, which correspond to eight species across three families (Helix 2017b) (Table 5.12; Figure 5.9 to Figure 5.11; Figure 5.16).

Representative photographs of four of the taxa are presented in Plate 5.3 to Plate 5.6. Two specimens failed to sequence and remained indeterminate as Pseudoscorpion sp. indet.. None of the eight species recorded have been previously detected in the Pilbara (Helix 2017b).

Table 5.12: Summary of pseudoscorpion taxa recorded from the current survey.

5.3.4 Order Schizomida (Schizomids)

A total of 45 schizomid specimens were sequenced as part of the Mesa H assessment. Fourteen were collected during the current survey (Table 5.13), 23 were collected during a previous survey at Mesa J (Biota 2009), and WAM also separately sequenced, and morphologically identified, eight specimens from historically sampled sites at Mesa H previously identified as *Paradraculoides* sp. nov. 'Mesa H' (see Section 4.4.2) (Cullen and Harvey 2017). Five lineages corresponding to four species were identified, with six of the 45 specimens unable to be assigned to a lineage due to failure to sequence or missing historical specimens (Table 5.13; Figure 5.16).

Of the four species detected, Hubbardiidae sp. 'SCH011' was recorded within the Mesa H development envelope and also from several sites across Mesa J (Table 5.13). Two lineages recorded from Mesa H were found to be closely related (at 4.3% divergence) and were grouped together as a single species based on habitat proximity and geology (Helix 2017b) (Figure 5.12). This species, Hubbardiidae sp. 'SCH015/SCH016' (Plate 5.7 and Plate 5.8) has also been recorded previously, from approximately 6 km southwest of the development envelope (T. Finston, Helix, pers. comm. April 2017). The WAM analysis of historical material was consistent with the Helix analysis, indicating the presence of two distinct lineages corresponding to Hubbardiidae sp. 'SCH011' and Hubbardiidae sp. 'SCH015/SCH016' (Table 5.13) (Cullen and Harvey 2017). The remaining two lineages were each assigned to new species within the genus *Paradraculoides* (*P.* sp. 'SCH038' and *P.* sp.'SCH039'; Table 5.13). Both species are previously unrecorded outside the development envelope.

Red boxes with dashed lines indicate groups requiring further investigation.

5.3.5 Order Scolopendromorpha (Centipedes)

A single centipede specimen was sequenced and assigned to the family Cryptopidae (Table 5.14; Figure 5.16). This specimen differed from reference specimens by more than 15% and is a new species (Figure 5.13)(Helix 2016).

(Numbers on major nodes correspond to posterior probabilities; values <50% are not shown. Specimens from the current study are highlighted in yellow; GenBank specimens are highlighted in turquoise.

5.3.6 Order Araneae (Spiders)

Two troglobitic spider specimens were recorded from Mesa H (Table 5.15; Figure 5.16).

After morphological examination by the WAM (Appendix 4), one adult male specimen from the family Oonopidae was assigned to a new species within the genus *Prethopalpus* (Table 5.15). No specimens from this genus have been previously collected from Mesa H and this species is considered likely to be an SRE species (Cullen et al. 2017).

The remaining specimen was a juvenile of the family Gnaphosidae and could not be identified to genus level. This specimen is considered to represent a potential SRE species (Cullen et al. 2017).

Table 5.15: Summary of spider taxa recorded from the current survey.

Oonopidae	*Prethopalpus* 'ARA052'	RC16JIM0019	1
Gnaphosidae	Genus indet. sp. 'Mesa H'	RC14MEH0270	1
		Total	2

5.3.7 Order Blattodea (Cockroaches)

Two troglobitic cockroach specimens were recorded from Mesa H (Table 5.16; Figure 5.16). Sequencing identified these as belonging to two separate lineages, which form part of a potential West Pilbara species complex: ?*Nocticola* sp. 'West Pilbara Complex' (family Nocticolidae; Table 5.16; Appendix 3). The two specimens from the current study differed from each other by 6.3%, which is greater than normally expected within a species, but the lineages within this potential species complex also show an equivalent average genetic distance of approximately 6% over a very large geographic range, including a record from Red Hill (some 60 km to the south) which varied from the RC16MEH0427 specimen from the current survey by only 4.2% (divergence more consistent with within-species variation; Appendix 3). The records have therefore been retained here as representatives of the ?*Nocticola* species complex until further work can clearly identify where any species boundaries should be ascribed within the complex.

Table 5.16: Summary of cockroach taxa recorded from the current survey.

(Numbers on major nodes correspond to posterior probabilities; values <50% are not shown. Specimens from the current study are highlighted in yellow. Red boxes with dashed lines indicate groups requiring further investigation.

5.3.8 Order Coleoptera (Beetles)

Eighteen specimens of Coleoptera from Mesa H were sequenced, with the specimens found to represent four phylogenetic lineages (Appendix 3). These correspond to three putative species, representing two families (Table 5.17). Two of the specimens could not be assigned to a lineage due to failure to sequence.

Curculionidae sp. 'CCU014' is a new species currently only known from the development envelope, but was recorded from three locations (Table 5.17). The remaining two beetle species are known from outside of the development envelope: Ptilidae sp. 'Robe Valley' was only recorded from the development envelope during the current survey, but it has previously been recorded elsewhere in the Robe Valley (lineage CP002 on Figure 5.15). Although the last taxon, Ptilidae sp. 'CP003' was recorded solely from site RC12MEH0221 within the development envelope, it is likely to represent the same species as Ptilidae sp. 1, as divergence from that taxon was only 4.4% (Figure 5.15). Ptilidae sp. 1 has been previously recognised by WAM from outside of the development envelope.

Table 5.17: Summary of beetle taxa recorded from the current survey.

5.3.9 Order Zygentoma (Silverfish)

Two troglobitic silverfish specimens, representing two different species, were recorded from Mesa H (Table 5.18). Both taxa were recorded from only within the development envelope (Figure 5.16).

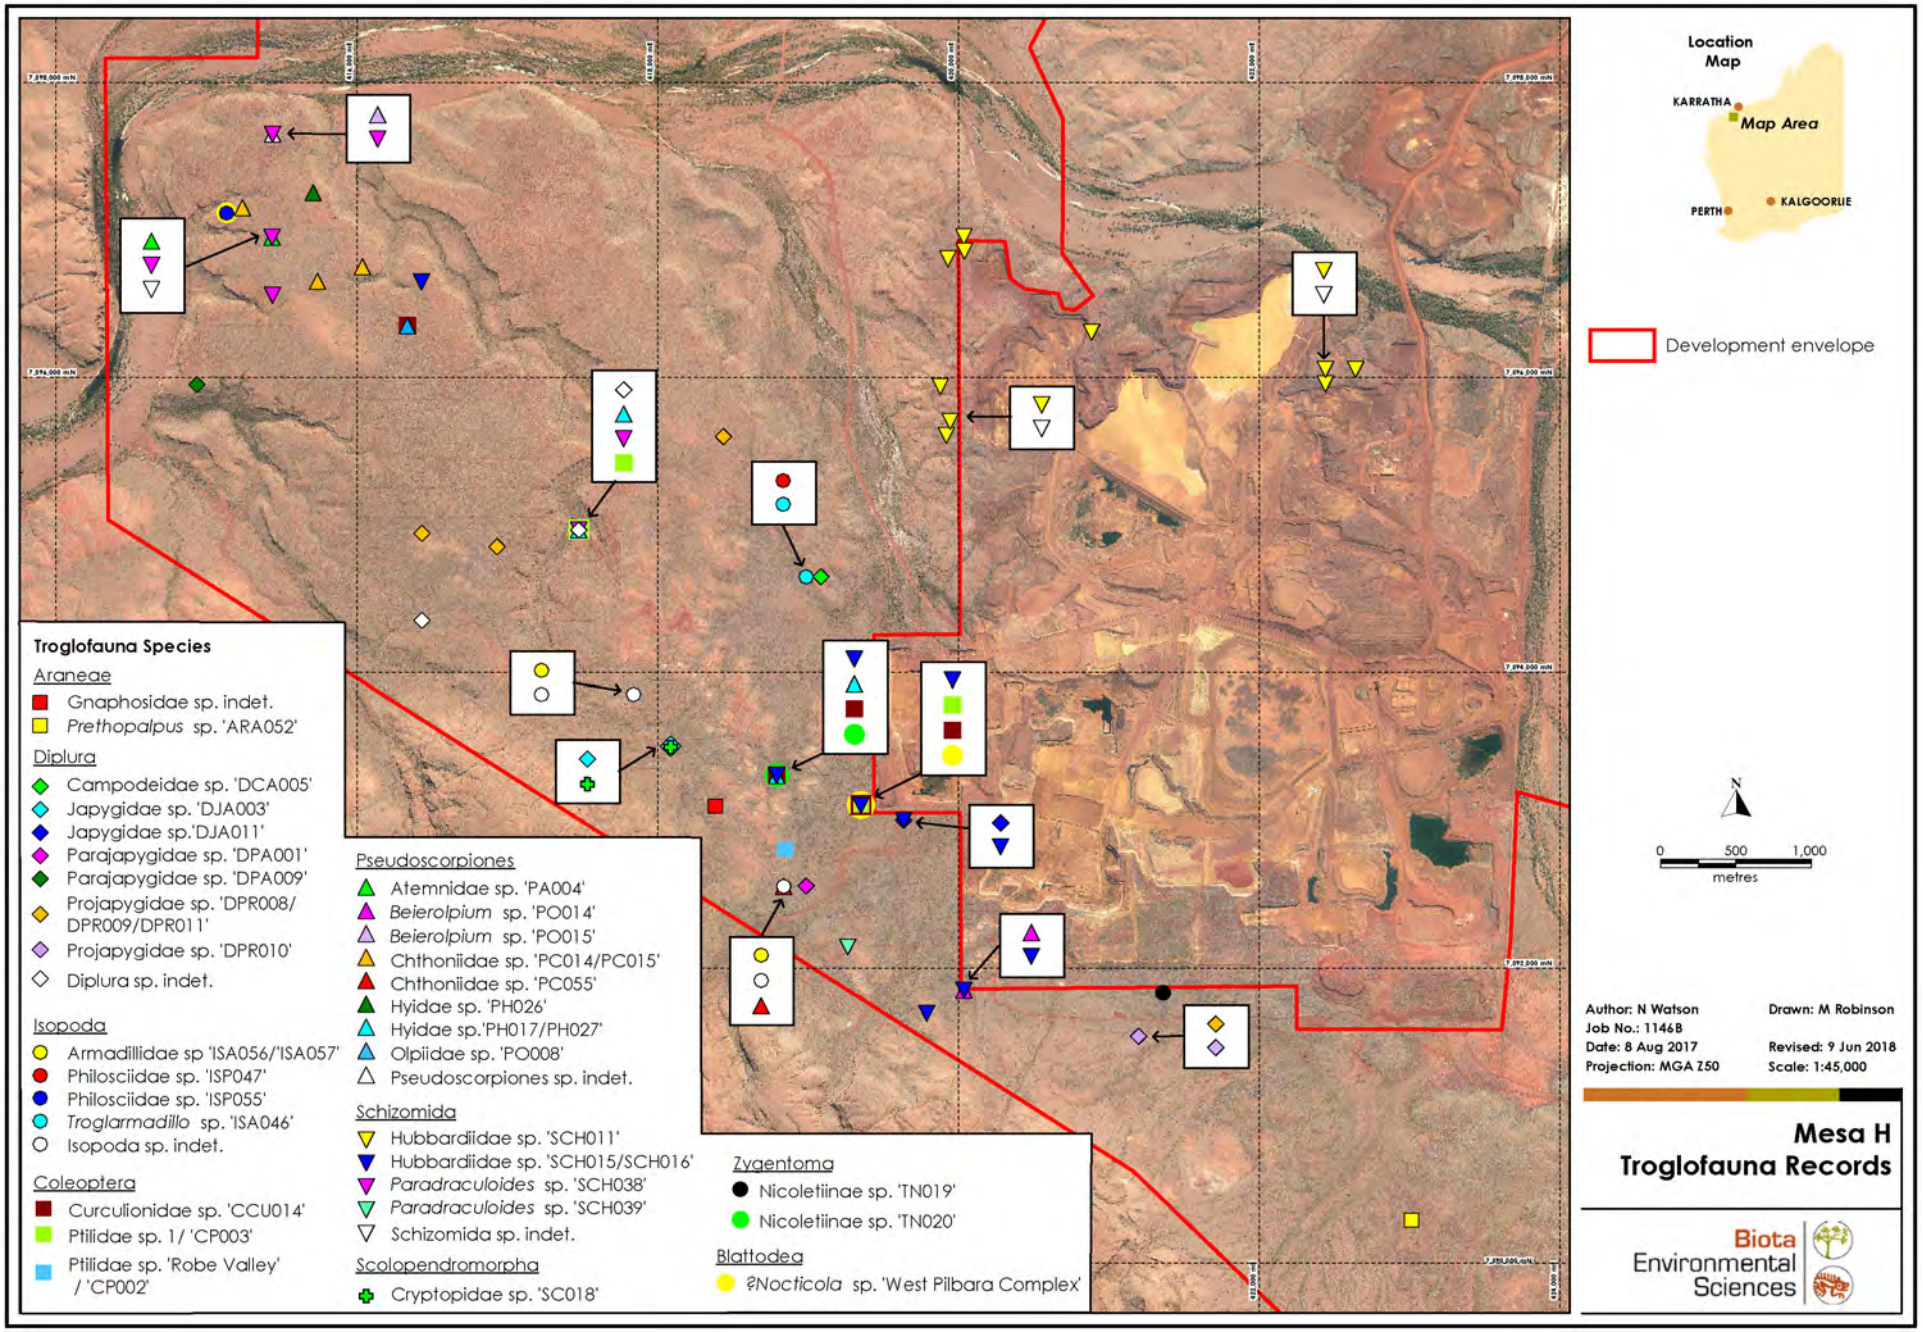

Figure 5.16: Troglofauna taxa recorded from Mesa H during the current survey.

6.0 Discussion

6.1 Known Subterranean Assemblage

6.1.1 Stygofauna

At least 43 species of stygofauna were recorded during the current survey (Section 5.1), with an additional 13 species-level taxa known from previous records (Section 4.4.1), bringing the total known assemblage of the survey area to 56 species (removing duplicated species in common to both the survey and the desktop review data set, and excluding indeterminate specimens).

Forty-six species occur in the immediate Mesa H locality (Rio Tinto 2019), and a subset of 32 of these species occurs within the drawdown extent: 14 recorded during the current survey plus an additional 18 from the desktop review (again, excluding indeterminate specimens and removing overlaps in the two data sets). The majority of these species (26 out of 32 taxa; 81%) are either widespread regionally or have records outside of the drawdown extent. The remaining seven taxa that are currently only known from the drawdown extent are not formally listed as being of conservation significance but are potential SRE taxa, the majority of which are represented by single specimens (see Section 6.3.1).

6.1.2 Troglofauna

Thirty-two troglobitic taxa were recorded from the Mesa H development envelope during the current survey, which, with one additional desktop taxon[1] (Section 4.4.2), brings the known total fauna of the development envelope to at least 33 troglobitic species.

Six of the 33 taxa have been recorded from outside of the development envelope and have demonstrated wider distributions, with the remaining 27 taxa currently only known from within the development envelope. Twenty of these latter were singleton taxa, making comment on their potential wider distributions difficult, but they have been retained as potential SRE taxa here to provide a precautionary assessment.

6.2 Conservation Significant Fauna

6.2.1 Stygofauna

No stygofauna specimens of conservation significance (i.e. listed as Priority, Schedule or Vulnerable at State or Federal levels) were collected during the current survey. Records of *Ophisternon candidum* were, however, obtained from eDNA analysis of environmental samples (Section 5.2).

Specimens of the Blind Cave Eel have now been collected from three sites in the Jimmawurruda and Bungaroo Creeks locality (BC186, JW023 and JW024; Figure 6.1), and a recent additional site on the Robe River immediately north of Mesa H (Biota 2018), in addition to occurring at Cape Range (Section 4.4.1.1).

Sampling targeting this species was conducted during this study using eDNA techniques (Section 3.4). This resulted in the detection of *Ophisternon* DNA at five additional locations, both along Jimmawurruda Creek and the Robe River, including at one site within the development envelope and two to the immediate southeast (Figure 6.1). This indicates that the species occurs more widely in the locality, having been recorded from nine locations in total, and it probably occurs in association with the major alluvial aquifers of the Bungaroo-Jimmawurruda-Robe system (Biota 2018).

[1] *Paradraculoides* sp. nov. 'Mesa H' was also identified from the Development Envelope during the desktop review in Section 4.4.2, but subsequent sequencing reassigned those historical specimens to other Schizomida taxa (Section 5.3.4), removing it from this final tally.

Two Amphipoda species of conservation significance have been recorded from multiple locations within the Mesa H drawdown extent during past surveys: *Nedsia hurlberti* and *Nedsia sculptilis*, both of which are Schedule 3 species collected during a survey at Bungaroo (Biota 2013) (Figure 6.1).

It is worth noting that theses two conservation significant amphipod species recorded from within the Mesa H development envelope have been described morphologically with no genetic analysis completed as part of their formal description (Bradbury and Williams 1996), whereas specimens from this survey were identified based on molecular analysis. Multiple studies in the Pilbara have indicated that amphipod species described solely on the basis of morphology may represent species complexes, or multiple species (Biota 2015b). Equally, past difficulties have arisen with resolving Amphipoda taxonomic boundaries based on morphology alone, where differences in characters has actually represented variation within a species rather than delineating separate species (Biota 2001). The large number of specimens that are juvenile and damaged, and are therefore not informative to morphological analysis, compounds these issues, reducing the power of morphological approaches and limiting determinations of species distribution based on this.

Given these considerations, genetic analysis is likely to be more effective and objective approach to assigning species, reviewing distributions, and thereby assessing conservation significance of putative species within this group. It is possible that taxa identified in this way on a molecular basis during the current study may represent either *Nedsia hurlberti* or *N. sculptilis* but a fuller taxonomic and phylogeographic review would be required to adequately resolve this.

6.2.2 Troglofauna

No troglofauna of conservation significance (i.e. those listed as Priority, Schedule or Vulnerable at State or Federal levels) were recorded during the survey at Mesa H.

One species of conservation significance was recorded from the desktop assessment, the schizomid *Paradraculoides kryptus* (Schedule 3), which to date has been recorded solely from Mesa K. It is unlikely that this species would occur at Mesa H.

6.3 Potential SRE Fauna

6.3.1 Stygofauna

Twenty-nine stygofauna species recorded from the Mesa H survey area are not formally listed as being of conservation significance but are considered to represent potential SRE fauna (Table 6.1). Eleven of these taxa are singletons, making comment on their true wider distribution difficult (Table 6.1). Specimens belonging to one higher rank taxon were unable to be identified to species level (*Gomphodella* sp. indet.) but were still retained as potential SRE stygofauna given distributional patterns in other members of this genus (Biota 2015c).

Thirteen of the 29 potential SRE taxa have been recorded within the drawdown extent (Figure 6.1), with seven of these either also recorded from sites outside of the drawdown extent or known to occur more widely in the region due to previous surveys (Table 6.1).

The remaining six potential SRE taxa are currently only known from the drawdown extent (Hydrobiidae sp. 2, Candoninae sp. 'BOS541', *Parastenocaris* sp. 'B28', *Haptolana* sp. 'B01', Paramelitidae sp. 'AMP003' and Paramelitidae sp. 'AMP037') (Figure 6.1; Table 6.1).

Table 6.1: Summary of conservation significant and potential SRE stygofauna species from the Mesa H survey area (combined desktop review and survey results; desktop records highlighted in grey shading; species in bold recorded from within the drawdown extent).

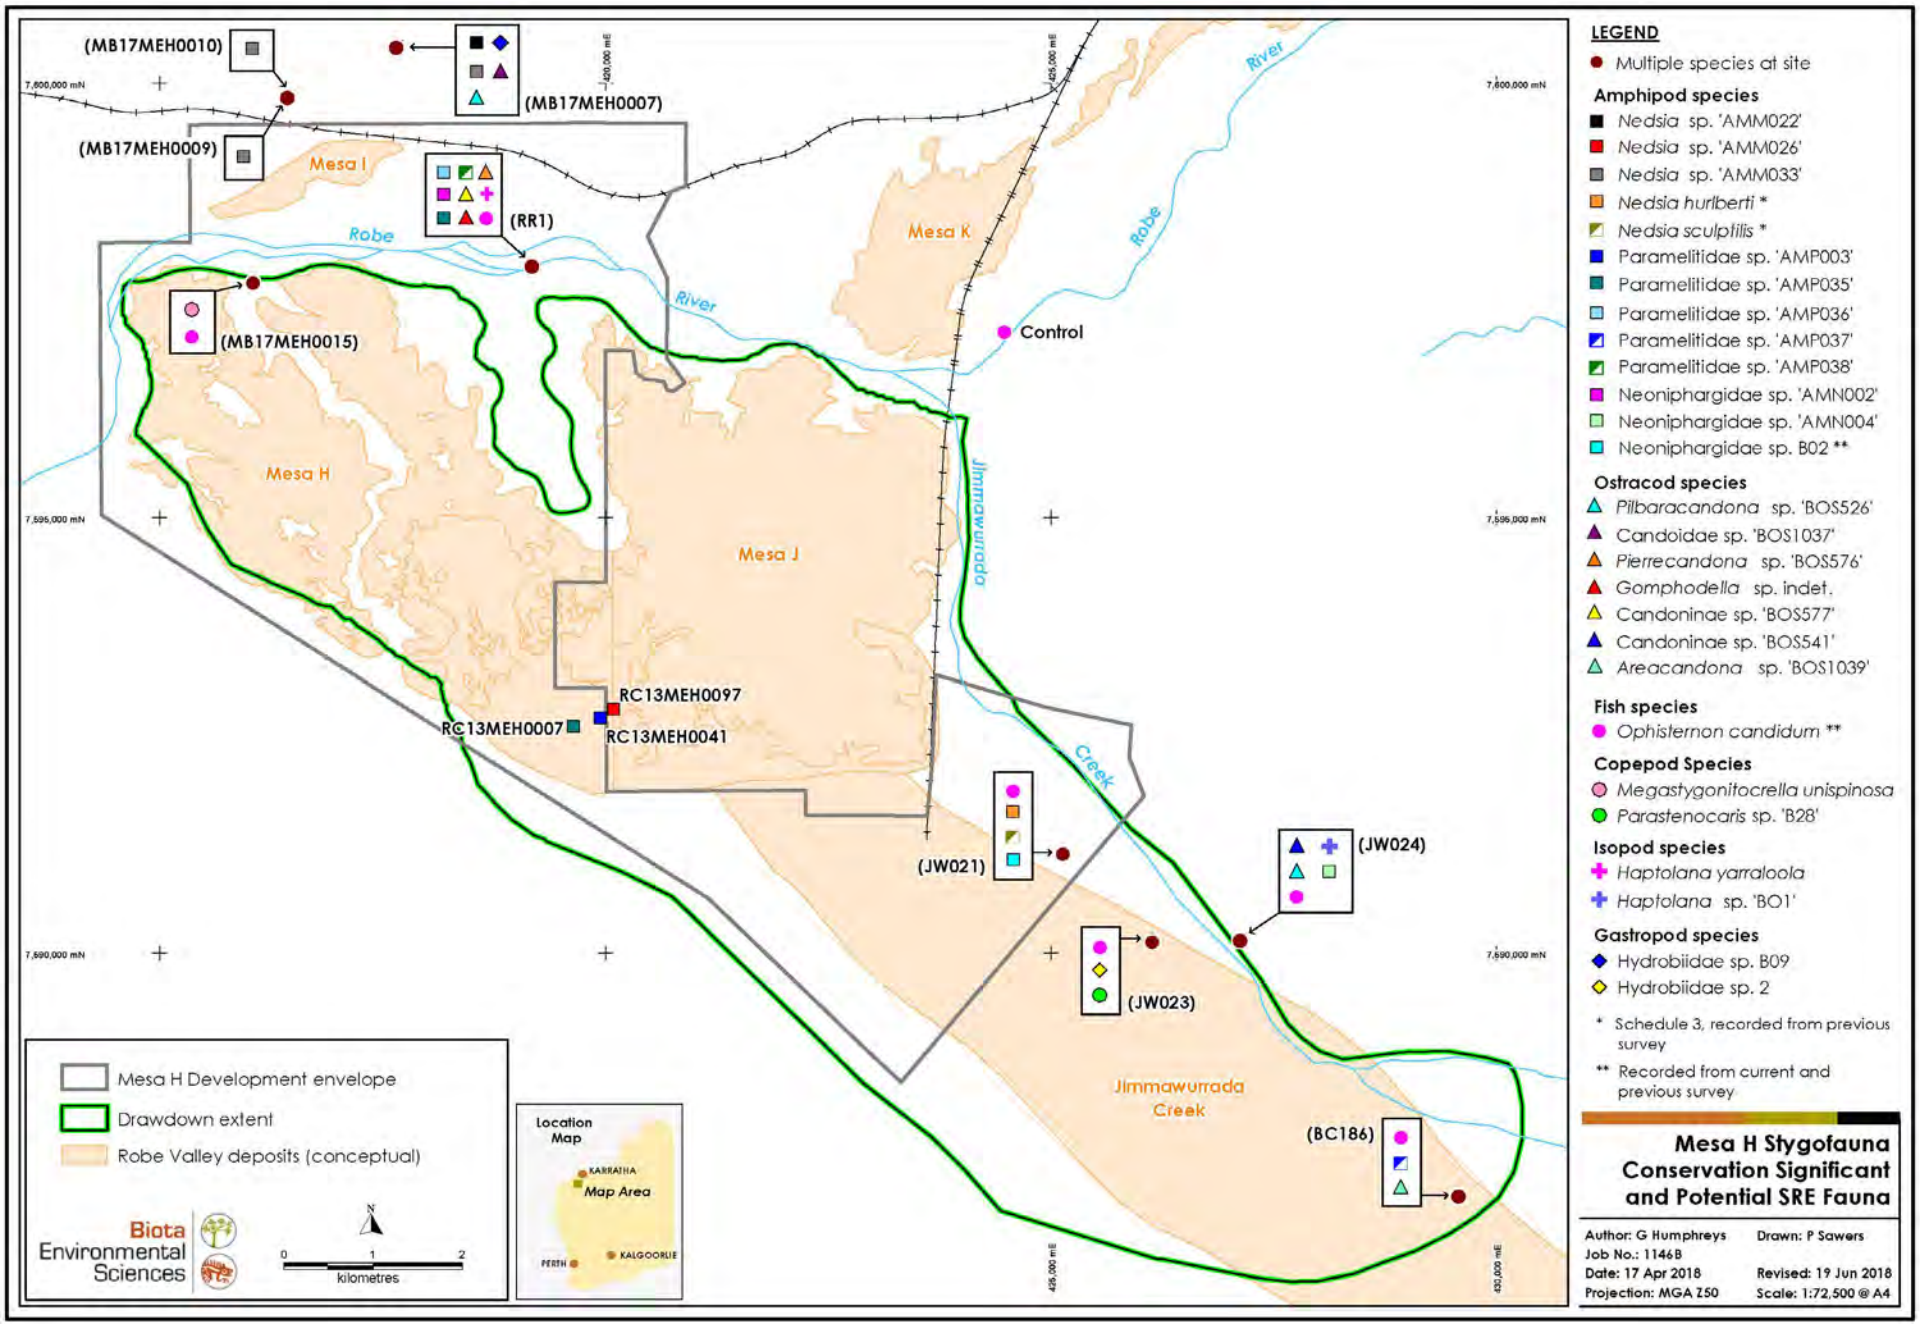

Figure 6.1: Distribution of conservation significant and potential SRE stygofauna relative to the Mesa H drawdown extent, including specimen and eDNA records of *Ophisternon candidum*, from both the current survey and past records.

6.3.2 Troglofauna

Specimens belonging to fiver higher rank troglobitic taxa could not be identified to species level (Diplura sp. indet., Pseudoscorpiones sp. indet., Isopoda sp. indet., Schizomida sp. indet. and Gnaphosidae sp. indet. (Section 4.4.2)). While it is highly likely that these specimens represent range-restricted species, it is not possible to reconcile whether they represent the same species as other records of their respective groups from within or outside the development envelope. The specimens still represent spatial records of potential SRE troglofauna (Figure 6.2), but most have not been recognised as distinct taxa in our conclusions (and are therefore not listed in Table 6.2). The only exception to this is the spider Gnaphosidae sp. indet. as this was the only specimen of its family and is clearly a discrete troglobitic taxon (Section 5.3.6) (Table 6.2).

Excluding indeterminate records, a total of 32 troglobitic taxa were recorded during the survey at Mesa H and all are regarded as potential SRE fauna (Figure 6.2; Table 6.2). Six of the potential SRE taxa have been recorded from both inside and outside of the development envelope: the schizomid species Hubbardiidae sp. 'SCH011' and Hubbardiidae sp. 'SCH015/SCH016', the isopod species Armadillidae sp. 'ISA056/ISA057', the blattodean ?*Nocticola* sp. 'West Pilbara Complex', and the beetles Ptilidae sp. 1/'CP003' and P. sp. 'Robe Valley'/'CP002' (Table 6.2).

The remaining 26 taxa recorded during the survey have been recorded solely from within the Mesa H development envelope based on current data (Figure 6.2; Table 6.2).

One additional potential SRE species recorded from previous surveys (Biota 2011c) occurs solely within the development envelope (Section 4.4.2); the isopod *Troglarmadillo* sp. 1, which is considered to represent a potential SRE species (Figure 6.2 and Table 6.2). It is probable that it represents the same species as other *Troglarmadillo* taxa recorded during the current survey.

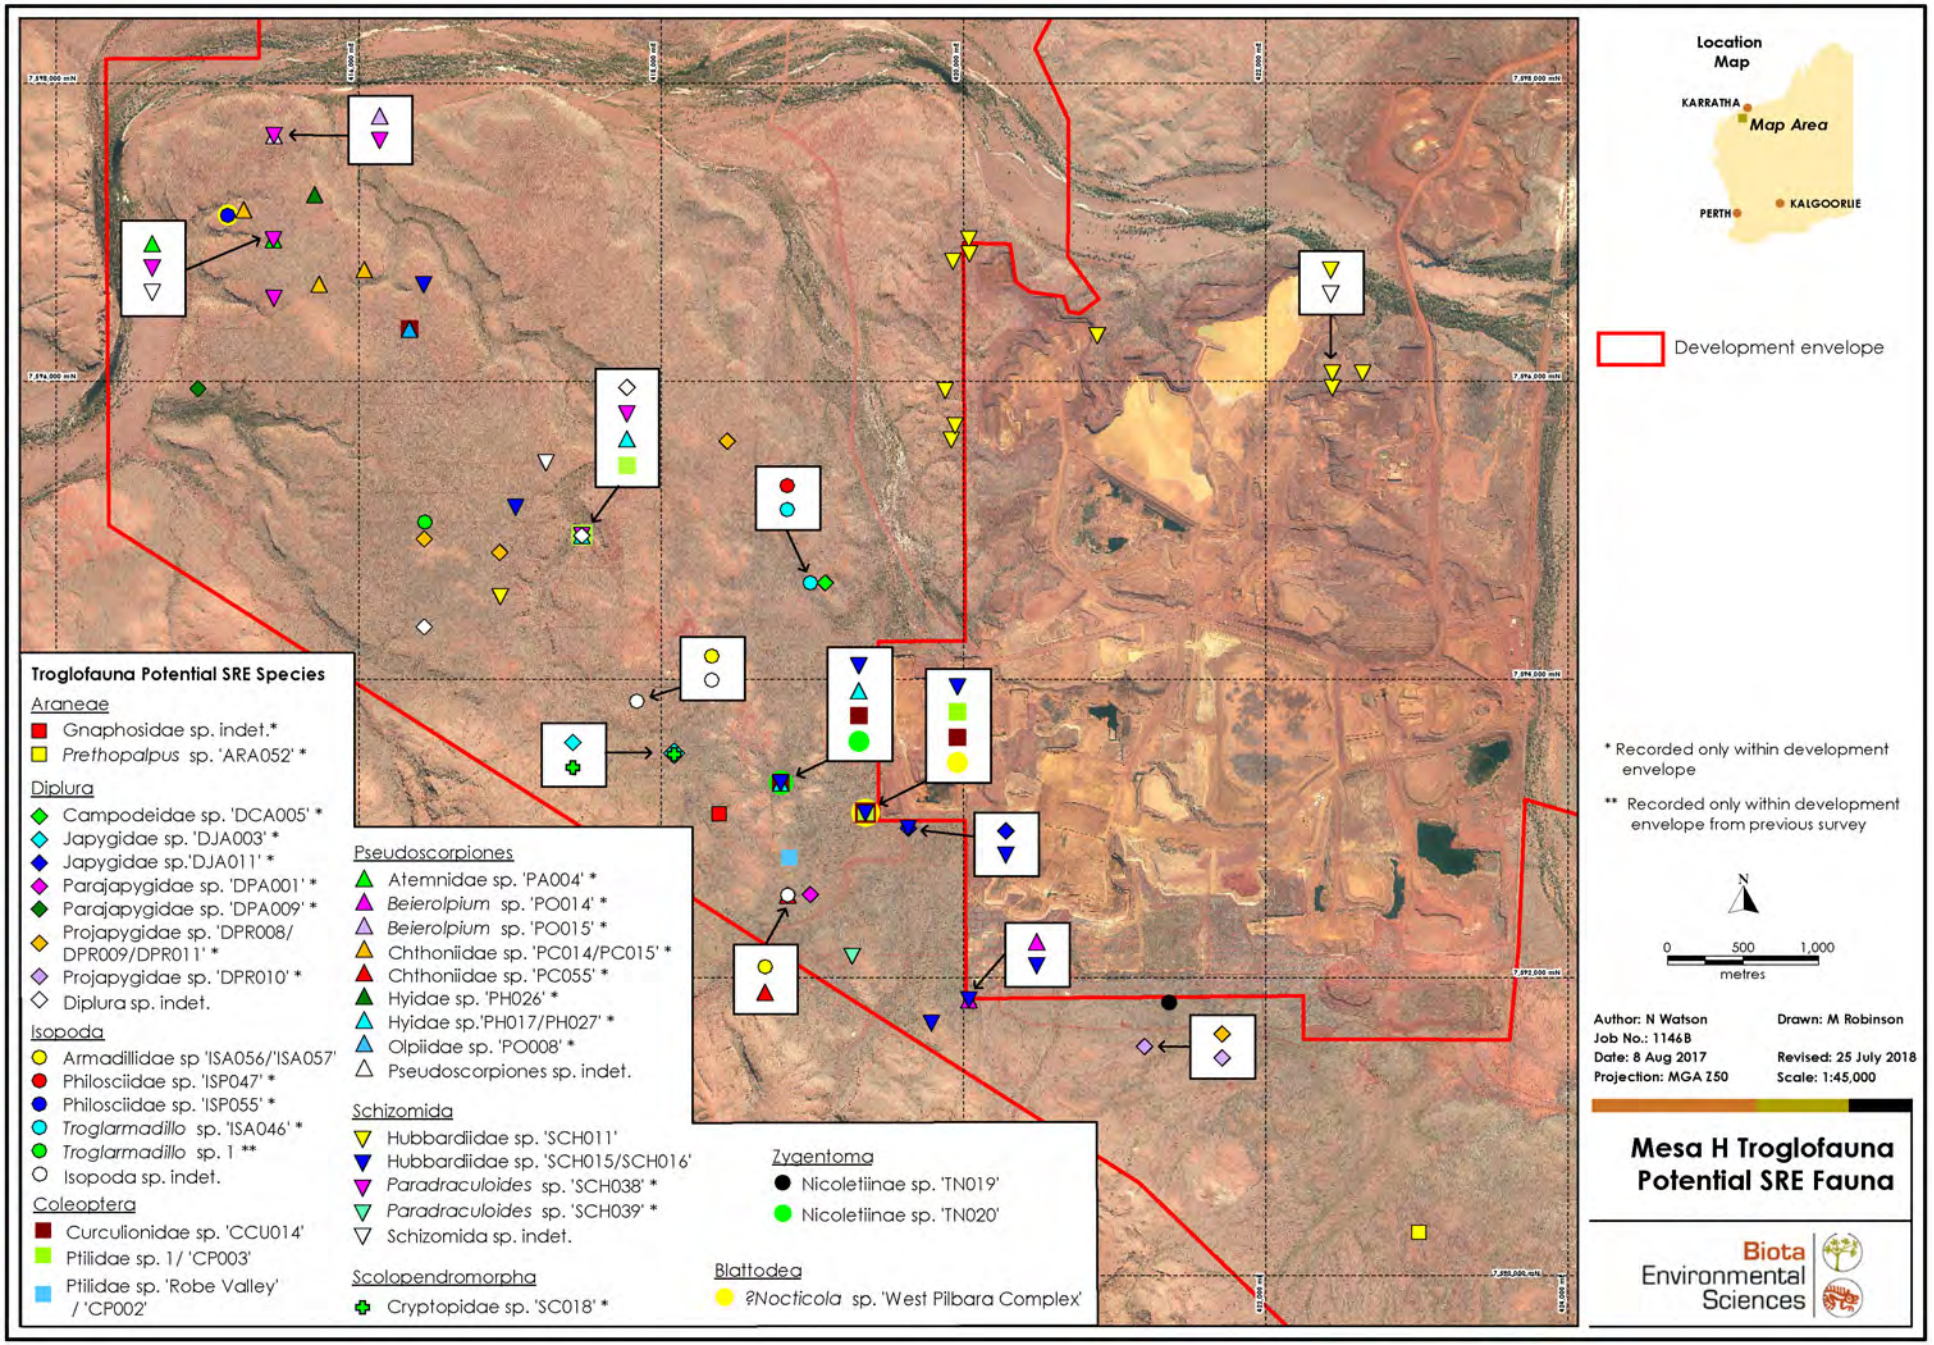

Figure 6.2: Potential SRE troglofauna recorded within the Mesa H development envelope (combined desktop review and survey results).

Table 6.2: Summary of potential SRE troglofauna species recorded within Mesa H development envelope (combined desktop review and survey results; desktop records highlighted in grey shading).

7.0 Glossary

Conservation significance	Listed as Priority, Schedule or Vulnerable at State level.
Edaphobitic / Edaphobite	Soil-dwelling fauna that can often display troglomorphic characteristics. Edaphobites are unlikely to have limited distributions and are therefore unlikely to be classified as short-range endemics.
EPA	Environmental Protection Authority of Western Australia.
Interstices	An opening or space, especially a small or narrow one between mineral grains in a rock or within sediments or soil.
Karst	Soluble-rock landscape; terrain with distinctive hydrology and landforms arising from a combination of high rock solubility and well-developed secondary porosity (Wilkens et al. 2000).
Short-Range Endemic (SRE)	A species that has a naturally small distribution and is often characterised by having poor dispersal capabilities, confinement to disjunct habitats and low fecundity.
Stygobite / Stygofauna	Obligate groundwater fauna.
Taxonomy	Theory and practice of biological classification.
Troglobite / Troglofauna	Species living obligatory in caves; also blind, depigmented and often having an elongate body morphology.
Troglomorphic	Pertaining to morphological, behavioural and physiological characters that are convergent in subterranean populations (Christiansen 1962).
Troglophilic / Troglophile	Species able to live and reproduce underground as well as in the epigean environment (Wilkens et al. 2000).
Vug	A small cavity in a rock or vein, often with a mineral lining of different composition from that of the surrounding rock.

WILDLIFE CONSERVATION ACT 1950
REGULATION 17

LICENCE TO TAKE FAUNA FOR SCIENTIFIC PURPOSES

THE UNDERMENTIONED PERSON MAY TAKE FAUNA FOR RESEARCH OR OTHER SCIENTIFIC PURPOSES AND WHERE AUTHORISED, KEEP IT IN CAPTIVITY, SUBJECT TO THE FOLLOWING AND ATTACHED CONDITIONS, WHICH MAY BE ADDED TO, SUSPENDED OR OTHERWISE VARIED AS CONSIDERED FIT.

DIRECTOR GENERAL

CONDITIONS

1 The licensee shall comply with the provisions of the Wildlife Conservation Act 1950, Wildlife Conservation Regulations 1970 and any notices in force under this legislation.
2 Unless specifically authorised in the Conditions of this Licence or otherwise in writing by the Director General, species of fauna declared as likely to become extinct, rare or otherwise in need of special protection shall not be captured or otherwise taken.
3 No fauna shall be taken from any Nature Reserve, National Park, Marine Park, Marine Nature Reserve, Timber Reserve or State Forest without prior written approval of the Director General. No fauna shall be taken from any other public land without the written approval of the Government Authority managing that land.
4 No entry or collection of fauna to be undertaken on any private property or pastoral lease without the consent in writing of the owner or occupier, or from any Aboriginal lands without the written approval of the Department of Aboriginal Affairs.
5 No fauna or their progeny shall be released in any area where it does not naturally occur, nor be handed over to any other person or authority unless approved by the Director General, nor shall the remains of such fauna be disposed of in such manner as to confuse the natural or present day distribution of the species.
6 This licence and the written permission referred to at conditions 3 & 4 must be carried by the licensee or authorised agent at all times for the purpose of proving their authority to take fauna when questioned as to their right to do so by a Wildlife Officer, any other State or Local Government employee or any member of the public.
7 Any interaction involving Gazetted Threatened Fauna that may be harmful and/or invasive may require approval from the Department of the Environment ph 02 6274 1111. Interaction with such species is controlled by the Commonwealth Government's "Environment Protection and Biodiversity Conservation Act 1999" and "Environment Protection and Biodiversity Conservation Regulations 2000" as well as this Department's Wildlife Conservation Act 1950 and Wildlife Conservation Regulations 1970.
8 No bioprospecting involving the removal of sample aquatic and terrestrial organisms (both flora and fauna) for chemical extraction and bioactivity screening is permitted to be conducted without specific written approval by the Director General.
9 Further conditions (numbered 1 to 9) are attached.

PURPOSE SUBTERRANEAN FAUNA SURVEY, USING REINFORCED STYGOFAUNA HAUL NETS AND TROGLOFAUNA COLONISATION TRAPS PLUS SCRAPING OF PLANKTON HAUL NETS, IN ACCORDANCE WITH EPA GUIDANCE STATEMENT 54A, FOR ENVIRONMENTAL IMPACT ASSESSMENT AT RIO TINTO MESAS J AND H 18KMS SOUTH WEST OF PANNAWONICA.

WILDLIFE CONSERVATION REGULATIONS 1970

Regulation 17:- Licence to Take Fauna for Scientific Purposes

FURTHER CONDITIONS (OF LICENCE NUMBER SF010536)

1. The licensee shall take fauna only in the manner stated on the endorsed Regulation 17 licence application form and endorsed related correspondence.

2. Except in the case of approved lethal traps, the licensee shall ensure that measures are taken in the capture and handling of fauna to prevent injury or mortality resulting from that capture or handling. Where traps or other mechanical means or devices are used to capture fauna these shall be deployed so as to prevent exposure of trapped animals to ants and debilitating weather conditions and inspected at regular intervals throughout each day of their use. At the conclusion of research all markers etc and signs erected by the licensee and all traps shall be removed, all pitfalls shall be refilled or capped and the study area returned to the condition it was in prior to the research/capture program. During any break in research, cage traps should be removed and pitfalls either removed, capped or filled with sand.

3. No collecting is to be undertaken in areas where it would impinge on pre-existing scientific research programs.

4. Any form of colour marking of birds or bats shall only be undertaken in accordance with the requirements of the Australian Bird and Bat Banding Scheme.

5. Any inadvertently captured specimen of fauna which is declared as likely to become extinct, rare or otherwise in need of special protection is to be released immediately at the point of capture. Where such a specimen is injured or deceased, the licensee shall contact Department of Parks and Wildlife licensing staff at Kensington (08 9219 9831) for advice on disposal. Records are to be kept of any fauna so captured and details included in the report required under further condition 6 below.

6. Within one month of the expiration of this licence, the holder shall submit an electronic return detailing the locality, site, geocode, date and number of each species captured, sighted or vouchered during the currency of the licence, into the Department of Parks and Wildlife Fauna Survey Database (FSD). A copy of any paper, report or thesis resulting from the research shall on completion be lodged with the Director General. If a renewal of this licence is required, the licensee shall submit a written progress report for activities undertaken during this licence period prior to the expiry of this licence.

7. Not more than ten specimens of any one protected species shall be taken and removed from any location less than 20km apart. Where exceptional circumstances make it necessary to take large series in order to obtain adequate statistical data the collector will proceed with circumspection and justify their actions to the Director General in advance.

8. All holotypes and syntypes and a half share of paratypes of species or subspecies permitted to be permanently taken under this licence shall be donated to the Western Australian Museum. Duplicates (one pair in each case) of any species collected which represents a significant extension of geographic range shall be donated on request to the Western Australian Museum.

9. To prevent any unnecessary collecting in this State, all specimens and material collected under the authority of this license shall, on request, be loaned to the Western Australian Museum. Also, the unused portion or portions of any specimen collected under the authority of this license shall be offered for donation to the Western Australian Museum or made available to other scientific workers if so required.

WILDLIFE CONSERVATION ACT 1950
REGULATION 17

LICENCE TO TAKE FAUNA FOR SCIENTIFIC PURPOSES

THE UNDERMENTIONED PERSON MAY TAKE FAUNA FOR RESEARCH OR OTHER SCIENTIFIC PURPOSES AND WHERE AUTHORISED, KEEP IT IN CAPTIVITY, SUBJECT TO THE FOLLOWING AND ATTACHED CONDITIONS, WHICH MAY BE ADDED TO, SUSPENDED OR OTHERWISE VARIED AS CONSIDERED FIT.

DIRECTOR GENERAL

CONDITIONS

1 The licensee shall comply with the provisions of the Wildlife Conservation Act 1950, Wildlife Conservation Regulations 1970 and any notices in force under this legislation.

2 Unless specifically authorised in the Conditions of this Licence or otherwise in writing by the Director General, species of fauna declared as likely to become extinct, rare or otherwise in need of special protection shall not be captured or otherwise taken.

3 No fauna shall be taken from any Nature Reserve, National Park, Marine Park, Marine Nature Reserve, Timber Reserve or State Forest without prior written approval of the Director General. No fauna shall be taken from any other public land without the written approval of the Government Authority managing that land.

4 No entry or collection of fauna to be undertaken on any private property or pastoral lease without the consent in writing of the owner or occupier, or from any Aboriginal lands without the written approval of the Department of Aboriginal Affairs.

5 No fauna or their progeny shall be released in any area where it does not naturally occur, nor be handed over to any other person or authority unless approved by the Director General, nor shall the remains of such fauna be disposed of in such manner as to confuse the natural or present day distribution of the species.

6 This licence and the written permission referred to at conditions 3 & 4 must be carried by the licensee or authorised agent at all times for the purpose of proving their authority to take fauna when questioned as to their right to do so by a Wildlife Officer, any other State or Local Government employee or any member of the public.

7 Any interaction involving Gazetted Threatened Fauna that may be harmful and/or invasive may require approval from the Department of the Environment ph 02 6274 1111. Interaction with such species is controlled by the Commonwealth Government's "Environment Protection and Biodiversity Conservation Act 1999" and "Environment Protection and Biodiversity Conservation Regulations 2000" as well as this Department's Wildlife Conservation Act 1950 and Wildlife Conservation Regulations 1970.

8 No bioprospecting involving the removal of sample aquatic and terrestrial organisms (both flora and fauna) for chemical extraction and bioactivity screening is permitted to be conducted without specific written approval by the Director General.

9 Further conditions (numbered 1 to 9) are attached.

PURPOSE SUBTERRANEAN FAUNA SURVEY, USING REINFORCED STYGOFAUNA HAUL NETS AND TROGLOFAUNA COLONISATION TRAPS PLUS SCRAPING OF PLANKTON HAUL NETS, IN ACCORDANCE WITH EPA GUIDANCE STATEMENT 54A, FOR ENVIRONMENTAL IMPACT ASSESSMENT AT RIO TINTO MESAS J AND H 18KMS SOUTH WEST OF PANNAWONICA.

WILDLIFE CONSERVATION REGULATIONS 1970

Regulation 17:- Licence to Take Fauna for Scientific Purposes

FURTHER CONDITIONS (OF LICENCE NUMBER SF 010915)

1. The licensee shall take fauna only in the manner stated on the endorsed Regulation 17 licence application form and endorsed related correspondence.

2. Except in the case of approved lethal traps, the licensee shall ensure that measures are taken in the capture and handling of fauna to prevent injury or mortality resulting from that capture or handling. Where traps or other mechanical means or devices are used to capture fauna these shall be deployed so as to prevent exposure of trapped animals to ants and debilitating weather conditions and inspected at regular intervals throughout each day of their use. At the conclusion of research all markers etc and signs erected by the licensee and all traps shall be removed, all pitfalls shall be refilled or capped and the study area returned to the condition it was in prior to the research/capture program. During any break in research, cage traps should be removed and pitfalls either removed, capped or filled with sand.

3. No collecting is to be undertaken in areas where it would impinge on pre-existing scientific research programs.

4. Any form of colour marking of birds or bats shall only be undertaken in accordance with the requirements of the Australian Bird and Bat Banding Scheme.

5. Any inadvertently captured specimen of fauna which is declared as likely to become extinct, rare or otherwise in need of special protection is to be released immediately at the point of capture. Where such a specimen is injured or deceased, the licensee shall contact Department of Parks and Wildlife licensing staff at Kensington (08 9219 9831) for advice on disposal. Records are to be kept of any fauna so captured and details included in the report required under further condition 6 below.

6. Within one month of the expiration of this licence, the holder shall submit an electronic return detailing the locality, site, geocode, date and number of each species captured, sighted or vouchered during the currency of the licence, into the Department of Parks and Wildlife Fauna Survey Database (FSD). A copy of any paper, report or thesis resulting from the research shall on completion be lodged with the Director General. If a renewal of this licence is required, the licensee shall submit a written progress report for activities undertaken during this licence period prior to the expiry of this licence.

7. Not more than ten specimens of any one protected species shall be taken and removed from any location less than 20km apart. Where exceptional circumstances make it necessary to take large series in order to obtain adequate statistical data the collector will proceed with circumspection and justify their actions to the Director General in advance.

8. All holotypes and syntypes and a half share of paratypes of species or subspecies permitted to be permanently taken under this licence shall be donated to the Western Australian Museum. Duplicates (one pair in each case) of any species collected which represents a significant extension of geographic range shall be donated on request to the Western Australian Museum.

9. To prevent any unnecessary collecting in this State, all specimens and material collected under the authority of this license shall, on request, be loaned to the Western Australian Museum. Also, the unused portion or portions of any specimen collected under the authority of this license shall be offered for donation to the Western Australian Museum or made available to other scientific workers if so required.

Re. Report on the molecular systematics of Amphipoda from Mesa H – Phase 4

Dear Nicola,

Following is a summary of the results of the Amphipoda study we have completed from Mesa H phase 4 collections. Eight distinct genetic lineages from three families (Melitidae, Niphargidae, Paramelitidae) were detected in the phase 4 collections, four of which have been detected previously in the Pilbara, and four of which appear to be new, based on the material available for comparsion.

Thanks once again for collaborating on this project with Helix. We hope we can continue to provide you with useful information, and feel free to contact us if you have any questions or would like to discuss the results in detail.

Sincerely,

Dr. Terrie Finston, Yvette Hitchen and Dr. Oliver Berry
Helix Molecular Solutions

Background and Objective

Forty-two specimens of Amphipoda were collected from Mesa H during phase 4 and sequenced for variation at the mitochondrial COI gene. The molecular data were assessed in order to determine the number of species present in each group and compare the results to those obtained during previous surveys at Mesa H and throughout the Pilbara.

Executive summary

- Forty-two specimens of amphipods from Mesa H phase 4 were sequenced for variation at the COI gene.
- Eight distinct genetic lineages from three families (Melitidae, Niphargidae, Paramelitidae) were detected among the 38 specimens for which sequences were obtained.
- Four of the eight lineages have been detected previously in the Pilbara.

Methods

Forty-two specimens of Amphipoda from 14 drillholes at Mesa H were sequenced for variation at the mitochondrial cytochrome oxidase subunit I gene (COI) using primers LCOI/HCO2.

Sequences were edited using GENEIOUS software (Drummond *et al.* 2011). Alignment was performed with CLUSTAL W (Thompson *et al*. 1994) using default parameters. Genetic distances between unique genetic sequences (haplotypes) were measured using uncorrected p-distances (total percentage of nucleotide differences between sequences).

MODELTEST software (Posada and Crandall, 1998) was used to determine the model of sequence evolution that best fitted the data for each taxonomic group. Bayesian analysis was used to construct the phylogenetic trees, incorporating the model as identified in MODELTEST for each taxonomic group. The phylogeny, branch lengths and posterior probabilities were obtained by running two trees simultaneously, each running four simultaneous MCMC chains. The number of cycles needed was determined by the standard deviation of the split frequencies of the two trees. The analysis was paused after every 1 x 10^6 generations and when the standard deviation fell below 0.01, the analysis was stopped. A majority rule consensus tree was constructed after discarding the "burn-in" trees in both analyses. The burn-in value was determined by plotting the posterior probabilities obtained after every generation and identifying the point at which the values reach stationarity (= the asymptote). Trees produced prior to stationarity were discarded.

For the purposes of this report, lineages were defined as haplotypes or groups of haplotypes differing from other such groups by >3% sequence divergence. This cut-off was selected based on bar-coding data, which indicates that intra-specific variation rarely exceeds 3% (Hebert et al., 2003b).

Results

Preliminary analysis - Reference sequences and outgroups

Forty-two specimens of amphipods from phase 4 were sequenced for COI (Table 1; Appendix 1). In order to reduce analysis time and to simplify the presentation of results, a preliminary neighbour-joining (NJ) analysis was conducted on the 38 Robe Valley amphipods for which sequences were obtained, and haplotypes were selected from each genetic lineage to include in a model-based phylogenetic analysis.

The neighbour-joining analysis placed the 38 specimens of amphipods into eight lineages (Figure 1). Comparisons to the GenBank sequence database indicated that four lineages were most similar to sequences of Niphargidae and one was most similar to Paramelitidae, whereas three lineages were most similar to sequences of Melitidae. The Paramelitidae and Niphargidae lineages each contained single specimens, whereas the Melitidae lineages contained between one and 25 specimens (Figure 1). The three lineages of Melitidae differed from one another by between 5.8 and 9.8% mean sequence divergence and the four lineages of Niphargidae differed from one another by between 12.1 and 18.9% sequence divergence (Table 2).

Differentiation within lineages for all three families ranged from 0 to 0.5% mean sequence divergence (Table 3).

The Paramelitidae and Niphargidae were analysed in a single phylogenetic analysis. For the Paramelitidae, 32 reference sequences were included in the phylogenetic analysis, six GenBank vouchers of Paramelitidae, *Maarrka etheli* (Genbank accession #DQ838031), two *Maarrka weeliwollii* (Genbank accession # DQ838032 and # DQ838033), Paramelitidae sp. 3 (Genbank accession # EF558852) and two references of 'Yilgarus' sp. (Genbank accession # EF118232 and EF118194) as well as 26 specimens from previous surveys of the Robe Valley, Central Pilbara, Barrow Island, Lower Shaw River, Fortescue River, and Marillana Creek, including one representative from a previous survey at Mesa H. For the Niphargidae, eight reference sequences were included in the analysis, six specimens from previous surveys in the Robe Valley, including one representative from Mesa H, and two Genbank reference sequences of *Niphargus*: *N. fontanus* (Genbank accession number KC315635) and *N. glenniei* (Genbank accession number KC315646). Two sequences of Melitidae, *Nedsia* sp. 1 (Genbank accession #EU304458), and *Norcapensis mandibulis* (Genbank accession # JQ608487)

For the Melitidae, 43 reference sequences were included in the phylogenetic analysis, two GenBank vouchers of Melitidae, *Nedsia* sp. 1 (Genbank accession #EU304458), and *Norcapensis mandibulis* (Genbank accession # JQ608487) as well as 41 specimens from previous surveys of the Robe Valley, Central Pilbara, Barrow Island, Lower Shaw River, Fortescue River, and Marillana Creek, including five representatives from previous surveys at Mesa H. Two sequences of the amphipod genus *Niphargus* were used as outgroups as follows: *N. fontanus* (Genbank accession number KC315635) and *N. glenniei* (Genbank accession number KC315646).

Phylogenetic analysis- Paramelitidae and Niphargidae
The phylogenetic analysis, which included the one representative of Paramelitidae and the four representatives of Niphargidae from Mesa H phase 4, in addition to 32 and eight reference specimens, respectively, revealed the presence of two well-supported major clades, corresponding to the two families (Figure 2). The phase 4 Mesa H specimen of Paramelitidae was placed in a single distinct lineage, which did not contain any reference specimens and thus was assigned to the new lineage AMP035 (Figure 2). The Mesa H phase 4 Niphargidae specimens were placed in four distinct genetic lineages, one of which also contained reference specimens from previous surveys at Mesa H and the Robe Valley (Figure 2). Specifically, specimen KE07 from bore 200, was placed in a lineage containing specimens from previous surveys in the Robe Valley and Mesa H (Daves, Budgie and bore 200) and thus was assigned to the existing lineage AMN008 (Figure 2). The remaining three lineages of Niphargidae from Mesa H phase 4 (KE18, KE28 and KE33) did not contain any reference specimens and thus were assigned to the new lineages AMN002, AMN003 and AMN004, respectively (Figure 2). Lineage KE28/AMN003 formed a well-supported clade with reference specimen IV129 from the Robe Valley (Figure 2).

Differentiation between lineages – Paramelitidae and Niphargidae
The Robe Valley Paramelitidae lineage represented by specimen KE16/AMP035 differed from the nearest reference specimen GK62 by 17.4% sequence divergence (Table 4). The Mesa H Niphargidae lineage represented by specimen KE07/AMN008 differed from the nearest reference specimens KJ64, KD39, IV100 and JN08 (lineage AMN008) by between 0.0 and 0.6% sequence divergence (Table 4). Phase 4 specimen KE28/AMN003 differed from the nearest reference specimen (IV129) by 6.3% sequence divergence and the remaining two lineages of Niphargidae from phase 4, KE18/AMN002 and KE33/AMN004 differed from the nearest reference specimens by >12% sequence divergence (Table 4).

Phylogenetic analysis- Melitidae
The phylogenetic analysis, which included the three representatives of Melitidae from Mesa H phase 4, in addition to 43 reference specimens, placed the Mesa H specimens in three distinct genetic lineages, all of which also contained reference specimens from previous surveys in the Pilbara (Figure 3). Specifically, specimen KE31 was placed in a lineage containing reference

specimens KJ65, IV97, IV126, JN17, KD49, JF02 and rr3a and thus was assigned to the existing lineage AMM001, and specimen KE05 was placed in a lineage containing reference specimens KJ73, KD45 and KD55 and thus was assigned to the existing lineage AMM031 (Figure 3), Specimen KE10 was placed in a lineage with reference specimens IV128 and JN05, and thus was assigned to the existing lineage AMM004 (Figure 3).

Specimens KE05 and KE031 were placed in a larger clade containing eight closely related lineages from the Robe Valley (AMM001, AMM002, AMM024, AMM025, AMM027, AMM029, AMM030 and AMM031; Figure 3).

Differentiation between lineages - Melitidae
All three specimens representing the three lineages collected in phase 4 were assigned to existing lineages and differed from the nearest reference specimens by <2.5% (Table 5). Specifically, KE031/AMM001 differed from the nearest reference specimens IV97, IV126, JN17, KD49, KJ65, JF02 and rr3a by between 0.2 and 2.2% sequence divergence and KE05/AMM031 differed from the nearest reference specimens KJ73, KD45 and KD55 by between 2.2 and 3.5% sequence divergence (Table 5). KE10/AMM004 differed from the nearest reference specimens IV128 and JN05 by between 0.0 and 0.2% sequence divergence (Table 5).

The genetic distance between specimens in the large well-supported clade comprising the eight closely related lineages (enclosed by a dashed red box in Figure 3) ranged from 0 – 7.8% and the mean was 4.9% sequence divergence.

Conclusions
COI is widely considered to show suitable variation to distinguish species (Hebert et al., 2003a). In a comparison of COI sequences for over 13,000 pairs of taxa, Hebert et al (2003b) found a mean of 11.1% sequence divergence between distinct species. Nearly 80% of the comparisons showed that species pairs differed from one another by greater than 8% sequence divergence. However, a taxon by taxon approach, examining the amount of phylogenetic variation within and between species is the most widely accepted method of defining species.

Paramelitidae

One lineage of Paramelitidae (AMP035) was detected at Mesa H during phase 4. The lineage differed from the nearest reference specimens by 17% or greater, indicating that it represents a distinct lineage and species that has not been detected previously.

AMP035 = one species from RR1, so far not detected previously in the Pilbara, based on the material available for comparison.

Niphargidae

Four lineages of Niphargidae were detected at Mesa H during phase 4. One lineage, AMN008, has been detected previously at Mesa H and other sites in the Robe Valley, whereas two (AMN002 and AMN004) have not been detected previously, based on the high level of sequence divergence between them and the nearest reference specimens (>12%). The fourth lineage requires further consideration. Lineage AMN003 differed from the nearest reference specimen (IV129/AMN007 from Daves bore in the Robe Valley) by 6.3% sequence divergence. This level of genetic divergence, while moderately low, is more than would be expected to be observed between individuals of the same species and particularly from the same region. For example, lineage AMN008 shares a similar distribution, being detected at Mesa H and Daves and Budgie bores, however differentiation between specimens in lineage AMN008 is <1%. Nevertheless, lineages AMN003 and AMN007 are closely related. Because sample sizes are low and the specimens were collected at different deposits in the Robe Valley, further sampling at intermediate sites may help resolve the relationship among these lineages.

AMN008 = one species from bore 200, detected previously in the Robe Valley at Daves and Budgie bores.
AMN002 = new species

AMN003 = new species; closely related to AMN007 and further investigation may help resolve the relationship between the two lineages
AMN004 = new species

Melitidae

Three lineages of Melitidae were detected at Mesa H, differing from one another by between 5.8 and 9.8% mean sequence divergence, indicating that each is likely to represent a distinct species (however see following comments). All three of the lineages were assigned to existing lineages (AMM001, AMM004, and AMM031).

Two of the three lineages detected in phase 4 at Mesa H (AMM001 and AMM031) were placed in a well-supported clade containing a group of closely related specimens (enclosed by a dashed red box in Figure 3), which differed by <5% mean sequence divergence (range = 0 – 7.8%). Thus this group may represent several closely related species (as shown by solid red boxes in Figure 3), or may represent a single species showing genetic differentiation across its range. Further investigation may be required to resolve relationships among the lineages, but the most likely explanation would be to consider them a single species, owing to the fact that they have a relatively wide distribution (Robe Valley to Barrow Island) and the observed genetic variation may reflect geographic variation associated with a 'stepping stone' pattern of gene exchange – populations that are near-by would be expected to exchange genes, but those on the geographic extremes are not exchanging genes. This clade forms a larger clade with additional lineages, including the Genbank reference specimen of *Nedsia* sp. 1, allowing us to assign the lineages to the genus *Nedsia* with some confidence.

AMM001, AMM031 } AMM001 was detected in eight bores at Mesa H as well as previously at Dave's and Budgie bores in the Robe Valley. AMM031 was detected in bore 200 at Mesa H as well as Budgie bore. May correspond to one species of *Nedsia,* but relationships among the clade members requires further investigation.

AMM004 = one species from bores 87 and 200, detected previously in the Robe Valley.

Re. Report on the molecular systematics of additional subfauna from the Mesa H – Phases 4 -6

Dear Nicola,

Following is a summary of the results of the subfauna study we have completed on four additional taxonomic groups (Diplura, Isopoda, Pseudoscorpiones, Schizomids) collected during Mesa H phases 4 - 6. Fourteen distinct genetic lineages were detected among the four groups. Two of the 14 lineages have been detected previously in the Pilbara, whereas the remaining 12 are new, based on the material available for comparison.

Thanks once again for collaborating on this project with Helix. We hope we can continue to provide you with useful information, and feel free to contact us if you have any questions or would like to discuss the results in detail.

Sincerely,

Dr. Terrie Finston, Yvette Hitchen and Dr. Oliver Berry
Helix Molecular Solutions

Background and Objective

Thirty-five specimens of subfauna belonging to four taxonomic groups (Diplura, Isopoda, Pseudoscorpiones, Schizomida) were collected from Mesa H, phases 4 - 6 and sequenced for variation at the mitochondrial COI gene. The molecular data were assessed in order to determine the number of species present in each group and compare the results to those obtained during previous surveys that have been undertaken for the these groups elsewhere in the Pilbara.

Executive summary

- Thirty-five specimens from Mesa H belonging to four taxonomic groups (Diplura, Isopoda, Pseudoscorpiones, Schizomida) were sequenced for variation at the COI gene.
- Fourteen lineages were detected among the four groups.
- Two of the lineages have been detected previously in the Pilbara, whereas the remaining 12 appear to be new, based on the material available for comparison.

Methods

Thirty-five specimens of subfauna from four taxonomic groups (Diplura, Isopoda, Pseudoscorpiones, Schizomida) collected from Mesa H, phases 4 - 6 were sequenced for variation at the mitochondrial cytochrome oxidase subunit I gene (COI) using multiple pairs of primers (LCOI/HCO2, LCOI-long/HCO2-long, NemF1/NemR1 and LCOI/CIN2341.

Sequences were edited using GENEIOUS software (Drummond *et al.* 2011). Alignment was performed with CLUSTAL W (Thompson *et al*. 1994) using default parameters. Genetic distances between unique genetic sequences (haplotypes) were measured using uncorrected p-distances (total percentage of nucleotide differences between sequences).

MODELTEST software (Posada and Crandall, 1998) was used to determine the model of sequence evolution that best fitted the data for each taxonomic group. Bayesian analysis was used to construct the phylogenetic trees, incorporating the model as identified in MODELTEST for each taxonomic group. The phylogeny, branch lengths and posterior probabilities were obtained by running two trees simultaneously, each running four simultaneous MCMC chains. The number of cycles needed was determined by the standard deviation of the split frequencies of the two trees. The analysis was paused after every 1 x 10^6 generations and when the standard deviation fell below 0.01, the analysis was stopped. A majority rule consensus tree was constructed after discarding the "burn-in" trees in both analyses. The burn-in value was determined by plotting the posterior probabilities obtained after every generation and identifying the point at which the values reach stationarity (= the asymptote). Trees produced prior to stationarity were discarded.

For the purposes of this report, lineages were defined as haplotypes or groups of haplotypes differing from other such groups by >3% sequence divergence. This cut-off was selected based on bar-coding data, which indicates that intra-specific variation rarely exceeds 3% (Hebert et al., 2003b).

We are currently developing a consistent and unique lineage and species naming system, so all lineages from previous phases will be consolidated in this report to aid in comparisons between phases.

Isopoda

Preliminary analysis, reference specimens and outgroups

Twenty specimens of Isopoda were sequenced from Mesa H phases 4 - 6 (Table 1). Ten of the 20 specimens yielded a DNA sequence; the remainder could not be amplified, despite trying three different primer pairs. A preliminary neighbour-joining analysis of the ten specimens revealed the presence of two distinct genetic groups (Figure 1). One group contained nine specimens from phase 6 and the second group contained a single specimen from phase 4 (Figure 1). A search of similar sequences on Genbank and in the Helix database indicated that the specimens from the first group were most closely matched with Armadillidae and the specimen from the second

group to the Philosciidae. Hence two separate phylogenic analyses were conducted; the first contained the one representative from the phase 6 Mesa H Armadillidae and included two Genbank voucher specimens of Armadillidae: *Troglarmadillo* sp. 6 (Genbank accession # KX656276) and *Spherillo* sp. Kazaki , as well as 37 reference specimens of Armadillidae from previous surveys in the Pilbara. Two specimens of the isopod genus *Haloniscus, Haloniscus* sp. 10 (Genbank accession #EU364592) and *Halonsicus* sp. 12 (Genbank accession #EU364601) were used as outgroups.

The second analysis contained the single specimen of Philosciidae from phase 4 and included GenBank voucher specimens of *Halonsicus* sp. 21 (Genbank accession #EU364622), *Haloniscus* sp. 10 (Genbank accession #EU364592), *Halonsicus* sp. 12 (Genbank accession #EU364601), which are assigned by different authours to either the Philosciidae or the Onisceidae and *Laevophiloscia yalgoorensis* (Genbank accession #EU364629) from the family Philosciidae, as well as 19 specimens of Philosciidae from previous surveys in the Pilbara. Two specimens of Armadillidae, *Armadillidium nasatum* (Genbank accession # FN824099) and *Troglarmadillo* sp. 6 (Genbank accession # KX656276) were used as outgroups.

Phylogenetic analysis

The phylogenetic analysis of the Armadillidae, which included the representative specimen from Mesa H (KU23), in addition to 39 reference specimens, placed the Mesa H specimen in a single distinct lineage (Figure 2). The lineage did not contain any of the reference specimens, so was assigned to the new lineage ISA057, however, specimen KU23 did form a well-supported clade with reference specimen KD23 from the Robe Valley, and the Genbank voucher specimen of *Spherillo* from Japan (Figure 2).

The phylogenetic analysis of the Philosciidae, which included the specimen from Mesa H (KE01), in addition to 23 reference specimens, placed the Mesa H specimen in a single distinct genetic lineage (Figure 3). The lineage did not contain any of the reference specimens, so was assigned to the new lineage ISP055, however, specimen KE01 did form a well-supported clade with reference specimen JF45 from a previous survey at Mesa H (Figure 3).

Differentiation within and between lineages

Specimens within the Mesa H lineage of Armadillidae differed from one another by 0.1% mean sequence divergence (Table 2). Specimen KU23 differed from the nearest reference specimen, KD23, by 4.5% sequence divergence and from the Genbank specimen of *Spherillo* by 6.1% sequence divergence (Table 3). Specimen KU23 differed from the remaining reference specimens by >30% sequence divergence (Table 3).

The Mesa H lineage of Philosciidae differed from the nearest reference specimen, JF45 from a previous survey at Mesa H, by 5.1% sequence divergence and from the remaining reference specimens by >15% sequence divergence (Table 4).

Diplura

Reference specimens and outgroups

Five specimens of Diplura from Mesa H phases 4 – 6 were sequenced for COI (Table 5). The four specimens for which sequences were obtained were analysed with 36 specimens of Diplura from the Pilbara belonging to five families: Anajapygidae, Campodeiidae, Japygidae, Parajapygidae and Projapygidae, as well as five Genbank voucher specimens, Diplura sp. (Genbank accession #HQ943342), *Japyx solifugus* (Japygidae; Genbank accession #AY771989) *Campodea tillyardi* (Campodeidae; Genbank accession # AF370844), *Lepidocampa weberi* (Campodeidae: Genbank accession #HQ882832) and *Parajapyx pauliani* (Genbank accession # JQ692327). The planthopper *Lycorma delicatula* (Genbank accession # FJ456942) and a specimen of Fulgoridae (Hemiptera; Genbank accession #GU671563) were used as outgroups.

Phylogenetic analysis

The phylogenetic analysis, which included the four specimens of Diplura from Mesa H, in addition to 41 reference specimens, placed the Mesa H specimens in four distinct lineages

(Figure 4). The four lineages were placed in three well-supported clades containing Genbank and Pilbara reference specimens of Japygidae (one lineage), Projapygidae (two lineages) and Parajapygidae (three lineages; Figure 4). None of the four Mesa H specimens were placed in lineages containing reference specimens, and thus were assigned to the new lineages DJA011, DPR010, DPR011 and DPA009 for KE04, KU01, KU02 and KU08, respectively (Figure 4). However, one, DPR011, was placed in a well-supported clade that also contained reference specimen JF40 from a previous survey at Mesa H (Figure 4).

Differentiation within and between lineages

The four lineages of Diplura from Mesa H phases 4 - 6 differed from one another by between 16.4 and 27.0% sequence divergence (Table 6). The four lineages differed from the nearest reference specimens by between 3.6 and 15.5% sequence divergence (Table 6). Specifically, DPR011 (KU02) differed from specimens JF40 and JF38 from a previous survey at Mesa H by 3.6% and 5.1% sequence divergence, respectively (Table 6). In contrast, the remaining lineages detected at Mesa H (DPR010, DPA009 and DJA011) differed from the nearest reference specimens by >12% (Table 6).

Pseudoscorpions

Reference sequences and outgroups

Five pseudoscorpions from phases 4 – 6 were sequenced from Mesa H (Table 7). A search of similar sequences on Genbank and in the Helix database indicated that one of the specimens most closely matched reference specimens of Chthoniidae, two of the specimens most closely matched reference specimens of Olpiidae and two of the specimens most closely matched reference specimens of Hyiidae. Based on those results, three separate phylogenetic analyses were conducted, one for each family. In addition, specimens of Atemnidae were analysed with the Olipiidae, because Atemnidae were detected in a previous survey at Mesa H.

For the Hyiidae, one GenBank voucher sequence of Hyiidae, *Indohya* sp JM 2008 (Genbank accession # EU559564) and 27 specimens of Hyiidae from previous surveys in the Pilbara were included in the analysis.

For the Olpiidae and Atemnidae, two Genbank voucher specimens of Olpiidae, *Beierolpium bornemisszai* (Genbank accession # EU559545) and *Calocheiridius termitophilus* (Genbank accession #EU559544) and two Genbank vouchers of Atemnidae, *Paratemnoides sumatranus* (Genbank accession # JN018204) and *Paratemnoides elongates* (Genbank accession #JQ040543) as well as 13 and four specimens from the Pilbara, respectively were included in the analysis.

For the Chthoniidae, a reference dataset of 76 Genbank and Pilbara specimens was reduced to a more manageable and relevant dataset by selecting only the 40 reference specimens that occurred in the same clades as the phase 4 – 6 specimens, based on a preliminary neighbour joining analysis. Two Genbank voucher sequences of Chthoniidae were included in the analysis, *Paraliochthonius* sp JM 2008 (Genbank accession #EU5595505) and *Tyrannochthonius aridus* (GenBank accession # KJ659959 from Western Australia) and in addition, as local references, 38 specimens of Chthoniidae from previous surveys in the Pilbara. Sequences of the scorpion *Pandinus imperator* (Genbank accession # AY1565821) and harvestman spider *Siro rubens* (Genbank accession # DQ5131111) were used as outgroups.

Phylogenetic analyses

The phylogenetic analysis of the Hyiidae, which included one specimen from Mesa H phase 4 (KE03) and one from phase 6 (KU28), in addition to 28 reference specimens of Hyiidae, placed the Mesa H specimens in two distinct genetic lineages, neither of which contained reference specimens (Figure 5). KE03 therefore was assigned to the new lineage PH026 and KU28 was assigned to the new lineage PH027 (Figure 5). KE03/PH026 formed a well-supported clade with specimens IV206 and IV209 from the Robe Valley (lineage PH001) and KU28 formed a well-supported clade with specimen JF56 (lineage PH017) from a previous survey at Mesa H and IV213 (lineage PH007) from the Robe Valley (Figure 5).

The phylogenetic analysis of the Olpiidae, which included the two specimens from Mesa H phase 5 (KU03, KU06), in addition to 15 reference specimens, placed the Mesa H specimens in two distinct genetic lineages, neither of which contained reference specimens (Figure 6). KU03 therefore was assigned to the new lineage PO014 and KU06 was assigned to the new lineage PO015 (Figure 6). KU03/PO014 and KU06/PO015 formed a well-supported clade with one another and two specimen of *Beierolpium :* specimen BQ20 from Wonmunna and the Genbank voucher specimen of *Beierolpium bornemisszai* (Figure 6).

The phylogenetic analysis of the Chthoniidae, which included the one Chthoniidae specimen from Mesa H phase 6 (KU29), in addition to 40 reference specimens, placed the Mesa H specimen in a distinct genetic lineage that did not contain any reference specimens (Figure 7). KU29 was therefore assigned to the new lineage PC055 (Figure 7). However the lineage showed significant although distant relationships with some reference specimens (Figure 7). Specifically, specimen KU29/PC055 formed a well-supported clade with specimens JU05, JU06 and JU08 from a previous survey at Mesa H and specimens IV210, IV268, IV269 and KD27, from previous surveys at Mesas A and B in the Robe Valley (Figure 7).

Differentiation within and between lineages

The two specimens of Hyiidae from Mesa H (KE03 and KU28) differed from one another by 24.9% sequence divergence (Table 8). Specimen KE03 differed from the nearest reference specimens IV206 and IV209 by 7.3 sequence divergence (Table 8). Specimen KU28 differed from the nearest reference specimens JF56 from Mesa H and IV213 from the Robe Valley by 4.0 and 7.1% sequence divergence, respectively (Table 8).

The two specimen of Olpiidae from the Mesa H (KU03 and KU06) differed from one another by 17.0% sequence divergence and from the reference specimens of *Beierolpium* (*B. bornemisszai* and BQ20) by between 16.6 and 23.8% sequence divergence (Table 9).

The specimen of Chthoniidae from Mesa H (KU29) differed from the nearest references (three specimens from a previous survey at Mesa H, JU05, JU06, JU08 and four specimens from Mesa A and B in the Robe Valley, IV210, IV268, IV269, KD27) by more than 16% sequence divergence (Table 10).

Schizomida

Preliminary analysis - Reference sequences and outgroups
Five schizomids from phases 4 – 6 were sequenced from Mesa H (Table 11). The specimens were analysed with >700 reference sequences of schizomids from previous surveys in the Pilbara to compile a manageable and relevant reference data set. The reference sequences were selected based on the criteria that they showed ≤ 15% sequence divergence from at least one of the Mesa H lineages. A reference dataset of 28 reference specimens was selected, 20 from previous surveys in the Pilbara and eight Genbank voucher sequences as follows: *Paradraculoides anachoretus* (Genbank accession # EU272709), *Paradraculoides eremius* (Genbank accession # KU291135), *Paradraculoides* sp. (Genbank accession # EU272697), *Paradraculoides bythius* (Genbank accession # EU272715), *Paradraculoides gnophicola* (Genbank accession # EU272716), *Paradraculoides kryptus* (Genbank accession # EU272724), *Draculoides vinei* (Genbank accession # EU272694), *Draculoides julianneae* (Genbank accession # EU272696) A specimen of schizomid from the family Hubbardiidae, *Brignolozomus woodwardi* (GenBank accession # EU272675) was used as an outgroup.

Phylogenetic analysis
The phylogenetic analysis, which included the five Mesa H specimens, in addition to 28 selected reference specimens of schizomids, placed the Mesa H specimens in three distinct lineages, two of which also contained reference specimens from previous surveys at Mesa H and the Robe Valley (Figure 8). Thus two of the specimens (KE02, KU30) were assigned to the existing lineage SCH038 and two (KU04, KU05) were assigned to the existing lineage SCH015 (Figure 8). The last

specimen KU3, was placed in a lineage that did not contain any reference specimens and thus was assigned to the new lineage SCH039 (Figure 8). Lineages SCH038 and SCH039 were placed in a well-supported clade containing the six Genbank reference specimens of *Paradraculoides* (Figure 8). Lineage SCH015 was placed in a clade that was distinct from both the *Paradraculoides* and *Draculoides* clades (Figure 8).

Differentiation within and between lineages
The five specimen of schizomids detected at Mesa H differed from one another by between 0 and 13.0% sequence divergence (Table 12). The two specimens in lineage SCH038 (KE02, KU30) differed from one another by 2.4% sequence divergence and the two specimens in lineage SCH015 (KU04, KU05) were genetically identical (Table 12).

Two of the lineages differed from the closest reference specimens by <3% sequence divergence (Table 12). Specifically, specimens KE02 and KU30 (lineage SCH038) differed from reference specimen JF48 by 0.8% sequence divergence but from the next nearest reference specimens (IT67 and HE12) by >10% (Table 12). Specimens KU04 and KU05 differed from the nearest reference specimens JF50 and GH11 by 2.1% and 2.7%, respectively, and from JU03 by 4.3% sequence divergence (Table 12). Specimens KU04 and KU05 differed from the remaining reference specimens by >12% sequence divergence (Table 12).

Conclusions
COI is widely considered to show suitable variation to distinguish species (Hebert et al., 2003a). In a comparison of COI sequences for over 13,000 pairs of taxa, Hebert et al (2003b) found a mean of 11.1% sequence divergence between distinct species. Nearly 80% of the comparisons showed that species pairs differed from one another by greater than 8% sequence divergence. However, a taxon by taxon approach, examining the amount of phylogenetic variation within and between species is the most widely accepted method of defining species.

<u>Isopoda</u>
Two distinct genetic lineages of Isopoda were detected at Mesa H, one of which was most similar to reference specimens of Armadillidae, and one of which was most similar to reference specimens of Philosciidae. Both lineages were assigned to new lineages, ISA057 and ISP055, respectively, because they differed from the reference lineages by > 3%.

While each is a new lineage, the Mesa H lineages did show moderately close relationships to reference specimens, which require further consideration. The Mesa H Armadillidae lineage ISA057 differed from a reference specimen at Mesa C by 4.5% sequence divergence and from the *Spherillo* specimen from Japan by 6.1%. These values are greater than the intraspecific variation generally observed within Isopoda lineages (<1%; Hutchins, 2007; Finston et al., 2009), however, given the geographic distance between sites where this clade was detected, this could represent a pattern of genetic diversity associated with geographic distance. Sampling intermediate sites may help determine whether there is a sharp break between haplotypes (this might indicate the presence two different species) or if there is a gradual shift from one haplotype to the next over that geographical space (this would suggest connectivity among populations and imply that we are observing variation within a single species). It is worth nothing that lineage ISA057 (KU23) was highly divergent from the remaining reference specimens of Armadillidae, so it is only tentatively placed in that family, however, it was most closely related to Armadillidae in both the Helix and GenBank databases.

Mesa H Philosciidae lineage ISP055 differed from reference specimen JF45 from a previous survey at Mesa H by 5.1%. In contrast to the Armadillidae, this level of genetic variation is detected over a relatively short geographic distance – both samples were taken from Mesa H. This would suggest a lack of gene flow between populations despite being geographically close, and may indicate the presence of two recently-separated but distinct species. Again, sampling of intermediate areas may help resolve this relationship.

Armadillidae

ISA057 = new lineage; species likely to have been detected previously at Mesa C but requires further investigation.

Philosciidae
ISP055 = new lineage; species may be new but requires further investigation

Diplura
Four distinct genetic lineages of Diplura were detected at Mesa H, one of which was most similar to reference specimens of Japygidae, two of which were most similar to reference specimens of Projapygidae, and one of which was most similar to reference specimens of Parajapygidae. All four lineages were assigned to new lineages, DJA011, DPR010, DPR011 and DPA009, because they differed from the reference lineages by > 3%.

While each is a new lineage, one Mesa H lineage did show a moderately close relationship to a reference specimen, which requires further consideration. The Mesa H Projapygidae lineage DPR011 differed from reference specimen JF40 from a previous survey at Mesa H by 3.6% sequence divergence and from JF38 by 5.1% sequence divergence. These values are greater than the intraspecific variation normally observed within Diplura lineages (mean = 1.9% for species in the genus *Japyx*; Bu et al, 2012). This would suggest limited gene flow between populations in this clade despite being geographically close, although we may be observing a 'stepping-stone' pattern of genetic diversity, where nearby populations exchange genes, whereas those at the extreme ends of the continuum do not. Again, sampling of intermediate areas may help resolve this relationship.

Japygidae
DJA011= new lineage; new species

Parajapygidae
DPA009= new lineage, new species

Projapygidae
DPR010= new lineage, new species
DPR011= new lineage; species may have been detected previously at Mesa H, but requires further investigation

Pseudoscorpiones

Five distinct genetic lineages of pseudoscorpions were detected at Mesa H phases 4 - 6: one Chthoniidae, two Olpiidae and two Hyiidae.

The two lineages of Hyiidae detected at Mesa H (PH026 and PH027) differed from one another by 24.9% sequence divergence, indicating that they represent two distinct species. While both lineages were new, differing from the reference specimens by >3% sequence divergence, one, PH027, is likely to belong to a species that has been detected previously at Mesa H, differing from reference specimen JF56 (lineage PH017) by 4.0% sequence divergence. This level of genetic differentiation however, indicates that gene flow may be low between sampling sites, perhaps owing to the poor dispersal ability of the taxon or geographic barriers. Lineages PH027 and PH017 in turn form a well-supported clade with specimen IV213 (lineage PH007) from the Robe Valley. The three specimens differ from one another by between 6.9 and 7.1% sequence divergence. This suggests that while closely related, the Robe Valley lineage is likely to represent a distinct species from the Mesa H lineage, although sampling intermediate sites may help resolve relationships between these lineages.

The second lineage of Hyiidae, PH026, formed a relatively close relationship with lineage PH003 (specimens IV206 and IV209) from the Robe Valley, forming a well-supported clade, and differing by 7.3% sequence divergence. Distances between specimens assigned to the same species in previous studies in the Pilbara (i.e. PC047, PH002) differ by ≤ 2.0%, so the distance between PH026 and PH003 is higher than appears typical for the Pseudoscorpiones. This suggests that while closely related, the two lineages are likely to represent distinct species, although sampling intermediate sites may help resolve relationships between these lineages.

The two lineages of Olpiidae detected at Mesa H, PO014 and PO015, represent both new lineages and new species, as they differed from the nearest reference specimens by >16% sequence divergence. However, we can tentatively assign both lineages to the genus *Beierolpium*, as PO014 and PO015 were both placed in a clade containing reference specimens of that genus.

The lineage of Chthoniidae detected at Mesa H, PC055, represents both a new lineage and a new species, as it differed from the nearest reference specimens by >16% sequence divergence.

Hyiidae
PH026 = new lineage, new species
PH027 = new lineage, species detected previously at Mesa H

Olpiidae
PO014 = new lineage, new species of *Beierolpium*
PO015 = new lineage, new species of *Beierolpium*

Chthoniidae
PC055 = new lineage, new species

Schizomida
Previous analyses of genetic variation between morphologically distinct species of Schizomida can be used as a genetic 'yardstick' to interpret the current data set. The five described species of *Paradraculoides* (Harvey et al, 2008) differ from one another by between 8.4 to 12.1% sequence divergence (uncorrected p-distances; calculated by us from the Harvey et al., 2008 data). Similarly, the four described species of *Draculoides* differ from one another by between 4.5 to 13.7% sequence divergence (uncorrected p-distances calculated by us from Harvey et al., 2008).

Three lineages of Schizomida were detected at Mesa H, phases 4 – 6, two *Paradraculoides* (SCH038, SCH039), and one not assigned to a family (SCH015). Two of the lineages (SCH015, SCH038) have been detected previously at Mesa H and in the Robe Valley, whereas one (SCH039) is new.

One of the *Paradraculoides* lineages, SCH038, is a lineage and species that has been detected previously at Mesa H, however, the new lineage, SCH039, likely represents a new species, as it differs from the nearest reference specimen by >7%. However, this level of sequence divergence is only moderate, and the nearest reference specimen was collected in Buckland Hills, thus sampling intermediate sites may resolve the relationship between these two lineages.

The lineage that we could not assign to a family (SCH015) has been detected previously at Mesa H and a second site in the Robe Valley. It does not appear to belong to *Draculoides*, *Paradraculoides* or *Bamazomus* (*Bamazomus* not shown), as it was placed in a clade that was distinct from the clades of these families. A closely related lineage (SCH016) was detected during a previous survey at Mesa H. Lineages SCH015 and SCH016 differ from one another by 4.3% and are likely to represent the same species, however, this level of divergence is somewhat elevated, given that the two lineages were both collected at Mesa H. This suggests there may be a barrier to gene flow at Mesa H between RC16JIM and RC15MEH.

Paradraculoides
SCH038 = lineage and species detected previously at Mesa H
SCH039 = new lineage, new species

Unknown family
SCH015 lineage and species detected previously at Mesa H and the Robe Valley

Re. Report on the molecular systematics of subfauna from Mesa H, phase 2 (Biota job 1146B)

Dear Penny,

Following is a summary of the results of the subfauna study we have completed on the additional specimens from Mesa H from four taxonomic groups (Diplura, Pseudoscorpiones, Scolopendrida and Schizomida). Six distinct genetic lineages from the four taxonomic groups were detected. The six lineages likely represent five species. None of the species appear to have been detected previously in the Pilbara, based on the material available for comparison, although the species of Schizomida is closely related to a species detected previously at Mesa H and Pannawonica.

Thanks once again for collaborating on this project with Helix. We hope we can continue to provide you with useful information, and feel free to contact us if you have any questions or would like to discuss the results in detail.

Sincerely,

Dr. Terrie Finston, Yvette Hitchen and Dr. Oliver Berry
Helix Molecular Solutions

Background and Objective

Eight specimens of subfauna (belonging to four taxonomic groups (Diplura, Pseudoscorpiones, Scolopendrida, and Schizomida) were collected from Mesa H and sequenced for variation at the mitochondrial COI gene. The molecular data were assessed in order to determine the number of species present in each group and compare the results to those obtained during previous surveys that have been undertaken for the these groups in the in the Pilbara.

Executive summary

- Eight specimens from Mesa H belonging to four taxonomic groups were sequenced for variation at the COI gene.
- Six lineages were detected among the four groups.
- The six lineages likely represent five species.
- None of the species appear to have been detected previously in the Pilbara, based on the material available for comparison, although the species of Schizomida is closely related to a species detected previously at Mesa H and Pannawonica.

Methods

Eight specimens of subfauna collected from Mesa H were sequenced for variation at the mitochondrial cytochrome oxidase subunit I gene (COI) using primers LCOI/HCO2 and LCOI/CIN2341.

Sequences were edited using GENEIOUS software (Drummond *et al.* 2011). Alignment was performed with CLUSTAL W (Thompson *et al*. 1994) using default parameters. Genetic distances between unique genetic sequences (haplotypes) were measured using uncorrected p-distances (total percentage of nucleotide differences between sequences).

MODELTEST software (Posada and Crandall, 1998) was used to determine the model of sequence evolution that best fitted the data for each taxonomic group. Bayesian analysis was used to construct the phylogenetic trees, incorporating the model as identified in MODELTEST for each taxonomic group. The phylogeny, branch lengths and posterior probabilities were obtained by running two trees simultaneously, each running four simultaneous MCMC chains. The number of cycles needed was determined by the standard deviation of the split frequencies of the two trees. The analysis was paused after every 1 x 10^6 generations and when the standard deviation fell below 0.01, the analysis was stopped. A majority rule consensus tree was constructed after discarding the "burn-in" trees in both analyses. The burn-in value was determined by plotting the posterior probabilities obtained after every generation and identifying the point at which the values reach stationarity (= the asymptote). Trees produced prior to stationarity were discarded.

For the purposes of this report, lineages were defined as haplotypes or groups of haplotypes differing from other such groups by >3% sequence divergence. This cut-off was selected based on bar-coding data, which indicates that intra-specific variation rarely exceeds 3% (Hebert et al., 2003b).

Results

Diplura

Reference specimens and outgroups

Two specimens of Diplura from two drillholes at Mesa H were sequenced (Table 1). The two specimens were analysed with 30 specimens of Diplura from the Pilbara belonging to four families: Anajapygidae, Japygidae, Parajapygidae and Projapygidae, as well as four Genbank voucher specimens, Diplura sp. (Genbank accession #HQ943342), *Japyx solifugus* (Japygidae; Genbank accession #AY771989) *Campodea tillyardi* (Campodeidae; Genbank accession # AF370844), *Lepidocampa weberi* (Campodeidae: Genbank accession #HQ882832). The planthopper *Lycorma delicatula* (Genbank accession # FJ456942) and a specimen of Fulgoridae (Hemiptera; Genbank accession #GU671563) were used as outgroups.

Phylogenetic analysis

The phylogenetic analysis, which included the two specimens of Diplura from Mesa H, in addition to 34 reference specimens, placed the Mesa H specimens in two distinct lineages (Figure 1). The Mesa H specimens showed no close relationship to any of the reference specimens, and thus were assigned to the new lineages DU and DV for JU01 and JU02, respectively (Figure 1). However, one, DU, was placed in a well-supported clade containing the Pilbara and GenBank reference specimens of Japygidae, while DV was placed in a well-supported clade containing the Pilbara and GenBank reference specimens of Campodeidae (Figure 1).

Differentiation within and between lineages

The two lineages of Diplura differed from one another by 25% sequence divergence (Table 2). DU (JU01) differed from the reference specimens by between 16.2 and 27.2% sequence divergence (Table 2). DV (JU02) differed from the reference specimens by between 23.5 and 28.6% sequence divergence (Table 2).

Distribution of lineages

Lineages DU and DV were each detected in single drillholes.

Pseudoscorpiones

Reference sequences and outgroups

Four pseudoscorpions were sequenced from three drillholes at Mesa H (Table 1). In order to reduce analysis time and to simplify the presentation of results, a preliminary search of similar sequences on Genbank and in the Helix database indicated that the specimen most closely matched specimens in the family Chthoniidae. Based on those results, GenBank voucher sequences were included as references as follows: four sequences belonging to three genera of Chthoniidae: *Tyrannochthonius* sp JM 2008 (Genbank accession # EU559506) from South America (Columbia), *Lagynochthonius johni* (Genbank accession # EU559503; from Indonesia), *Austrochtonia* sp JM 2008 (Genbank accession # EU559513; from Australia) and *Tyrannochthonius aridus* (GenBank accession # KJ659959 from Western Australia). As local references, 27 specimens of Chthoniidae from 12 sites in the Pilbara (Helix, 2012) were included in the analysis. Sequences of the scorpion *Pandinus imperator* (Genbank accession # AY1565821) and harvestman spider *Siro rubens* (Genbank accession # DQ5131111) were used as outgroups.

Phylogenetic analyses

The phylogenetic analysis, which included the four specimens from Mesa H, in addition to 31 reference specimens, placed the Mesa H specimens in two distinct genetic lineages that formed a well-supported clade (Figure 2). The Mesa H lineages did not show a close relationship to any of the Pilbara reference specimens, and were assigned to the new lineages P14 and P15; however they formed a well-supported clade with a specimen from the Highway and Tod bore deposit in the Robe Valley (Figure 2). Specimens assigned to *Tyrannochthonius* and *Lagynochthonius* on the basis of morphology did not form monophyletic clades (Figure 2).

Differentiation within and between lineages

The two lineages of pseudoscorpion from Mesa H differed from one another by 3.0% mean sequence divergence. The three specimens within lineage P14 differed from one another by 0.1% mean sequence divergence. Mesa H lineages P14 and P15 differed the reference specimens by between 13.3 and 28.0% and 13.6 and 28.8% sequence divergence, respectively (Table 3).

Distribution of lineages

The Mesa H pseudoscorpion lineage P14 was detected in two drillholes: RC15MEH0315 and GR15MEH0015, and lineage P15 was detected in one drillhole, RC15MEH0335.

Schizomids

Preliminary analysis - Reference sequences and outgroups

One schizomid was sequenced from drillhole RC12MEH0221 at Mesa H (Table 1). In order to reduce analysis time and to simplify the presentation of results, a preliminary neighbour-joining (NJ) analysis was conducted with the new Mesa H specimen and >500 reference sequences of schizomids from previous surveys in the Pilbara to compile a manageable and relevant reference data set. The reference sequences were selected based on the criteria that they showed ≤ 15% sequence divergence from the Mesa H lineage. In addition, representatives of the five described species of *Paradraculoides* and the four described species of *Draculoides* were included in the analysis. Two specimens of schizomids from the family Hubbardiidae, *Brignolozomus woodwardi* (GenBank accession # EU272675) and Bamazomus sp. (GenBank accession # EU272676) were used as outgroups.

Phylogenetic analysis
The phylogenetic analysis, which included the single Mesa H specimen, in addition to 11 reference specimens of schizomids, placed the Mesa H specimen in a distinct lineage within a well-supported clade containing reference specimens from previous surveys at Mesa H and Pannawonica (Figure 3). It was assigned to the new lineage SCH016 (Figure 3).

Differentiation within and between lineages
The Mesa H specimen differed from the closest reference specimens (JF50 and GH11, from Mesa H and Pannawonica, respectively) by 5.2% and 5.3% sequence divergence (Table 4).

Distribution of lineages
The new Mesa H specimen was detected in drillhole RC12MEH0221.

Scolopendrida

One specimen of Scolopendrida from Mesa H was sequenced (Table 1). A search of similar sequences on GenBank and the Helix database indicated that the specimen belongs to the family Cryptopidae, thus the specimen was analysed with a Genbank vouchers of Cryptopidae as follows: Cryptops japonicas (Genbank accession # AB610778 as well as 15 reference specimens of Cryptopidae from nine sites in the Pilbara. Two specimens of Onychophora, *Metaperipatus inae* (Genbank accession # HQ453464) and *Opisthopatus cinctipes* (Genbank accession #NC014273) were used as outgroups.

Phylogenetic analysis

The phylogenetic analysis, which included the specimen from Mesa H, in addition to 16 reference specimens, placed the Mesa H specimen in a genetically distinct lineage and thus was assigned to the new lineage SC18 (Figure 4). The specimen formed a well-supported clade with the Genbank specimen of *Cryptops japonicas* as well as reference specimens from the Pilbara assigned to the genus *Cryptops* (Figure 4).

Differentiation within and between lineages

The Mesa H lineage of Scolopendrida differed from the reference specimens by between 16.4 and 22.8% sequence divergence (Table 5).

Distribution of lineages

The Mesa H lineage of Scolopendrida was detected at drillhole RC14MEH0388.

Conclusions
COI is widely considered to show suitable variation to distinguish species (Hebert et al., 2003a). In a comparison of COI sequences for over 13,000 pairs of taxa, Hebert et al (2003b) found a mean of 11.1% sequence divergence between distinct species. Nearly 80% of the comparisons showed that species pairs differed from one another by greater than 8% sequence divergence. However, a taxon by taxon approach examining the amount of phylogenetic variation within and between species is the most widely accepted method of defining species.

Diplura

Two distinct lineages of Diplura were detected at Mesa H, representing two species, owing to the high level of sequence divergence between them. Lineage DU belongs to the Japygidae, however it differed from the nearest reference specimens by >16% sequence divergence, indicating that it is likely to belong to a new species, which has so far not been detected in the Pilbara, based on the material available for comparison. Lineage DV may belong to the Campodeidae, but differs from the nearest reference specimen by >20% and in the phylogenetic analysis, was the most external branch in the Campodeidae clade. Thus it is only tentatively assigned to this family, until further reference sequences become available. The large sequence divergence between it and the reference specimens indicates that it is a new species, which has so far not been detected in the Pilbara, based on the material available for comparison.

Pseudoscorpiones

Two lineages, of Pseudoscorpiones, P14, P15, were detected at Mesa H, differing from one another by 3% mean sequence divergence. The two lineages belong to the family Chthoniidae and are likely to represent a single species, showing genetic divergence owing to their occurrence in different drillholes and poor dispersal abilities of the taxon. The species differs from the reference specimens by >13% sequence divergence, and hence is likely to be a new species based on the material available for comparison. The taxonomy of the Chthoniidae is in need of revision (M. Harvey, pers. comm.), so we did not attempt to place the Mesa H specimen into a genus.

Schizomida

Previous analyses of genetic variation between morphologically distinct species of Schizomida can be used as a genetic 'yardstick' to interpret the current data set. The five described species of *Paradraculoides* (Harvey et al, 2008) differ from one another by between 8.4 to 12.1% sequence divergence (uncorrected p-distances; calculated by us from the Harvey et al., 2008 data). Similarly, the four described species of *Draculoides* differ from one another by between 4.5 to 13.7% sequence divergence (uncorrected p-distances calculated by us from Harvey et al., 2008).

One lineage of schizomid was detected at Mesa H, SCH016. The lineage was placed in a clade with specimens from a previous survey at Mesa H and the Pannawonica area. It shows a moderately low level of sequence divergence from these reference specimens (approximately 5%), but more than is usually detected between species of schizomids as described above. Thus it may represent a new species, however sampling of intermediate sites and or morphological data are needed to confirm the relationship between these specimens. We cannot assign the specimen to a genus, as it was placed outside the clade containing the reference specimens of both *Draculoides* and *Paradraculoides*.

Scolopendrida

A single genetically distinct lineage of Scolopendrida, SC18, was detected at Mesa H, likely belonging to the family Cryptopidae. The lineage differed from the nearest reference specimen by >15% sequence divergence, and is likely to be a new species, based on the material available for comparison.

Summary

Six lineages from four taxonomic groups (Diplura, Pseudoscorpiones, Scolopendrida, Schizomida) were detected at Mesa H, as summarised below. The six lineages likely represent five species. None of the species appear to have been detected previously in the Pilbara, based on the material available for comparison, although the species of Schizomida is closely related to a species detected previously at Mesa H and Pannawonica.

Diplura

Two lineages of Diplura were detected at Mesa H, one Japygidae and one Campodeidae. The lineages differed from the reference specimens by >15% sequence divergence, and hence both are likely to be new species, based on the material available for comparison.

Pseudoscorpiones
Two lineages of Pseudoscorpiones were detected at Mesa H, belonging to the family Chthoniidae. They likely represent a single species, which appears to be new, based on the material available for comparison.

Schizomida
A single lineage was detected at Mesa H, corresponding to a single species. The lineage likely cannot be placed in a genus. The species is similar to one detected previously at Mesa H and Pannawonica, however shows enough genetic divergence from these reference specimens to warrant further investigation.

Scolopendrida
A single genetically distinct lineage of Scolopendrida was detected at Mesa H, likely belonging to the family Cryptopidae. The lineage differed from the nearest reference specimen by >15% sequence divergence, and is likely to be a new species, based on the material available for comparison.

Re. Report on the molecular systematics of additional subfauna from Mesa H

Dear Nicola,

Following is a summary of the results of the subfauna study we have completed on three additional taxonomic groups (Blattodea, Coleoptera, Thysanura) collected at Mesa H. Eight distinct genetic lineages were detected among the three groups. Two of the eight lineages have been detected previously in the Pilbara, whereas the remaining six are new, based on the material available for comparison.

Thanks once again for collaborating on this project with Helix. We hope we can continue to provide you with useful information, and feel free to contact us if you have any questions or would like to discuss the results in detail.

Sincerely,

Dr. Terrie Finston, Yvette Hitchen and Dr. Oliver Berry
Helix Molecular Solutions

Background and Objective

Twenty-two specimens of subfauna belonging to three taxonomic groups (Blattodea, Coleoptera, Thysanura) were collected from Mesa H and sequenced for variation at the mitochondrial COI or 12s gene. The molecular data were assessed in order to determine the number of species present in each group and compare the results to those obtained during previous surveys that have been undertaken for these groups elsewhere in the Pilbara.

Executive summary

- Twenty-two specimens of subfauna belonging to three taxonomic groups (Blattodea, Coleoptera, Thysanura) were collected from Mesa H and sequenced for variation at the mitochondrial COI or 12s gene
- Eight lineages were detected among the three groups
- Two of the lineages have been detected previously in the Pilbara, whereas the remaining six appear to be new, based on the material available for comparison

Methods

Twenty-two specimens of subfauna belonging to three taxonomic groups (Blattodea, Coleoptera, Thysanura) were collected from Mesa H and sequenced for variation at the mitochondrial COI or 12s gene using multiple pairs of primers (LCOI/HCO2, LCOI /HCO-out, L2020/H2619 for COI and 12Sai/12SRJ for 12s).

Sequences were edited using GENEIOUS software (Drummond *et al.* 2011). Alignment was performed with CLUSTAL W (Thompson *et al*. 1994) using default parameters. Genetic distances between unique genetic sequences (haplotypes) were measured using uncorrected p-distances (total percentage of nucleotide differences between sequences).

MODELTEST software (Posada and Crandall, 1998) was used to determine the model of sequence evolution that best fitted the data for each taxonomic group. Bayesian analysis was used to construct the phylogenetic trees, incorporating the model as identified in MODELTEST for each taxonomic group. The phylogeny, branch lengths and posterior probabilities were obtained by running two trees simultaneously, each running four simultaneous MCMC chains. The number of cycles needed was determined by the standard deviation of the split frequencies of the two trees. The analysis was paused after every 1 x 10^6 generations and when the standard deviation fell below 0.01, the analysis was stopped. A majority rule consensus tree was constructed after discarding the "burn-in" trees in both analyses. The burn-in value was determined by plotting the posterior probabilities obtained after every generation and identifying the point at which the values reach stationarity (= the asymptote). Trees produced prior to stationarity were discarded.

For the purposes of this report, lineages were defined as haplotypes or groups of haplotypes differing from other such groups by >3% sequence divergence. This cut-off was selected based on bar-coding data, which indicates that intra-specific variation rarely exceeds 3% (Hebert et al., 2003b).

We are currently developing a consistent and unique lineage and species naming system, so all lineages from previous phases will be consolidated in this report to aid in comparisons between phases.

Results

Blattodea

Reference specimens and outgroups

Two specimens of Blattodea from two bores were sequenced from Mesa H (Table 1). A search of the reference database GenBank indicated that both specimens were most closely matched to the genus *Nocticola*. A reference database of 35 *Nocticola* specimens from previous surveys in the Pilbara were analysed with the specimens from Mesa H. Two Genbank reference specimens of *Nocticola* from the Pilbara were also included as references, *N. quartermaini* (Genbank accession #KU258365) and *N. cockingi* (Genbank accession #KU258378). Two specimens of the closely related Blattodea family Coryiidae, *Latindia* sp. 13

FL2015 (Genbank accession # KP986417) and *Eupoyphaga sinensis* (Genbank accession #NC014274) were used as outgroups.

Phylogenetic analysis

The phylogenetic analysis, which included the two specimens from Mesa H in addition to 37 reference specimens, placed the Mesa H specimens in two distinct lineages (Figure 2). Neither of those lineages contained reference specimens and thus were assigned to the new lineages BN020 and BN021 (Figure 2). Specimen MF01 (lineage BN020) formed a moderately well-supported clade with seven specimens of Nocticolidae from Western Hub, Red Hill and Buckland Hills (Figure 1). Specimen MF02 (lineage BN021), formed a clade with three specimens from the Central Pilbara, Buckland Hills and the Hamersley Range, however the relationship was not well-supported (Figure 1). The two lineages were placed in a large widespread clade containing the Genbank reference specimen *N. quartermaini* and reference specimens of *Nocticola* and Nocticolidae from the Pilbara (Figure 1).

Differentiation within and between lineages

The two Mesa H lineages of *Nocticola* differed from one another by 6.3% sequence divergence (Table 2). The Mesa H specimens of *Nocticola* differed from the reference specimens by between 4.2 and 8.1% sequence divergence (Table 2). Specifically, lineage BN020 differed from the nearest reference specimens at Western Hub, Red Hill and Buckland Hills by between 4.2 and 5.1% sequence divergence and lineage BN021 differed from the nearest reference specimens from the Central Pilbara, Buckland Hills and the Hamersely Range by between 5.0 and 6.0% (Table 2). Specimens in the large, widespread clade differed from one another by between 0.2 and 9.1% sequence divergence (Table 2).

Coleoptera

Reference specimens and outgroups

Eighteen specimens of Coleoptera from Mesa H were sequenced for COI (Table 1). In order to reduce analysis time and to simplify the presentation of results, a preliminary neighbour-joining (NJ) analysis was conducted on the Mesa H specimens in order to identify the number of lineages present. Four distinct genetic lineages were detected among the 16 specimens for which sequences were obtained (Figure 2). A representative of each lineage was compared to the GenBank sequence database. One lineage was most closely matched to reference specimens of Curculionidae and three lineages were most closely matched to reference specimens of Ptilidae. Thus, four haplotypes, representing the four lineages were analysed with 44 reference sequences of Curculionidae and Ptilidae, including 14 provided by the WAM and 30 from previous surveys in the Pilbara, including Mesas B and C. Two specimens of Coleoptera from the family Dermestidae, *Dermestes maculatus* (Genbank accession # HM909035) and *Dermestes frischii* (Genbank accession # KM578824) were used as outgroups.

Phylogenetic analysis

The phylogenetic analysis, which included the four specimens from Mesa H, in addition to 44 reference specimens, placed the Mesa H specimens in four distinct genetic lineages, two of which also contained reference specimens (Figure 3). Specifically one lineage contained reference specimens of Ptilidae sp. 1 from the WAM and one lineage contained reference specimens of Ptilidae from the Robe Valley, and thus were assigned to the existing lineages CP001 (Ptilidae sp. 1) and CP002 (Figure 3). The remaining two lineages did not contain reference specimens, and thus were assigned to the new lineages CP003 and CCU014 (Figure 3).

Differentiation within and between lineages

Differentiation within the four lineages of Coleoptera detected at Mesa H ranged from 0 to 1.6% mean sequence divergence (Table 3). The three lineages of Ptilidae from Mesa H differed from one another by between 4.6 and 15.9% mean sequence divergence (Table 4).

The one lineage of Curculionidae detected at Mesa H, CCU014, differed from the nearest reference specimens by ≥ 13.0% (Table 5).

The three lineages of Ptilidae differed from the reference specimens by between 1.6 and 16.1% sequence divergence (Table 6). In particular, lineage CP001 differed from the nearest reference specimens (WAM Ptilidae sp. 1) by 1.7% sequence divergence and lineage CP002 differed from the nearest reference specimens (IV44 – IV47) by 1.6% sequence divergence (Table 6). Lineage CP003 differed from the nearest reference specimens (WAM Ptilidae sp. 1) by 4.4% sequence divergence (Table 6).

Thysanura

Reference specimens and outgroups

Two specimens of Thysanura from Mesa H were sequenced for 12s (Table 1). A search of similar sequences on Genbank and in the Helix database indicated that the specimens most closely matched database specimens of the subfamily Nicoletiinae. Based on those results, GenBank voucher sequences were included as reference sequences of Nicoletiinae (two specimens) as follows: *Trinemura callawa* and *T. cundalin* (GenBank accession #JQ282164 and JQ282165, respectively). In addition, as local references, 43 specimens of Nicoletiinae were included in the analysis. A specimen of Atelurinae was used as an outgroup: *Atelura formicaria* (Genbank accession # EU084035).

Phylogenetic analyses

The phylogenetic analysis, which included the two new specimens from Mesa H, in addition to 45 reference specimens, placed the Mesa H specimens in two distinct genetic lineages, neither of which contained reference specimens, thus the two were assigned to the new lineages TN019 and TN020 (Figure 4). Mesa H lineage TN020 formed a well-supported clade with lineage TN011 from the Robe Valley, and lineage TN019 formed a clade with lineage TN008 from Christmas Creek, but the relationship was not well-supported (Figure 4).

Differentiation within and between lineages

Mesa H lineage TN019 differed from the nearest reference specimens (CQ8, CQ10) by >10% sequence divergence, and lineage TN020 differed from nearest reference specimen (IV334) by 7.2% sequence divergence (Table 7).

Conclusions

COI is widely considered to show suitable variation to distinguish species (Hebert et al., 2003a). In a comparison of COI sequences for over 13,000 pairs of taxa, Hebert et al (2003b) found a mean of 11.1% sequence divergence between distinct species. Nearly 80% of the comparisons showed that species pairs differed from one another by greater than 8% sequence divergence. However, a taxon by taxon approach, examining the amount of phylogenetic variation within and between species is the most widely accepted method of defining species.

Blattodea

Two distinct genetic lineages of Nocticolidae (Blattodea) were detected at Mesa H (BN020, BN021). The two lineages differed from one another by 6.3 % sequence divergence. This is generally more sequence divergence than would be expected within a single species, however, it suggests that the lineages are closely related and may represent incipient species or a species complex. Morphological evidence or sampling additional specimens from intermediate areas may help resolve this relationship. The two Mesa H lineages are placed within a large clade containing reference specimens of *Nocticola* and Nocticolidae from Pannawonica, the Western Hamersley Range and Central Pilbara. This widely distributed clade has an average genetic distance of approximately 6% (range 0.2 – 9.1) across a large geographical range, thus it may represent a species complex of closely related, recently diverged species (possibly in the genus *Nocticola*).

Nocticola

BN020 = new lineage, may belong to a species complex detected at Western Hub, Red Hill and Buckland Hills

BN021 = new lineage, may belong to a species complex detected at Buckland Hills, the Central Pilbara and Hamersley Range.

Coleoptera

A single genetic lineage of Curculionidae and three lineages of Ptilidae were detected at Mesa H. They differed from the nearest reference specimens by between 1.6 and >13% sequence divergence.

For comparison, differentiation within the four WAM species of Curculionidae for which there are multiple sequences (species 1, 3, 4, 8) ranges from a mean of 0.9% (species 1) to a mean of 5.2% (species 4). The eight species differed by a mean of 11.3 to 24.3% sequence divergence. The two specimens of Pitlidae sp. 1 shared the same haplotype.

The Curculionidae lineage from Mesa H differed from the nearest reference specimens by ≥ 13%, indicating that the specimen likely represents a new lineage and species of Curculionidae that has not been detected previously.

Two of the Mesa H lineages of Ptilidae were placed in a clade containing reference specimens from the WAM, assigned to the species Ptilidae sp. 1. The Mesa H lineages CP001 and CP003 differed from the WAM reference specimens of Ptilidae sp. 1 by between 1.6 and 4.4% sequence divergence, suggesting that the lineages from Mesa H belong to Ptilidae sp. 1. However, owing to the moderate level of sequence divergence (4.4%) morphological characters may be useful to confirm this placement.

Curculionidae

CCU014 = new lineage and species, not detected previously in the Pilbara

Ptilidae

CP001 = WAM Ptilidae sp. 1, previously detected in the Pilbara
CP002 = lineage and species detected previously in the Robe Valley
CP003 = new lineage; likely to belong to previously detected species WAM Ptilidae sp. 1, but morphology should be used to confirm.

Thysanura

The mitochondrial gene 12S is widely used in insect systematics (Simon, 1991; Caterino et al., 2000), although in contrast to the mitochondrial gene COI, fewer broadscale comparative studies are available to provide a basis for species discrimination. Nonetheless, 12S has proven useful for establishing phylogenetic relationships in many insect groups (Caterino et al., 2000). The 12S gene evolves approximately 1.5 times (Mueller, 2006) more slowly than COI. Hence we would expect that the threshold for species discrimination using 12S would be, by inference, lower than COI.

Two distinct genetic lineages of Thysanura were detected at Mesa H, Nicoletiinae lineages TN019 and TN020. Both differed from the nearest reference specimens by >7% sequence divergence.

For comparison, the six specimens of *Trimenura callawa* differ by a mean of 0.4% sequence divergence (range = 0 to 0.9% at 12s) and *T. callawa* and *T. cundaline* differ by 6.5% mean sequence divergence at 12s. Given the relatively high genetic distance between Mesa H lineages TN019 and TN020 and the reference specimens (>7%), but keeping in mind that our conclusions are based on current understanding of 12s evolution rates, it is likely that both new lineages from Mesa H represent new species of Nicoletiinae.

Nicoletiinae

TN019 = new lineage and species
TN020 = new lineage and species

Table 3. Mean genetic distance (D) and standard error (s.e.) within lineages of Coleoptera as shown in Figure 2. N= number of specimens in the lineage; Rep= specimen used to represent the lineage in the model-based phylogenetic analysis. n/c= not calculated where the number of specimens in the lineage is 1.

Lineage	D	s.e.	N	rep
1	0.000	0.000	4	MF09
2	0.003	0.002	4	MF20
3	0.009	0.003	4	MF11
4	0.016	0.003	4	MF03

Table 4. Mean genetic distance (D; below diagonal) and standard error (s.e.; above diagonal, in blue) between lineages of Coleoptera as shown in Figure 2.

Lineage	1	2	3	4
1		0.007	0.012	0.016
2	0.046		0.013	0.015
3	0.159	0.157		0.016
4	0.264	0.265	0.260	

Table 5. Genetic distances (below diagonal) and standard error (above diagonal, in blue) between specimens of Curculionidae (Coleoptera) detected at Mesa H and the reference lineages as shown in Figure 3. Distances between the Mesa H specimens and the reference specimens are highlighted in yellow.

Re. Report on the molecular systematics of Amphipoda from Mesa H (Biota 1146f)

Dear Garth,

Following is a summary of the results of the Amphipoda study we have completed from Mesa H. Fifteen distinct genetic lineages from three families (Melitidae/Eriopisidae, Neoniphargidae, Paramelitidae) were detected in the collections, nine of which have been detected previously in the Pilbara.

Thanks once again for collaborating on this project with Helix. We hope we can continue to provide you with useful information, and feel free to contact us if you have any questions or would like to discuss the results in detail.

Sincerely,

Dr. Terrie Finston, Yvette Hitchen and Dr. Oliver Berry
Helix Molecular Solutions

Background and Objective

One hundred twenty-one specimens of Amphipoda were collected from Mesa H and sequenced for variation at the mitochondrial COI gene. The molecular data were assessed in order to determine the number of species present and compare the results to those obtained during previous surveys in the Pilbara.

Executive summary

- One hundred twenty-one specimens of amphipods from Mesa H were sequenced for variation at the COI gene.
- Fifteen distinct genetic lineages (eight Melitidae/ Eriopisidae, two Neoniphargidae and five Paramelitidae) were detected among the 95 specimens for which sequences were obtained.
- Nine of the lineages have been detected previously in the Pilbara, whereas six (two Melitidae/Eriopisidae and four Paramelitidae) appear to be new, based on the material available for comparison.

Methods

One hundred twenty-one specimens of Amphipoda from 12 drillholes at Mesa H were sequenced for variation at the mitochondrial cytochrome oxidase subunit I gene (COI) using primers LCOI/HCO2.

Sequences were edited using GENEIOUS software (Drummond *et al.* 2011). Alignment was performed with CLUSTAL W (Thompson *et al*. 1994) using default parameters. Genetic distances between unique genetic sequences (haplotypes) were measured using uncorrected p-distances (total percentage of nucleotide differences between sequences).

MODELTEST software (Posada and Crandall, 1998) was used to determine the model of sequence evolution that best fitted the data for each taxonomic group. Bayesian analysis was used to construct the phylogenetic trees, incorporating the model as identified in MODELTEST for each taxonomic group. The phylogeny, branch lengths and posterior probabilities were obtained by running two trees simultaneously, each running four simultaneous MCMC chains. The number of cycles needed was determined by the standard deviation of the split frequencies of the two trees. The analysis was paused after every 1 x 10^6 generations and when the standard deviation fell below 0.01, the analysis was stopped. A majority rule consensus tree was constructed after discarding the "burn-in" trees in both analyses. The burn-in value was determined by plotting the posterior probabilities obtained after every generation and identifying the point at which the values reach stationarity (= the asymptote). Trees produced prior to stationarity were discarded.

For the purposes of this report, lineages were defined as haplotypes or groups of haplotypes differing from other such groups by >3% sequence divergence. This cut-off was selected based on bar-coding data, which indicates that intra-specific variation rarely exceeds 2-3% (Hebert et al., 2003b).

Results

Preliminary analysis - Reference sequences and outgroups

One hundred twenty-one specimens of amphipods from Mesa H were sequenced for COI (Table 1). In order to reduce analysis time and to simplify the presentation of results, a preliminary neighbour-joining (NJ) analysis was conducted on the 95 amphipods for which sequences were obtained, to identify unique haplotypes to include in a model-based phylogenetic analysis. Thirty-eight unique haplotypes were detected among the 95 sequences; these haplotypes were further sorted into 15 lineages. Comparisons to the GenBank sequence database indicated that five lineages were most similar to Paramelitidae and two were most similar to Niphargidae (Figure 1). Eight lineages were most similar to sequences of Melitidae/ Eriopisidae (Figure 2).

The three families were analysed in separate phylogenetic analyses with relevant reference specimens. The Niphargidae are not found in Australia, thus the lineages are likely to belong to

the closely related family Neoniphargidae, which is represented in Australia by seven genera (World Register of Marine Species – WORMS). Genbank lacks sequences of Neoniphrgidae for COI, thus the closest matches appear to be from the family Niphargidae. Ten reference sequences of presumptive Neoniphargidae from previous surveys in the Robe Valley were included in the analysis, one from a borehole in which other specimens were identified as *Wesniphargus* sp. on the basis of morphology. Two Genbank reference sequences of Niphargidae, *Niphargus*: *N. fontanus* (Genbank accession number KC315635) and *N. glenniei* (Genbank accession number KC315646) were also included. Two sequences of Melitidae/ Eriopisidae, *Nedsia* sp. 1 (Genbank accession #EU304458), and *Norcapensis mandibulis* (Genbank accession # JQ608487) were used as outgroups.

For the Paramelitidae, 48 reference sequences were included in the phylogenetic analysis, nine GenBank vouchers of Paramelitidae, as well as 39 specimens from previous surveys of the Robe Valley, Central Pilbara, Barrow Island, Lower Shaw River, Fortescue River, and Marillana Creek. Two sequences of the amphipod genus *Niphargus* were used as outgroups as follows: *N. fontanus* (Genbank accession number KC315635) and *N. glenniei* (Genbank accession number KC315646). Two sequences of Melitidae/Eriopisidae, *Nedsia* sp. 1 (Genbank accession #EU304458), and *Norcapensis mandibulis* (Genbank accession # JQ608487) were used as outgroups.

For the Melitidae/Eriopisidae, 52 reference sequences were included in the phylogenetic analysis. The genus *Nedsia* has been reassigned to the family Eriopsidae (WAM, pers. comm.) so GenBank vouchers of both Melitidae and Eriopisidae, *Nedsia* sp. 1 (Genbank accession #EU304458), and *Norcapensis mandibulis* (Genbank accession # JQ608487) as well as 50 specimens from previous surveys of the Robe Valley, Central Pilbara, Barrow Island, Lower Shaw River, Fortescue River, and Marillana Creek were included in the phylogenetic analysis. Two sequences of the amphipod genus *Niphargus* were used as outgroups as follows: *N. fontanus* (Genbank accession number KC315635) and *N. glenniei* (Genbank accession number KC315646).

Phylogenetic analysis- Neoniphargidae

The phylogenetic analysis, which included the five haplotypes of Neoniphargidae from Mesa H in addition to 13 reference specimens, placed the Mesa H haplotypes in two distinct genetic lineages. One lineage contained several reference specimens from Dave's and Budgie bores, and thus was assigned to the existing lineage AMN008 (Figure 3). The second lineage contained a reference specimen from a bore where other individuals were identified as *Wesniphargus* sp. on the basis of morphology and thus was assigned to the existing lineage *Wesniphargus* sp. AMN004 (Figure 3). Lineages AMN004 and AMN008 formed a well-supported clade (Figure 3).

Differentiation between lineages –Neoniphargidae

The Mesa H Neoniphargidae assigned to lineage AMN008, represented by three haplotypes (NH20, NH29 and NH32), differed from the nearest reference specimens KJ64, KD39, KE07, IV100, JN08 and LI20 (reference lineage AMN008) by between 0.4 and 1.4% sequence divergence, and from the remaining reference specimens by >12% sequence divergence (Table 2). The Mesa H Neoniphargidae assigned to lineage AMN004, represented by two haplotypes (NH67 and NH69) differed from the nearest reference specimen KE33 (reference lineage *Wesniphargus* sp. AMN004) by between 0.5 and 0.6% sequence divergence, and from the remaining reference specimens by >12 sequence divergence (Table 2). Lineages AMN004 and AMN008 differed from one another by ≥12% sequence divergence (Table 2).

Phylogenetic analysis- Paramelitidae

The phylogenetic analysis, which included the seven haplotypes of Paramelitidae from Mesa H in addition to 48 reference specimens, placed the Mesa H haplotypes in five distinct genetic lineages (Figure 4). One of the lineages also contained reference specimens. Specifically, haplotype NH12 was placed in the existing lineage AMP009 containing two haplotypes from Barrow Island and Budgie bore (Figure 4). The remaining six haplotypes were placed in four lineages that did not contain reference specimens, so were assigned to the new lineages AMP035, AMP036, AMP037 and AMP038 (Figure 4). Three of those new lineages, AMP036, AMP037 and AMP038, were placed in well supported clades with other reference lineages

(Figure 4). Specifically, lineage AMP036 was placed in a moderately well-supported clade containing reference specimens of *Chydaekata*, and lineage AMP037 was placed in a well-supported clade with lineage AMP032 from Mesa B (Figure 4). Lineage AMP038 was placed in a well-supported clade containing lineage AMP033 from Mesa C (Figure 4). The remaining new lineage, AMP035, did not show close relationships to reference specimens (Figure 4).

Differentiation between lineages –Paramelitidae

The Mesa H haplotype NH12 that was assigned to lineage AMP009 differed from the reference specimens in lineage AMP009 by 0.9 to 1.1% sequence divergence and from the remaining reference specimens by >12% sequence divergence (Table 3). Haplotype NH53D, which was assigned to the new lineage AMP037, differed from the nearest reference specimen, IS39 in lineage AMP032, by 4.1% sequence divergence and from the remaining reference specimens by approximately 8% sequence divergence (Table 3). Specifically, it differed from specimens in lineage AMP023 by between 7.9 and 8.0% sequence divergence (Table 3). Haplotypes NH54 and NH90, assigned to the new lineage AMP038, differed from the nearest reference specimen, IT25 in lineage AMP033 by between 3.7 and 4.0% sequence divergence and from the remaining reference specimens by >14% (Table 3). The remaining two new lineages, AMP035 and AMP036 differed from the nearest reference specimens by >17% sequence divergence (Table 3).

Phylogenetic analysis- Melitidae/ Eriopisidae

The phylogenetic analysis, which included the 26 haplotypes of Melitidae/ Eriopisidae from Mesa H, in addition to 52 reference specimens, placed the Mesa H specimens in eight distinct genetic lineages, all but two of which also contained reference specimens from previous surveys in the Pilbara (Figure 5). Specifically, haplotypes NH37 and NH39 were placed in existing lineage AMM006, containing reference specimen IV134 from Warramboo, and haplotype NH104 was placed in lineage AMM022, containing reference specimen IS37 from Red Hill (Figure 5). Haplotype NH63 was placed in existing lineage AMM026, containing reference specimens JN22, JF21 and LI10 from Mesas C and H, and haplotypes NH33 , NH35 and NH38 were placed in lineage AMM004, containing reference specimens IV128, JN05, KE10 and LI11 from Mesa C and Red Hill (Figure 5). Haplotype NH36 was placed in existing lineage AMM031 with specimens LI25, KE05, KD45 and KD55 from Budgie bore and Mesa C (Figure 5). Fifteen haplotypes were placed in existing lineage AMM001 with eight reference specimens from Budgie bore, Mesa H and other bores in the Robe River valley (Figure 5).

Three haplotypes from Mesa H were placed in two lineages that did not contain any reference specimens. Specifically, haplotype NH62 was placed in a distinct lineage that did not contain any reference specimens and was assigned to the new lineage AMM032 (Figure 5). Likewise, NH46 and NH 110 were placed in a second distinct lineage that did not contain any reference specimens and were assigned to lineage AMM033 (Figure 5).

Three of the lineages, AMM001, AMM026, and AMM031 were placed in well supported clades with other reference lineages (Figure 5). Specifically, lineage AMM001 was placed in a large, well-supported clade containing multiple lineages, AMM025, AMM024, AMM029, AMM030 and AMM002 (Figure 5). Lineage AMM026 was placed in a well-supported clade containing reference lineage AMM021 from Red Hill, and lineage AMM031 was placed in a well-supported clade with lineage AMP027 from Budgie bore, and more distantly, with the AMM001 lineage complex (Figure 5). The remaining lineages did not show close relationships to reference specimens (Figure 5), although both lineage AMM026 and AMM004 showed significant relationships with reference specimens of *Nedsia*, suggesting they may belong to that genus.

Differentiation between lineages – Melitidae/Eriopisidae

The six Melitidae/Eriopisidae lineages detected at Mesa H that were assigned to existing lineages AMM001, AMM004, AMM006, AMM022, AMM026 and AMM031 differed from the nearest reference specimens by ≤2.5%, with the exception of lineage AMM031 where distances between haplotypes ranged from 0 – 3.5% (Table 4). Lineages AMM004, AMM006 and AMM022 differed from the remaining reference specimens by >9.5% (Table 4). Lineage AMM026 formed a well-supported clade with AMM021 and differed from that lineage by 4.6%, and from the remaining reference specimens by >8% (Table 4).

Lineage AMM031 formed a well-supported clade with AMM027 and differed from that lineage by 4% (Table 5). Lineage AMM001 formed a well-supported clade with multiple lineages (=AMM001 lineage complex) as well as with lineage complex AMM031 + AMM027 (Figure 5). Genetic distances between specimens in lineage complex AMM001 (enclosed by a dashed red box in Figure 5), ranged from 0 – 7.8% and the mean was 4.9% sequence divergence.

Haplotype NH62, in the new lineage AMM032, differed from the reference specimens by >14% sequence divergence (Table 4). Haplotypes NH46 and NH110, in the new lineage AMM033, differed from the reference specimens by >9% sequence divergence (Table 4).

Conclusions

COI is widely considered to show suitable variation to distinguish species (Hebert et al., 2003a). In a comparison of COI sequences for over 13,000 pairs of taxa, Hebert et al (2003b) found a mean of 11.1% sequence divergence between distinct species. Nearly 80% of the comparisons showed that species pairs differed from one another by greater than 8% sequence divergence. However, a taxon by taxon approach, examining the amount of phylogenetic variation within and between species is the most widely accepted method of defining species.

Neoniphargidae

Two lineages of Neoniphargidae, AMN004 and AMN008, were detected at Mesa H during the current collection phase, both of which have been detected previously in the Pilbara. The two lineages differ from other reference lineages by >12% sequence divergence, thus they are likely to correspond to two distinct species. Lineage AMN004 is tentatively assigned to the genus *Wesniphargus*, owing to it containing a reference specimen from a bore at Mesa H where another individual was assigned to that genus, while lineage AMN008 has been detected previously at Mesa C and other sites in the Robe Valley.

AMN004 = species detected previously at Mesa H; may belong to the genus *Wesniphargus*.

AMN008 = species detected previously in the Robe Valley at Dave's and Budgie bores in the Robe Valley.

Paramelitidae

Five lineages of Paramelitidae were detected at Mesa H, differing from one another by >15%, indicating that each is likely to represent a distinct species. One of the lineages has been detected previously (AMP009) and four appear to be new (AMP035, AMP036, AMP037 and AMP038), based on the material available for comparison. Of the four new lineages, two (AMP037 and AMP038) showed close relationships with other lineages. Specifically, lineage AMP037 formed a well-supported clade with lineage AMP032 from Mesa B and differed from it by 4.1% sequence divergence. While there are two lineages present, we cannot say if they represent one or two species, based on the current information; for this reason we will refer to the clade as a species complex. Similarly, lineage AMP038 formed a well-supported clade with lineage AMP033 from Mesa C, and differed from it by between 3.7 and 4.1%, again suggesting the presence of a species complex – two distinct lineages represented by an unknown number of species. Further research into these groups is necessary to define species boundaries.

AMP009: species previously detected at Barrow Island and Budgie bore
AMP035; new lineage and species, forms poorly supported clade with a reference specimen of *Yilgarus*
AMP036; new lineage and species, forms moderately well-supported clade with reference specimens of *Chydaekata*
AMP037; new lineage; belongs to a species complex with lineage AMP032 detected previously at Red Hill
AMP038; new lineage; belongs to a species complex with lineage AMP033 detected previously at Buckland Hill

Melitidae/Eriopisidae

Eight lineages of Melitidae/Eriopisidae were detected at Mesa H, six of which were assigned to existing lineages. With the exception of distances between lineages AMM001 and AMM031, the lineages differed from one another by >9.0% sequence divergence, indicating that each is likely to represent a distinct species. One of the lineages, AMM026, formed a well-supported clade with reference lineage AMM021 and differed from that lineage by 4.6%. While there are two lineages present, we cannot say if they represent one or two species, based on the current information; for this reason we will refer to the clade as a species complex. Further research into this group is necessary to define species boundaries.

Lineages AMM001 and AMM031 formed a well-supported clade with one another and with multiple, closely related lineages that require further consideration (enclosed by a dashed red box in Figure 5). The specimens in this group differed by <5% mean sequence divergence (range = 0 – 7.8%). While there are clearly multiple lineages present, we cannot say how many species they represent, based on the current information; for this reason we will refer to the clade as a species complex. Further research into this group is necessary to define species boundaries.

AMM004 = species detected previously at Mesa H and Dave's bore in the Robe Valley.
AMM006 = species detected previously at Warramboo.
AMM022 = species detected previously at Red Hill.
AMM026 = lineage detected previously at Mesa C and Mesa H; forms a species complex with lineage AMM021 from Red Hill

AMM001
AMM031
} = large species complex comprised of multiple lineages; relationships among the clade members requires further investigation.

AMM032 = new lineage and species based on the material available for comparison
AMM033 = new lineage and species based on the material available for comparison

Table 4 (attached). Genetic distances (below diagonal) and standard error (above diagonal, in blue) between haplotypes of Melitidae/Eriopisidae (Amphipoda) detected at Mesa H and the reference lineages as shown in Figure 5. Distances between the Mesa H specimens and the reference specimens are highlighted in yellow.

Re. Report for the analysis of environmental water samples collected during December 2017 for the presence of blind eel DNA (Helix Job 484)

Executive Summary

- Eighty-nine samples from 17 sites were extracted and analysed using the *O. candidium* probe.
- Amplification was observed in seven samples from three sites. The control site (n=3), 25 site (n=1) and MB17MEH0015 site (n=3).
- All samples were run with the 16S mammal probe as an extraction positive control. Of the 89 samples only 59 samples amplified for the presence of mammal DNA.
- All samples that amplified with the *O. candidium* probe also amplified for the mammal probe

Methods

A modification to previous collections methods was in how filters were stored during transport. In previous collection filter papers were stored in 100% ethanol. A modification in this study was filter papers were stored in a sterile plastic bag at -20ºC for transport. Furthermore only half of the filter paper was sent for analysis. Upon reaching the lab all samples were stored at -80ºC.

Samples were extracted using the QIAGEN Blood and Tissue Kit (QIAGEN, Hilden, Germany) and as with previous studies all starting volumes were doubled to ensure that the filter was covered during incubation. All samples had two elutes of 50µl each.

The extracted DNA was run with the species diagnostic assay for *Ophisternon candidum* and the mammal control assay (16S) as per previous studies.

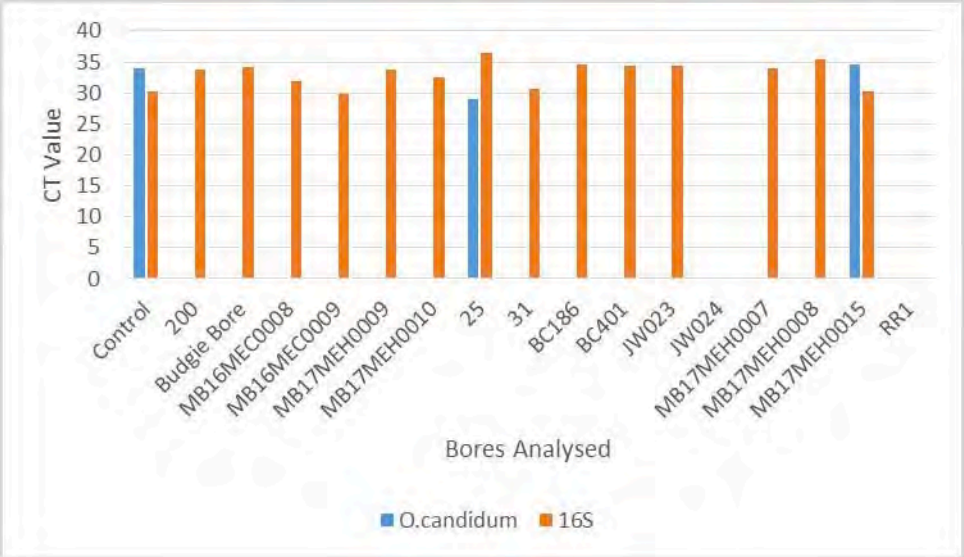
Results

Seventeen sites were sampled with three to six filters per site using two collection methods (bailer and pump) (Appendix 1). Of the 89 filters tested seven amplified from three different sites for the presence of *O. candidium* DNA (Figure 1). These sites were the control site, site 25 and site MB17MEH0015. For the control site three filters were collected all of which amplified for the presence of O. candidium. For site 25 only one of the five filters collected amplified, and for MB17MEH0015 three of the five filters amplified.

From the 89 filters sent for analysis, 59 filters amplified with the control probe. The 20 filters that failed to amplify may have been due to no mammal DNA present in the bore or the presence of only degraded DNA. Two sites were noted to have failed across all filters collected (JW024 and RR1).

All samples had three replicates for the O. candidium probe and one replicate for the control probe. Amplification of the *O. candidium* was noted in all replicates except NI84 in which the third replicate failed to amplify. This was most likely the result of degradation.

Figure 1: Sites sampled during the December 2017 collection and the results for *O. candidium* specific qPCR assay. No bar indicates no amplification.



Conclusion

In conclusion, we confirm that *O. candidium* DNA was observed in three sites. The control site (n=3), 25 site (n=1) and MB17MEH0015 site (n=3). Both sampling methods (bailer and pump) collected *O. candidium* DNA even though varying volumes of water were used (500-1000ml). The modified methods of storing filters at -20ºC for transport and -80ºC for storage appear to be affective in addition to using only half the filters.

Three replicates were done for each sample and a range of 5.09 - 7.68% increase in the CT value was noted between replicates. As expected eDNA is susceptible to degradation even via limited freezer thaw cycles. For future work it is suggested that freeze thaw cycles be limited as much as possible.
