Curtin University eDNA Metabarcoding Report

eDNA Metabarcoding Preliminary Report: Blind Cave Eel survey in the Pilbara WA

Prepared for

Rio Tinto
Level 24, 152-158 St Georges Terrace
Perth, WA, 6000

Prepared by

Trace and Environmental DNA (TrEnD) Laboratory

Curtin University

21st March 2018

Report Authors: Dr Nicole White and Prof. Michael Bunce (TrEnD laboratory)

Signature:

(Dr Nicole White) **Date: 21st March 2018**

Disclaimer:
The Trace and Environmental DNA (TrEnD) laboratory offers DNA services across a number of biological applications. While TrEnD stands by the validity of its work and the science that underpins it, stakeholders should use the information contained within the report at their own risk. We suggest using DNA results we report as a line of evidence in decision making processes and it may be appropriate to repeat results, re-sample at sites, corroborate data using other DNA markers or use other non-molecular methods. TrEnD accepts no liability or responsibility for it in respect of any use of or reliance upon this report by any third party. Executive Summary:

Overall Project objective:

The aim of this pilot project was to use an environmental DNA (eDNA) metabarcoding approach to determine presence/absence of Blind Cave Eel (*Ophisternon candidum*) from within and outside the Mesa H project area in the Pilbara region of Western Australia. The data was to be incorporated into an environmental impact statement (EIS) by Rio Tinto. This interim report documents the results to date and will be superseded by the final report on the project which involves replication of data and design of new assays for eel detection.

Outputs:

- Two collection trips in 2017 were conducted (i) June 2017: 91 water samples from 18 bores were collected and filtered by Michelle Guzik (University of Adelaide. (ii) December 2017: 85 water samples were collected and filtered by Jason Alexander (Biota) from 16 bores and one open surface water sample from the Robe River (5x 1 liter replicates). The TrEnD lab at Curtin University successfully isolated DNA from 122 of these samples.
  .
- As a preliminary first-pass to determine the presence of Blind Cave Eel (*O. candidum*) from 122 water membranes the TrEnD labs Fish 16S assay was used. Although this DNA assay (Fish 16S) isn't specific for Blind Cave Eel our previous research has demonstrated successful amplification of eel DNA.

- The June 2017 water membranes detected the possibility of Blind Cave Eel (*O. candidum*) from bore JW021. The December 2017 water membranes detected the possibility of Blind Cave Eel (*Ophisternon candidum*) from bore 25 and bore RR1. This result is preliminary in nature – detections are currently un-replicated. Additional sites could yield eel signatures as assays are repeated and modified.

- Blind Cave Eel (*O.candidum*) tissue was sourced from the Western Australia Museum (WAM) for comparative purposes. We have sequenced the 16S barcode from this sample.

- Comparisons of the potential Blind Cave Eel (*O. candidum*) DNA sequences from bore JW021 with the National Centre for Biotechnology Information (NCBI) database showed an 85.9% match to *O. bengalense*, an eel-like fish found in northern Australia and 85.9% match to *Synbranchid* sp., a freshwater eel-like fish.

- Comparisons of the potential Blind Cave Eel (*O. candidum*) DNA sequences from bore 25 and RR1 with the NCBI database showed an 87.7%% match to *O. bengalense* and 87.1% match to *Synbranchid* sp.

- Comparisons of the potential Blind Cave Eel (*O. candidum*) DNA sequences from bore JW021, 25 and RR1 with the reference sample obtained from the WAM showed 100% match to the DNA sequences obtained from bore JW021 and 97% match to the DNA sequences from bore 25 and RR1. The genetic sequences in bores 25 and RR1 are 100% similar to each other but distinctly different from the WAM reference or the JW021 sequence. The significance of this genetic difference is unknown.

Recommendations:

- An eDNA approach using a Fish 16S assay has successfully detected Blind Cave Eel from three bores within and outside the Mesa H project area. The sensitivity and reproducibility of these findings still need to be confirmed by the ongoing research program. The successful detection of Blind eel from a non-invasive sample speaks to the promise of eDNA approaches for the detection of taxa in subterranean environments.

1. Introduction

eDNA refers to all genetic material that is recovered from environmental substrates (such as water or sediment). DNA directly from an organism (e.g. microorganisms) as well as trace amounts of DNA that are shed by all organisms is collectively termed eDNA. This preserved, but often degraded, genetic material provides a means to audit species composition and communities at a given location. When combined with recently developed DNA sequencing technologies (termed 'next generation' or 'high-throughput' sequencing), eDNA can provide a wealth of information for studies of introduced marine pests (IMP), biodiversity surveys, food web dynamics, and diet analysis.

Potential applications for monitoring using eDNA include:

- Biosecurity: to detect the presence/absence of introduced species
- Environmental Impact Assessment: baseline/ongoing monitoring and assessment; audit
- Conservation: to detect the presence/absence of threatened species

Rio Tinto has partnered with the Trace and Environmental DNA (TrEnD) Laboratory at Curtin University to develop eDNA tools for Blind Cave Eel (*Ophisternon candidum*) as a means to use DNA-based bio surveys in groundwater monitoring and management.

eDNA sampling has benefits over other traditional survey methods including:

- highly cost-effective monitoring compared to traditional survey methods
- rapid sample collection that is non destructive to habitats, flora and fauna
- non-reliance on individuals with taxonomic expertise, provision of consistent results between monitoring programs, independent of surveyors

The objectives of this project, albeit preliminary, were to use an environmental DNA (eDNA) metabarcoding approach to determine the presence/absence of Blind Cave Eel (*Ophisternon candidum*) a threatened species within the groundwater systems of the Pilbara in Western Australia, specifically the Mesa H area (Rio Tinto). The data was to be incorporated into an environmental impact statement.

2. Methods and Samples

Water samples were collected by Michelle Guzik (University of Adelaide; June 2017) and Jason Alexander (Biota; December 2017) and filtered using a Sentino pump (Pall corporation) as outlined in TrEnD standard operating procedures (available upon request). Turbidity in the water resulted in varying volumes of water that could be filtered between the bores and replicates (see table 1 below and attached electronic data file).

eDNA was extracted using Qiagen Blood & Tissue DNeasy kits in the TrEnD laboratory at Curtin University in dedicated facilities (inclusive of laboratory clean rooms) suited for eDNA workflows. eDNA derived from the Fish 16S assay was amplified using PCR, followed by sequencing on an Illumina MiSeq in the TrEnD Laboratory. Negative laboratory controls were included (and sequenced if identified as positive) to control for environmental laboratory contamination.

The 16S DNA sequences recovered were compared to the National Centre for Biotechnology Information (NCBI) database for taxonomic identification and to reference Blind Cave Eel (*Ophisternon candidum*) obtained from the WAM (P.34817-001).

3. Results and Discussion

The following table outlines the taxonomic assignments from each bore water sample for which suspected Blind Cave Eel (*Ophisternon candidum*) was amplified and sequenced. Taxonomic assignments are to genera and species with the per cent match genetic similarity to the DNA sequences contained on the reference database (NCBI). At the time of this report, the taxonomic assignments for the DNA sequences obtained from the bore water samples (i.e. DNA 'barcodes') are listed in the table below and the electronic file accompanying this report. The environmental laboratory controls for this work were identified as negative and not included in the Table.

Table 2

Taxonomic Assignments			
AWFS ID	**Bore**	**% match (NCBI)**	**Species**
AWFS-I17-107B	JW021	85.9	Synbranchid sp. VietNam-TC-2002 haplotype 1
		85.9	Ophisternon bengalense voucher MRS haplotype OB1
AWFS-I18-001A	25	87.1	Synbranchid sp. VietNam-TC-2002 haplotype 1
		87.1	Ophisternon bengalense voucher MRS haplotype OB1
AWFS-I18-013A	RR1	87.1	Synbranchid sp. VietNam-TC-2002 haplotype 1
		87.1	Ophisternon bengalense voucher MRS haplotype OB1
AWFS-I18-013C	RR1	87.1	Synbranchid sp. VietNam-TC-2002 haplotype 1
		87.1	Ophisternon bengalense voucher MRS haplotype OB1
AWFS-F18-005 BlindEel_WAM P.34817-001		85.9	Synbranchid sp. VietNam-TC-2002 haplotype 1
		85.9	Ophisternon bengalense voucher MRS haplotype OB1

Fish DNA was detected in a number of sampling locations. This preliminary report is only reporting on, and presenting data from, those bores that yielded eel DNA.

Comparisons of the potential Blind Cave Eel (*O. candidum*) DNA sequences from bore JW021 with the NCBI database showed an 85.9% match to *O. bengalense*, an eel-like fish found in northern Australia and 85.9% match to *Synbranchid* sp., a freshwater eel-like fish (see Table 2). The DNA barcode recovered from JW021 was a 100% match to the reference DNA sequence from the WAM Blind Cave Eel (*O. candidum*) sample. Eel DNA was recovered in one of two replicates from bore JW021

Comparisons of the potential Blind Cave Eel (*O. candidum*) DNA sequences from bore 25 and RR1 with the NCBI database showed an 87.7%% match to *O. bengalense* and 87.1% match to Synbranchid sp. (see table 2). The DNA barcode recovered from bore RR1 and bore 25 was a 97% match to the reference DNA sequence from the WAM Blind Cave Eel (*O. candidum*) sample. Eel DNA was recovered in two of the five replicates from bore RR1 and one of five replicates from bore 25.

The genetic sequences in bores 25 and RR1 are 100% similar to each other but distinctly different from the WAM reference or the JW021 sequence. The significance of this genetic difference is

unknown it may represent variation within the species or a distinct lineage. There is a distinctive DNA 'insertion' in the sequences obtained from JW021 and the WAM reference that is the major distinguishing feature (see Figure 1)

Figure 1: 16S DNA sequences from bore JW021, RR1, 25 and *O. candidum* (WAM P.34817-001)

4. Findings, Recommendations and Concluding remarks

The Fish 16S metabarcoding assay utilised on the bore water samples collected in June and December 2017 detected the potential Blind Cave Eel (*O. candidum*) in three of 34 bores. To our knowledge this represents the first time an eDNA based approach has been used in the ground water system(s) in the Pilbara for the detection of a restricted species. The gaps in the reference databases often prevent definitive assignments to genus and/or species at the time of this report. Although comparisons of the suspected Blind Cave Eel (*O. candidum*) DNA sequences with the DNA sequences obtained from a tissue sample of Blind Cave Eel (*O. candidum*) from the WAM indicate the strong likelihood of Blind Cave Eel (*O. candidum*). Current laboratory work is underway to sequence the complete mitochondrial genome from the WAM reference sample and develop a metabarcoding assay specific for Blind Cave Eel (*O. candidum*). Once completed, the Blind Cave Eel (*Ophisternon candidum*) metabarcoding assay will be used to re-screen the 122 water samples to validate the findings from the Fish 16S assay and potentially find additional bores that may contain Blind Cave Eel (*O. candidum*).

The DNA yields recovered from the bores was low and, as expected, not every replicate from positive wells yielded a positive detection. The sensitivity of the assays and the level of replication appropriate is yet to be determined for bores in the Pilbara. The development of additional assays and optimisation of existing assays (and sampling protocols) is ongoing and will likely enhance the likelihood of detections.

5. Appendices and additional information

- An electronic file titled; Appendix_BlindCaveEel_March2018.xlsx is attached to this report.

- Additional information on sampling and methods are available from TrEnD upon request however the exact nature of the assays and workflow are proprietary.

- Below is a list of acronyms, abbreviations and definitions that may apply to aspects of this report.

% value in data	Represents the percentage similarity of a DNA sequence recovered from a sample compared to reference sequences in a database (e.g. compared to DNA databases such as GenBank or references generated in-house)
(x) value in data	Represents the frequency the % value was recorded in the dataset
16S rRNA	The 16S rRNA refers to a conserved gene region of mitochondrial DNA, which codes for a subunit of the ribosome. 16S rRNA is found in all eukaryotes making it a good candidate for DNA barcoding and is used extensively to detect vertebrate taxa such as fish and mammals.
18S rRNA	The 18S rRNA refers to a conserved gene region of nuclear DNA, which codes for a subunit of the ribosome. 18S rRNA is found in all eukaryotes making it a good candidate for DNA barcoding
18S IMS reference database	Reference 18S rRNA sequences of invasive marine species that are available in DNA databases
Assay	In the context of metabarcoding an assay is a molecular test (using PCR) that is implemented to target a group of taxa within a mixed biological substrate. It is akin to using a magnet to selective enrich for needles (the target) in the context of a haystack (the total DNA from a sample).
COI	The gene region that is being used as the standard barcode for almost all animal groups is a 648 base-pair region of the mitochondrial cytochrome c oxidase 1 gene ("CO1"). COI is proving highly effective in identifying birds, butterflies, fish, flies and many other animal groups. COI is not an effective barcode region in plants because it evolves too slowly, but two gene regions in the chloroplast, matK and rbcL, have been approved as the barcode regions for plants
CO1 IMS reference database	Reference COI sequences of invasive marine species that are available in DNA databases
DNA	Deoxyribonucleic Acid (DNA) is the hereditary material that contains the genetic information of an organism
DNA metabarcoding	Is a genetic technique that simultaneously amplifies and sequences barcode regions

	(e.g. COI, 18S, 16S) of many different species in parallel
eDNA	Environmental DNA (eDNA) refers to genetic material that is recovered from an environmental substrate (e.g. water, sediment, air)
eukaryotes	An organism where cells contain a nucleus surrounded by a membrane and has the DNA bound together by proteins (histones) into chromosomes. The cells of eukaryotes also contain an endoplasmic reticulum and numerous specialised organelles not present in prokaryotes, especially mitochondria, golgi bodies, and lysosomes
Fisheries	Department of Primary Industries and Regional Development, Fisheries Division, Aquatic Biosecurity Section
GenBank	Publically available repository of genetic information. Contains the barcode information of genes that have previously been sequenced
Genome	A genome is all the genetic material of an organism. It consists of DNA (or RNA in RNA viruses). The genome includes both the genes (the coding regions) and the noncoding DNA. In eukaryotes it refers to the genomes of the nucleus, mitochondria and chloroplasts. In prokaryotes, there is a single genome (as they do not contain mitochondria or chloroplasts)
Illumina MiSeq	Next generation sequencing platform developed by the company Illumina
IMP	Introduced marine pests
IMS	Introduced marine species
Metabarcoding assay	A PCR reaction using a specific set of primers that simultaneously amplifies the same gene target from multiple species
Mitochondria	The mitochondrion (plural mitochondria) is a double membrane-bound organelle found in all eukaryotic organisms, although some cells in some organisms may lack them (e.g. Red blood cells). It contains its own genome
Mitogenomes	Refers to the mitochondrial genome
NGS	Next generation sequencing or second generation sequencing refers to massively parallel sequencing technology, as opposed to first generation sequencing or sanger sequencing where only a single template is sequenced at one time
Nucleotide	A compound consisting of a nucleoside linked to a phosphate group. Nucleotides form the basic structural unit of nucleic acids such as DNA
PCR	Polymerase chain reaction (PCR) is the technique that is used to amplify (akin to photocopying DNA) specific regions of the genome from specific groups of taxa
Primer	A short DNA strand (≈20bp in size) used in PCR to target particular groups of organisms and genes. Two of them are required for PCR (a forward and a reverse)
Primer binding site	A primer-binding site is the target region of a genome where the primer attaches to start replication. The primer binding site is on one of the two complementary strands of a double-stranded nucleotide polymer, in the strand which is to be copied, or is within a single-stranded nucleotide polymer sequence
prokaryote	Any of the typically unicellular microorganisms that lack a distinct nucleus and

	membrane-bound organelles and that are classified as a kingdom (Prokaryotae syn. Monera) or into two domains (Bacteria and Archaea)
RNA	Ribonucleic acid (RNA) is a polymeric molecule implicated in various biological roles in coding, decoding, regulation, and expression of genes
rRNA	ribosomal ribonucleic acid is the RNA component of the ribosome, and is essential for protein synthesis in all living organisms
Sequence	DNA sequencing is the process of determining the precise order of nucleotides within a DNA molecule. It includes any method or technology that is used to determine the order of the four bases—adenine, guanine, cytosine, and thymine—in a strand of DNA
Shotgun sequencing	Refers to randomly sequencing short pieces of DNA (≈150bp in size) after shearing or cutting DNA (e.g. fragmenting a genome)

Executive Summary:

Overall Project objective:

The aim of this pilot project was to use an environmental DNA (eDNA) metabarcoding approach to determine presence/absence of Blind Cave Eel (*Ophisternon candidum*) from within and outside the Mesa H project area in the Pilbara region of Western Australia. The data was to be incorporated into an environmental impact statement (EIS) by Rio Tinto.

Outputs:

- This report is a follow-up of the results from the EelFishCOI 'molecular magnet' designed for Blind Cave Eel (*Ophisternon candidum*) detection. This report presents the eDNA results following on from the report issued to RioTinto on the 13th July 2018 by the TrEnD lab.

- The presence of Blind Cave Eel (*Ophisternon candidum*) DNA was confirmed from two sample sites of the Robe River and bores JW021, JW024, BC186, 25, RR1 and MB17MEH0015. Blind Cave Eel DNA was not previously detected from MB17MEH0015 with the EelFish16S assay reported on 13th July 2018. Re-screening all 122 eDNA water membranes collected in June and December 2017 with Fish16S and EelFishCOI 'molecular magnets' confirms the presence of *O. candidum* from this additional bore.

Recommendations:

- This is the first time eDNA metabarcoding methods have been implemented in the Pilbara groundwater systems. The Fish16S, EelFish16S and EelFishCOI metabarcoding assays designed by the TrEnD lab indicates that an eDNA approach is able to detected Blind Cave Eel (*Ophisternon candidum*) from the survey area as a non-invasive method. Blind Cave Eel (*Ophisternon candidum*) DNA was isolated and DNA sequenced from 6 bores sampled, in addition to two open surface water samples collected from the Robe River, which indicates eDNA metabarcoding is capable of detecting threatened species. Finally it is worth noting that these eDNA assays are performing at the limits of detection and further gains in sensitivity may be achievable with optimised sampling.
-

1. Introduction

eDNA refers to all genetic material that is recovered from environmental substrates (such as water or sediment). DNA directly from an organism (e.g. microorganisms) as well as trace amounts of DNA that are shed by all organisms is collectively termed eDNA. This preserved, but often degraded, genetic material provides a means to audit species composition and communities at a given location. When combined with recently developed DNA sequencing technologies (termed 'next generation' or 'high-throughput' sequencing), eDNA can provide a wealth of information for studies of introduced marine pests (IMP), biodiversity surveys, food web dynamics, and diet analysis.

Potential applications for monitoring using eDNA include:

- Biosecurity: to detect the presence/absence of introduced species
- Environmental Impact Assessment: baseline/ongoing monitoring and assessment; audit
- Conservation: to detect the presence/absence of threatened species

Rio Tinto has partnered with the Trace and Environmental DNA (TrEnD) Laboratory at Curtin University to develop eDNA tools for Blind Cave Eel (*Ophisternon candidum*) as a means to use DNA-based bio surveys in groundwater monitoring and management.

eDNA sampling has benefits over other traditional survey methods including:

- highly cost-effective monitoring compared to traditional survey methods
- rapid sample collection that is non destructive to habitats, flora and fauna
- non-reliance on individuals with taxonomic expertise, provision of consistent results between monitoring programs, independent of surveyors

The objectives of this project were to use an environmental DNA (eDNA) metabarcoding approach to determine the presence/absence of Blind Cave Eel (*Ophisternon candidum*) a threatened species within the groundwater systems of the Pilbara in Western Australia, specifically the Mesa H area (Rio Tinto). The data is to be incorporated into an environmental impact statement.

2. Methods and Samples

Please refer to report "**eDNA Metabarcoding Report: Blind Cave Eel survey in the Pilbara WA**" issued to RioTinto by the TrEnD lab on 13th July 2018.

3. Results and Discussion

Table 1 list the water samples from each bore and those for which Blind Cave Eel (*Ophisternon candidum*) were detected with the Fish16S, EelFish16S and EelFishCOI metabarcoding assays. DNA sequences obtained for *O. candidum* can be found in the Supplementary Information accompanying this report.

Table 1: Results of eDNA metabarcoding (Fish16S, EelFish16S, EelFishCOI) from groundwater for Blind Cave Eel (*Ophisternon candidum*) detection.

4. Findings, Recommendations and Concluding remarks

At the time of report "**eDNA Metabarcoding Report: Blind Cave Eel survey in the Pilbara WA**" issued to RioTinto by the TrEnD lab on 13th July 2018, the water samples identified as positive from the EelFishCOI and Fish16S metabarcoding assays had not been DNA sequenced and bioinformatically processed.

The Fish16S, EelFish16S and EelFishCOI assays utilised on bore water samples collected in June and December 2017 detected Blind Cave Eel (*Ophisternon candidum*) from two sample locations of the Robe River, in addition to bores JW021, JW024, BC186, 25, RR1 and MB17MEH0015. To our knowledge this represents the first time an eDNA based metabarcoding approach, specific for *Ophisternon candidum*, has been applied to samples from ground water system(s) in the Pilbara, Western Australia. Sequencing the mitochondrial genome of *Ophisternon candidum* (WAM P.34817-001) has provided definitive assignments of DNA sequences from eDNA groundwater samples to genus and species.

5. Appendices and additional information

- An electronic file titled; SupplementaryInformation_EelFish16SandCOI_August2018.xlsx is attached to this report.

- Additional information on sampling and methods are available from TrEnD upon request however the exact nature of the assays and workflow are proprietary.

- Below is a list of acronyms, abbreviations and definitions that may apply to aspects of this report.

% value in data	Represents the percentage similarity of a DNA sequence recovered from a sample compared to reference sequences in a database (e.g. compared to DNA databases such as GenBank or references generated in-house)
(x) value in data	Represents the frequency the % value was recorded in the dataset
18S rRNA	The 18S rRNA refers to a conserved gene region of nuclear DNA, which codes for a subunit of the ribosome. 18S rRNA is found in all eukaryotes making it a good candidate for DNA barcoding
18S IMS reference database	Reference 18S rRNA sequences of invasive marine species that are available in DNA databases
Assay	In the context of metabarcoding an assay is a molecular test (using PCR) that is implemented to target a group of taxa within a mixed biological substrate. It is akin to using a magnet to selective enrich for needles (the target) in the context of a haystack (the total DNA from a sample).
COI	The gene region that is being used as the standard barcode for almost all animal groups is a 648 base-pair region of the mitochondrial cytochrome c oxidase 1 gene ("CO1"). COI is proving highly effective in identifying birds, butterflies, fish, flies and many other animal groups. COI is not an effective barcode region in plants because it evolves too slowly, but two gene regions in the chloroplast, matK and rbcL, have been approved as the barcode regions for plants
CO1 IMS reference database	Reference COI sequences of invasive marine species that are available in DNA databases
DNA	Deoxyribonucleic Acid (DNA) is the hereditary material that contains the genetic information of an organism
DNA metabarcoding	Is a genetic technique that simultaneously amplifies and sequences barcode regions (e.g. COI, 18S, 16S) of many different species in parallel
eDNA	Environmental DNA (eDNA) refers to genetic material that is recovered from an environmental substrate (e.g. water, sediment, air)

eukaryotes	An organism where cells contain a nucleus surrounded by a membrane and has the DNA bound together by proteins (histones) into chromosomes. The cells of eukaryotes also contain an endoplasmic reticulum and numerous specialised organelles not present in prokaryotes, especially mitochondria, golgi bodies, and lysosomes
Fisheries	Department of Primary Industries and Regional Development, Fisheries Division, Aquatic Biosecurity Section
GenBank	Publically available repository of genetic information. Contains the barcode information of genes that have previously been sequenced
Genome	A genome is all the genetic material of an organism. It consists of DNA (or RNA in RNA viruses). The genome includes both the genes (the coding regions) and the noncoding DNA. In eukaryotes it refers to the genomes of the nucleus, mitochondria and chloroplasts. In prokaryotes, there is a single genome (as they do not contain mitochondria or chloroplasts)
Illumina MiSeq	Next generation sequencing platform developed by the company Illumina
IMP	Introduced marine pests
IMS	Introduced marine species
Metabarcoding assay	A PCR reaction using a specific set of primers that simultaneously amplifies the same gene target from multiple species
Mitochondria	The mitochondrion (plural mitochondria) is a double membrane-bound organelle found in all eukaryotic organisms, although some cells in some organisms may lack them (e.g. Red blood cells). It contains its own genome
Mitogenomes	Refers to the mitochondrial genome
NGS	Next generation sequencing or second generation sequencing refers to massively parallel sequencing technology, as opposed to first generation sequencing or sanger sequencing where only a single template is sequenced at one time
Nucleotide	A compound consisting of a nucleoside linked to a phosphate group. Nucleotides form the basic structural unit of nucleic acids such as DNA
PCR	Polymerase chain reaction (PCR) is the technique that is used to amplify (akin to photocopying DNA) specific regions of the genome from specific groups of taxa
Primer	A short DNA strand (≈20bp in size) used in PCR to target particular groups of organisms and genes. Two of them are required for PCR (a forward and a reverse)
Primer binding site	A primer-binding site is the target region of a genome where the primer attaches to start replication. The primer binding site is on one of the two complementary strands of a double-stranded nucleotide polymer, in the strand which is to be copied, or is within a single-stranded nucleotide polymer sequence
prokaryote	Any of the typically unicellular microorganisms that lack a distinct nucleus and membrane-bound organelles and that are classified as a kingdom (Prokaryotae syn. Monera) or into two domains (Bacteria and Archaea)
RNA	Ribonucleic acid (RNA) is a polymeric molecule implicated in various biological roles in coding, decoding, regulation, and expression of genes

rRNA	ribosomal ribonucleic acid is the RNA component of the ribosome, and is essential for protein synthesis in all living organisms
Sequence	DNA sequencing is the process of determining the precise order of nucleotides within a DNA molecule. It includes any method or technology that is used to determine the order of the four bases—adenine, guanine, cytosine, and thymine—in a strand of DNA
Shotgun sequencing	Refers to randomly sequencing short pieces of DNA (≈150bp in size) after shearing or cutting DNA (e.g. fragmenting a genome)

WAM Morphological Identification of Troglobitic Spiders

WAM Report

Troglobitic Spiders from Mesa H, Robe Valley, Western Australia

(Project *Mesa H Troglobitic Spiders*)

Report to Biota

16 Mar 2017

Karen Cullen, Mark S. Harvey, Julianne Waldock

Department of Terrestrial Zoology, Western Australian Museum,

Locked Bag 49, Welshpool DC, Western Australia 6986, Australia

Although identifications in this report were consistent with the best available information and current scientific thinking at the time of identification the use of this report is at the risk of the user. Any liability to users of this report for loss of any kind arising out of the use of this report or the information and identifications it contains is expressly disclaimed.

SUMMARY

Specimens were submitted to the Western Australian Museum on the 13th March 2017. The project contained: A Spider from the family Oonopidae (n=1) and a spider from the family Gnaphosidae (n=1). A summary of specimen identifications together with their SRE status may be found in Table 1. A full explanation of the SRE categories used by the Western Australian Museum may be found in Appendix 1.

Table 1. Summary of specimen identifications and SRE status.

ORDER	FAMILY	GENUS	SPECIES	# OF SPECIMENS	SRE STATUS	SRE SUB-CATEGORY
Araneae	Oonopidae	*Prethopalpus*	`ARA052`	1	Potential SRE	(E) Research and experience
Araneae	Gnaphosidae	Genus indet.	`sp. indet. (juv.)`	1	Potential SRE	(A) Juvenile

SHORT-RANGE ENDEMISM

The terrestrial invertebrate fauna of inland Australia contains a plethora of species, and just the arthropods were recently estimated to consist of more than 250,000 species (Yeates, Harvey et al. 2004; Chapman 2009). The vast majority of these are found within the Insecta and Arachnida, although significant numbers of millipedes are to be expected. For many years, the prospect of including invertebrates in assessments of biological systems subject to modification proved daunting because of the large numbers of unknown species. These animals were largely ignored, as they were too diverse and their taxonomy too little known for them to be considered in environmental surveys that require a rapid turn-around time.

In a recent publication, the issue of Short-Range Endemism in the Australian invertebrate fauna was examined (Harvey 2002). Species that could be defined as Short-Range Endemics (SRE) were those that had a naturally small range of less than 10,000 km^2. Harvey (2002) found that those species possessed a series of distinct ecological and life-history traits that contributed to their limited distributions, including:

- poor powers of dispersal;
- confinement to discontinuous habitats;
- usually highly seasonal, only active during cooler, wetter periods; and
- low levels of fecundity.

A number of major invertebrate groups have a high proportion of individual species that show these traits and can be considered SRE's. The Western Australian fauna contains a number of SRE taxa, including millipedes, land snails, trap-door spiders, some pseudoscorpions, slaters, and onychophorans and these represent focal groups in Environmental Impact Assessment studies in the state (EPA 2009). The south coast region is relatively well known compared with other regions of the state (Framenau, Moir et al. 2008), but there are many poorly known species and gaps in our understanding of the distributions of many species.

METHODS

Specimens collected by Biota were submitted to the Western Australian Museum on the 13th March 2017. The specimens were examined at the WA museum using Leica dissecting microscopes (MZ6, MZ16). The SRE status of the taxonomic group was given using the SRE categorisation system developed and implemented by the Western Australian Museum. A full explanation of the WAM SRE categories is available in Appendix 1.

SIGNIFICANT OUTCOMES

This project has found one species that may have significant SRE outcomes.

The significant findings are summarised below.

ARACHNIDA

ORDER ARANEAE

Family Oonopidae

1. *Prethopalpus `ARA052`*
    - **SRE Category: Potential SRE; (B) Habitat indicators; (E) Research and experience.**
    - Examination of the adult male morphology, specifically the shape of the male pedipalp and abdominal scutae, combined with the locality would indicate that it is likely an undescribed species within *Prethopalpus* and has been allocated the WAM species code 'ARA052'.

      Baehr *et al*. (2014) described 14 troglobitic *Prethopalpus* species from the arid zone of Western Australia, all of which are SREs and many known only from a single bore. Two species have been recorded from the Robe River Valley, *Prethopalpus scanloni* from bore DBRC089 and the other *P*. `ARA051` from bore MEBRC0073, Mesa B. No specimens of this genus have yet been collected from Mesa H. This species is similar to that of *P. scanloni* in having a bulging epigastric plate in lateral view, but differs by having a dorsal scute, whereas *P. scanloni* does not. Further, given the limited distributional ability of this taxa, and its location within an isolated mesa (Mesa H), makes this species likely to be an SRE. Collections of adult troglobitic spiders are patchy and occur rarely, so this find is particularly significant.

APPENDIX 1. WAM SHORT-RANGE ENDEMIC CATEGORIES

	Taxonomic Certainty	Taxonomic Uncertainty
Distribution < 10 000km^2	**Confirmed SRE** • *A known distribution of < 10 000km².* • *The taxonomy is well known.* • *The group is well represented in collections and/ or via comprehensive sampling.*	**Potential SRE** • *Patchy sampling has resulted in incomplete knowledge of the geographic distribution of the group.* • *We have incomplete taxonomic knowledge.* • *The group is not well represented in collections.* • *This category is most applicable to situations where there are gaps in our knowledge of the taxon.* **Sub-categories for this SRE designation are outlined below**
Distribution > 10 000km^2	**Widespread (not an SRE)** • *A known distribution of > 10 000km².* • *The taxonomy is well known.* • *The group is well represented in collections and/ or via comprehensive sampling.*	

SRE SUB-CATEGORIES

If a taxon is determined to be a "Potential SRE", the following sub-categories will further elucidate this status.

A. *Data Deficient:*
- There is insufficient data available to determine SRE status.
- Factors that fall under this category include:
  - New species.
  - Lack of geographic information.
  - Lack of taxonomic information.
  - The group may be poorly represented in collections.
  - The individuals sampled (e.g. juveniles) may prevent identification to species level.

B. *Habitat Indicators:*
- It is becoming increasingly clear that habitat data can elucidate SRE status.
- Where habitat is known to be associated with SRE taxa and vice versa, it will be noted here.

C. *Morphology Indicators:*
- A suite of morphological characters are characteristic of SRE taxa.
- Where morphological characters are known to be associated with SRE taxa and vice-versa, it will be noted here.

D. *Molecular Evidence:*
- If molecular work has been done on this taxon (or a close relative), it may reveal patterns congruent or incongruent with SRE status.

E. *Research & Expertise:*
- Previous research and/ or WAM expertise elucidates taxon SRE status.
- This category takes into account the expert knowledge held within the WAM.

Mesa H Project Subterranean Fauna Habitat and Impact Risk Assessment

Contents

1.0 Introduction 9
- 1.1 Project Background 9
- 1.2 Terminology 9
- 1.3 Purpose and Scope of this Report 9

2.0 Methodology 11
- 2.1 Policy Framework 11
- 2.2 Approach 11
- 2.3 Impact Sources and Pathways 11
- 2.4 Identification of Subterranean Fauna Key Receptors 12
- 2.5 Habitat Assessment 13
- 2.6 Impact Assessment 15

3.0 Project Definition 19
- 3.1 Development Envelope 19
- 3.2 Dewatering Extent 21

4.0 Potential Impacts 23
- 4.1 Impact Sources 23
- 4.2 Impact Pathways 23

5.0 Key Receptors Species and Communities 27
- 5.1 Stygofauna 27
- 5.2 Troglofauna 29

6.0 Key Receptor Habitats 33
- 6.1 Stygofauna Habitat 33
- 6.2 Troglofauna Habitat 37

7.0 Impact Assessment 43
- 7.1 Stygofauna Impacts 43
- 7.2 Troglofauna Impacts 53

8.0 Conclusions 63
- 8.1 Stygofauna 63
- 8.2 Troglofauna 65
- 8.3 Summary of Significant Impacts 66

9.0 Glossary 69

10.0 References 71

Appendix 1

Conceptual Flowchart of Troglofauna Habitat CID Modelling

Tables

Table 4.1: Summary of relevant characteristics of the Mesa H project and related impact sources. 23

Table 5.1: All stygofauna species currently known from within the dewatering extent (Impact sites), and any records from outside of the dewatering extent (Reference sites) (species only known from the dewatering extent from desktop assessment records shown in grey; source: Biota (2019)). 27

Table 5.2: All potential SRE troglofauna species currently known from within the development envelope (Impact sites), and any records from outside of the development envelope (Reference sites) (species only known from the development envelope from desktop assessment records shown in grey; source: Biota (2011; 2019)). 29

Table 6.1: Geology units identified as stygofauna habitat in the dewatering extent and wider locality. 33

Table 6.2: Geological units identified as troglofauna habitat within the development envelope. 39

Table 7.1: Summary of records of impacted stygofauna key receptors relative to the maximum predicted drawdown extent at 2030 under the base case (Reference sites from Biota (2019); Species shaded grey known only from the drawdown extent). 45

Table 7.2: Troglofauna species currently known only from within the development envelope and their distribution relative to the proposed mine pits (species shaded grey currently only known from the mine pits). 55

Table 7.3: Cumulative direct impacts from the Mesa H mine pits on troglofauna PECs, in context with other habitat removal (ignoring overlaps in mapped PEC extents within the development envelope). 58

Figures

Figure 1.1: Location map of the Mesa H project area. 10

Figure 2.1: Environmental impacts assessment model used in this report. 15

Figure 3.1: Development envelope and project footprint for the Mesa H proposal (source: Rio Tinto). 20

Figure 3.2: Maximum extent of predicted groundwater drawdown from the Mesa H proposal (base case year 2030, including the use of thickener in process water). 22

Figure 4.1: Relationship between impact sources, pathways and impacts on subterranean ecosystems (direct impacts in red and orange; indirect impacts in pink). 24

Figure 6.1: Cross-sections of Jimmawurrada Creek, showing depth of alluvium relative to underlying CID and basement units in difference sections of the creek (source: Rio Tinto). 34

Figure 6.2: Surface geology units representing stygofauna habitat showing spatial relationship with confirmed stygofauna records. 35

Figure 6.3: Isometric view of stygofauna habitat at Mesa H, overlain with the locations of confirmed stygofauna records. 36

Figure 6.4: Mesa H surface geology (left) and cross-sections (right) illustrating troglofauna habitat strata at depth across three sections of Mesa H (A, B and C) (blue horizontal line on cross-sections represents approximate water table depth). 38

Figure 6.5: High likelihood troglofauna habitat in the development envelope showing spatial relationship with confirmed troglofauna records. 40
Figure 6.6: Isometric view of troglofauna habitat at Mesa H, overlain with the locations of confirmed troglofauna records. 41
Figure 7.1: Distribution of stygofauna species key receptors within the maximum (2030 base case) proposal drawdown extent. 44
Figure 7.2: Longitudinal cross-section along Jimmawurrada Creek area, showing pre-mining water table, predicted maximum drawdown from the proposal in 2030 (dashed in red) and alluvial and CID stygofauna habitats that will remain saturated (below the red dashed line) (source Rio Tinto). 46
Figure 7.3: Records of *Nedsia hurlberti* on NatureMap (blue circles) (arrow indicates development envelope). 48

1.0 Introduction

1.1 Project Background

Rio Tinto is evaluating the potential development of a number of iron ore deposits within the Robe River valley in the Pilbara region of Western Australia. This includes the development of the Mesa H deposit (15 km southwest of Pannawonica) (Figure 1.1).

Previous studies have documented the occurrence of subterranean fauna communities within the Robe River valley, including both troglofauna (air-breathing species living below ground but above the water table) and stygofauna (species living in groundwater systems). Troglofauna, in particular, demonstrate extreme short-range endemism as a result of geological barriers, with many Robe River valley species being isolated to individual mesa formations (Biota 2006a, Harvey et al. 2008). Some stygofauna species can also represent short-range endemic (SRE) taxa and all are restricted to groundwater habitats. Given these considerations, subterranean fauna are of relevance to the environmental impact assessment (EIA) of proposed developments affecting their habitat (EPA 2016a).

The development of the Mesa H deposit has the potential to impact subterranean fauna, and Rio Tinto commissioned Biota Environmental Sciences (Biota) to complete subterranean fauna surveys to collect baseline data to inform the assessment of these impacts (Biota 2019). This report draws on the findings of those surveys, and combines this with project definition provided by Rio Tinto, to assess the potential impacts on troglofauna and stygofauna of the Mesa H project.

1.2 Terminology

For the purposes of this report, the following terms are used as defined below:

- development envelope – the Mesa H project boundary, which will accommodate the full extent of the physical components of the project (Figure 1.1);
- desktop review area – an area encompassing the development envelope, and a 15 km square around it, used by Biota (2019) to take account of data from previous surveys undertaken near Mesa H (Figure 1.1);
- drawdown extent – the spatial extent of the maximum groundwater dewatering influence for the base case for the Mesa H project, which extends beyond the development envelope to the east and southeast (Figure 1.1); and
- survey area – the area surveyed for subterranean fauna by Biota (2019), including the development envelope and drawdown extent, and reference sites outside of this areas within the Robe River valley (Figure 1.1).

1.3 Purpose and Scope of this Report

The purpose of this report is to inform the impact assessment of proposed mining activities within the Mesa H development envelope. It is intended as a supporting study to the Environmental Review Document Rio Tinto is preparing for the formal assessment of the proposed Mesa H project under Section 38 of the *Environmental Protection Act 1986*.

This report consolidates the results of all subterranean fauna data from the survey area with available habitat information to develop a model of demonstrated and inferred fauna distributions and habitat connectivity. The key characteristics of the Mesa H project, and their potential impact mechanisms, are then considered against this, to provide a risk-based assessment of the impacts on subterranean ecosystems within the development envelope, consistent with current Environmental Protection Authority (EPA) guidance (Section 2.1).

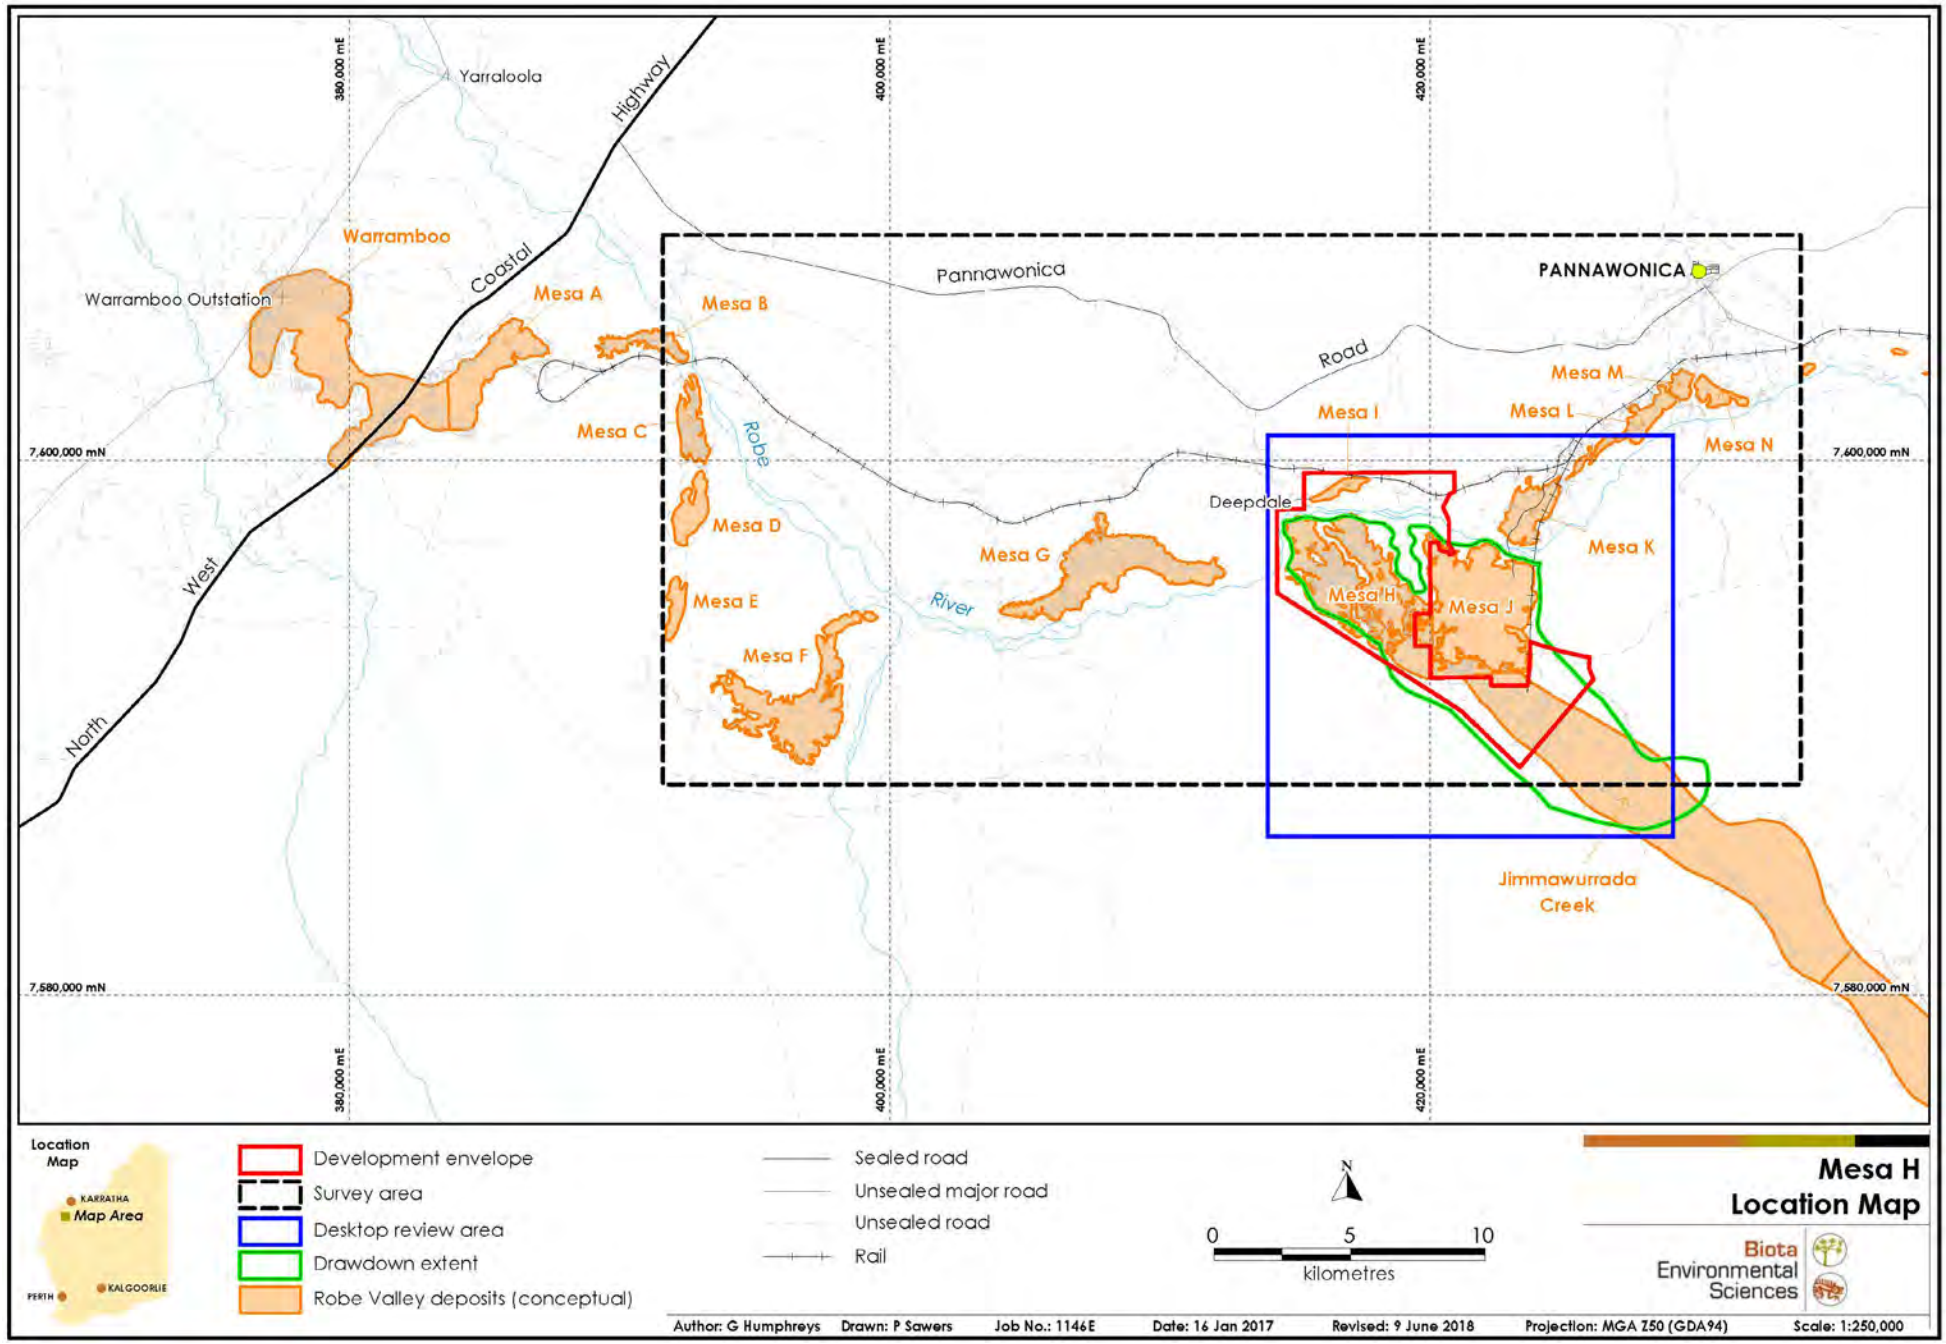

Figure 1.1: Location map of the Mesa H project area.

2.0 Methodology

2.1 Policy Framework

The impact assessment was completed in accordance with:

- EPA Statement of Environmental Principles, Factors and Objectives (EPA 2018);
- Environmental Factor Guideline – Subterranean Fauna (EPA 2016a);
- Technical Guidance - Subterranean fauna survey (EPA 2016b); and
- Technical Guidance - Sampling methods for subterranean fauna (EPA 2016c).

2.2 Approach

This impact assessment has adopted an overall approach of initially identifying all subterranean fauna receptors relevant to the EPA assessment of the Mesa H project (on the basis of the Biota (2019) surveys) and defining the habitats within which they occur. Key receptors were then identified and the predicted impacts of the project, including extent, consequences and resilience of the key receptors, were then assessed, including the level of confidence in predictions.

This approach is aligned with EPA (2018) guidance on determining the significance of impacts: in the case of species or habitats that are more widespread than the impact area, are not of conservation significance, or otherwise unlikely to be impacted, the project would be considered unlikely to have a significant impact in the context of EPA's objective for subterranean fauna.

While all subterranean fauna were considered, the species, communities or habitats that are of restricted distribution, or otherwise of conservation significance, were treated as the key receptors for more detailed evaluation of potential impacts, which is consistent with the guidance provided by EPA (EPA 2016a, 2018).

The logical sequence followed by this document then is to:

1. review, characterise and quantify the key aspects of the Mesa H project to define potential impact sources and pathways (Section 2.3);
2. document all subterranean fauna species and communities present in the development envelope (for troglofauna and stygofauna) and the drawdown area (for stygofauna only), and determine if they represent key receptors (Section 2.4); and
3. delineate the habitats occupied by the key receptors and assess the risk of significant impacts arising from the proposal (Section 2.5 and 2.6).

2.3 Impact Sources and Pathways

2.3.1 Impact Sources

Impact sources inherent to the Mesa H project were identified by collating and reviewing relevant project aspects and attributes. These were compiled from the proposal definition provided by Rio Tinto, comprising the key characteristics, development envelope, indicative arrangement, pit and dump designs, and modelling information.

2.3.2 Impact Pathways

Impact pathways are the mechanisms by which the impact sources result in an impact on subterranean receptors, and these can be broadly categorised as either direct or indirect (EPA 2016a). The most important, direct impact pathways are well recognised and have regularly arisen during past EPA assessments involving impacts on subterranean fauna.

These direct pathways, such as troglofauna habitat removal for mine pits, can typically be spatially quantified and are thereby the clearest to assess. Direct impacts were addressed here through the use of MapInfo Professional Geographical Information System (GIS) v12 (MapInfo). The components of the indicative arrangement and groundwater modelling outputs provided by Rio Tinto were intersected in GIS with subterranean fauna habitats, records of key receptors and other ecological data to quantify impact extents and identify the predicted influence of the proposal.

2.4 Identification of Subterranean Fauna Key Receptors

Key subterranean fauna species and habitat receptors in this impact assessment were those from the list of all relevant subterranean receptors that:

1. meet the criteria outlined in Section 2.4.1 and 2.4.2 below; and/or
2. the basis for their conservation listing and identified threatening processes are relevant to the proposed development; and/or
3. their known distribution, habitat requirements and ecology suggest they may be significantly affected by the impact pathways arising from the project.

This provided a means of focussing the list of all subterranean species known from the development envelope and drawdown extent down to those species most relevant to the impact assessment. Other species recorded during subterranean fauna surveys determined by Biota (2019) as widespread were excluded from the final impact assessment, and records where species level determinations could not be made were excluded from consideration altogether.

Similarly, some subterranean habitats occurring in the development envelope would not be considered key receptors. The criteria applied for determining habitats to be key receptors, and therefore considered in this impact assessment, are detailed in Section 2.4.3.

2.4.1 Species and Communities of Conservation Significance

All species or ecological communities occurring or likely to occur in the development envelope and drawdown extent that are currently listed as:

1. Threatened species under the Commonwealth *Environment Protection and Biodiversity Conservation* (*EPBC) Act 1999*;
2. Schedule species under the State *Wildlife Conservation Act 1950*;
3. Priority species by the Department of Biodiversity, Conservation and Attractions (DBCA); or
4. Priority Ecological Communities (PECs) recognised by DBCA.

All qualified as key receptors for this impact assessment.

2.4.2 Other Species of Significance

Consistent with Biota (2019), for the purposes of this report, other subterranean fauna known from the development envelope that are relevant to impact assessment but not formally listed as conservation significant were categorised as:

- Confirmed short-range endemic (SRE) species: Species where sufficient taxonomic expertise is available, and with adequate representation in the Western Australian Museum collections or genetic databases, that are known to be limited in distribution.
- Potential SRE species: Species where there is insufficient taxonomic knowledge, or there are too limited a number of collections, to determine SRE status. Habitat, morphology, molecular or taxonomic data is deficient for these species, but they belong to groups that may display short-range endemism.

Where species recorded by Biota (2019) are either confirmed or potential SREs, they were treated as key receptors.

2.4.3 Subterranean Habitat Receptors

Subterranean fauna habitats treated as key receptors were identified as either Medium or High prospectivity for stygofauna or troglofauna, following the methodology detailed in Section 2.5.

2.5 Habitat Assessment

2.5.1 Stygofauna Habitat Information Review

The suitability of geological formations as core habitat for subterranean fauna is predominantly determined by the availability of cavities and spaces within the rock type, and potential for water and nutrient infiltration and movement. In the case of stygofauna, this may be refined to where such rock formations occur below the water table and, in the Pilbara, where the depth from the ground surface to the water table does not exceed approximately 40-50 m (Halse et al. (2014); Eberhard et al. (2009); Biota (unpublished data)).

Several geological units are now well recognised as being core habitat for stygofauna as they characteristically form fractures, interstices, cavities and vugs, which allows for fauna dispersal and nutrient infiltration. These units include limestone karstic systems, calcrete, alluvium, gravels, fractured rock aquifers, limonite and dolomite (Marmonier et al. 1993, Humphreys 1999, Halse et al. 2014). In the broader Robe Valley setting, important habitat that has also been well documented with diverse stygofauna communities occurring in the locality includes valley fill units where alluvium, gravels, calcrete and channel iron deposits (CID) occur below the water table (Biota 2010, 2015, 2016a). Where these units occur below water table in the Mesa H development envelope, they were also identified here as potential key habitat receptors for stygofauna (Section 2.5.3).

Hydrogeological and stratigraphic information was used to identify and delineate stygofauna habitat, by considering inputs both:

1. spatially (2D) – including accounts of the aquifers and host rock types documented in Rio Tinto hydrogeology reports, Rio Tinto surface geology mapping and regional Geological Survey of WA (GSWA) surface geology; and
2. vertically (3D) – using Rio Tinto drill logs and stratigraphic cross-sections, a digital elevation model constructed from contour data (to identify units associated with valleys and drainage systems), depth to water table, and hydrogeological descriptions of the vertical arrangement, hydrogeological conductivity and connectivity of aquifers.

2.5.2 Troglofauna Habitat Information Review

Like stygofauna, core habitat for troglofauna is also a function of available spaces within the rock formation, along with the ability to maintain a consistently high humidity and the potential for nutrient input from surface systems (Humphreys 1991, Dole-Oliver et al. 2009, Biota and DC Blandford & Associates 2013)

Geological units previously recognised as primary troglofauna habitat include karstic limestone systems, calcrete and CID above water table (Humphreys 1991, Marmonier et al. 1993, Biota 2006a). Physical characteristics common to these formations again include fractures, caverns, vugs, or interstices of sufficient size to physically accommodate troglobitic fauna. Many of these formations include lithologies with important hydrological functions, such as impeding layers and clay lenses which store infiltrated water from recharge events, maintaining humidity in the system (Biota and DC Blandford & Associates 2013).

The importance of above water table CID formations as troglofauna habitat in the Robe Valley, particularly when occurring as mesa landforms, has now been well established (Biota 2006a, 2007, 2009a, Harvey et al. 2008, Biota and DC Blandford & Associates 2013). All CID units above water table were therefore treated as potential key habitat receptors for more detailed assessment here, with other rock types present that had suitable physical characteristics also considered (Section 2.5.4).

Troglofauna habitat was determined in a similar fashion to stygofauna, by consideration of inputs both:

1. spatially (2D) – Rio Tinto surface geology mapping and the spatial extent of Rio Tinto CID ore body strands (which provide more detailed descriptions of CID structure, grade and texture); and

2. vertically (3D) – CID thickness modelling completed by Rio Tinto (see Appendix 1), Rio Tinto drill logs and stratigraphic cross-sections, a digital elevation model (to identify units associated with elevated mesa landforms), downhole geophysical data including cavities and depth to water table (which effectively sets the lower limit of troglofauna habitat) (Appendix 1).

2.5.3 Stygofauna Habitat Characterisation

The habitat units identified from the inputs consolidated in Section 2.5.1 were assigned a likelihood to support stygofauna of Low, Moderate or High, based on the following attributes:

A) Presence of interstitial spaces or vugs.

B) Structural continuity, hydraulic connectivity and transmissivity of the local occurrence of the geological unit below the water table.

C) Demonstrated occurrence of stygofauna in equivalent rock types during previous surveys.

D) Fine sediments such as clays and silts do not dominate the geological unit.

E) Surface conditions permit infiltration of surface water and nutrients.

F) The geological unit is saturated and occurs below the water table.

Likelihood categories were then determined for each geological unit as:

High – Majority (five or more) of attributes confirmed for the unit, including the presence of continuous, transmissive aquifer (A, B, D). Surface geology sufficiently porous to allow nutrient infiltration from surface inputs (E), and unit partially or completely saturated below the water table (F). Stygofauna routinely recorded from the same rock type (C)

Medium – Unit at least partially saturated below the water table (F). Presence of interstitial spaces and cavities (A), with limited fine sediments within the unit (D). Stygofauna occasionally recorded from this geology during previous surveys (C).

Low – Suitable geological unit may occur only above the water table within the study area. Rock type may have limited interstitial spaces (A) however the unit may also be dominated by fine sediments, which reduce usability of spaces (D). Stygofauna not known from previous studies sampling of the same geology (C).

The adequacy of the habitat characterisation was then assessed by plotting all available stygofauna records from the survey area within the High and Medium likelihood habitat extents in MapInfo GIS software. This enabled a more accurate delineation of areas of prospective habitat on the combined basis of physical habitat attributes and the presence of confirmed fauna records.

Spatial correlation between the records and the habitat units assessed as High and Medium likelihood for stygofauna was then used to infer other prospective stygofauna habitat in the same units outside of sampling locations.

2.5.4 Troglofauna Habitat Characterisation

Similar to stygofauna, the habitat units identified as likely troglofauna habitat from the information consolidated in Section 2.5.2 were assigned a likelihood to support troglofauna of Low, Moderate or High, based on the following attributes:

A) Presence of cavities, vugs and interstitial spaces.

B) Known hydration, weathering or significant cavity zones.

C) Presence of clay lenses or impeding layers to maintain stable humidity.

D) Demonstrated occurrence of troglofauna in equivalent rock types during past surveys.

E) Occurs above water table within the survey area.

Likelihood categories were then assigned to the geological units as:

High – Majority (four or more) of habitat attributes confirmed for the unit, including, known to occur above water table (E), presence of interstitial spaces (A) and significance cavity zones (B), and troglofauna routinely recorded from the same rock type (D).

Medium – Suitable geology likely or known to occur above the water table in the survey area (E). Geology known to have interstices or vugs (A) and troglofauna have occasionally been detected in similar rock types previously (D). Geology may be subject to seasonal inundation (e.g. alluvium and colluvium). Where known, units of high prospectivity were categorised as medium if less than 5 m in thickness.

Low – Suitable geology only occurs below water table in the survey area. Rock type may have B), C) and E) characteristics but locally lacking suitable habitat space. Few or no troglofauna records from previous sampling of the same rock type (D).

Similar to stygofauna, the adequacy of the troglofauna habitat characterisation was then assessed by plotting all available troglofauna records from the survey area within the High and Medium habitat extents in MapInfo. Spatial correlation between the records and the High and Medium likelihood habitats both validated their status as troglofauna habitat, and was used to infer other prospective habitat in the same units outside of sampling locations.

2.6 Impact Assessment

2.6.1 Impact Assessment Model

This document considers impacts in a hierarchical framework, with outcomes for the key receptors treated as a consequence of the generalised impact stages shown in Figure 2.1.

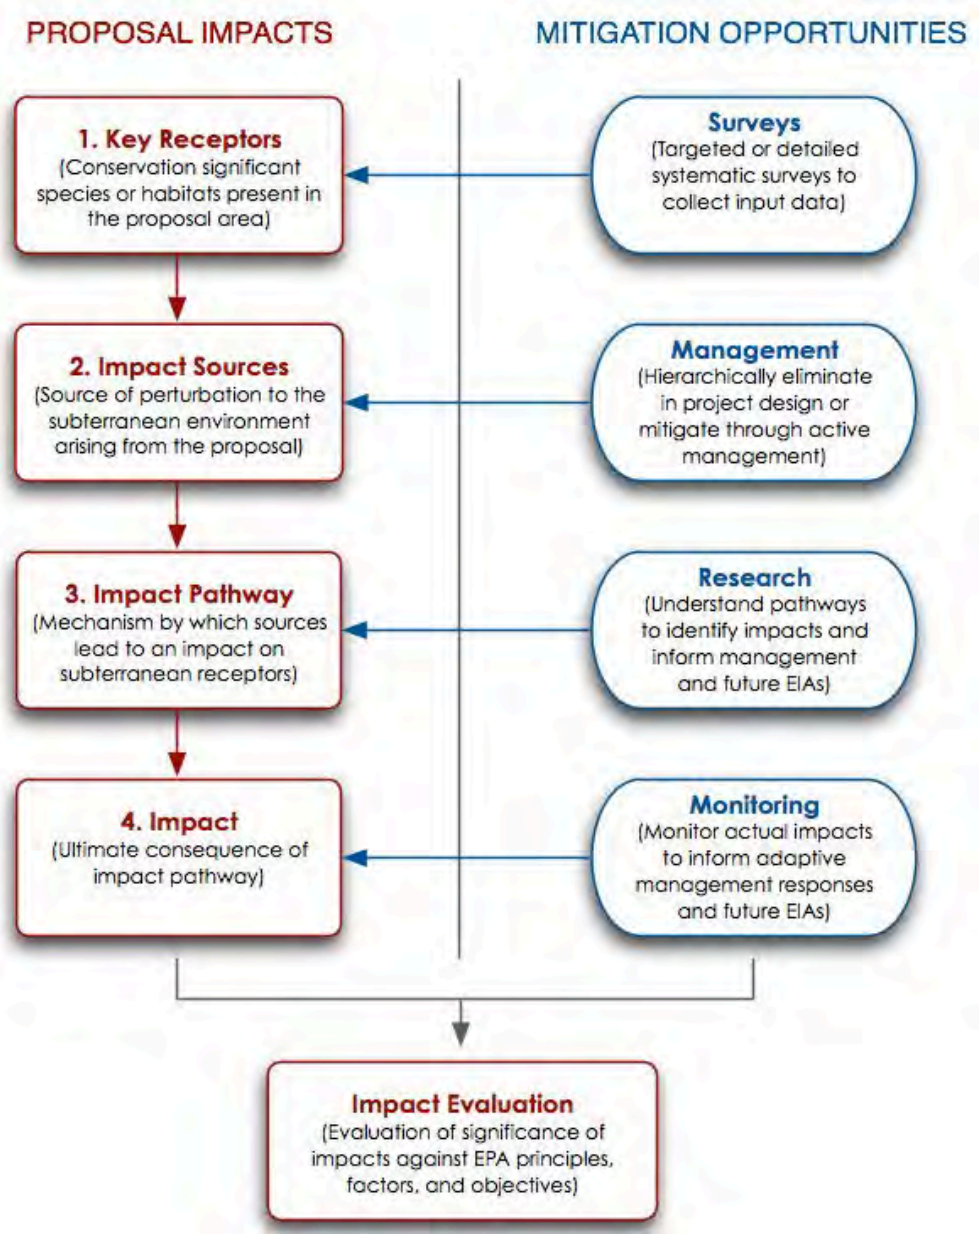

Figure 2.1: Environmental impacts assessment model used in this report.

Opportunities exist at each of the impact stages to address the impact sequence and mitigate the ultimate impact, via project design, management, research or appropriate monitoring and management response (Figure 2.1).

The identification of primary impact sources provides the first opportunity to reduce or eliminate potential impacts at the early project feasibility stage through design modifications (Figure 2.1). The Rio Tinto project design for the Mesa H proposal, and the adjustments already made by the proponent to eliminate impacts, have therefore been considered as part of this impact assessment.

Literature reviews for indirect impact pathways have been conducted previously and were leveraged to inform these assessments where relevant. Anecdotal observations and inference-based information on impact pathways from existing mining operations have also been considered in this impact assessment where informative for particular pathways and key receptors.

Opportunities usually exist for research or monitoring to better document the nature of actual impacts arising from identified pathways and to inform management at the final impact source tier (Figure 2.1). As these are effectively a lagging mitigation approach, they have not been considered in this impact assessment, given the current stage of the proposal's formal assessment.

2.6.2 Impacts

Impacts are the ultimate consequences of project impact pathways, and at a generic level they are reasonably well recognised. These consequences include impacts on key receptors such as:

- individual mortality;
- habitat loss;
- habitat fragmentation and population subdivision;
- reduced population viability; and
- local extinction.

The prediction of impacts should ideally be evidence-based, but the documentation of impacts is often subjective or anecdotal and there is a general paucity of empirical data from field programs that adequately quantify the impacts on subterranean ecosystems.

In recognition of this, impacts on key receptors were conservatively assessed on the basis of the identified impact pathways and giving consideration to two key criteria comprising:

1. spatial extent of the predicted impact (where this could be quantified), as a surrogate for population impacts; and
2. duration of the impact, considered as short-term (less than one year), long-term (years to decades), or permanent.

The extent, duration and magnitude of the impacts on the key receptors were placed into local and regional context to assist in assessing significance, considering:

- the documented and inferred distribution of the species or assemblage it forms part of;
- the spatial and vertical (2D and 3D) extent of suitable subterranean fauna habitats; and
- what is known or currently hypothesised in respect of subterranean fauna ecology, particularly whether species and communities are predisposed to impacts from a given pathway.

These considerations allowed the likely consequences and magnitude of the impact to be assessed, which was categorised as:

- Negligible: displacement or loss of individual animals;
- Minor: reduction of less than 10% of the known or inferred distribution and habitat extent;
- Moderate: reduction of 10-50%[1] of the known or inferred distribution and habitat extent; or
- Major: loss of more than 50%[1] of the known or inferred distributional extent and/or change in conservation status of the species.

[1] Derived from the International Union for the Conservation of Nature (IUCN) Red List criterion whereby a species' conservation state would shift from the Least Concern category to Vulnerable (IUCN 2012).

The level of certainty with which this assessment could categorise the risk of impacts on the key receptors was then assessed as:

- High: the outcome is quantifiable and can be predicted with confidence from a reasoned evidence base or the impact has previously occurred during similar mining developments;
- Medium: a reasonable body of data exist to predict the outcome and it could reasonably be expected to arise from the current proposal;
- Low: the outcome has not previously occurred during similar mining developments, but expert opinion or other data suggest it might arise, or there is insufficient information to quantify the impact.

2.6.3 Impact Evaluation

The significance of the identified impacts on the key receptors was then evaluated by reference to the EPA's objective for subterranean fauna, which comprises: "*To protect subterranean fauna so that biological diversity and ecological integrity are maintained.*" (EPA 2016a). Ecological integrity, in this context, is "*the composition, structure, function and processes of ecosystems, and the natural range of variation of these elements*" (EPA 2016a).

In practice, this is a somewhat challenging definition to objectively measure significance against for subterranean ecosystems in particular. Instead then, this impact assessment has adopted a more reductionist approach by addressing the specific items that EPA (2018) indicates the EPA will give regard to in determining whether an impact is significant.

Paraphrasing from EPA (2018) to those relevant to subterranean fauna and the current proposal, these comprise:

1. values, sensitivity and quality of the environment which is likely to be impacted – informed by the identification of key receptors (Section 2.4);
2. extent (intensity, duration, magnitude and geographic footprint) of the likely impacts, including cumulative impacts where appropriate – addressed here through the identification of impact sources and pathways arising from the proposal (Section 2.3);
3. consequence of the likely impacts (or change), including the resilience of the environment to cope with the impacts or change – addressed here as set out in Section 2.6.2; and
4. level of confidence in the prediction of impacts and the success of proposed mitigation – qualitatively assessed but within a defined framework, as set out in Section 2.6.2.

On this basis then, this impact assessment treats a significant impact (after EPA (2016a)) as a Moderate or Major impact on a key receptor that is predicted to arise with High or Medium certainty (following the criteria in Section 2.6.2).

This page intentionally blank.

3.0 Project Definition

3.1 Development Envelope

The Mesa H project includes the development of above and below water table open cut iron ore mine pits and associated infrastructure, including water management infrastructure. The current indicative project design for the proposal is shown in Figure 3.1.

Based on Rio Tinto (2017a), and subsequent information on project revisions provided by Rio Tinto, the characteristics of the proposal comprise:

1. Mine pits - development of open above water table (AWT) and below water table (BWT) iron ore pits, including advance abstraction of groundwater to lower the water table to access the ore body.
2. Dewatering infrastructure – infrastructure including but not limited to bores, pipelines, and discharge outlet(s) to effect the dewatering of the ore body (Section 3.2).
3. Surplus water management – including but not limited to use in processing, on-site use and controlled discharge to the Robe River and tributaries.
4. Mineral waste management – including but not limited to backfilling, ex-pit waste dumps, low grade ore dumps, topsoil and sub-soil stockpiles.
5. Processing facilities – the project will be supported by the existing processing facilities at Mesa J but may require other processing facilities including but not limited to waste fines storage facilities.
6. Support facilities – including but not limited to workshops, power supply infrastructure, hydrocarbon storage, laydown areas, offices and wastewater treatment plants.
7. Surface water management – including but not limited to surface water diversion drains, levees and culverts.
8. Linear infrastructure – including but not limited to heavy vehicle and light vehicle access roads, upgrades to existing vehicle access roads; pipelines and power (including sub-stations) and communications distribution networks.
9. Water supply – utilising groundwater abstracted for dewatering, surface water that reports to pits, the existing Mesa J bore field (Southern Cutback bore field) and potential additional bores.

For the purposes of this impact assessment, and in the interests of conciseness, the proposal characteristics can be functionally grouped under five headings that present essentially similar potential impacts to subterranean ecosystems (Section 4.1). In reference to project characteristics 1 to 9 listed above, these categories comprise:

- Mine pits: 1. Mine pits;
- Water management: 2. Dewatering infrastructure and dewatering (Section 3.2), 3. Surplus water management and 9. Water supply;
- Waste dumps and stockpiles: 4. Mineral waste management;
- Haul roads and access roads: 8. Linear infrastructure; and
- Processing and support infrastructure: 5. Processing facilities, 6. Support facilities and 7. Surface water management.

Project characteristics are grouped under the five categories above for the balance of this impact assessment.

Rio Tinto has also identified a proposed Mining Exclusion Zone (MEZ), within which no mine pits will be created (Figure 3.1). The primary purpose of the MEZ is to provide for the retention of adequate troglofauna habitat to ensure that EPA's objectives for the Subterranean Fauna factor can be met.

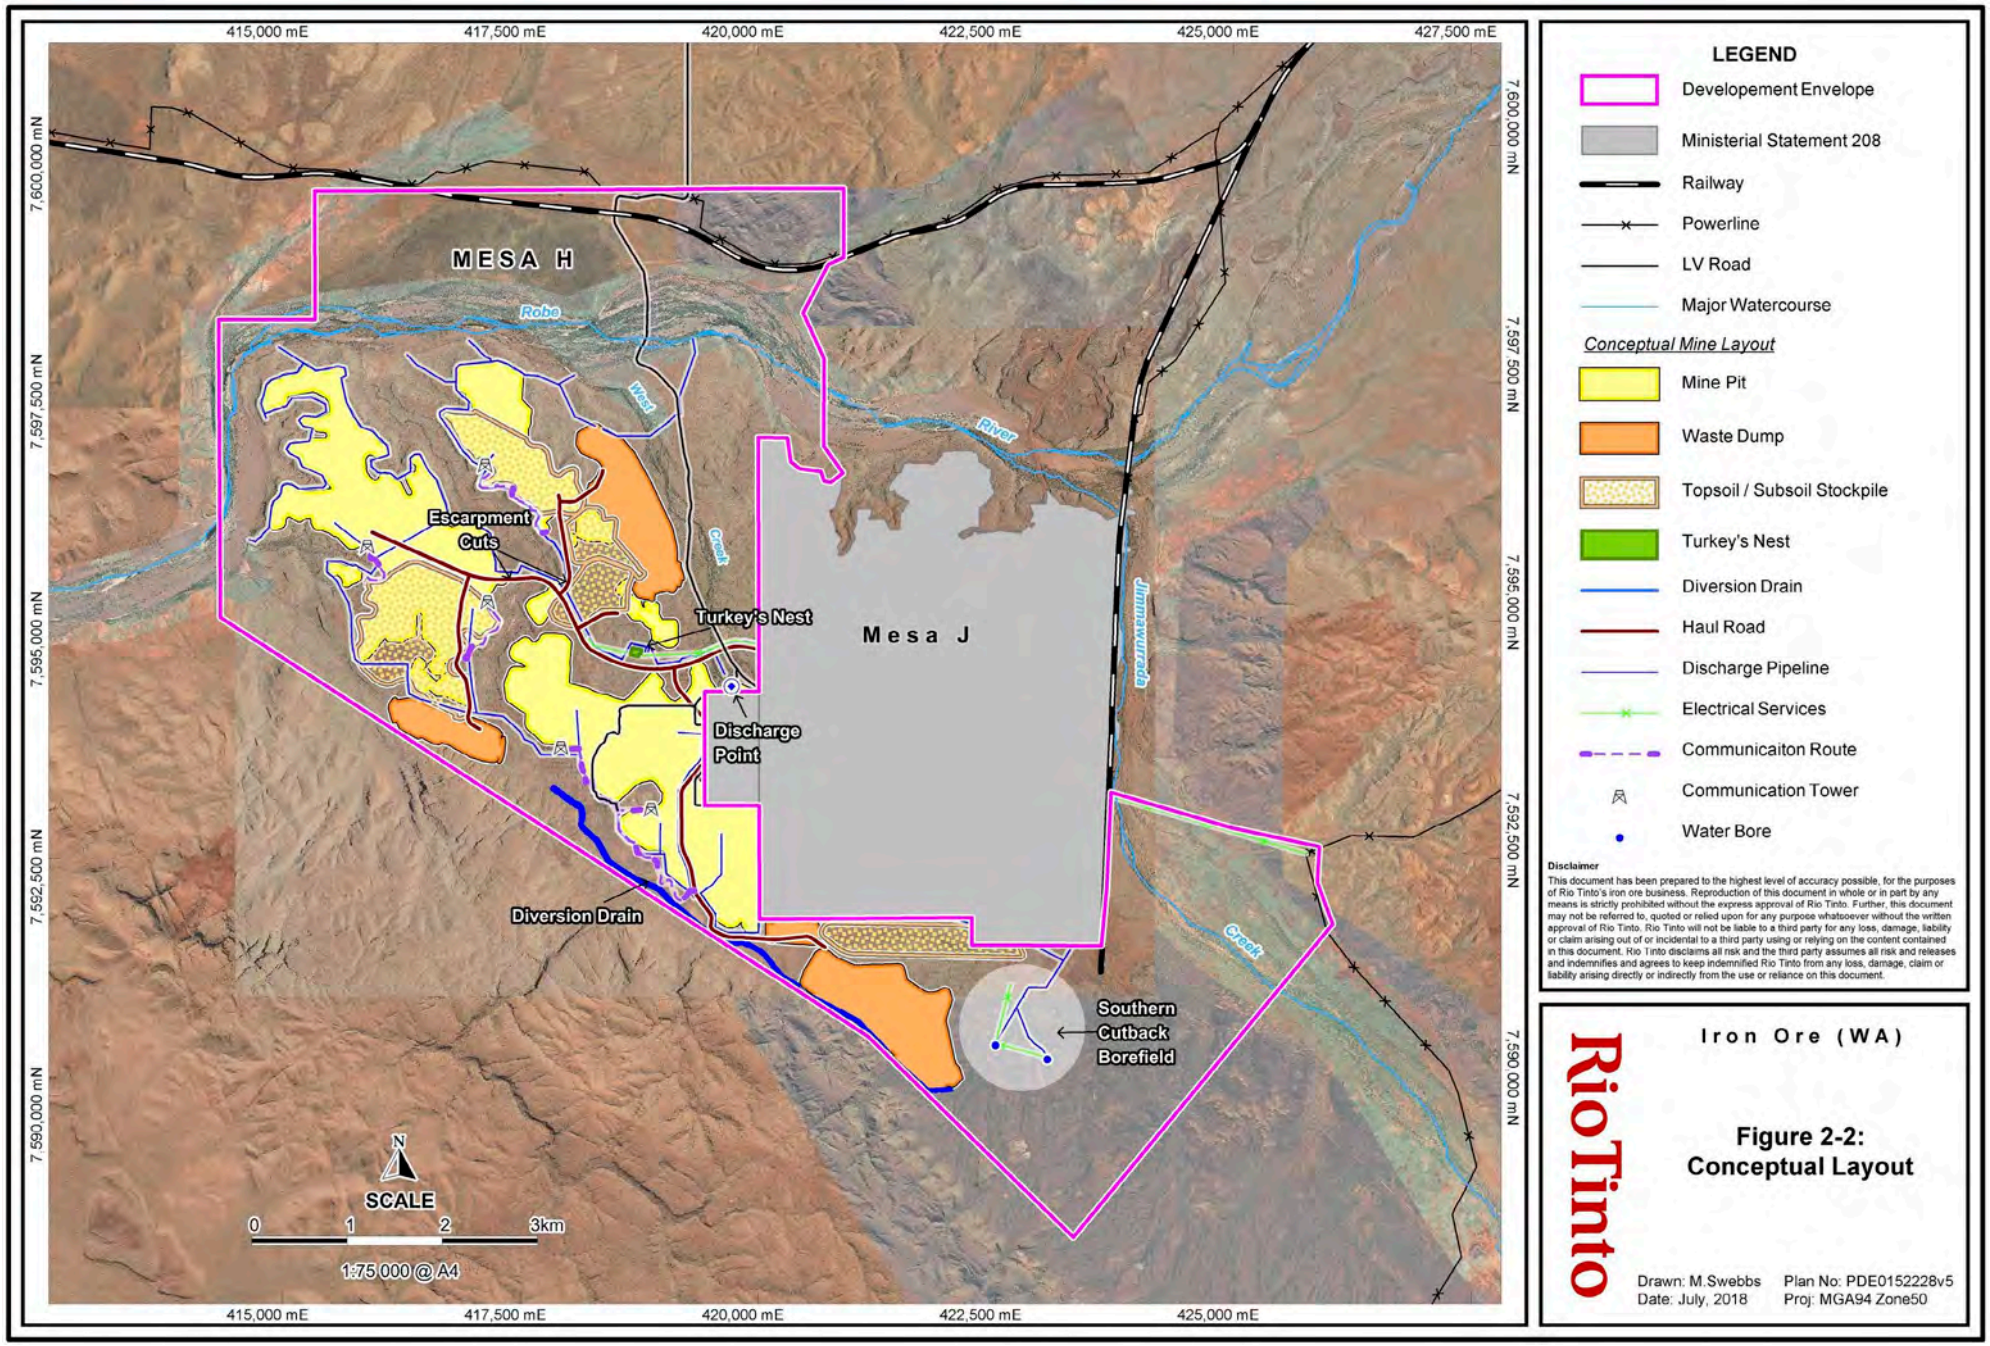

Figure 3.1: Development envelope and project footprint for the Mesa H proposal (source: Rio Tinto).

3.2 Dewatering Extent

Approximately 20% of the Mesa H ore body currently occurs BWT and dewatering will be required to access the ore. In addition, a water supply (proposed from the Southern Cutback Borefield) will be required to meet wet ore processing water demands. The combination of groundwater abstraction for BWT mining and cumulative drawdown from the borefield for operational supply will result in drawdown of the aquifer systems within the Development Envelope, with the drawdown extending outside of the Development Envelope to the east and southeast (see Figure 3.2).

In the northern portion of the development envelope, the Robe River is predicted to be impacted by less than 1 m of drawdown by the end of mining, which, given the magnitude and frequency of stream flow events, is unlikely to cause any permanent adverse impact to the alluvial aquifers of the system.

Updated hydrogeological modelling based on the inclusion of a thickener plant (Rio Tinto 2019a) estimates that drawdown will lower the water table across a 12 km section of Jimmawurrada Creek, with a maximum predicted drawdown of 9 m over a 6.5 km section (based on pre-mining water table levels) by 2030, mostly as a result of BWT mining at Mesa J. This is the base case impact prediction that is primarily assessed in this assessment. However, if natural recharge is reduced by 50% due to an extended period of drought, as per the H3 numerical model 'Uncertainty Run 2' (Rio Tinto 2019a), then the water table levels could be lowered by almost 3 m in addition to the natural seasonal fluctuations (2-3 m); this would translate to localised changes in water table depths of up to 14 m from pre-mining conditions, or ~18 m bgl by 2030. This latter drought scenario is addressed in the Environmental Review Document (ERD) for the Mesa H proposal, with the primary impact assessment scenario considered here the base case modelling for the maximum predicted drawdown under typical conditions at 2030.

Once mining is complete and dewatering ceases, groundwater levels in the Mesa J and Mesa H mining areas will recover until a balance is reached between groundwater inflows and groundwater outflows (Rio Tinto 2019a). In the event that pit voids are in-filled with waste / waste fines storage, groundwater levels will eventually recover to pre-development levels. The complete aquifer recovery is predicted to take up to 60 years, however, the majority of the drawdown along the Robe River and Jimmawurrada Creek is expected to recover after the first significant stream flow following a cyclonic event (Rio Tinto 2019a).

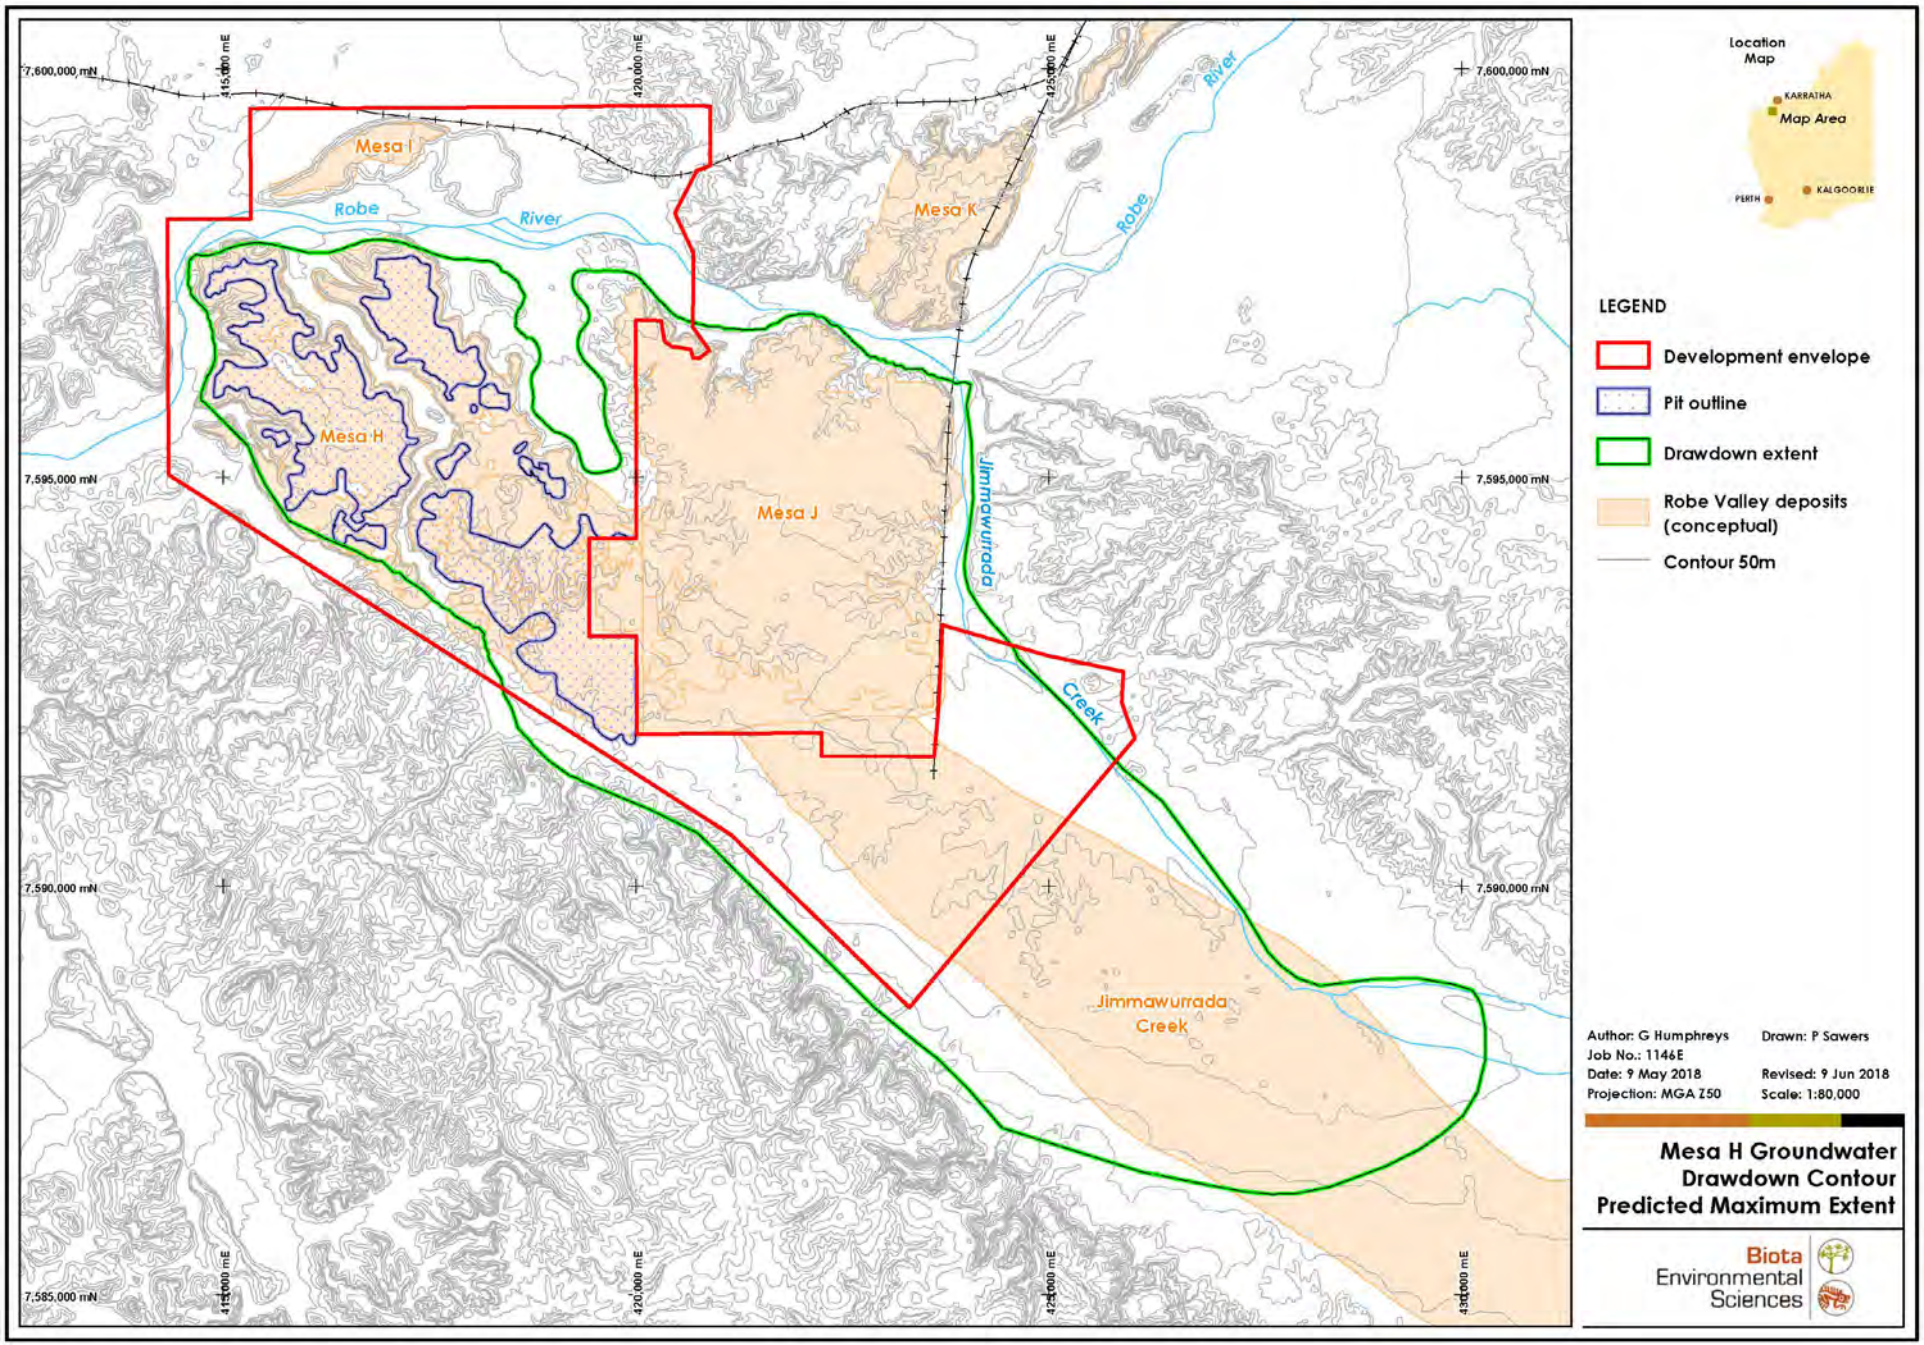

Figure 3.2: Maximum extent of predicted groundwater drawdown from the Mesa H proposal (base case year 2030, including the use of thickener in process water).

4.0 Potential Impacts

4.1 Impact Sources

A summary of the relevant characteristics of the Mesa H project, and the respective impact sources that they represent for subterranean ecosystems, is provided in Table 4.1.

Table 4.1: Summary of relevant characteristics of the Mesa H project and related impact sources.

Relevant Project Characteristics / Impact Sources					
Mine Pits	Water Management	Waste Dumps and Stockpiles	Haul Roads and Access Roads	Processing and Support Infrastructure	Impact Pathway
✓	-	-	-	-	Subterranean habitat excavation
✓	✓	-	-	-	Stygofauna habitat dewatering
✓	-	✓	✓	✓	Removal of vegetation
✓	✓	✓	✓	✓	Altered surface hydrology
✓	-	✓	✓	✓	Vibration
-	-	-	-	✓	Waste fines leakage
-	-	-	-	✓	Hydrocarbon spills

The pathways by which these impact sources may potentially impact on subterranean ecosystems are outlined in Section 4.2.

4.2 Impact Pathways

The sources of impact in Section 4.1 have the potential to affect key receptors via a range of impact pathways. These may either be direct (Section 4.2.1) or indirect (Section 4.2.2) and some impact sources may result in both types of impact pathways.

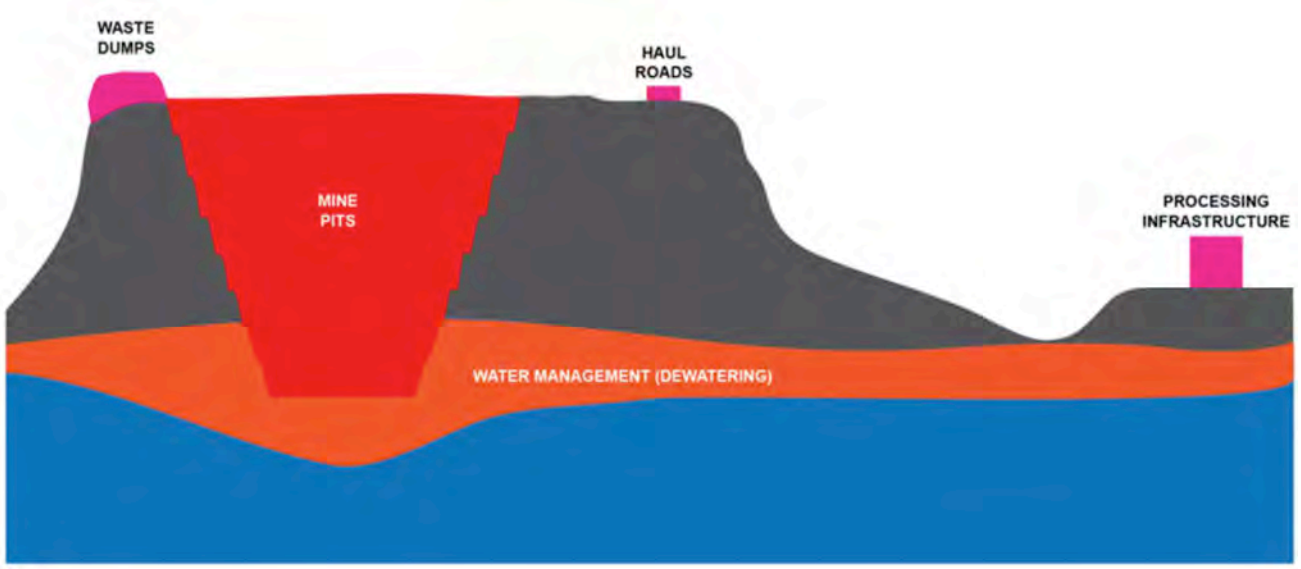
Figure 4.1 summarises the relationship between the impact sources, pathways and types of ultimate impacts on fauna that may arise from the Mesa H project.

4.2.1 Direct

The impact sources identified in Section 4.1 that may affect key receptors via direct impact pathways are:

- Subterranean habitat excavation – leading to habitat loss for both troglofauna and stygofauna, and direct loss of animals occupying the removed habitat, along with potential reduction in habitat quality in adjoining areas.
- Stygofauna habitat dewatering – leading to loss of saturated habitat for stygofauna, and presumed direct loss of animals utilising the dewatered habitat, and possible disturbance responses in individual animals to avoid dewatered areas.

These direct impacts are typically the most significant and primary impacts of the proposal on subterranean fauna receptors, and represent the key impact pathways considered in the balance of this assessment.



Impact Sources	Impact Pathways		Impacts
Mine pits	Excavation	Troglofauna and stygofauna habitat loss	Reduced diversity Reduced ecological integrity
Water management	Dewatering	Stygofauna habitat loss	Reduced diversity Reduced ecological integrity
Waste dumps and stockpiles	Removal of vegetation Sealing ground surfaces	Reduced nutrient input Reduced recharge Reduced humidity	Reduced habitat quality Reduced abundance
Processing and support infrastructure	Removal of vegetation Sealing ground surfaces Vibration Waste fines leakage Hydrocarbon spills	Reduced nutrient input Reduced humidity Reduced recharge Sediment infiltration Hydrocarbon infiltration	Reduced habitat quality Reduced abundance
Haul roads and access roads	Removal of vegetation Sealing ground surfaces Vibration	Reduced nutrient input Reduced humidity Sediment infiltration	Reduced habitat quality Reduced abundance

Figure 4.1: Relationship between impact sources, pathways and impacts on subterranean ecosystems (direct impacts in red and orange; indirect impacts in pink).

4.2.2 Indirect

The impact sources identified in Section 4.1 that may indirectly affect key receptors are:

- Removal of vegetation – as the primary production that provides energy to subterranean ecosystems is assumed to be derived from surface autotrophy, removal of vegetation may lead to a reduction of energy and nutrient inputs, indirectly resulting in a reduction in subterranean habitat quality and the abundance and/or distribution of subterranean fauna;
- Altered surface hydrology – resulting in decreased recharge into water storage within troglofauna habitat (and the potential resultant long term change to humidity), increased run-off and reduced recharge to aquifers;
- Vibration – with the potential to generate increased sediment loads in the aquifer when sediment is mobilised into subterranean habitats during recharge events, and reduce habitat space in troglofauna habitat strata above the water table;
- Waste fines seepage – the proposal includes provision for a waste fines storage facility as part of product wet processing (Section 3.0), which may have some low-level leakage over time,

resulting in localised sedimentation of troglofauna habitat strata and underlying aquifers, but this will be consolidated with existing waste fines management facilities at the current Mesa J operations; and

- Hydrocarbon spills – resulting in localised reduction in groundwater quality and troglofauna habitat quality via small-scale pollutants spills and infiltration into subterranean habitat.

These indirect impact pathways, and the significance of their ultimate impacts, are less well demonstrated and the extent to which they actually result in impacts on subterranean fauna populations is poorly understood.

In the interests of a precautionary assessment, they have, however, been retained here as potential impacts and assessed separately in Section 7.0, but are considered lower-level, secondary impacts compared with the direct impacts identified in Section 4.2.1 above.

This page intentionally blank.

5.0 Key Receptors Species and Communities

5.1 Stygofauna

5.1.1 Impact Area Species

A total of 855 stygofauna specimens were recorded over the five-phase stygofauna survey completed for the proposal, comprising at least 43 species-level taxa (Biota 2019). The recorded fauna was dominated by the Crustacea, which was represented by seven faunal groups and accounted for 98% of the specimens. Excluding indeterminate records, and allowing for species already recorded during the Mesa H survey, an additional 13 species were identified as occurring during the desktop review, bringing the total known fauna to 56 species (Biota 2019). A subtotal of 46 of these species occur within the immediate locality of Mesa H (Rio Tinto 2019b).

While the BWT mine pits are a direct impact (Section 4.2.1), the primary spatial context for the assessment of impacts on stygofauna is the wider groundwater drawdown extent that will arise from the cumulative dewatering required for the proposal (which takes into consideration groundwater drawdown from adjacent projects) (Section 3.2). The drawdown extent also encompasses the area that will be directly impacted by the pits themselves. It is therefore logical to identify the full set of stygofauna species and communities that occur within this extent as the starting point for impact assessment.

Table 5.1 lists the 32 stygofauna taxa documented by Biota (2019) that occur within the dewatering extent.

Table 5.1: All stygofauna species currently known from within the dewatering extent (Impact sites), and any records from outside of the dewatering extent (Reference sites) (species only known from the dewatering extent from desktop assessment records shown in grey; source: Biota (2019)).

* Species formally listed under legislation as being of conservation significance.
** Species assessed as a potential SRE by Biota (2019) meeting potential SRE criteria.

Sixteen of the 32 species known from the dewatering extent (*Enchytraeus* sp. 'AP PSS1', *Areacandona triangulum, Areacandona brookanthana, Areacandona lepte, Humphreyscandona fovea, Humphreyscandona waldockae, Humphreyscandona* sp. 2, *Pilbaracandona rosa, Diacyclops cockingi, Diacyclops humphreysi humphreysi*, *Halicyclops calm, Halicyclops rochai*, *Stygoridgewayia trispinosa, Halosbaena tulki, Kagalana tonde* and *Nedsia* sp. 'AMM001'), are all relatively abundant and frequently recorded from Reference sites outside of the drawdown extent and/or have known wider distributions in the Pilbara bioregion (Biota 2019). While still informative for context to impact assessment, they are not retained as key receptors for the balance of this assessment as they are not restricted in distribution to the drawdown extent and will remain occurring more widely with the implementation of the Mesa H proposal. This leaves 16 stygofauna species as key receptors (three of conservation significance; Section 5.1.2.1 and 13 potential SREs; Section 5.1.2.2).

5.1.2 Key Receptors

5.1.2.1 Species and Communities of Conservation Significance

Two species of amphipod that occur within the drawdown extent (Table 5.1) are of conservation significance (Biota 2019) and are thereby key receptors for this assessment:

- the amphipod *Nedsia hurlberti* – Schedule 3 (State); and
- the amphipod *Nedsia sculptilis* – Schedule 3 (State).

An additional species of conservation significance, the Blind Cave Eel *Ophisternon candidum* (Vulnerable (Commonwealth); Schedule 3 (State)), occurs within the drawdown extent (Table 5.1) and is therefore also a key receptor for this impact assessment.

One PEC listed by DBCA occurs in the southeast of the drawdown extent (Biota 2019) and is a key receptor for this impact assessment:

- Stygofaunal Community of the Bungaroo Aquifer (Priority 1): "*A unique assemblage of aquatic subterranean fauna including eels, snails and other stygofauna. Threats include groundwater drawdown and mining*" (Department of Parks and Wildlife 2016).

5.1.2.2 Other Species of Significance

Thirteen of the stygofauna species known from the drawdown extent are considered to represent potential SRE fauna, half of which are amphipod taxa (Table 5.1; Biota 2019). As potential SREs, these species are key receptors for this impact assessment and comprise:

- the snail Hydrobiidae sp. 2;
- ostracod *Areacandona* sp. 'BOS1039';
- the ostracod Candoninae sp. 'BOS541';
- the ostracod *Pilbaracandona* sp. 'BOS526';
- the copepod *Megastygonitocrella unispinosa;*
- the copepod *Parastenocaris* sp. 'B28';
- the isopod *Haptolana* sp. 'B01';
- the amphipod *Nedsia* sp. 'AMM026';
- the amphipod Paramelitidae sp. 'AMP003';
- the amphipod Paramelitidae sp. 'AMP035';
- the amphipod Paramelitidae sp. 'AMP037';
- the amphipod *Wesniphargus* sp. 'AMN004'; and
- the amphipod Neoniphargidae sp. 'B02'.

5.2 Troglofauna

5.2.1 Impact Area Species

A total of 150 troglobitic specimens were collected across the six phases of sampling of the Mesa H survey area, with 32 additional specimens from past surveys identified in desktop review (Biota 2019). The survey specimens represented five classes and nine orders, with 32 species-level taxa identified. The orders Coleoptera and Schizomida were the greatest contributors to faunal composition, accounting for 33% and 25% of the specimens, respectively (Biota 2019). Excluding indeterminate records, two additional species (*Barrowdillo* sp. 1 and *Troglarmadillo* sp. 1) were identified as occurring within the development envelope from historical surveys, bringing the total known fauna to 34 species.

Unlike stygofauna, the development envelope fully encompasses all the direct impact sources relevant to troglofauna (Section 4.1) and it therefore sets the spatial context to identify species known from within the proposal impact area. Again unlike stygofauna, there were no Reference sampling sites in the Biota (2019) survey and all sites sampled for troglofauna were inside the development envelope. All 34 species recorded at Mesa H therefore occur within the development envelope.

Table 5.2: All potential SRE troglofauna species currently known from within the development envelope (Impact sites), and any records from outside of the development envelope (Reference sites) (species only known from the development envelope from desktop assessment records shown in grey; source: Biota (2011; 2019)).

Blattodea		
?Nocticola sp. 'West Pilbara Complex'	RC12MEH0221, RC16MEH0427	Red Hill

* Gnaphosidae sp. indet. was the only specimen of its family and was retained as a discrete troglobitic taxon (Biota 2019).

Six of the 34 troglofauna species known from the development envelope; Hubbardiidae sp. 'SCH011', Hubbardiidae sp. 'SCH015/SCH016', Armadillidae sp. 'ISA056/ISA057', Ptilidae sp. 1/'CP003', Ptilidae sp. 'Robe Valley'/'CP002' and *?Nocticola* sp. 'West Pilbara Complex', all have documented wider distributions in the region (Table 5.2; Biota 2019).

While the five species of stygofauna known from outside of the dewatering extent were not retained as key receptors (Section 5.1.2), they were very widespread and common in the region, whereas the six troglofauna species with records outside of the development envelope still only have relatively restricted distributions in the Robe Valley, most of which are also subject to potential impacts from other proposals (see Table 5.2). To provide a conservative assessment, they are therefore still

retained as key receptors, meaning all 34 troglofauna species known from the development envelope are treated as key receptors for this assessment (Section 5.2.2.2).

5.2.2 Key Receptors

5.2.2.1 Species and Communities of Conservation Significance

No formally listed troglofauna species are known from the Mesa H development envelope (Biota 2019).

Two PECs listed by DBCA occur within the development envelope (Biota 2019) and are key receptors for this impact assessment:

- Subterranean invertebrate communities of mesas in the Robe Valley region (Priority 1): *"A series of isolated mesas occur in the Robe Valley in the state's Pilbara Region. The mesas are remnants of old valley infill deposits of the paleo Robe River. The troglobitic faunal communities occur in an extremely specialised habitat and appear to require the particular structure and hydrogeology associated with mesas to provide a suitable humid habitat. Short range endemism is common in the fauna. The habitat is the humidified pisolitic strata. Threats include mining"* (Department of Parks and Wildlife 2016); and
- Subterranean invertebrate community of pisolitic hills in the Pilbara (Priority 1): *"A series of isolated low undulating hills occur in the state's Pilbara region. The troglofauna are being identified as having very short range distributions. Threats include mining"* (Department of Parks and Wildlife 2016).

While two separate PECs are recognised by DBCA, for the purposes of this impact assessment they are effectively the same ecological community, being the troglofauna assemblage occurring within Mesa H. The distinction appears to largely be driven by whether the landforms with the extents mapped by DBCA are mesas (the former PEC) or less well formed mesas / hills (the latter), though in practice these landforms are not always clearly delineated in the locality and both contain subterranean assemblages of conservation value.

5.2.2.2 Other Species of Significance

The 34 development envelope species are all regarded as potential SRE fauna (Biota 2019) and are therefore key receptors for this impact assessment.

Twenty of the 34 species were singletons, making comment on their potential wider distributions difficult, but they have been conservatively retained here as potential SRE taxa and key receptors to provide a precautionary assessment.

This page intentionally blank.

6.0 Key Receptor Habitats

6.1 Stygofauna Habitat

Groundwater within the Development Envelope occurs predominantly within three key aquifers:

- Robe River and Jimmawurruda Creek alluvial aquifers: extensive and unconfined superficial aquifer consisting of Quaternary alluvial sediments (shingles, conglomerates and coarse sand), deposited along the contemporary surface drainages with an approximate 20 m thickness and average width of 400 m along the Robe River (Rio Tinto 2017b). The alluvium associated with Jimmawurruda Creek varies in depth from approximately 24 m thickness in the southeast, increasing up to 40 m in thickness in the northwest reaches closest to Mesa H (see Figure 6.1).
- CID aquifer: an unconfined aquifer consisting of CID pisolitic sediments below Mesa H with an average of 20-30 m thickness below the pre-mining water table; and
- Wittenoom aquifer: a largely confined aquifer underlying the CID aquifer, consisting of weathered dolomite and dolomitic shale (Paraburdoo and Bee Gorge Member) and weathered Banded Ironstone Formation (BIF; Marra Mamba Iron Formation) with a thickness of approximately 25 m.

Pre-mining depth to groundwater within the Mesa H CID aquifer is generally between 25 and 45 m below surface within higher elevation areas, but the water table is considerably shallower in the Robe River and Jimmawurruda Creek alluvial aquifers. Depth to pre-mining groundwater in these alluvial aquifers ranges from approximately 4 – 12 m below surface along Jimmawurruda Creek, and approximately 2 – 5 m below surface along the Robe River. These groundwater levels fluctuate by up to 3 m seasonally, depending on climatic variability and rainfall patterns.

The basal Robe Pisolite (Tpb) is a 5 -10 m thick layer deposited at the base of the CID Aquifer, consisting of a variable clay-rich pisolite. While its hydraulic properties have not yet been defined, the largely impermeable physical characteristics of the unit mean it is expected to function as a partial barrier to groundwater flow between the CID Aquifer and the underlying Wittenoom Aquifer (Rio Tinto 2017b).

The Robe River and Jimmawurrada alluvium aquifers and the CID aquifers, are the most likely to provide habitat for stygofauna, based on their physical and hydraulic characteristics. In addition to the extensive data sets that exist from sampling of equivalent aquifers in the locality, the Robe River and Jimmawurrada alluvium aquifers are the primary groundwater system that provides habitat to stygofauna in the wider locality, having yielded many stygofauna records. The Mesa H CID aquifer, while deeper and thereby likely to host less fauna (Section 2.5.1), is also structurally suitable as stygofauna habitat and has some existing data to confirm that stygofauna utilise the aquifer. Given its depth, confined nature, lower transmissivity host rock, and limited connectivity to more superficial systems, the Wittenoom Aquifer is considered unlikely to represent significant habitat for stygofauna.

While detailed aquifer definition exists for the development envelope, this is not available for the wider locality. The aquifers that provide stygofauna habitat at Mesa H broadly correspond to the regional surface geology map units (1:250,000) and more detailed 1:10,000 local Rio Tinto geological mapping available for the locality and provide a means of setting wider context to the stygofauna habitats of the dewatering extent. The units that represent High or Medium likelihood stygofauna habitat within the dewatering extent and the wider locality are summarised in Table 6.1 and mapped in Figure 6.2. All stygofauna records from the locality were plotted on these habitat units (Figure 6.2) and visualised in a three-dimensional isometric view (Figure 6.3).

Table 6.1: Geology units identified as stygofauna habitat in the dewatering extent and wider locality.

Code	Unit	Description	Likelihood to Support Stygofauna (Attributes; Section 2.5.3)
Qr	Alluvium	Unconsolidated fluviatile deposits.	High (A, B, C, D, E, F)
Ql	Lacustrine deposits	Clay, silt; saline in part, flood deposits. Unconsolidated fluviatile and sheet flood deposits in levees and river terraces.	High (A, B, C, E, F)
Qg/Czc	Colluvium	Partly consolidated valley-fill deposits; Unconsolidated to loosely consolidated slope deposits	High (A, C, D, E, F)

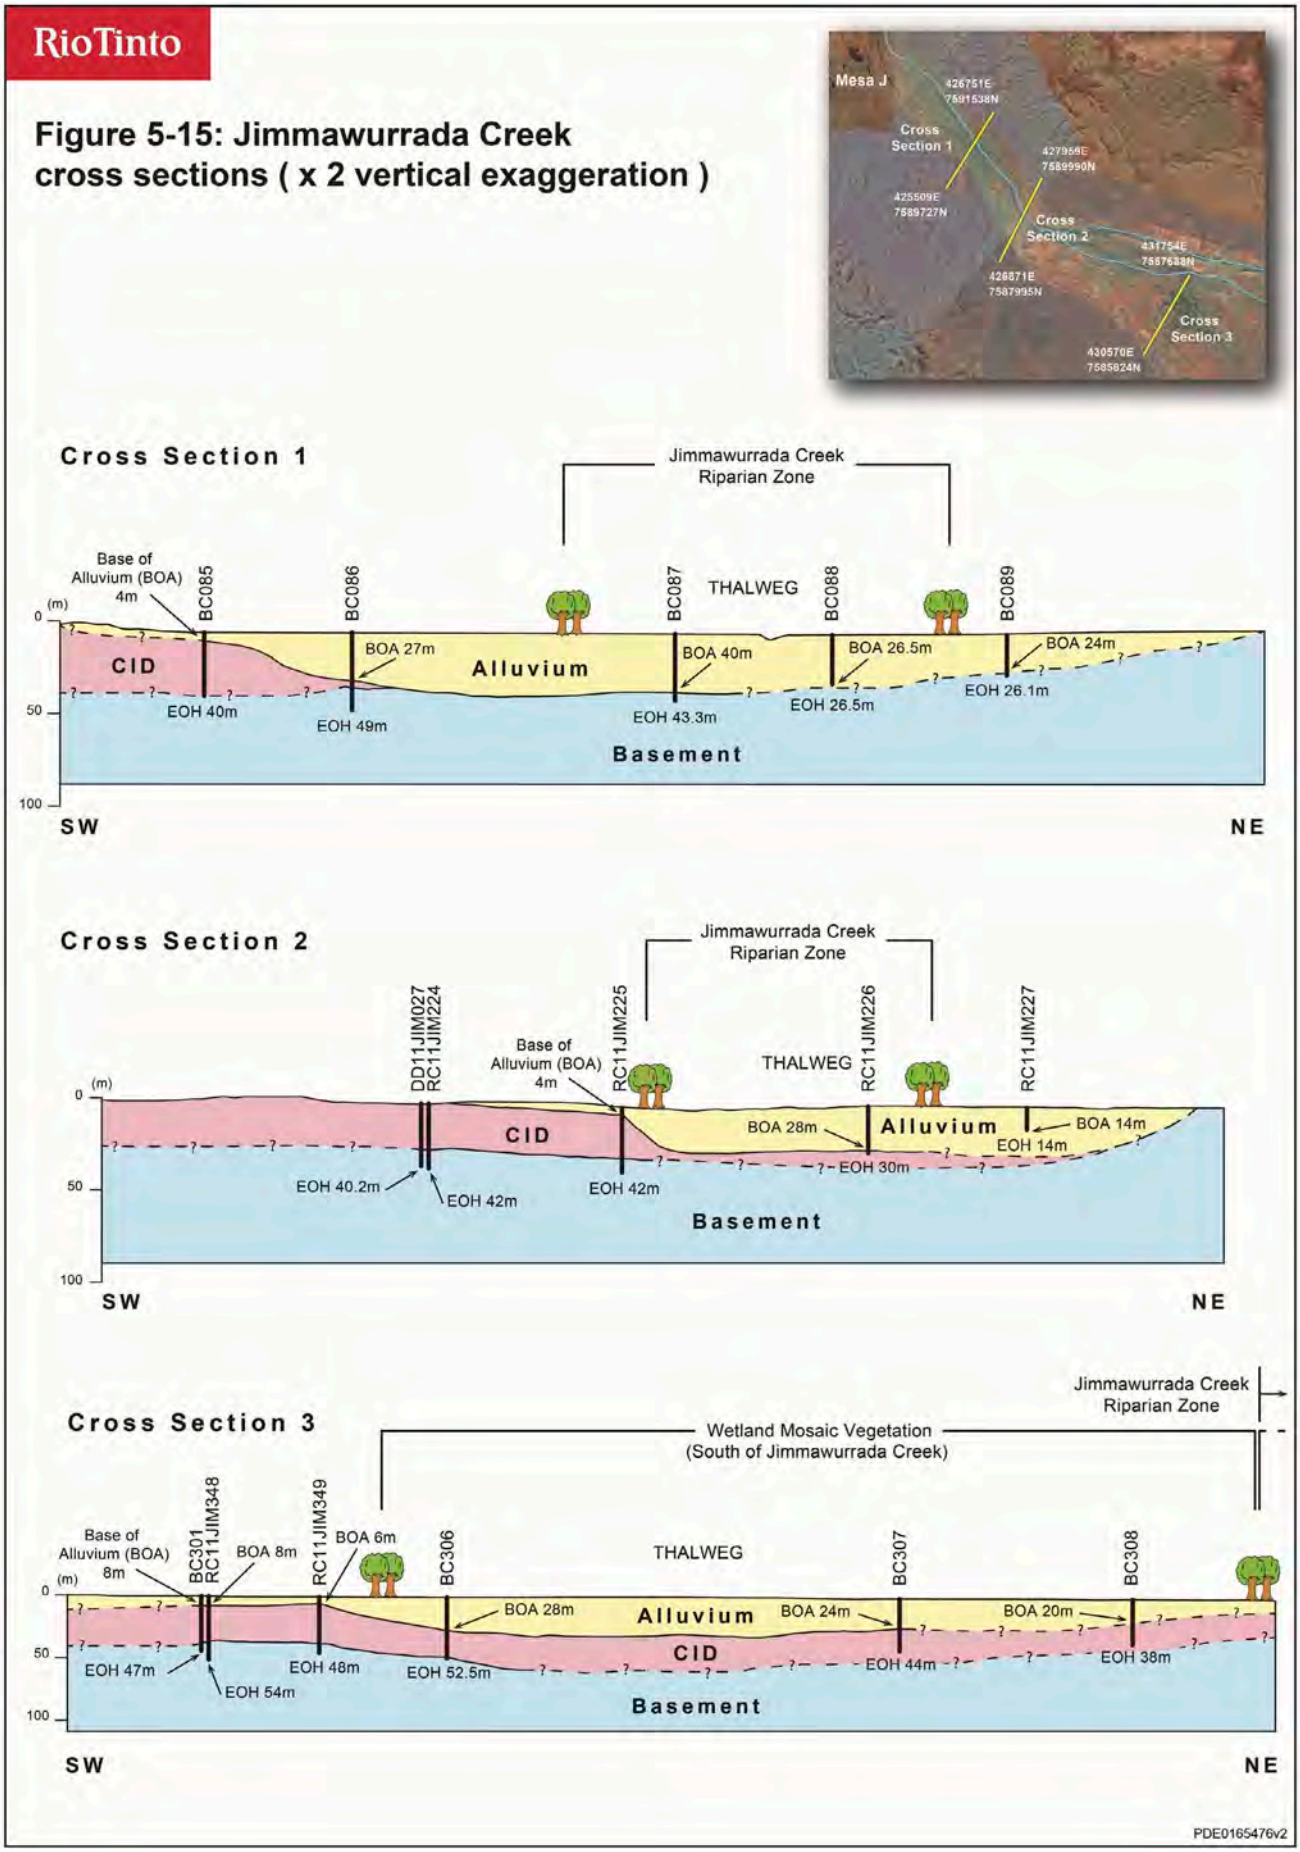

Figure 6.1: Cross-sections of Jimmawurrada Creek, showing depth of alluvium relative to underlying CID and basement units in difference sections of the creek (source: Rio Tinto).

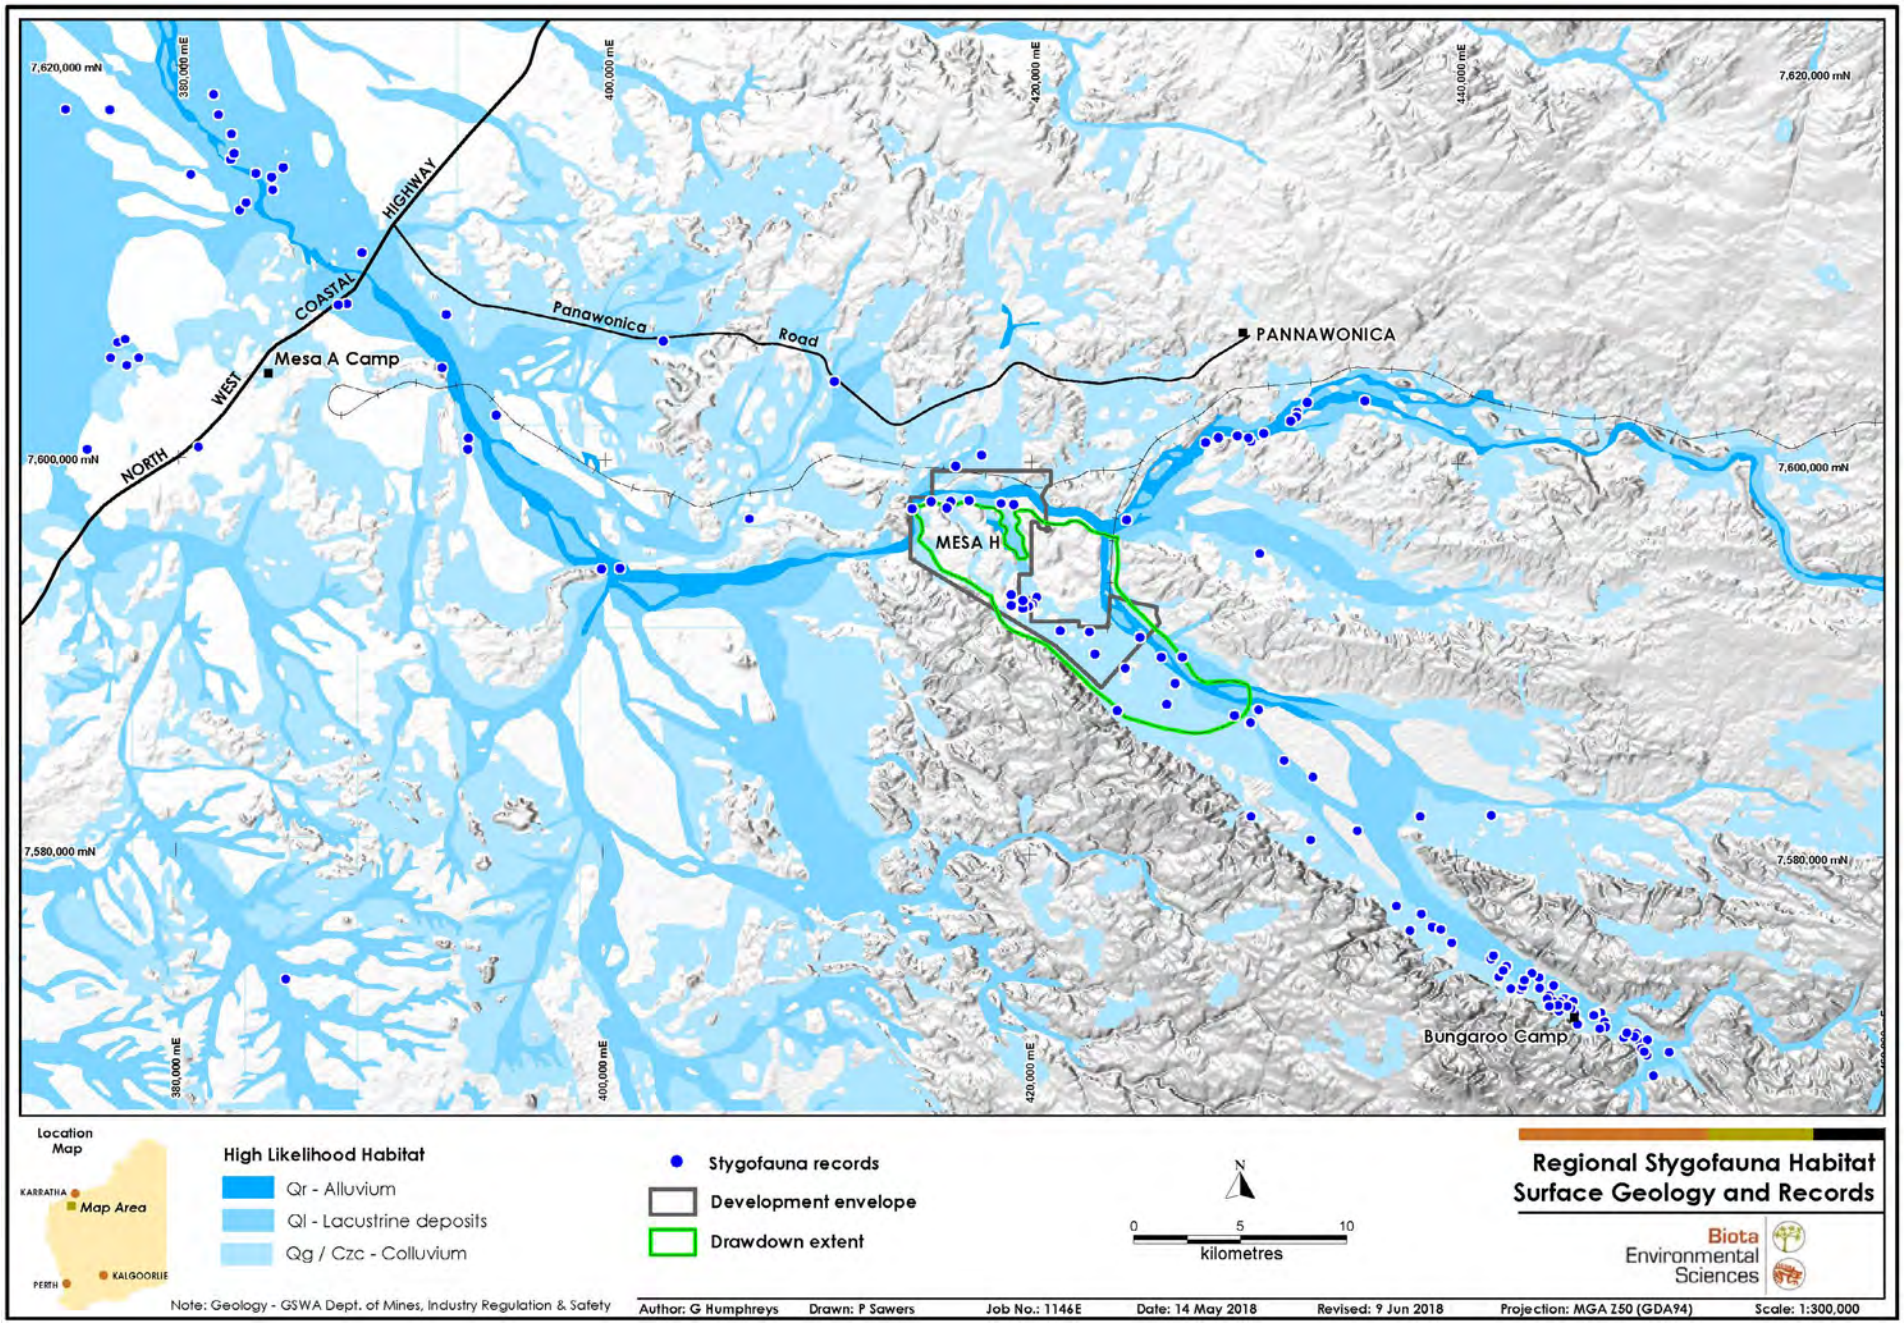

Figure 6.2: Surface geology units representing stygofauna habitat showing spatial relationship with confirmed stygofauna records.

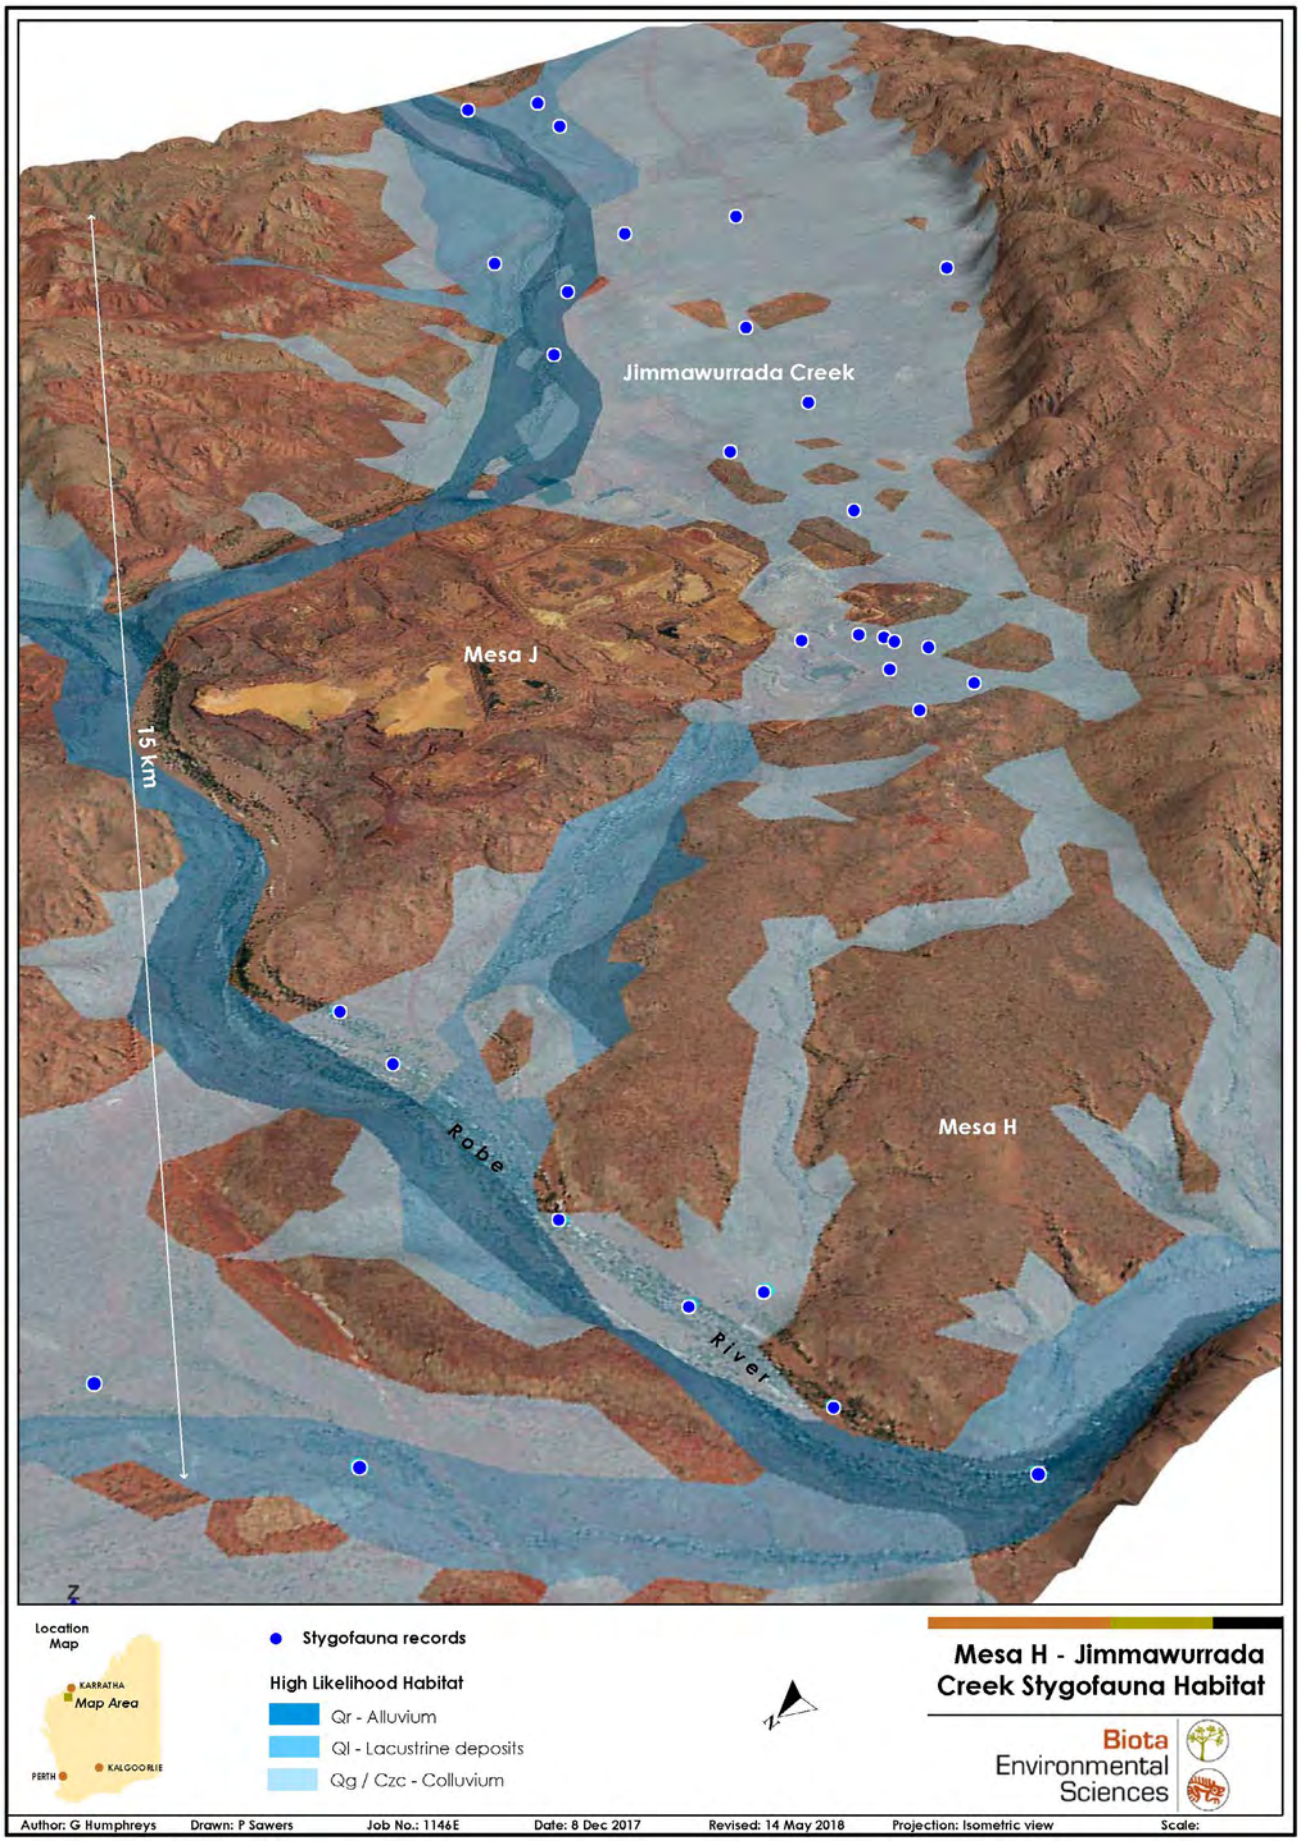

Figure 6.3: Isometric view of stygofauna habitat at Mesa H, overlain with the locations of confirmed stygofauna records.

These show a strong spatial correlation with stygofauna record locations, with 129 of the 133 known stygofauna locations falling within units mapped as High likelihood habitat (97%) (Figure 6.2). The landscape setting of these units also confirms that these habitats occur as low elevation valley fill units (Figure 6.2 and Figure 6.3).

Given their structural suitability, and this high level of validation from confirmed fauna records, the regional mapping units can be reliably used to set wider context to the impacts of the proposal on stygofauna habitat (Section 7.1). Subsequent three-dimensional geological mapping completed by Rio Tinto using 'Leapfrog' modelling software (Appendix 1) has also validated this approach across the Development Envelope and within the predicted impact areas for the proposal.

6.2 Troglofauna Habitat

Mesa H is one of several CID deposits that comprise the Robe Pisolite Formation; a series of paleodrainage channels that meander through the Robe River valley. CIDs are often preserved in an inverted topography as mesas landforms which are remnants of ancient palaeochannels in the landscape (Ramanaidou et al. 2003).

The Mesa H development envelope includes 13 surface geology units (Biota 2019). By area however, the majority of the development envelope is accounted for by just two of these units: colluvium, accounting for 36%, and the CID Robe Pisolite Formation (a further 33%) (Biota 2019). (Figure 6.4; Table 6.2). Both of these geological units have been shown to represent suitable habitat for subterranean fauna in the Robe valley and the wider Pilbara region, with CID / Robe Pisolite in particular recognised as core habitat for troglofauna (Section 2.5.2).

At a finer scale, Rio Tinto classify CID deposits such as Mesa H into intra pisolite strata or 'strands', based on mineral grade, clay content and other structural and textural features (Figure 6.4; Table 6.2). The CID strands that represent troglofauna habitat at Mesa H comprise:

- Tp - Tertiary pisolite;
- Tpb - Basal Tertiary pisolite, which ranges from conglomeratic to clay rich, and relatively vuggy at Mesa H;
- Tpc - Tertiary pisolite with clay strata;
- Tpd - Denatured Tertiary pisolite, similar to Tpm but with less clay;
- Tph - Hard competent pisolite (mostly below water table at Mesa H);
- Tpm - 'Mixed' Tertiary pisolite composed of altered other pisolitic strands including hydrated material (mostly below water table at Mesa H); and
- Htp - Hardcap – weathered / altered pisolite and goethite, containing many vugs and cavities (mostly superficial at Mesa H)

The prospectivity of the geological units within the development envelope to represent troglofauna habitat was characterised as High, Medium or Low likelihood, based on relevant habitat attributes and how these are represented within the development envelope (see Section 2.5.4).

Following these criteria, the Robe pisolite (Tp) represents core habitat for troglofauna within the development envelope, being broadly assessed as High likelihood of troglofauna occurring, with the strands present at depth within the pisolite (Figure 6.4) mostly also either High or Medium likelihood (Table 6.2). Two other units were identified as having Medium likelihood for fauna to occur, comprising colluvium and Wittenoom formation (Table 6.2; Figure 6.4), and this likelihood is increased when the units occur in contact with the adjacent and underlying Robe pisolite as they do within the development envelope. These units were considered to represent potential troglofauna habitat by EPA (2013), and the Robe Pisolite unit was also used as the basis for mapping the local extent of the two troglofauna PECs that occur in the development envelope (Section 5.1.2.1).

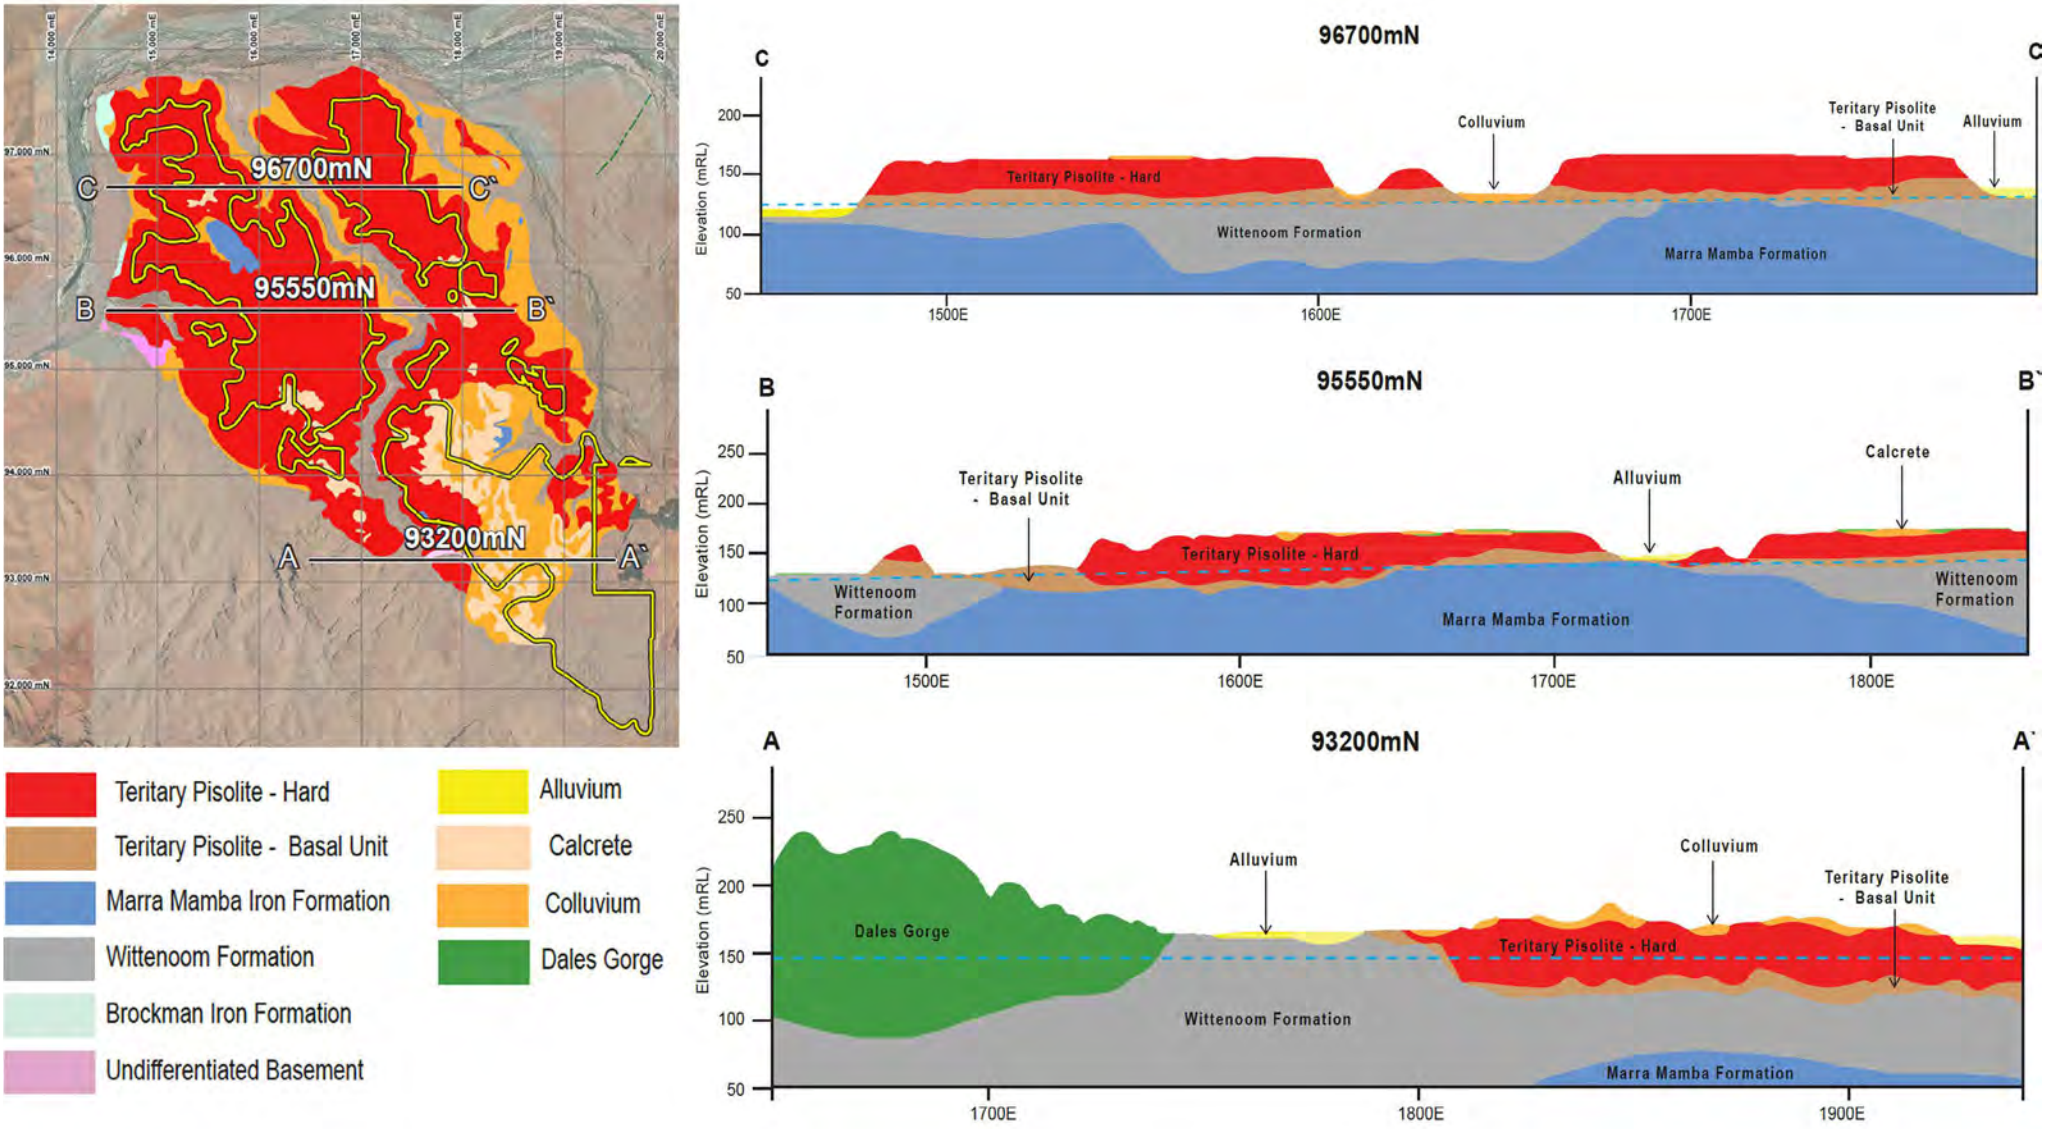

Figure 6.4: Mesa H surface geology (left) and cross-sections (right) illustrating troglofauna habitat strata at depth across three sections of Mesa H (A, B and C) (blue horizontal line on cross-sections represents approximate water table depth).

Table 6.2: Geological units identified as troglofauna habitat within the development envelope.

Code	Unit	Description	Likelihood to Support Troglofauna (Attributes)
Tp	Robe Pisolite	Tertiary pisolitic limonite deposits, which Rio Tinto stratigraphically classifies into strands of:	High (A, B, C, D, E)
	Tpb	Basal, clay and pisolite	Medium (A, B, C)
	Tpc	Clay bands	Low (C)
	Tpd	Denatured and friable ore	Low (C)
	Tph	Competent hard pisolitic ore	High (A, B, C, D, E)
	Tpm	Mix of Tpc, Tpd and Tph	Medium (A, C, E)
	Htp	Hydrated Tertiary pisolite	High (A, B, D, E)
Qg	Colluvium	Unconsolidated to loosely consolidated slope deposits	Medium (A, D, E)
Wd	Wittenoom Formation	Calcitic dolomite	Medium (A, D, E)

Basal pisolite (Tpb) underlies the other Tertiary pisolite strata, and is often below water table in the development envelope (e.g. cross-sections A and B on Figure 6.4). Tpb is, however, still at least Medium likelihood troglofauna habitat in the development envelope in locations where it occurs above water table (e.g. cross-section C on Figure 6.4) (Table 6.2). This is primarily due to its higher frequency of vugs and cavities at Mesa H specifically compared to basal pisolite in other parts of the Robe valley.

Cross-section C of Figure 6.4 also intersects the central creek gorge system that runs north-south through Mesa H, where Tpb outcrops to the surface and also laterally adjoins and overlies dolomite as part of the Wittenoom Formation (shown in grey on Figure 6.4). This latter unit, while not specifically identified in Table 6.2 as it is mostly below water table at Mesa H, also has potential to provide troglofauna habitat in the areas where it is above water table, given it contains cavities and vugs, and that it is in contact with the primary Tertiary pisolite habitat (a Medium likelihood rating; attributes A, D, E; Table 6.2). Additionally, the hydrological and recharge function of this central creek gorge system is likely to deliver water to the subterranean habitats of the Mesa H landform during major recharge events; a key functional process for sustaining humidity and providing organic inputs to subterranean ecosystems (Biota and DC Blandford & Associates 2013).

Rio Tinto provided modelled AWT CID (based on 3D modelling from drillhole data) from across the development envelope and surrounds (Appendix 1) and this was used to generate CID thickness contours to effectively map troglofauna habitat (using the Medium and High likelihood strands from Table 6.2 with a minimum of 5 m thickness AWT). This was then refined spatially on the basis of aerial photography overlain on a digital terrain model to inspect landforms and arrive at a mapped extent of habitat informed by both three-dimensional geology and geomorphology.

All troglofauna records from Mesa H were then plotted on the mapped habitat to provide independent validation of the intrinsic habitat assessment (Figure 6.5). This showed that the landforms associated with the mapped troglofauna habitat have a very strong spatial correlation with known troglofauna distribution, with 98% of the record locations falling within units mapped as habitat (Figure 6.5). Figure 6.6 depicts the habitat in a landscape isometric view, illustrating this strong relationship with mesa and hill landforms. This includes troglofauna records from the central creek gorge system at Mesa H, providing validation of the assessment of basal pisolite (Tpb) overlaying Wittenoom dolomite as troglofauna habitat (Figure 6.6).

The identified troglofauna habitat units can therefore be relied upon as a framework for the balance of this impact assessment.

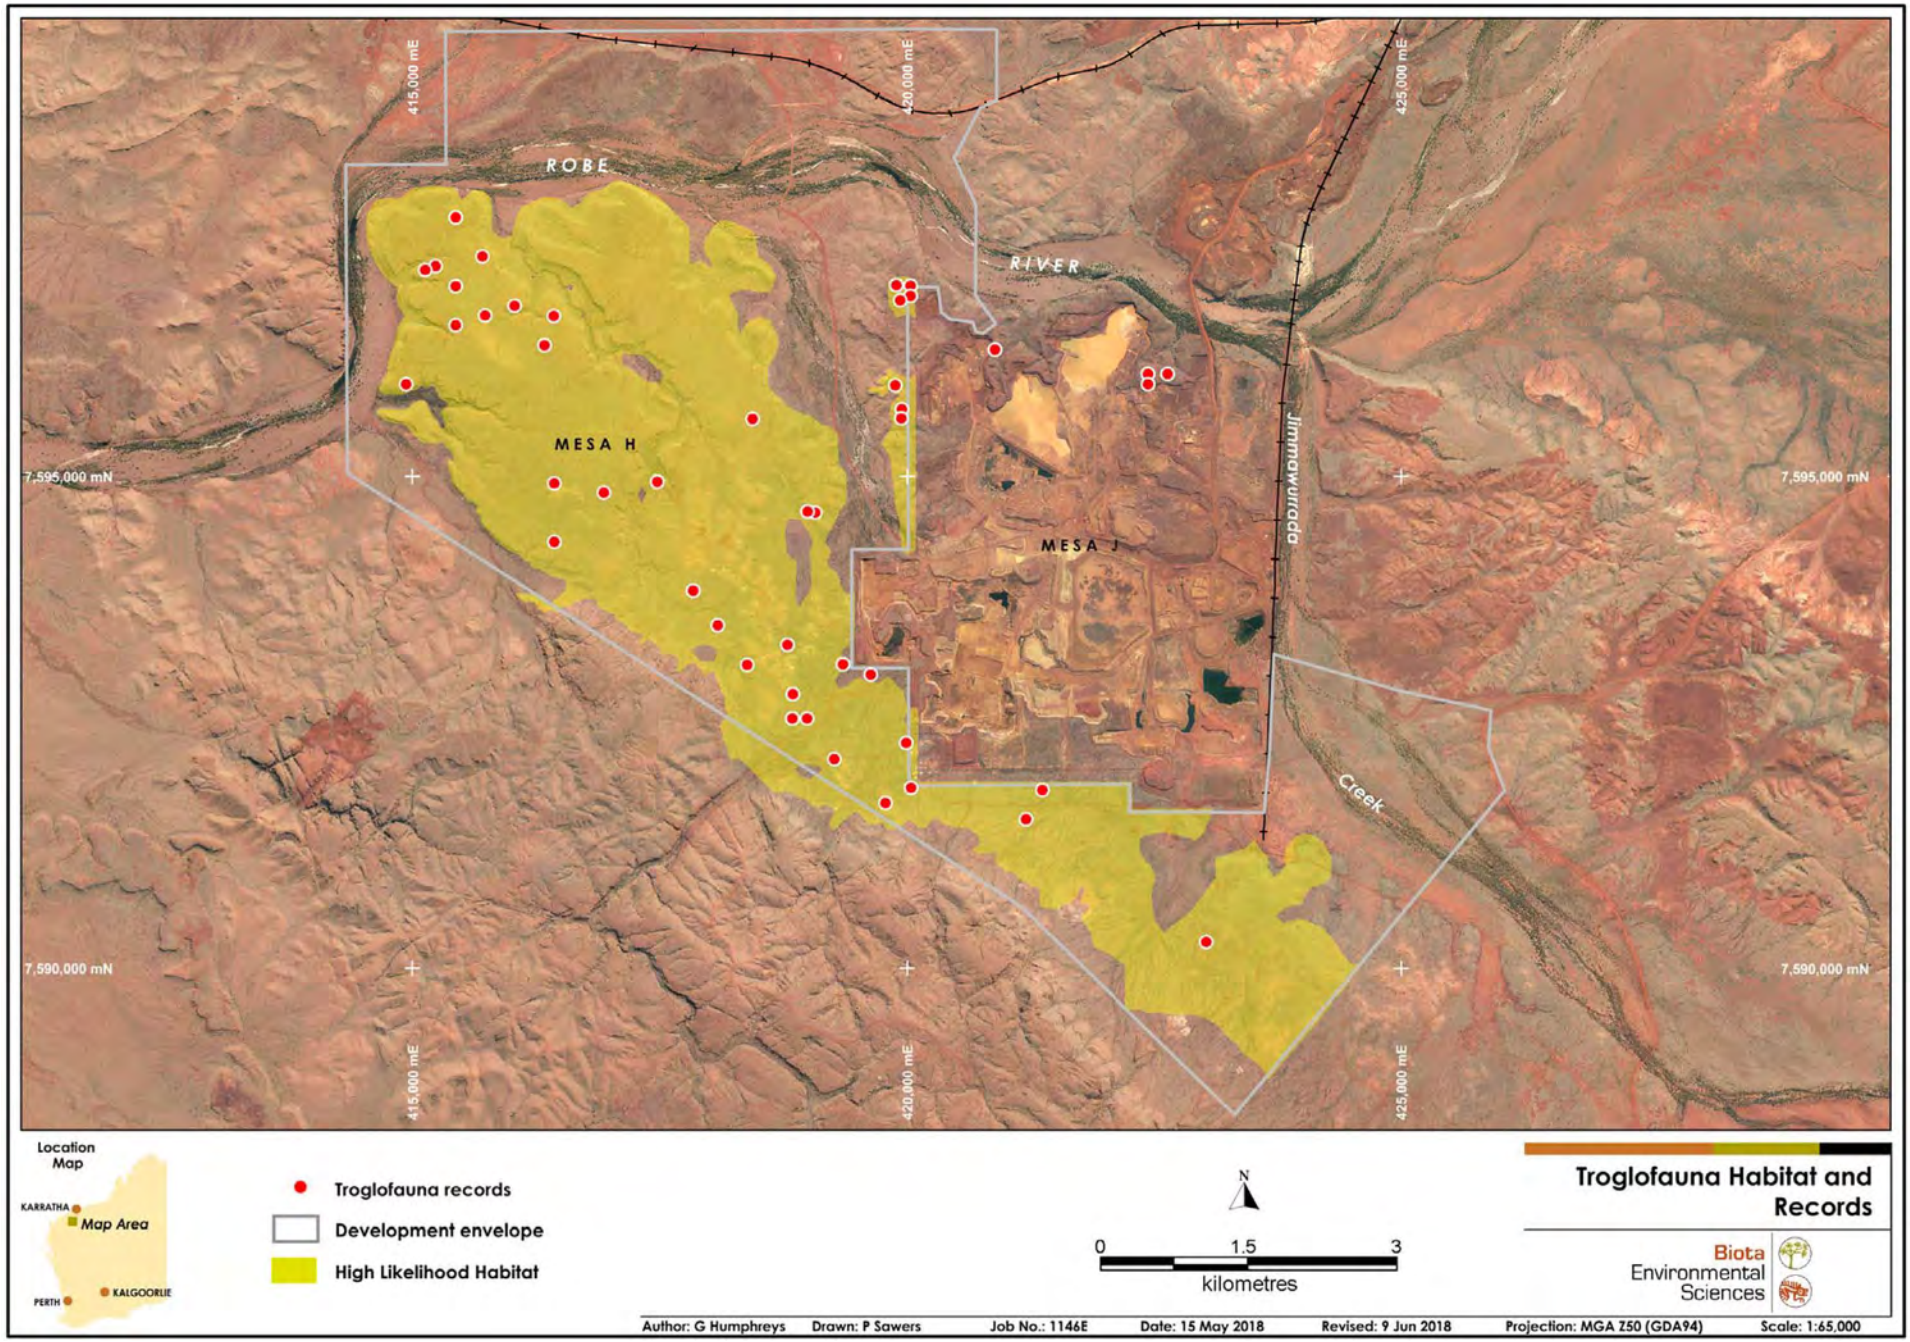

Figure 6.5: High likelihood troglofauna habitat in the development envelope showing spatial relationship with confirmed troglofauna records.

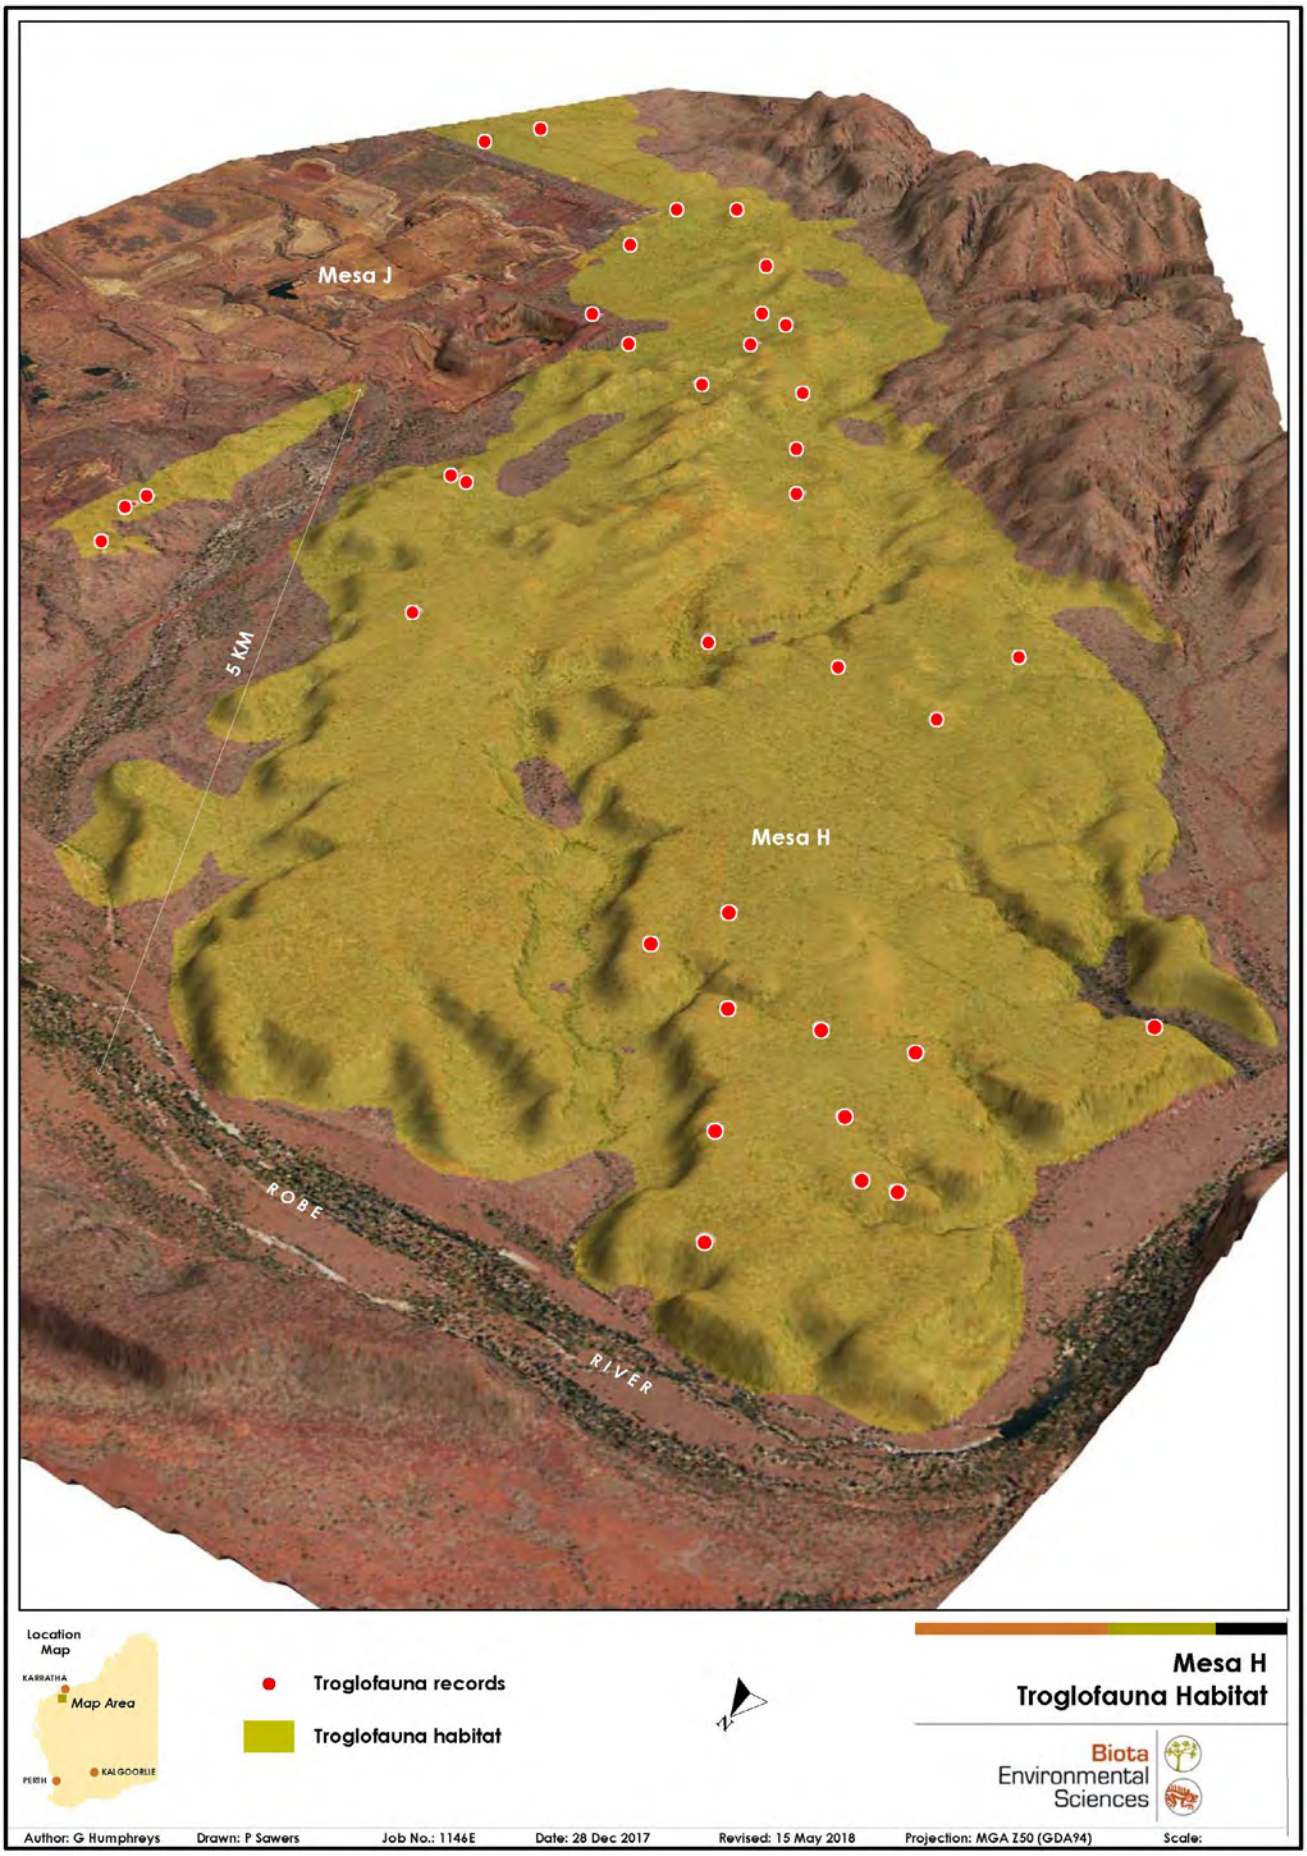

Figure 6.6: Isometric view of troglofauna habitat at Mesa H, overlain with the locations of confirmed troglofauna records.

7.0 Impact Assessment

7.1 Stygofauna Impacts

Sixteen of the 32 stygofauna species known from the dewatering extent are either of listed conservation significance or are potential SRE taxa, and represent the key stygofauna receptors for this impact assessment (Section 5.1.2).

The 16 relevant species comprise:

- Blind Cave Eel *Ophisternon candidum* – Vulnerable (Commonwealth), Schedule 3 (State);
- the amphipod *Nedsia hurlberti* – Schedule 3 (State);
- the amphipod *Nedsia sculptilis* – Schedule 3 (State);
- the snail Hydrobiidae sp. 2 (potential SRE);
- ostracod *Areacandonda* sp. 'BOS1039' (potential SRE);
- the copepod *Megastygonitocrella unispinosa* (potential SRE);
- the ostracod Candoninae sp. 'BOS541';
- the ostracod *Pilbaracandona* sp. 'BOS526';
- the copepod *Parastenocaris* sp. 'B28';
- the isopod *Haptolana* sp. 'B01';
- the amphipod *Nedsia* sp. 'AMM026' (potential SRE);
- the amphipod Paramelitidae sp. 'AMP003' (potential SRE);
- the amphipod Paramelitidae sp. 'AMP035' (potential SRE);
- the amphipod Paramelitidae sp. 'AMP037' (potential SRE);
- the amphipod *Wesniphargus* sp. 'AMN004'; and
- the amphipod Neoniphargidae sp. 'B02' (potential SRE).

At the ecological community level, there is a single stygofauna key receptor (Section 5.1.2.1):

- Stygofaunal Community of the Bungaroo Aquifer (Priority 1).

7.1.1 Direct Impacts on Stygofauna Key Receptor Species

Direct impacts on stygofauna species comprise both habitat removal where the mine pits extend below water table and the dewatering necessary to enable this to occur (Section 4.2.1). While it is possible stygofauna may be able to actively respond to declining water table levels and move to habitat that remains viable, it is currently assumed that saturated habitat strata that are completely dewatered are no longer viable habitat and the individuals of species utilising those strata are conservatively considered to have been lost due to mortality. Where habitat strata have a substantial saturated thickness, and dewatering would only partially affect this; leaving connected viable habitat, the species would be likely to locally persist.

Sixteen of the 32 receptor species that occur within the dewatering extent have been recorded from Reference sites outside of the drawdown extent and have been commonly recorded elsewhere within the wider Pilbara bioregion (Section 5.1.1). While individuals of these species will be impacted by the mine pits and dewatering, no changes to their conservation status would be predicted given their wider distributions.

Figure 7.1 shows the distribution of the remaining 16 key receptor species relative to the mine pits and the maximum modelled drawdown extent for the proposal, and Table 7.1 summarises the sites they occur at and the level of predicted groundwater drawdown impact.

Ten of 16 key receptors have also been recorded from Reference sites outside of the drawdown extent (Table 7.1). Three of these 10 more widely-recorded species, *Ophisternon candidum*, *Nedsia hurlberti* and *Nedsia sculptilis*, are of formally listed conservation significance, so, while all three are also known from outside the drawdown extent, they are provided specific consideration in Section 7.1.2 in recognition of their elevated conservation status.

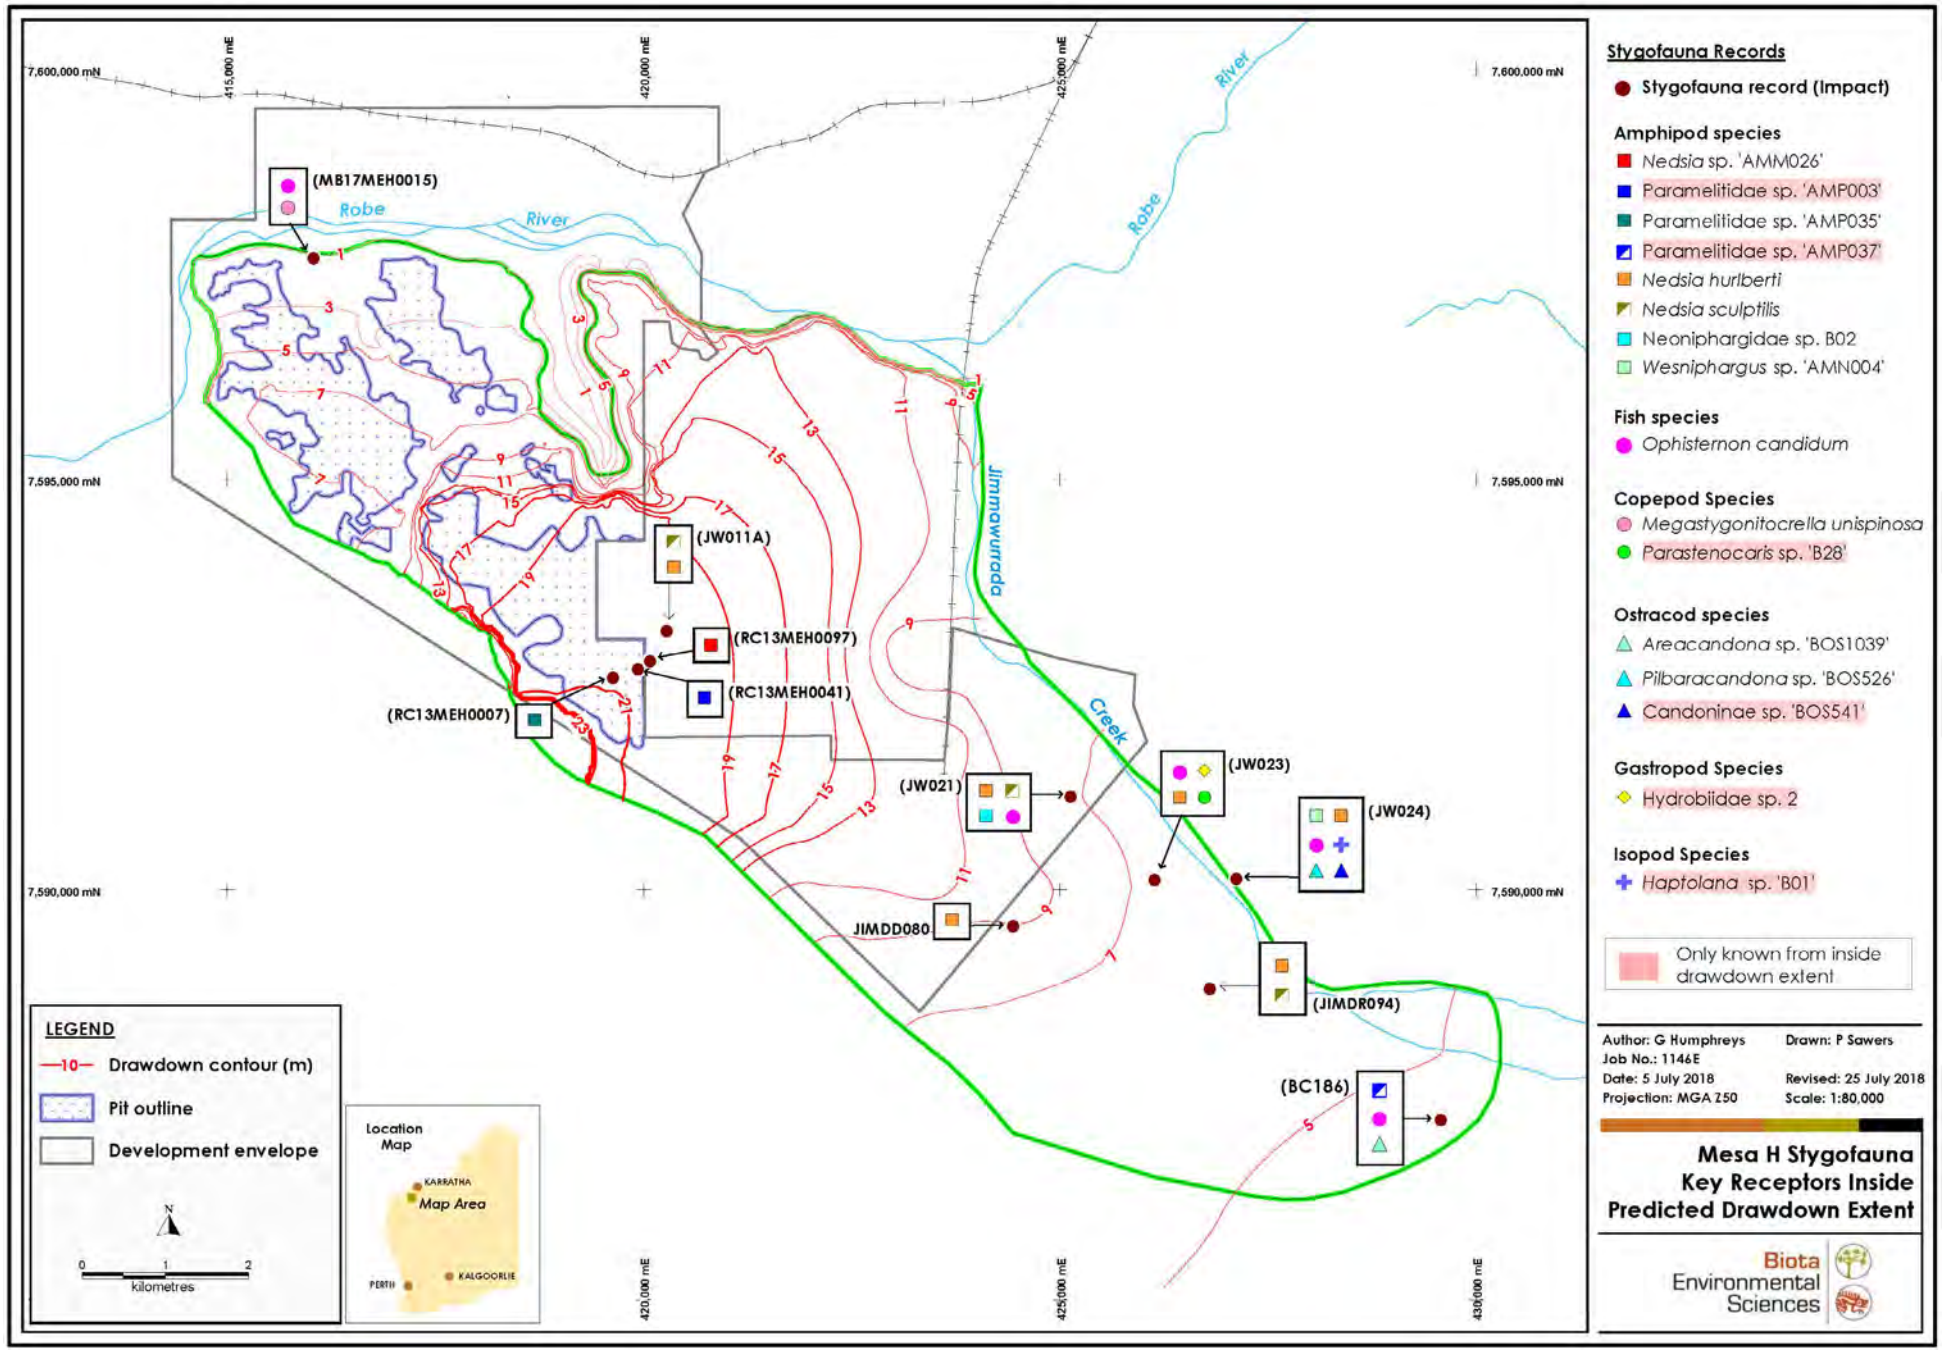

Figure 7.1: Distribution of stygofauna species key receptors within the maximum (2030 base case) proposal drawdown extent.

The other seven key receptors with demonstrated wider distributions would not be placed at significant risk to a change in their conservation status. Three of these species, *Areacandona* sp. 'BOS1039', *Nedsia* sp. 'AMM026' and Neoniphargidae sp. 'B02', were all recorded from outside of the drawdown extent at Reference site 31 further upstream on the Robe River, in the Pannawonica town bore field area ((Biota 2019); Table 7.1). *Megastygonitocrella unispinosa, Pilbaracandona* sp. 'BOS526', *Wesniphargus* sp. 'AMN004' and Paramelitidae sp. 'AMP035', have also been recorded more widely in the Robe River valley, outside of the drawdown extent (Table 7.1).

Table 7.1: Summary of records of impacted stygofauna key receptors relative to the maximum predicted drawdown extent at 2030 under the base case (Reference sites from Biota (2019); Species shaded grey known only from the drawdown extent).

Neoniphargidae sp. 'B02'	JW021	7	31

* Formally listed as being of conservation significance

This leaves six species of stygofauna that are currently known only from the drawdown extent and, from the most precautionary perspective, are potentially restricted in distribution to that area: the aquatic snail Hydrobiidae sp. 2, the ostracods Candoninae sp. 'BOS541', the copepod *Parastenocaris* sp. 'B28', the isopod *Haptolana* sp. 'B01', and two amphipod species: Paramelitidae sp. 'AMP003' and Paramelitidae sp. 'AMP037' (Table 7.1; Figure 7.1).

Four of these six species, Hydrobiidae sp. 2, Candoninae sp. 'BOS541', *Parastenocaris* sp. 'B28' and *Haptolana* sp. 'B01', were recorded from two sites in close vicinity along Jimmawurruda Creek: JW023 and JW024 (Figure 7.1 and Table 7.1). The stygofauna habitat in this area is a sequence of saturated alluvium associated with the creek that is approximately 22-24 m in thickness down to the underlying CID (Figure 7.2). The two sites are on the eastern margin of the predicted drawdown for the proposal (Figure 7.1), with a maximum drawdown of >7 m on the pre-mining water table (Table 7.1 and Figure 7.1). Uncertainty in the model and seasonal water level fluctuation could have under-predicted the maximum drawdown, but it is expected that at least 15 m of alluvium will remain saturated below water table in the area where the four species have been recorded with the implementation of the proposal (see Figure 7.2). In the unlikely event that these species are restricted in distribution to this very small locality, this will still represent a refuge habitat at the time of peak dewatering for the project, which is expected to remain hydraulically connected to saturated alluvium habitat along the length of Jimmawurrada Creek, and will be seasonally connected to a greater extent during major rainfall events (Figure 7.2). These two potentially restricted key receptors are therefore not at significant risk of taxon-level impacts from the dewatering.

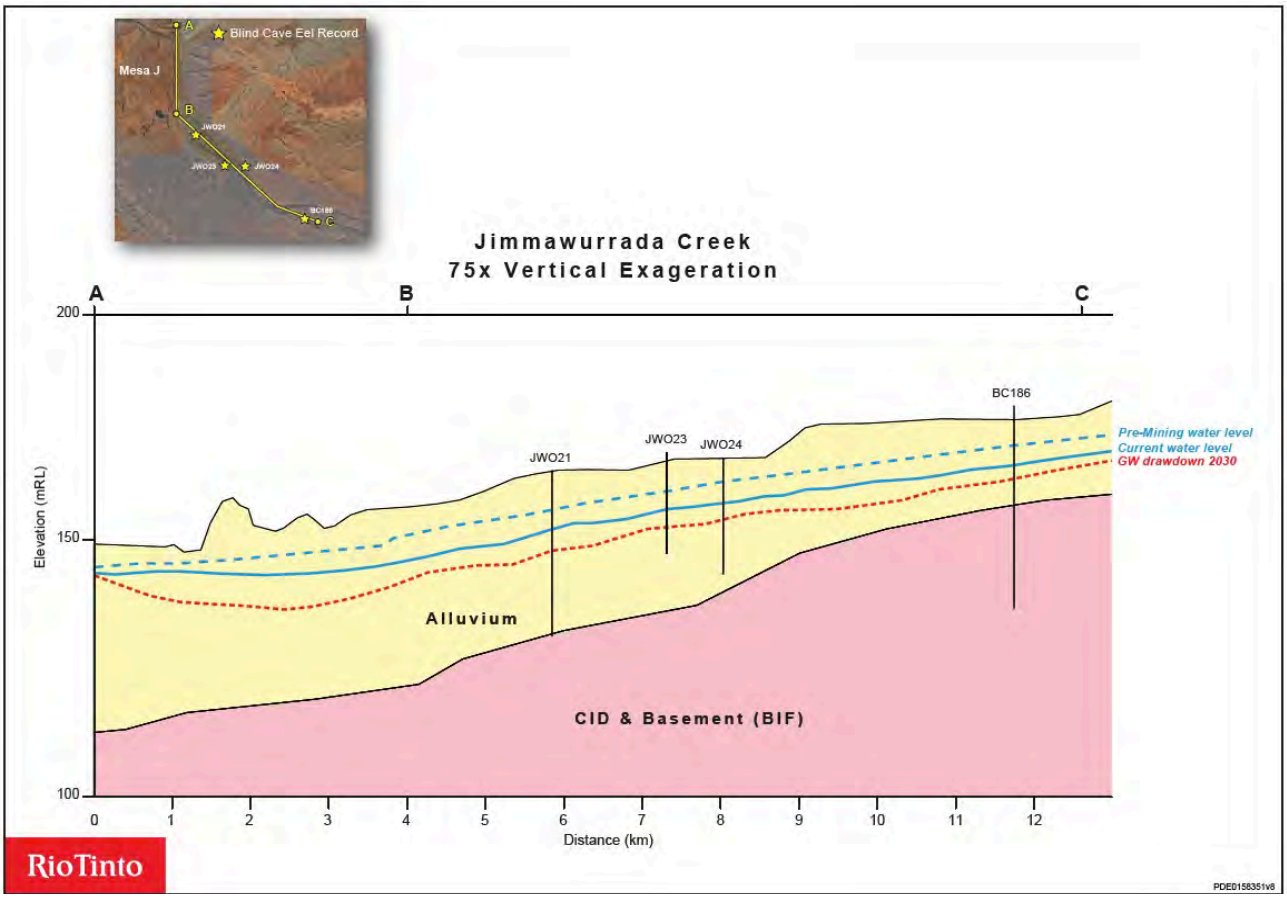

Figure 7.2: Longitudinal cross-section along Jimmawurrada Creek area, showing pre-mining water table, predicted maximum drawdown from the proposal in 2030 (dashed in red) and alluvial and CID stygofauna habitats that will remain saturated (below the red dashed line) (source Rio Tinto).

This leaves the amphipod species Paramelitidae sp. 'AMP003' and Paramelitidae sp. 'AMP037' as the last two species currently known from the drawdown extent. Both are only known from a single Impact site and both will be more substantially affected by the predicted drawdown:

- Paramelitidae sp. 'AMP003' would be the most substantially affected, having been recorded from site RC13MEH0041 within the proposed mine pit area, which will be subject to approximately 20 m drawdown in the water table (Table 7.1; Figure 7.1) and direct habitat removal from mine pit development. Given the location of the site beneath the Mesa H landform, it appears likely that this species occurs at least within the CID aquifer.
- Paramelitidae sp. 'AMP037' was recorded at the southeast limits of the drawdown extent at site BC186, which will be drawn down by >5 m below the pre-mining water table (Table 7.1; Figure 7.1). This site intersects the alluvial aquifer of the Jimmawurrada – Bungaroo Creek system, which represents the habitat the species was recorded from.

The key impact assessment question for these taxa is whether they are truly restricted to their currently recorded sites or actually occur more widely. This can be evaluated on the basis of multiple lines of evidence, utilising both physical and biological information:

1. Animal abundance
   Both species are represented by a single specimen only. With singleton taxa such as these it is difficult to determine if their apparent restriction is real or simply that they are actually more widespread but naturally at low abundance and/or difficult to collect with conventional methods. In cases where species are readily collected in good numbers, but are only ever detected from closely neighbouring sites, it is less likely that the restricted distribution is due to sampling effects and more likely it is genuine. This is not the case with the two amphipod species in question, with only a single individual each, therefore a probability exists that the result is due to ecological sampling effects.

2. Groundwater habitats
   It appears likely that Paramelitidae sp. 'AMP003' occurs within the CID aquifer, which is relatively confined and limited horizontally in the locality (Rio Tinto 2017b). The degree of hydraulic connection between the CID aquifer and the wider alluvial aquifers of the locality is not well defined, but basement groundwater flow may connect it with the Robe River aquifers to the north (Rio Tinto 2017b). The CID in this area is also inter-connected to the southeast with the broader Jimmawurrada – Bungaroo CID aquifer and overlying colluvium (Figure 6.1 and 6.2).

   Paramelitidae sp. 'AMP037' was recorded from site BC186, which intersects the widespread, highly transmissive and connected alluvial aquifer associated with Jimmawurrada Creek (Section 6.1), which overlies a substantive CID aquifer.

3. Assemblage distribution
   Paramelitidae sp. 'AMP003' was collected from site RC13MEH0041. Only one other stygofauna species was recorded from this same sampling site: *Nedsia* sp. 'AMM001' (Biota 2019) which, at a broad level, is morphologically and ecologically similar to Paramelitidae sp. 'AMP003' but occurs widely in the locality, covering a minimum distribution of 501 km^2 based on records from the Biota (2019) survey alone. That result does not indicate a higher risk of Paramelitidae sp. 'AMP003' being locally restricted in distribution, and conversely that it, too, may be more likely to follow a similar distribution pattern to the related, sympatric amphipod species. These observations also lend support to the view above that the CID aquifer beneath Mesa H is connected by groundwater flow to the wider Jimmawurrada – Bungaroo CID aquifer which is directly connected to the Jimmawurrada alluvial aquifer, which in turn is a tributary into (and connected to) the Robe River alluvial aquifer: if this were not the case, it would be very unlikely that *Nedsia* sp. 'AMM001' from site RC13MEH0041 would have remained so genetically similar to other individuals in the wider locality (Biota 2019).

   Multiple other stygofauna species co-occur at site BC186 with Paramelitidae sp. 'AMP037': *Enchytraeus* sp. 'AP PSS1' (which also occurs 39 km away downstream in the Robe River); *Areacandona* sp. 'BOS1039' (also at site 31 at the Pannawonica bore field); *Stygoridgewayia trispinosa* (also at 18 other sites along the length of the Robe Valley up to 59 km away); *Areacandona triangulum* (also recorded at three Reference sites up to 41 km away) and *Ophisternon candidum* (recorded from six other sites along Jimmawurrada and the Robe River) (Biota 2019). With the exception of the singleton Paramelitidae sp. 'AMP037', every other species recorded from site BC186 is more widely distributed within the Robe River valley. As these taxa span a range of body sizes, morphologies and ecologies, their locally widespread distributions do not indicate any evidence of local barriers to fauna dispersal and gene flow for stygofauna, which by inference would also apply to Paramelitidae sp. 'AMP037' at the same site.

4. Distributions of closely-related taxa
   Seventeen other Amphipoda species were recorded by Biota (2019), including four other taxa belonging to the same family as Paramelitidae sp. 'AMP003' and P. sp. 'AMP037'. Revisiting point 1 above regarding low frequency taxa: it is notable that all of the paramelitids were detected from few (or in many cases one) individuals, including two other singleton species (Biota 2019). The only paramelitid amphipod species that was recorded from more than one

site was Paramelitidae sp. 'AMP035', which was recorded within the drawdown extent at site RC13MEH0007 but has been shown to also occur outside of this impact area (Table 7.1). That site is immediately adjacent to site RC13MEH0041, where Paramelitidae sp. 'AMP003' was collected, and the distribution of the more widely recorded, but closely-related, Paramelitidae sp. 'AMP035' then suggests that Paramelitidae sp. 'AMP003' may also occur more widely.

The above lines of physical and biological evidence are all parallel in suggesting connectivity between site RC13MEH0041 (where Paramelitidae sp. 'AMP003' was recorded) and the wider Robe River aquifers and stygal assemblage, and similarly for BC186 (Paramelitidae sp. 'AMP037') and the wider habitats in the locality. Data from other co-occurring species, related amphipod taxa and groundwater habitat information do not signal a high degree of isolation in stygofauna species in the locality of either site where the singleton species were recorded. It appears unlikely that either of the two amphipod species would be truly restricted to the dewatering extent and more likely that their current apparently restricted distributions are due to ecological sampling effects.

7.1.2 Direct Impacts on Conservation Significant Species

Individuals of the Schedule-listed amphipods *Nedsia hurlberti* and *Nedsia sculptilis* will not be directly impacted by the mine pits, but will be impacted by the cumulative dewatering at multiple record sites, with approximately 20 m of groundwater drawdown predicted at JW011A where both species have been historically recorded (Table 7.1).

However, while both species are listed as Schedule 3 at State level, they also occur more widely, both in the west Pilbara and as far afield as Barrow Island (Table 7.1; Figure 7.3; Figure 7.4).

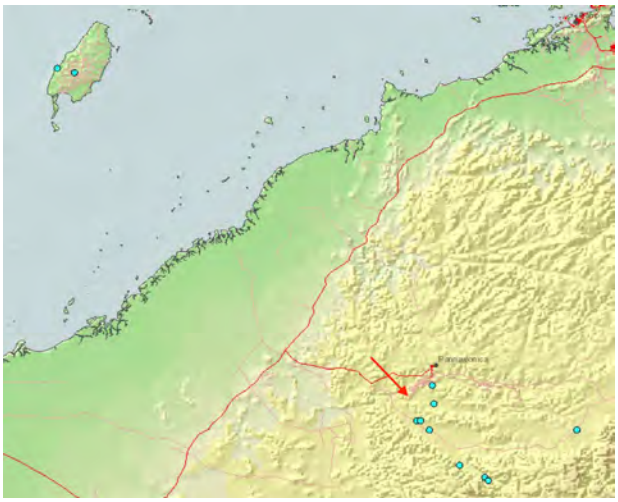

Figure 7.3: Records of *Nedsia hurlberti* on NatureMap (blue circles) (arrow indicates development envelope).

Figure 7.4: Records of *Nedsia sculptilis* on NatureMap (blue circles) (arrow indicates development envelope).

The current survey records of the two species from Mesa H are in addition to those used by DBCA to assign the species' conservation listing, and the local impact on individuals arising from the proposal would therefore not alter their overall current conservation status.

In addition, stratigraphic cross-sections along the length of Jimmawurrada Creek, where site JW021 is situated, combined with hydrogeological modelling, show that a substantial thicknesses of alluvium (a minimum of approximately 17 m) and underlying CID will remain saturated along Jimmawurrada Creek during the period of maximum drawdown for the project (Figure 7.2). While the alluvial aquifer is likely to be the primary habitat for the species, both units provide habitat for stygofauna below water table, meaning this will represent a substantial refugium habitat for both amphipod species at the time of peak dewatering for the project.

The third conservation significant species, the Blind Cave Eel (*Ophisternon candidum*), also occurs along Jimmawurrada Creek and has been recorded from four sites there, in addition to five other sites in the broader locality (Figure 7.5) (Biota 2019). The ecology and distribution of the species is poorly understood (Biota and Helix 2014), but the surveys and related investigations completed for

the Mesa H proposal have substantially improved the overall knowledge base for the species in the west Pilbara (Moore et al. 2018, Biota 2019). Specimen records and eDNA evidence now indicate the species occurs within not only the Bungaroo Creek alluvial aquifer (Biota 2009b), but also in the Jimmawurrada Creek and Robe River alluvial aquifers ((Biota 2019); Figure 7.5).

Spatially then, there are five sites in the Mesa H locality where the species has been recorded that are outside of the proposal's drawdown extent (Figure 7.5). Similar to other stygofauna species, the records of *O. candidum* also show a high spatial correlation to the High likelihood stygofauna habitat units: Taking account of all confirmed record locations, the distribution of this habitat suggests that suitable connected habitat for the species occurs along the length of the Robe River catchment (Figure 7.5). It is notable that one of the Reference site eDNA records for the species came from the Control site sampled by Biota (2019): this site was a surface water pool on the Robe River and consistently yielded eDNA detections for the species from multiple replicate samples (Helix 2018). This may suggest that the species utilises shallow groundwater habitats in the alluvial sequence of the Robe River, including the phreatic zone, and this could contribute to maintenance of gene flow and population connectivity within the species' overall range. This theory is consistent with the Robe River alluvium hypotheses of Moore et al. (2018) and is supported by the subsequent and recent collection of an additional specimen from the phreatic zone of the Robe River during aquatic fauna sampling in a surface pool in the river (WRM 2018, in prep.).

In addition, one of these Reference sites (site 25; Figure 7.5) is part of the Pannawonica town bore field, which is subject to a low level of groundwater drawdown itself, being pumped at sustainable yield for water supply (Rio Tinto 2016). This alluvial aquifer habitat has been abstracted from since 1981 (Rio Tinto 2016), which is indicative of both the significant recharge capacity of the Robe River alluvial aquifer and, by inference, that *Ophisternon candidum* is at least tolerant to this level of groundwater impact in the medium term (with the bore field having being in operation for 37 years at the time the recent eDNA record was obtained; Biota 2019).

Even within the drawdown extent, the alluvial aquifer habitat of Jimmawurrada Creek where *O. candidum* occurs is subject to the same predictions as those noted above for *Nedsia hurlberti* and *N. sculptilis*: that is, when considered vertically, there will be a substantial saturated thickness remaining along the length of the creek at the peak of groundwater drawdown for the project in 2030. Similar to the *O. candidum* records from the Pannawonica town bore field, the sites on sites on Jimmawurrada Creek have also been subject to groundwater drawdown associated with the existing Mesa J operations and the species still utilises the area. Figure 7.2 shows the four sites where *O. candidum* has been recorded along Jimmawurrada Creek, illustrating that a continuous and connected saturated alluvium habitat varying between 5 and 17 m thick will remain within the system at the peak of dewatering. This is in addition to the underlying saturated CID, which may also provide potential habitat to the species (Figure 7.5).

In summary then:

- four of the known sites where *Ophisternon candidum* occurs are currently affected by groundwater drawdown, and will be subject to further groundwater drawdown from between 1 m up to a temporary peak of 6 m on the current water table but a substantial thickness of saturated alluvium and CID will remain as a refuge even within the impact areas (Table 7.1 and Figure 7.2);
- there are a further five known sites where the species occurs within the Robe Valley that are outside of the drawdown extent, including along the Robe River (Figure 7.1);
- inferences drawn from one of those sites at the Pannawonica town bore field suggest the species may be tolerant to lower levels of groundwater perturbations; and
- both the distributions of the known records, and habitat mapping with a strong evidence base from the broader stygal assemblage (Section 6.1), indicate it is likely that the species is distributed more widely along the Robe River catchment alluvial aquifer.

The above suggest that while some individuals of the species may be directly impacted by the groundwater drawdown, the species will remain locally represented within the Mesa H locality, in addition to its possible occurrence further along the connected alluvial aquifer habitats downstream along the Robe River and further afield at Cape Range (Biota 2019).

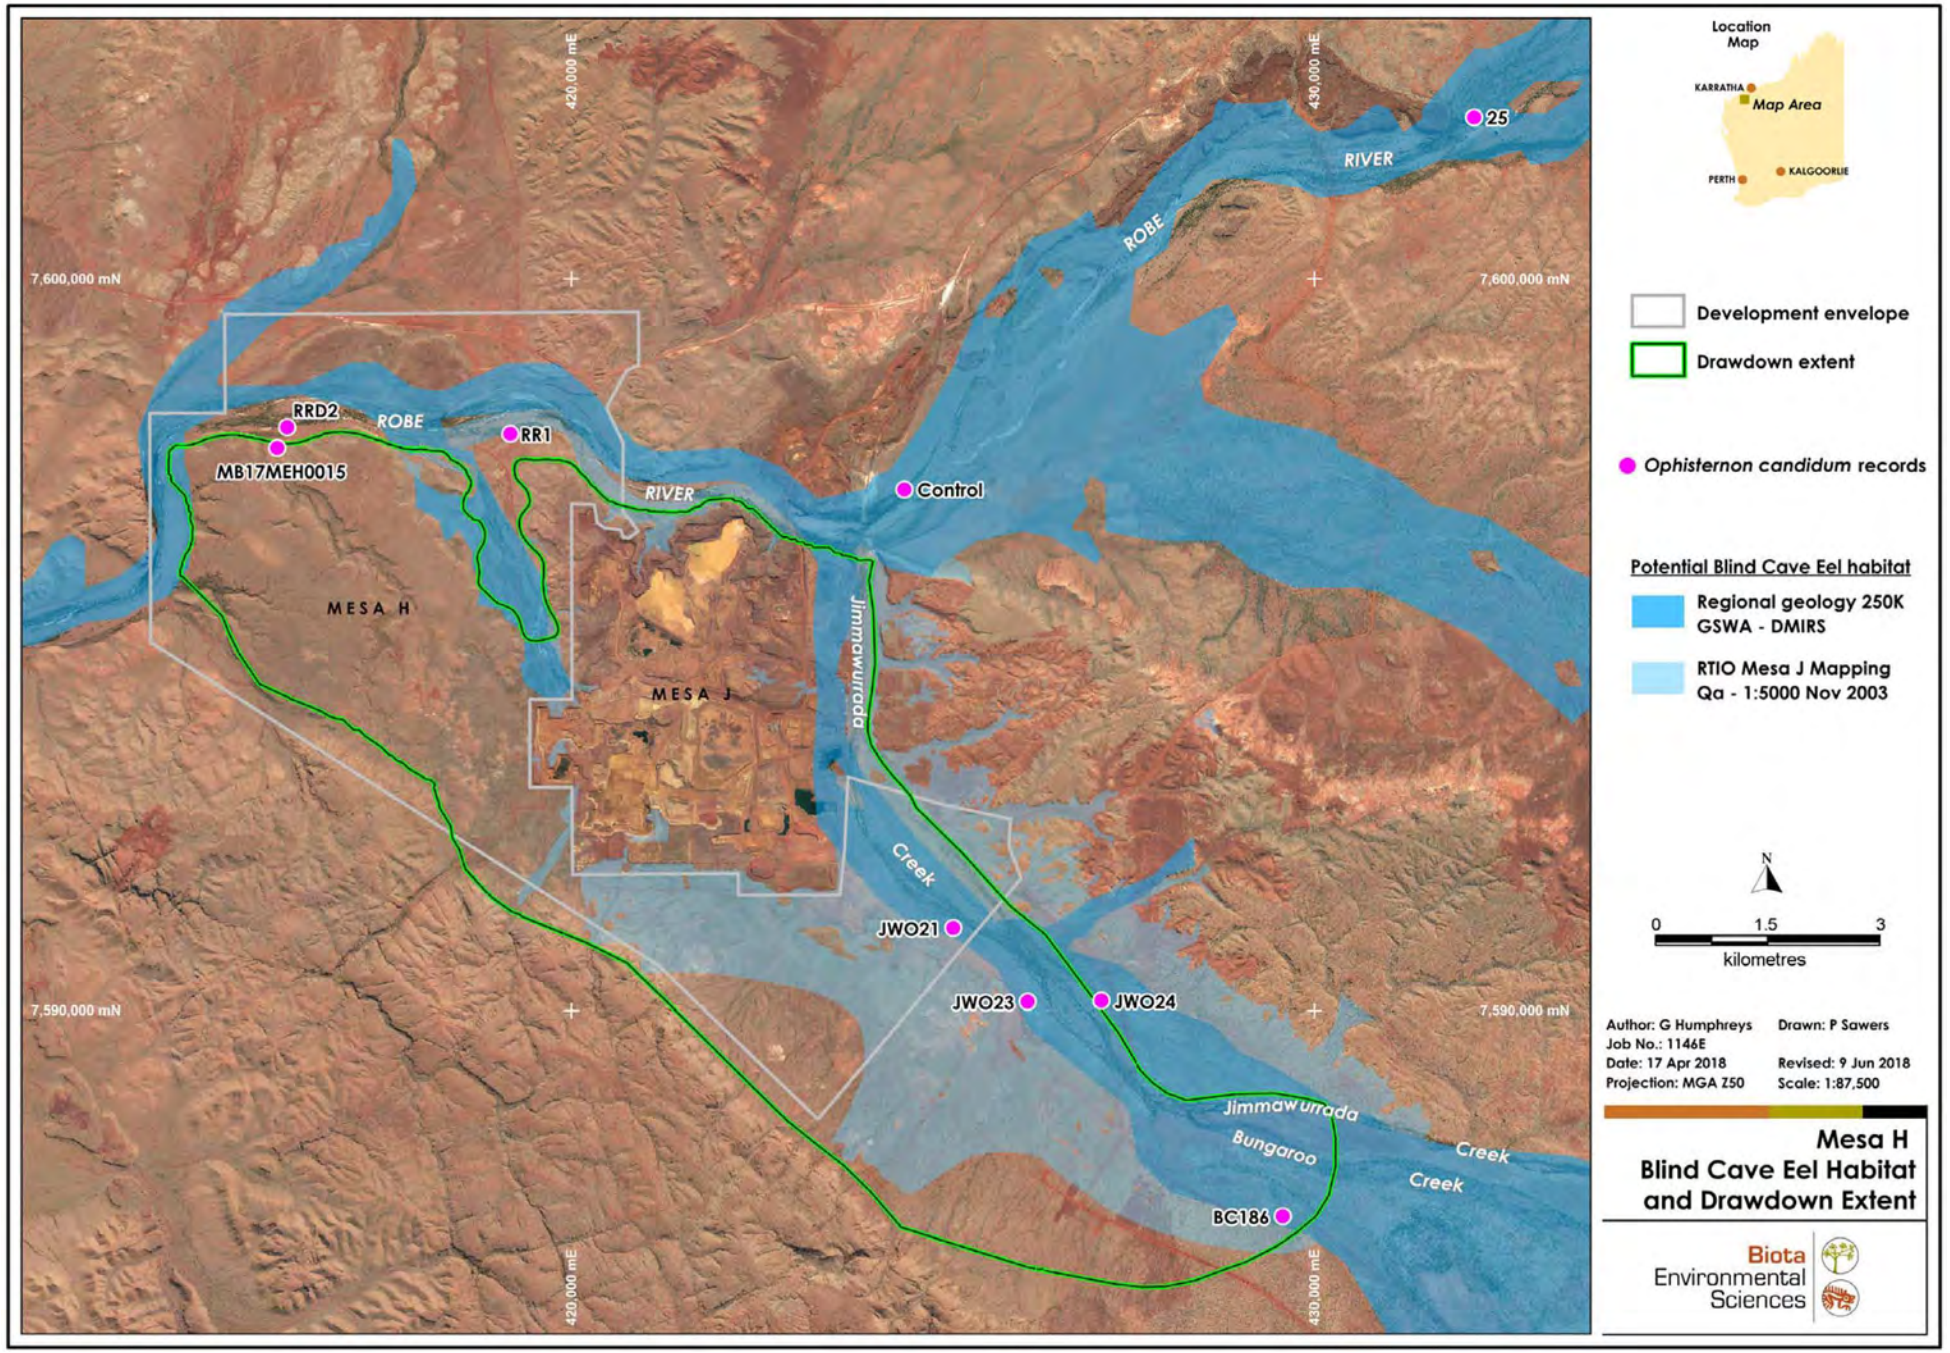

Figure 7.5: Blind Cave Eel Records and potential habitat for the species relative to the extent of direct impacts arising from the Mesa H project.

7.1.3 Direct Impacts on Stygofauna Community and Habitat Key Receptors

This drawdown extent relative to the Stygofaunal Community of the Bungaroo Aquifer PEC is shown in Figure 7.6.

The drawdown extent for the proposal will have a relatively minor effect on the northwestern limit of the PEC as mapped by DBCA. The total mapped extent of the Bungaroo aquifer PEC is 106,703 ha, of which 3,287 ha falls within the drawdown extent (3.1% by area; Figure 7.6). Therefore, while the proposal will have an impact on the PEC, 97% of its extent as currently recognised by DBCA, or over 100,000 ha in real terms, will remain unaffected by the Mesa H proposal.

At the scale of stygofauna habitats in the wider Robe River catchment (as illustrated in Figure 6.2), the proportion of aquifer habitat impacted by the dewatering is an order of magnitude smaller than the PEC impact, and is thereby not considered further in this assessment.

7.1.4 Indirect Impacts

The pathways by which the proposal that may indirectly impact stygofauna comprise:

1. clearing of terrestrial vegetation and hardstand sealing of surfaces, leading to changes to groundwater recharge and nutrient infiltration;
2. increased sedimentation of the aquifers beneath the project footprint due to the creation of waste landforms and waste fines management; and
3. risk of hydrocarbon or other groundwater contamination (see Section 4.2.2).

All of these impact pathways are likely to be secondary tier impacts by comparison to the direct impacts (Section 7.1.1 to 7.1.3) and their effects can typically be minimised through project design and operational environmental management measures that are now well-established and effective. The primary focus for the assessment of the impacts then remains the direct impacts of the proposal on stygofauna from mine pit construction and dewatering.

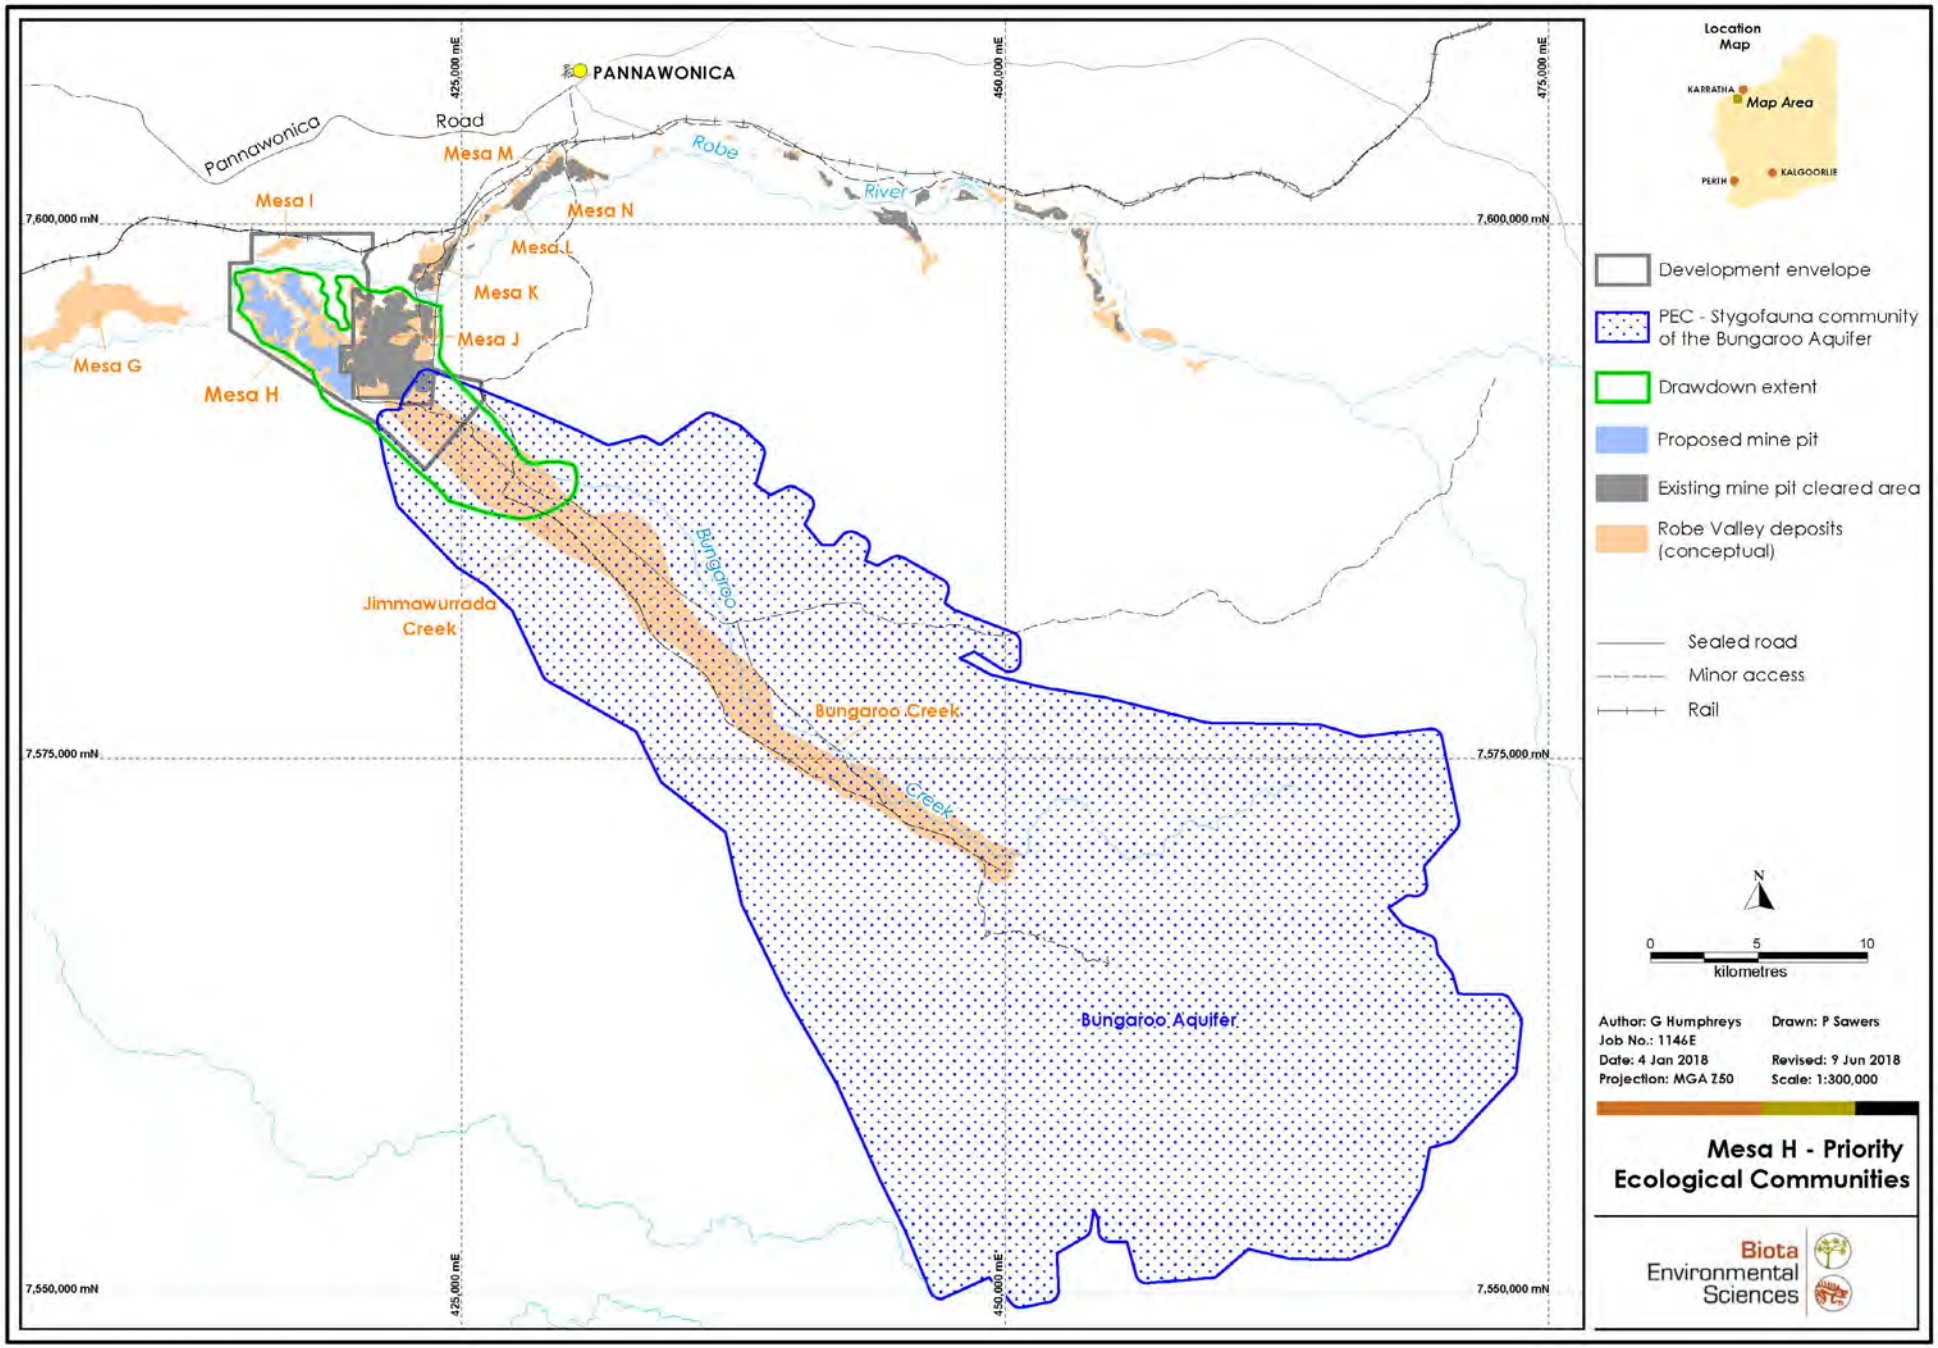

Figure 7.6: Mapped extent of stygofauna community key receptor relative to the extent of direct impacts arising from the Mesa H project.

7.2 Troglofauna Impacts

This assessment identified 33 development area species that are potential SRE taxa and represent the troglofauna key receptors for this impact assessment.

These comprise:

- eight pseudoscorpion species (Hyidae sp.'PH017/PH027', Hyidae sp. 'PH026', Olpiidae sp. 'PO008', *Beierolpium* sp. 'PO014', *Beierolpium* sp. 'PO015', Atemnidae sp. 'PA004', Chthoniidae sp. 'PC014/PC015' and Chthoniidae sp. 'PC055');
- four schizomid species (*Paradraculoides* sp. 'SCH038', *Paradraculoides* sp. 'SCH039', Hubbardiidae sp. 'SCH011' and Hubbardiidae sp. 'SCH015/16');
- one centipede species (Cryptopidae sp. 'SC018');
- seven dipluran species (Parajapygidae sp. 'DPA001', Parajapygidae sp. 'DPA009', Projapygidae sp. 'DPR008/DPR009/DPR011', Projapygidae sp. 'DPR010', Japygidae sp. 'DJA003', Japygidae sp. 'DJA011', and Campodeidae sp. 'DCA005');
- five isopod species (Philosciidae sp. 'ISP047', Philosciidae p. 'ISP055', *Troglarmadillo* sp. 1, *Troglarmadillo* sp. 'ISA046'; and Armidillidae sp. 'ISA056/ISA057');
- three beetle species (Curculionidae sp. 'CCU014', Ptilidae sp. 1/'CP003' and Ptilidae sp. 'Robe Valley'/'CP002');
- two silverfish species (Nicoletiinae sp. 'TN019' and Nicoletiinae sp. 'TN020');
- two spider species (*Prethopalpus* sp. 'ARA052' and Gnaphosidae sp. indet.); and
- one cockroach species *(?Nocticola* sp. 'West Pilbara Complex').

Taken together, the higher order taxonomic composition of the fauna of the development envelope is representative of virtually all components of the best-sampled pisolitic mesa habitats of the Robe valley (Biota 2006a, 2016b, 2017). The development area can therefore be considered adequately sampled (Biota 2019) and the survey data inputs (the first tier of the impact assessment model followed here; Figure 2.1) adequate for the purposes of the current assessment.

At this troglofauna ecological community level, there are also two key receptors for this impact assessment (following the criteria in Section 2.4):

- Subterranean invertebrate communities of mesas in the Robe Valley region (Priority 1); and
- Subterranean invertebrate community of pisolitic hills in the Pilbara (Priority 1) (Section 5.2.2.1).

7.2.1 Direct Impacts on Troglofauna Species Key Receptors

The clearest direct impact on both troglofauna species and communities key receptors is the habitat removal that will occur to accommodate the proposed mine pits (Section 4.2.1). This will result in the loss of troglofauna habitat and the mortality of individual animals occurring within it.

Records of the 33 troglofauna species known from the development envelope are show in Figure 7.7. Six of these 33 have also been recorded from outside of the development envelope and have demonstrated wider distributions:

- two schizomid species: Hubbardiidae sp. 'SCH011' (also known from remnant CID habitat north of Mesa J; Figure 7.7) and Hubbardiidae sp. 'SCH015/SCH016' (previously recorded from 6 km southwest of the development envelope; Biota (2019));
- the isopod species Armadillidae sp. 'ISA056/ISA057' (also known from 27 km to the west at Mesa C (Biota 2019) and is therefore likely to occur more widely at other locations);
- the blattodean ?*Nocticola* sp. 'West Pilbara Complex' (relatively widespread in the locality, including up to 60 km to the south (Biota 2019)); and
- two beetle species: Ptilidae sp. 1/'CP003' and P. sp. 'Robe Valley'/'CP002' (both of which have been recorded more widely within the Robe River valley (Biota 2019).)

The remaining 27 key receptor species have currently only been recorded from within the development envelope (Biota 2019). The key question for this assessment in respect of these species then becomes their distribution relative to the proposed extent of the mine pits.

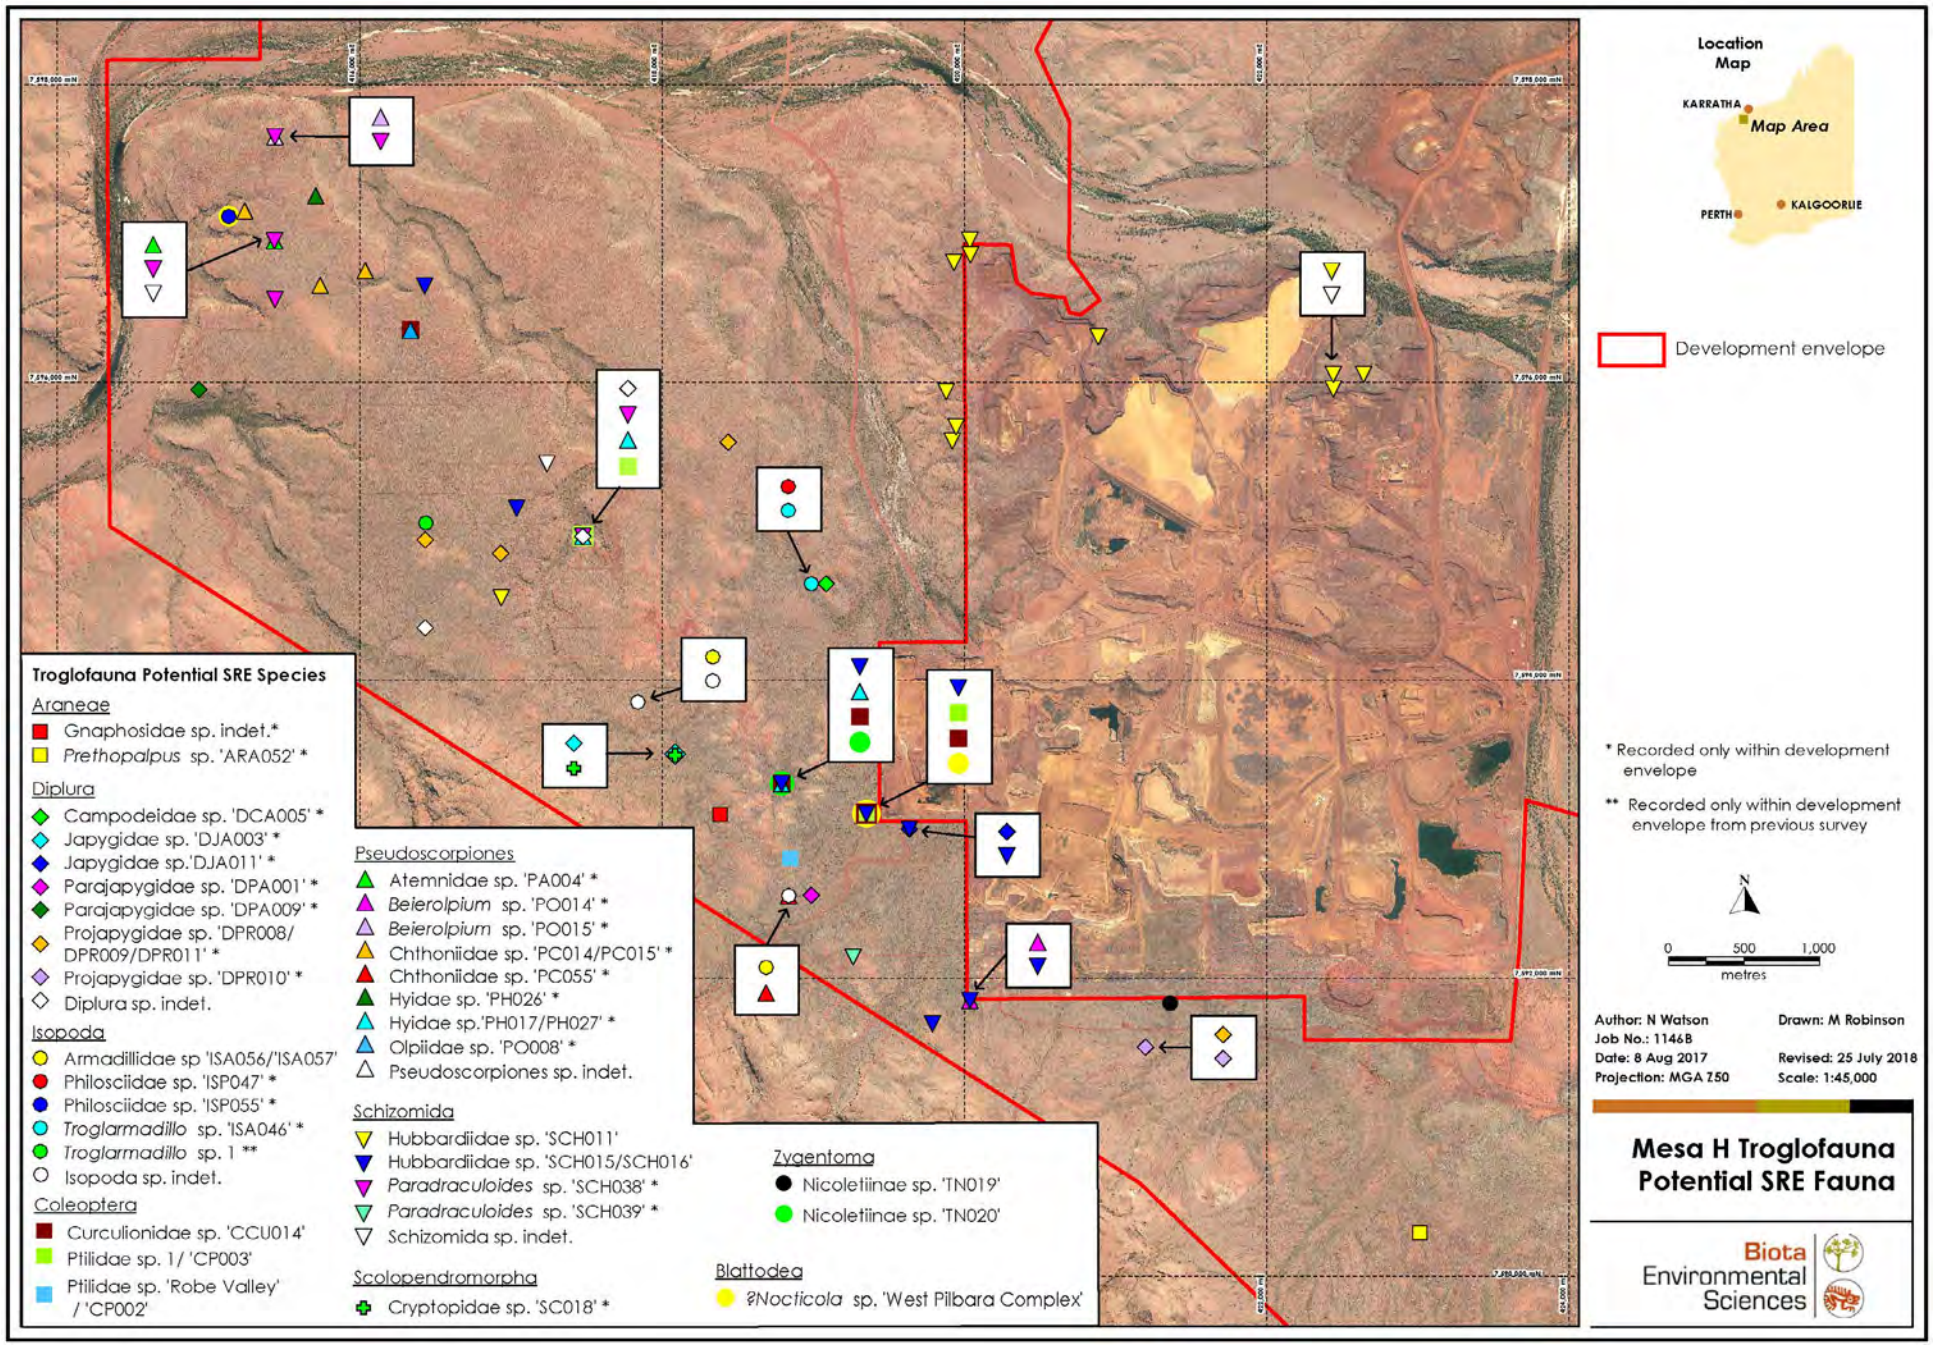

Figure 7.7: Distribution of all troglofauna key receptor species within the development envelope.

The records of the 27 species only known from the development envelope are summarised in Table 7.2, which categorises the sites where they have been recorded into sites within the mine pits and sites outside of this that will not be directly impacted. These data show that 23 of the 27 species have only been recorded from habitat outside of the proposed pit areas, with the proposed pits not directly impacting them at all from current data, and half of those 23 un-impacted species are also confirmed within the MEZ (Table 7.2).

This avoidance of direct impact on most species occurring within the development envelope is due to Rio Tinto's elimination of impacts during the project design (the 'Management' tier mitigation opportunity in the impact assessment model; see Figure 2.1): the design of the mine pit boundaries was specifically tailored to avoid troglofauna species records where feasible, and the MEZ was designed to incorporate locations where species were recorded; adopting a precautionary approach to their distributions. This has resulted in 70% of the development envelope troglofauna species being avoided entirely by the proposed mine pit footprint.

Table 7.2: Troglofauna species currently known only from within the development envelope and their distribution relative to the proposed mine pits (species shaded grey currently only known from the mine pits).

Araneae			
Prethopalpus sp. 'ARA052'	-	-	RC16JIM0019
Gnaphosidae sp. indet.	-	RC14MEH0270	-

Five of the remaining six species that occur within the mine pits have distributions demonstrated to extend beyond the pit boundaries (Table 7.2; Figure 7.8). Again, this is a function of the proposed mine pit and MEZ design having been specifically modified in response to the troglofauna survey data to avoid or minimise direct impacts.

With the pit design mitigation already undertaken, there is only one species currently known only from within the proposed pit outlines: the dipluran Japygidae sp. 'DJA011' (Table 7.2; Figure 7.8). A key impact assessment question that arises for this proposal, and has arisen for numerous previous proposals where Subterranean Fauna has been a relevant factor, is whether this species is truly restricted to the mine pit impact areas. This can be addressed by consideration of the survey data, distributional records of all troglofauna species known from Mesa H, and the extent and configuration of interconnected troglofauna habitat in the locality.

Both the results of the current Biota (2019) investigations, and past work in the Robe valley (Biota 2006a, 2016b, 2017), indicate that the appropriate spatial scale at which to evaluate this is the CID landforms and associated AWT troglofauna habitat of Mesa H itself. This is due to the endemism common in the fauna, with over 80% of the recorded species only known to occur at Mesa H. This is consistent with the configuration and extent of troglofauna habitat, with the habitats identified for Mesa H bounded by major geomorphological features; comprising the Robe River to the north and Jimmawurrada Creek to the east, and southerly limits on AWT habitat, where the CID habitat abuts the Brockman Iron Formation ranges rising to the southwest (Section 6.2). The context for assessing the risk to the potentially restricted species is therefore to consider whether very small scale and localised restrictions in species distributions could exist within the extent of troglofauna habitat mapped for Mesa H (Figure 6.5 and Figure 6.6 of Section 6.2).

The risk that the species in question is truly restricted to the mine pits can consider:

1. Animal abundance
   The species is represented by a single specimen only. As discussed for the equivalent stygofauna singleton taxa (Section 7.1.1), this makes assessing its true distribution more difficult and introduces the probability that the apparent isolation to the record site is an artefact of ecological sampling effects.
2. Troglofauna habitats
   The combination of surface geology habitat mapping, AWT CID thickness data, and stratigraphic cross-sections (Figure 6.5 and Figure 6.6), all indicate continuity and connectivity of AWT troglofauna habitats across the extent mapped within the development envelope.
3. Assemblage distribution
   Other troglofauna species recorded from the same drillhole as the species in question have demonstrated distributions that extend beyond the direct impact areas. Japygidae sp. 'DJA011' was recorded from DD13MEH0007, where it co-occurs there with Hubbardiidae sp. 'SCH015/SCH016'; a species that has been recorded both inside and outside the pits, including in habitat that will remain unmined 1.2 km to the south (Figure 7.3) and is also known from outside the development envelope (Biota 2019).

   At the overall assemblage level, there are 11 troglofauna species known to occur within the mine pit boundaries and 10 of these have proven wider distributions within Mesa H or further afield, with records from either the MEZ or other troglofauna habitat that will remain unmined (Figure 7.3). This pattern in the fauna indicates connectivity of habitat across the extent of the landform and across the mine pit boundaries, rather than a pattern of very localised isolation. Consistent with this, past surveys at other Robe River valley mesas has shown that troglofauna species typically have distributions equivalent to at least the extent of contiguous, AWT CID landforms, once sufficient sampling has been undertaken to demonstrate this (e.g. Biota 2006b, 2007, 2016c).

The above lines of physical and biological evidence are parallel in suggesting that the dipluran Japygidae sp. 'DJA011' appears unlikely to be truly restricted to the small portions of the Mesa H landform from which it has currently been recorded. Data from other co-occurring species, and the broadly continuous nature of AWT CID habitats within Mesa H, suggest that the apparent restriction of the species is due to ecological sampling effects and that it occurs more widely within the local habitat extent.

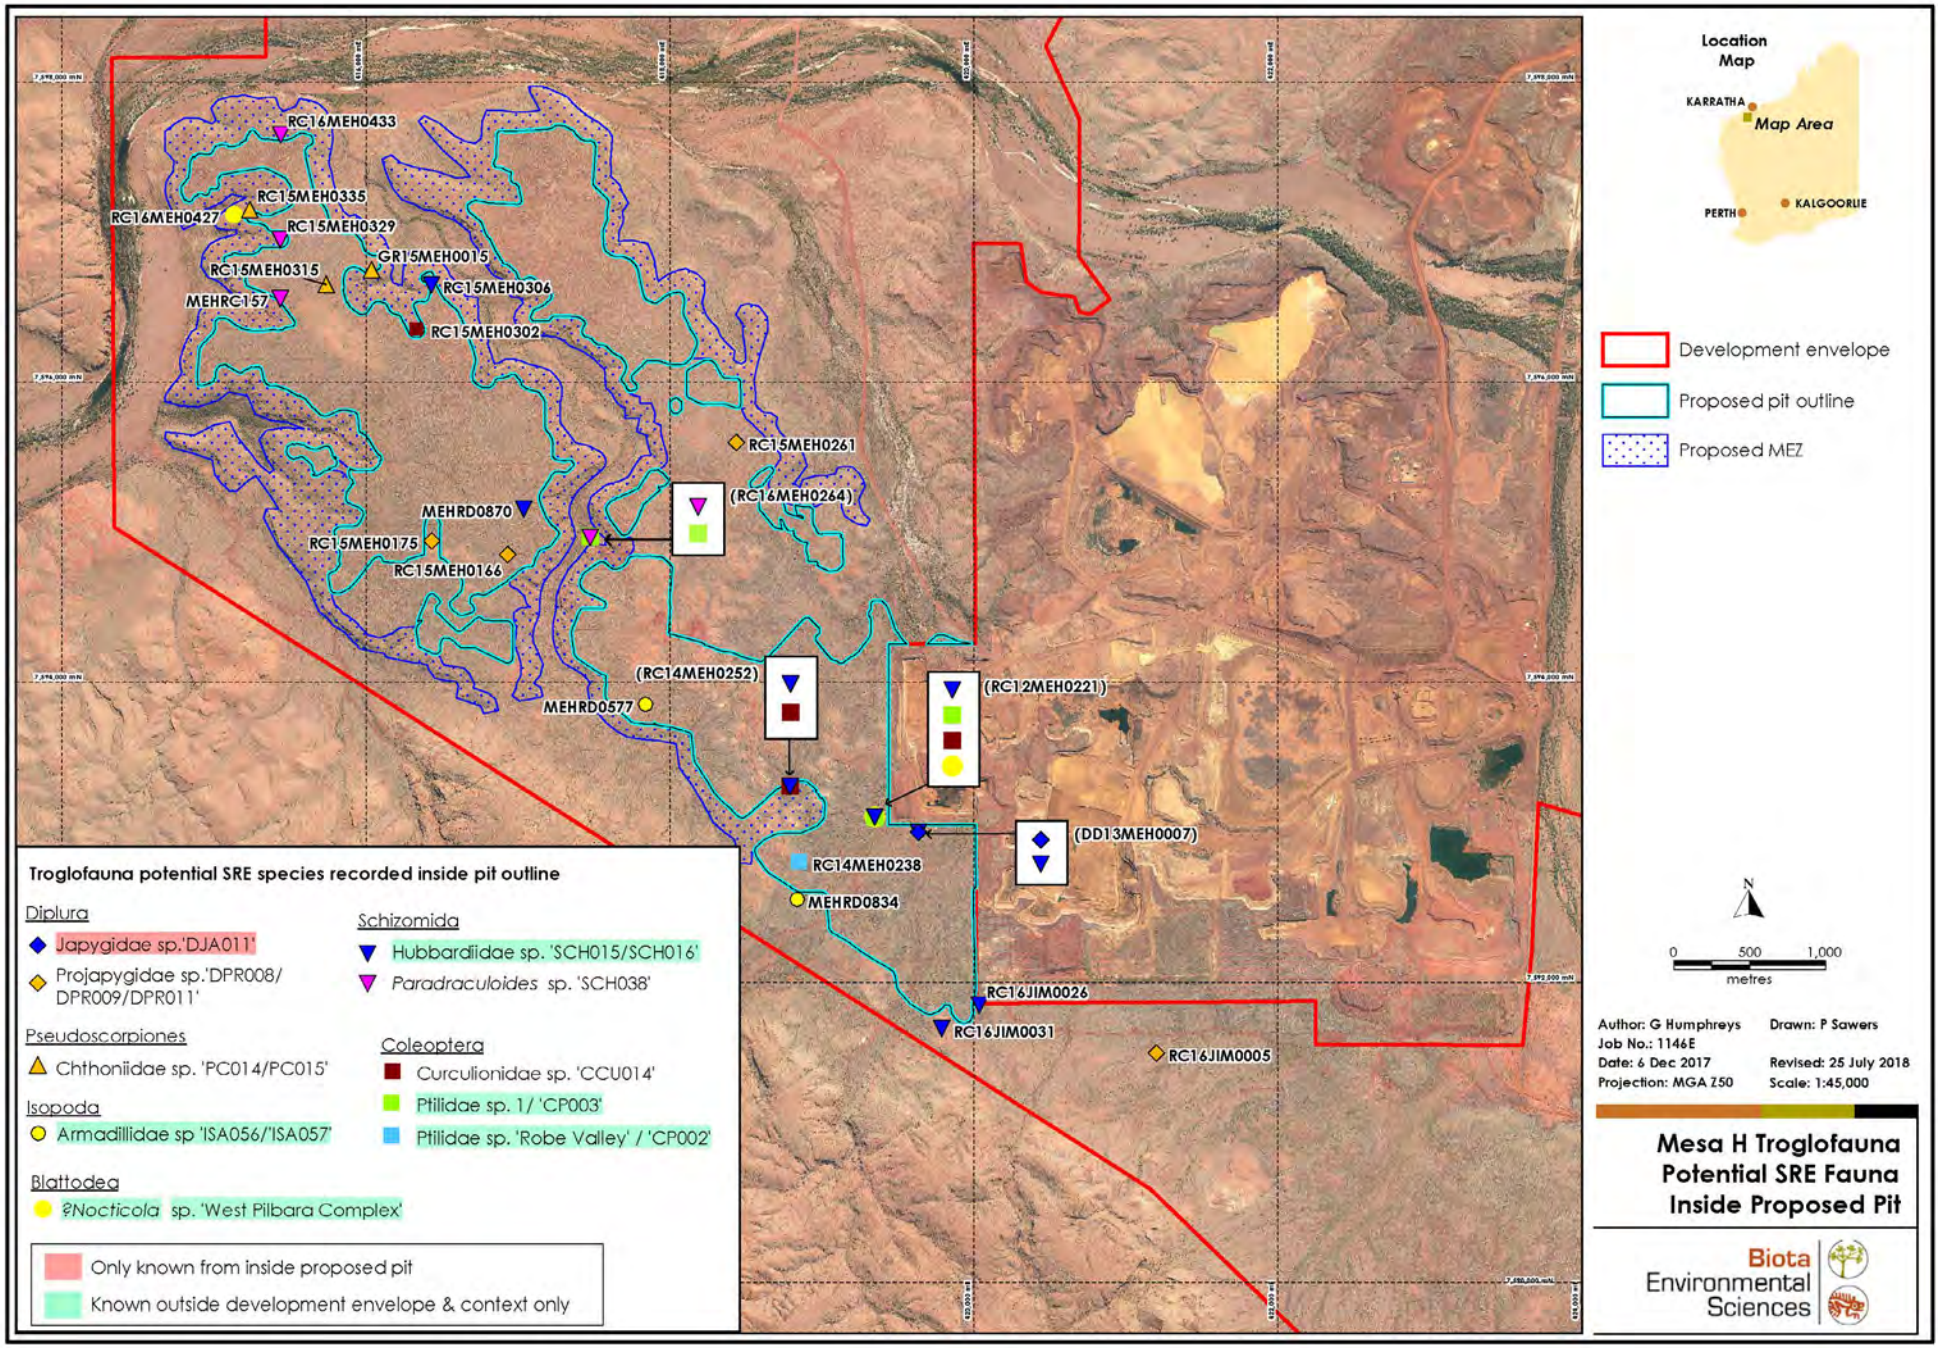

Figure 7.8: Distribution of troglofauna key receptor species relative to the extent of direct impacts arising from the Mesa H project.

7.2.2 Direct Impacts on Troglofauna Community and Habitat Key Receptors

The extents of the two troglofauna PECs relevant to this impact assessment are shown in Figure 7.9, which are the assumed original extent of these PECs, prior to any past disturbance, as mapped by the now DBCA.

As discussed in Section 5.2.2.1, the two PECs appear to have only been distinguished on the basis of perceived landform differences ('mesas' versus 'hills'; Table 7.3), but in reality both actually represent troglobitic communities of elevated CID landform habitats along the Robe River palaeodrainage. This somewhat arbitrary naming has caused spatial overlaps between the buffers of the two PECs; including small areas within the western and eastern parts of the development envelope (Figure 7.9). Given these overlaps, and that DBCA still recognise the PECs as separate entities, the potential impacts of the proposal on each of the PECs have been considered separately.

With the history of resource development in the Robe valley, and consistent with the guidance of EPA (2016a), it is appropriate to place potential impacts on the PECs into a cumulative impact context. Table 7.3 and Figure 7.9 summarise the extent of proportionate habitat loss that has already occurred due to previously approved (in grey on Figure 7.9) and reasonably foreseeable projects (outlined blue on Figure 7.9), and quantify the additional direct loss of PEC extent that will arise as a result of the Mesa H proposal.

Table 7.3: Cumulative direct impacts from the Mesa H mine pits on troglofauna PECs, in context with other habitat removal (ignoring overlaps in mapped PEC extents within the development envelope).

PEC	Original Assumed Extent of PEC	Current Extent after Other Habitat Loss *	Extent after Habitat Loss from this Proposal	Incremental Impact
Subterranean invertebrate communities of mesas in the Robe Valley region	13,753.9 ha (100%)	11,773.4 ha (85.60%)	11,764.2 ha (85.53%)	9.20 ha (0.07%)
Subterranean invertebrate community of pisolitic hills in the Pilbara	9,889.7 ha (100%)	7,952.3 ha (80.41%)	7,164.2 ha (72.44%)	788.1 ha (7.97%)

*Including both impacts that have already occurred or are reasonably foreseeable from other proposed developments.

The incremental impact of the proposal on the 'Subterranean invertebrate communities of mesas in the Robe Valley region' PEC is very minor at 0.07% of its original extent (Table 7.3). This is especially the case when the mapping of this PEC that falls within the development envelope is almost certainly only a buffer area on the true extent of the PEC itself (Figure 7.9).

The incremental loss of habitat from the 'Subterranean invertebrate community of pisolitic hills in the Pilbara' PEC is greater at 7.97% of its original extent (Table 7.3). This is largely a function of this second PEC being restricted to just Mesa H and the Warramboo locality (Figure 7.9), as both were considered by DBCA to represent 'hills' rather than mesas. Even with this, over 72% of the original assumed extent of this PEC, at 7,164.2 ha, would still remain with the implementation of the Mesa H proposal (Table 7.3). Combining both PECs, given that they both represent effectively the same types of troglobitic communities within elevated CID landform habitats along the Robe River palaeodrainage, provides a total incremental impact of 3.4 % of the combined PECs.

Within the spatial extent of Mesa H itself, a key assessment question relates to the viability of troglofauna populations in the habitat that will remain once mining is complete; particularly in respect to the in-pit troglofauna species remaining at Mesa H. This is likely to be a function of the extent, configuration and intactness of the portions of the Mesa H landforms left undisturbed by proposed mining activities; both within the proposed MEZ and in other remnant habitat within and adjoining the development envelope.

Figure 7.10 shows the mapped extent of troglofauna habitat at Mesa H, and the area that would be directly impacted by the mine pits. The total area of troglofauna habitat within the development envelope is 2,497.3 ha, and 751.5 ha of this falls within the mine pit boundaries, leaving approximately 70% of the spatial habitat unmined (1,745.8 ha) (Figure 7.10). The MEZ, which Rio Tinto has committed to not mine and thereby has greater certainty of retention, accounts for approximately a quarter of this habitat area at 443.3 ha. Overall, the unmined habitat would include records of 33 of the 34 troglofauna species known from the development envelope in a relatively well connected and contiguous extent of AWT troglofauna habitat (Figure 7.10).

From a three-dimensional habitat volume perspective, Rio Tinto mine planning and modelling has also calculated the remaining volume of the CID strands representing habitat for troglofauna on completion of the project: this will exceed 50% of the current pre-mining habitat volume, similar to past Robe Valley projects which have been approved to proceed (e.g. EPA 2007).

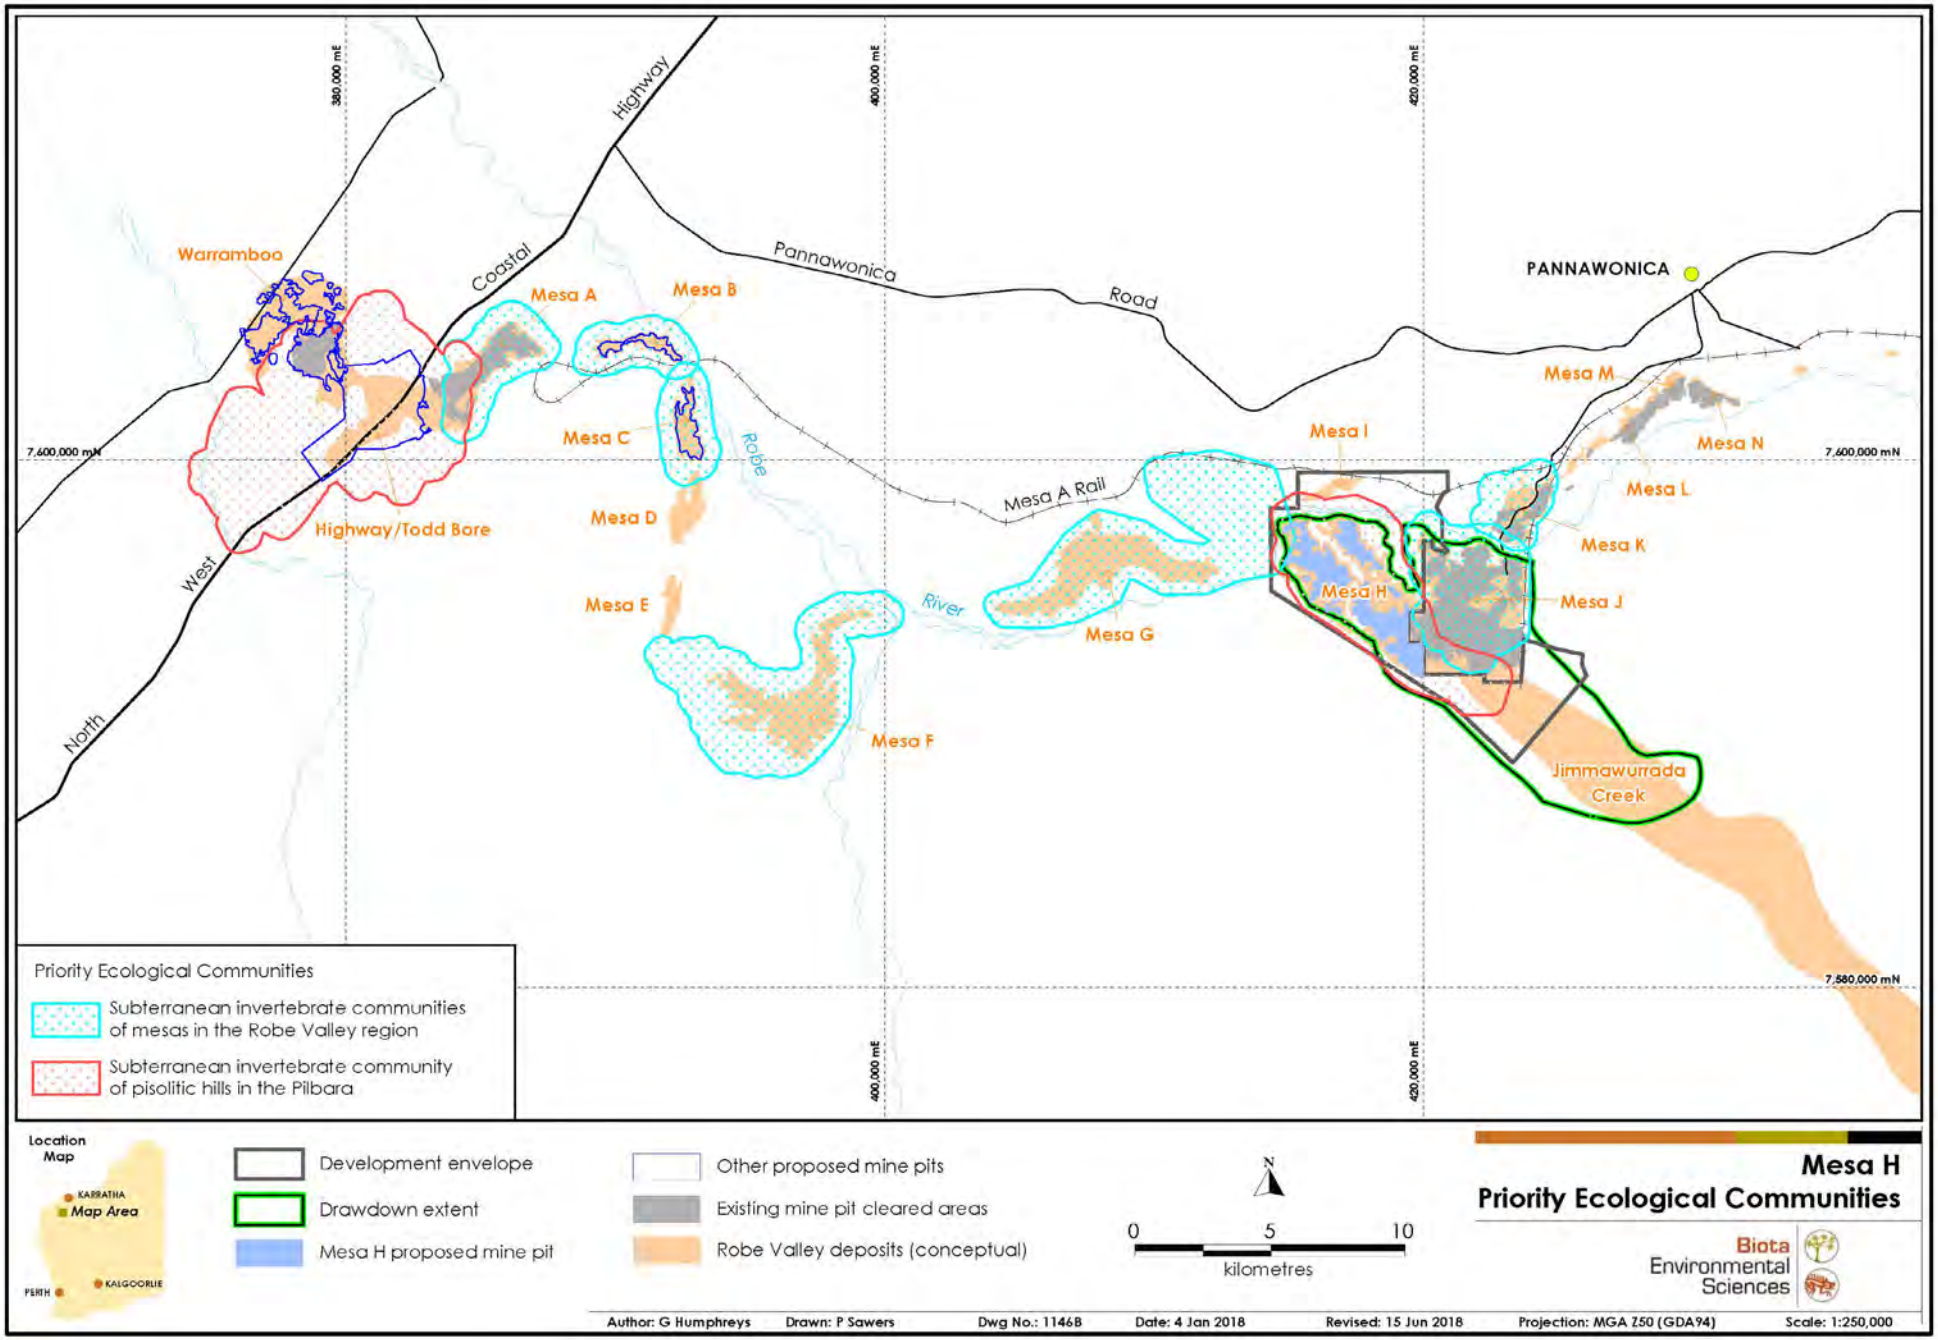

Figure 7.9: Mapped extent of troglofauna communities key receptors relative to the extent of direct impacts arising from the Mesa H project.

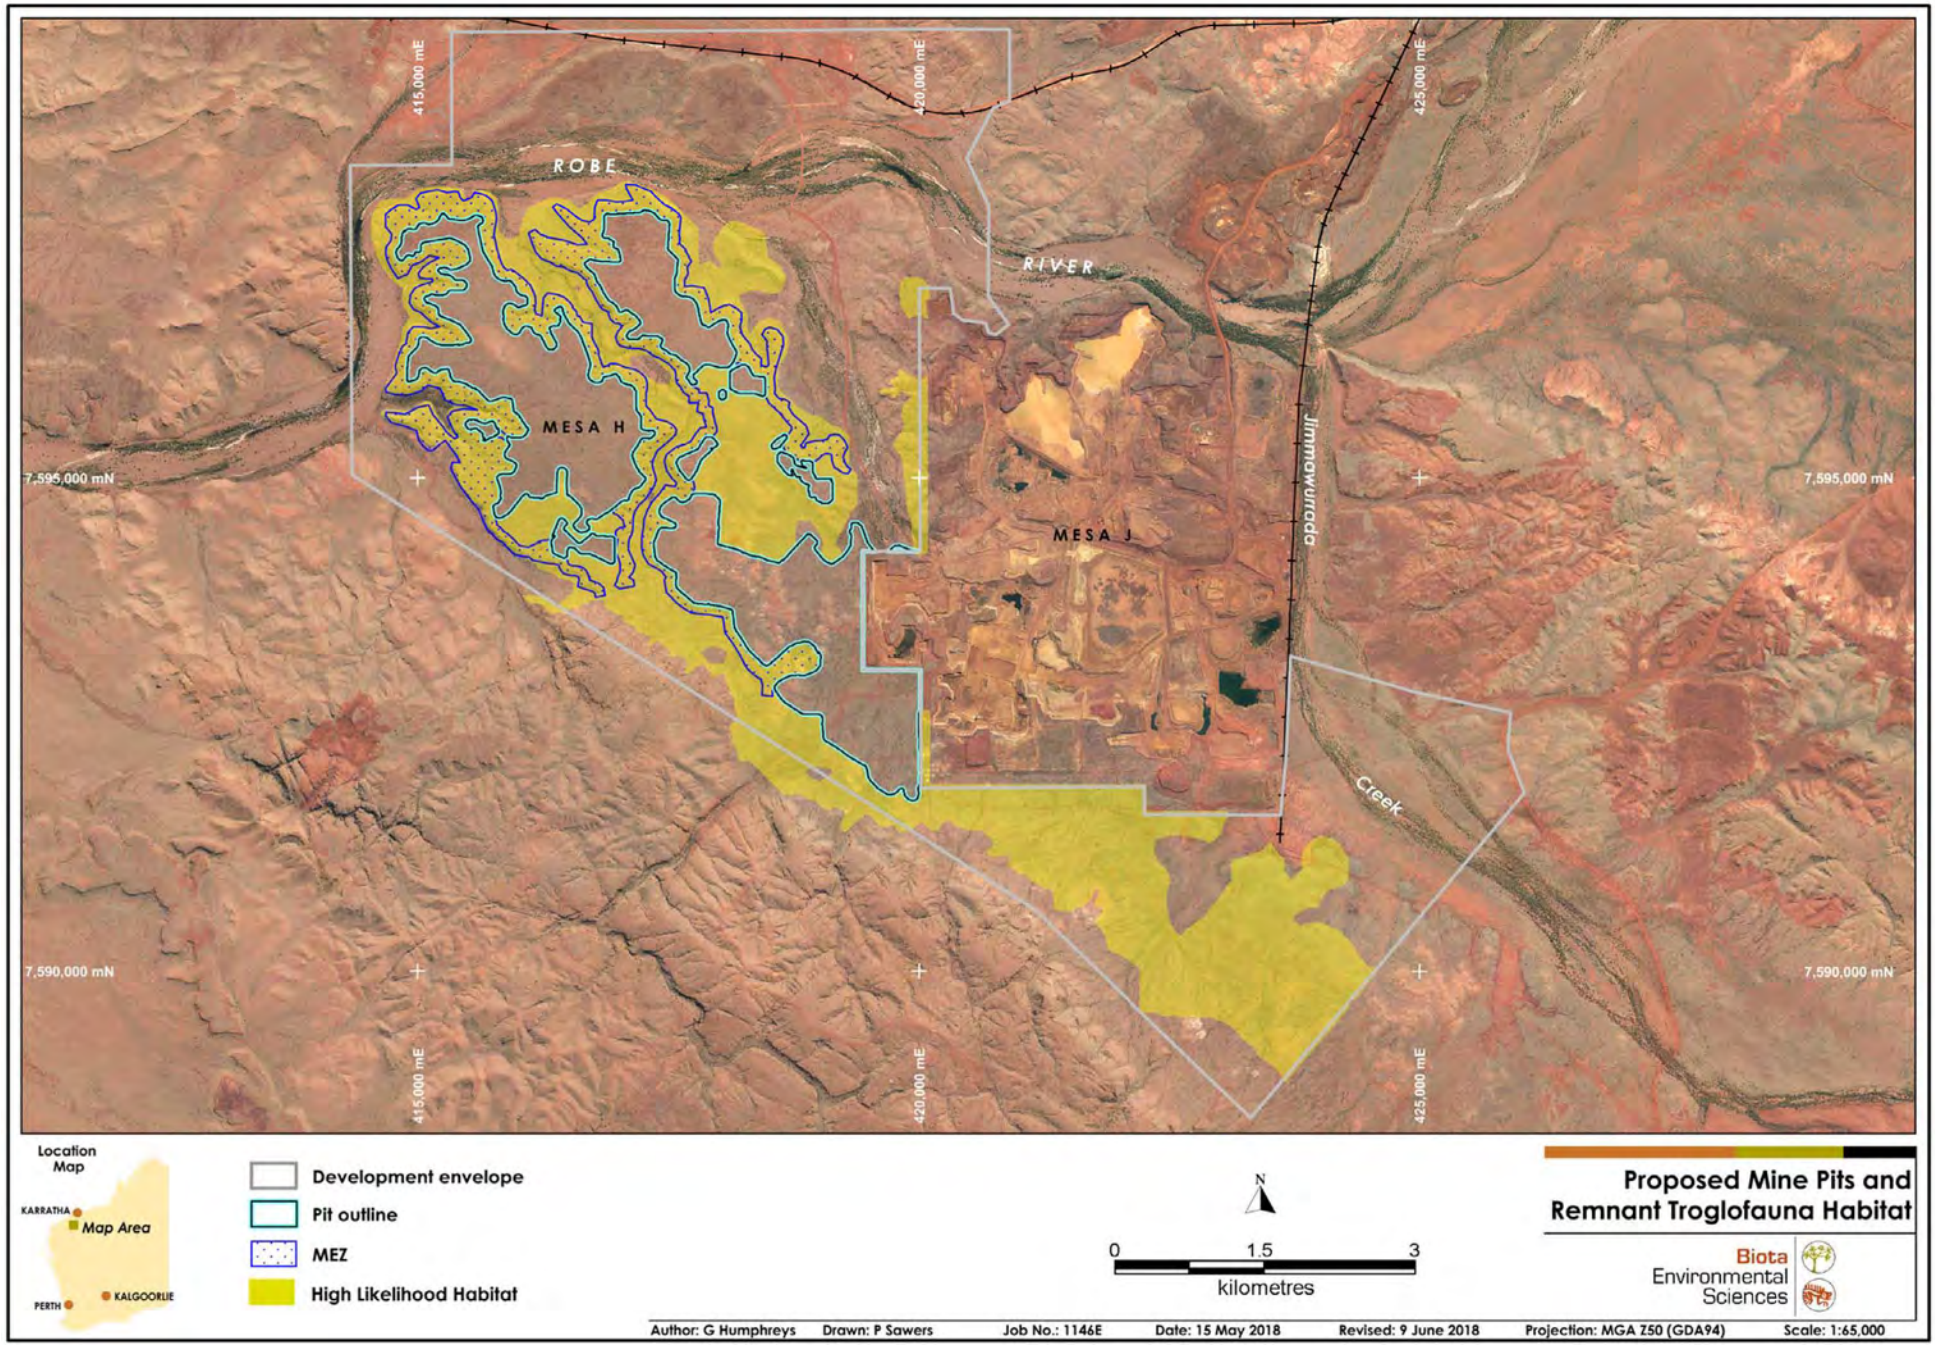

Figure 7.10: Extent of proposed mine pits and troglofauna habitat that will remain intact within the development envelope.

7.2.3 Indirect Impacts

In addition to the primary impact of habitat removal for mining pits, other indirect impacts could also affect troglofauna habitat retained within the development envelope outside of the pit outlines (as identified in Section 4.2.2). The ongoing suitability of habitat to support troglofauna in these ex-pit areas is linked to the maintenance of the existing biophysical conditions and processes that contribute to the stable and humid conditions that characterise troglofauna habitat. Indirect impact pathways have the potential to degrade habitat quality by reducing, or locally altering, these conditions and processes (Section 4.2.2).

The only indirect potential impact that will remain in operation for the long term will be the effect of the waste dumps arising from the proposal (Section 3.0; Figure 3.1). The waste dumps have the potential to reduce hydrological and nutrient inputs to underlying troglofauna habitat, which could in turn reduce habitat quality or animal abundance (Section 4.2.2; Figure 4.1). This impact mechanism has not, however, been empirically demonstrated to occur, and some limited data suggest that troglofauna persist beneath waste dumps in at least the medium term (with schizomid records from beneath waste dumps at nearby Mesa K, decades after their creation; Biota (2007)). Despite this, and in the interests of a precautionary assessment, a GIS spatial analysis was conducted for this assessment, intersecting the proposed waste dump footprints shown on Figure 4.1 with the records of all troglofauna species known from the development envelope. This analysis showed that not only are none of the 33 species known from Mesa H restricted in distribution to the waste dump footprints, but there are in fact no records of any troglofauna from either the Biota (2019) survey or desktop sources. This result, combined with the earlier observations that this impact process has not been clearly proven, suggest that the indirect impact of the waste dumps would not be significant (a Negligible impact with at least a Medium level of certainty, following the framework set out in Section 2.6.2).

Compared to direct impacts, the spatial extent, duration and magnitude of the impact footprints that could arise from the other indirect impact pathways are all relatively limited (Section 3.0). The majority of the indirect impact pathways can also be further mitigated through project design, environmental management controls and monitoring during project implementation. The primary focus for the assessment of the impacts then remains the direct impacts of the proposal on troglofauna.

This page intentionally blank.

8.0 Conclusions

This impact assessment followed a series of defined criteria to identify species and ecological community key receptors of potential impacts from the Mesa H project. The impact sources and pathways arising from the proposal have been imposed on the known distributions of the species and community key receptors to identify potentially significant impacts. Sections 8.2 and 8.1 synthesise these outcomes with the models of subterranean fauna habitat presented earlier in Section 6.0, to arrive at an assessment of the risk of significant impacts on troglofauna and stygofauna respectively.

To recap Section 2.6.2, the framework used for reaching an assessment on the significance of the potential impacts was based on consequences and magnitudes of the impact for the receptors, and level of certainty:

Consequences of Impact	Criteria
Negligible	Displacement or loss of individual animals
Minor	Reduction in less than 10% of the known or inferred distribution and habitat extent
Moderate	Reduction in 10-50%[2] of the known or inferred distribution and habitat extent
Major	Loss of more than 50%[2] of the known or inferred distribution and habitat extent and/or change in conservation status of the species

Level of Certainty	Criteria
High	The outcome is quantifiable and can be predicted with confidence from a reasoned evidence base or the impact has previously occurred during similar mining developments
Medium	A reasonable body of data exists to predict the outcome and the outcome could reasonably be expected to arise from the current proposal
Low	The outcome has not previously occurred during similar mining developments, but expert opinion or other data suggest it might arise, or there is insufficient information to quantify the impact

A significant impact (after EPA (2016a)) is considered for the purposes of this review to be a Moderate or Major impact on a key receptor that is predicted to arise with High or Medium certainty (following the criteria in Section 2.6.2).

The concluding assessment is summarised for species and ecological community receptors for stygofauna and troglofauna in Sections 8.1 and 8.2, respectively.

8.1 Stygofauna

8.1.1 Species Receptors

A total of 32 species of stygofauna occur within the modelled dewatering extent for the proposal, which sets the spatial limit of predicted direct impacts.

Sixteen of these species are widely distributed in the region and not of listed conservation significance and the impact of the dewatering would not be significant at taxon level; assessed as Minor with a High degree of certainty (the extent and duration of the impact has been quantitatively predicted, approached conservatively and a sound data set exists to demonstrate the species' wider occurrence).

[2] Derived from the International Union for the Conservation of Nature (IUCN) Red List criterion whereby a species' conservation state would shift from the Least Concern category to Vulnerable (IUCN 2012).

Thirteen of the remaining 16 species are potential SREs that occur within the dewatering extent, with the other three being species of conservation significance that are addressed separately in Section 8.1.2 below.

Seven of the 13 potential SRE species occurring within the drawdown extent (*Areacandona* sp. 'BOS1039', *Pilbaracandona* sp. 'BOS526', *Megastygonitocrella unispinosa, Nedsia* sp. 'AMM026', Paramelitidae sp. 'AMP035', *Wesniphargus* sp. 'AMN004' and Neoniphargidae sp. 'B02') were recorded outside of the drawdown extent, or have demonstrated wider distributions in the locality, and would not be placed at significant risk to a change in their conservation status. Based on this, and the considerable extent of stygofauna habitat in the locality (Figure 6.2), the impact of the dewatering on these seven taxa would not be considered significant at species level (a Minor impact with a High degree of certainty).

Four of the remaining six potential SREs within the drawdown extent (Candoninae sp. 'BOS541', *Haptolana* sp. 'B01', Hydrobiidae sp. 2 and *Parastenocaris* sp. 'B28') were all recorded from the alluvial habitats of Jimmawurrada Creek at sites JW023 and JW024. With the wider distributions of other potential SRE stygofauna species in the survey area, it is unlikely that these species are truly restricted to the vicinity of these two sites, but even if this was the case, refugial habitat will be retained there at the peak of modelled dewatering. The predicted drawdown at these sites is moderate at a less than 7 m below the pre-mining water table level, leaving a saturated alluvial sequence varying between 5 and 17 m in thickness connected along the length of the creek at the peak of the proposal impact (Section 7.1.1). These refugia would also be additionally hydraulically connected and supplemented during flooding and seasonal recharge events along Jimmawurrada Creek. Based on this, and recognising that the species are likely to be more widely distributed, the impact of the dewatering on these four taxa would not be considered significant at species level (a Minor impact with a High degree of certainty).

The final two potential SRE species, Paramelitidae sp. 'AMP003' and Paramelitidae sp. 'AMP037', are currently known only from the drawdown extent from several areas that would be more significantly dewatered (drawdowns of 20 m and 4 m on the pre-mining water table respectively, and direct removal of habitat for Paramelitidae sp. 'AMP003'; Section 7.1.1). Both biological and physical evidence suggests connectivity of aquifer habitats and stygofauna populations to at least the local catchment scale, and that the apparent very small distributions of these two species is due to ecological sampling effects (Section 7.1.1). Assuming this is the case, these species would also not be significantly impacted (Minor impact with a High degree of certainty).

However, as this is a risk-based approach, the distribution of these singleton species cannot be assessed with confidence with the available data, and a more precautionary approach may be to assess the impact on the assumption that they are locally restricted and a greater proportion of their known distribution would be impacted by the dewatering, meaning the predicted impact would be significant (a Moderate or Major impact with a High degree of certainty).

8.1.2 Species of Conservation Significance

Three stygofauna species occurring within the drawdown extent are of formally listed conservation significance, but two (the Schedule 3 amphipods *Nedsia hurlberti* and *N. sculptilis*) also occur far more widely in the region. The dewatering extent would represent less than 10% of the known distributional extent for both species, and would thereby represent a Minor impact, in addition to the likelihood that refugia habitat will be retained locally within the alluvial aquifer of Jimmawurrada Creek (Section 7.1.2). Given the level of hydrogeological investigation completed to understand the predicted impacts and habitat change, and the distributional data for both species, the assessment of a Minor level of impact would be regarded as having a High degree of certainty, which would not be significant for most stygofauna species. However, given the Schedule listing of the two *Nedsia* taxa, it is possible that the impact may be elevated on that basis to be deemed significant.

The impact assessment context and predictions for the third conservation significant species, the Blind Cave Eel *Ophisternon candidum*, is broadly similar to that for *Nedsia hurlberti* and *N. sculptilis*: *O. candidum* was recorded from the same site as the two amphipod species (JW021) and appears to have a similar distribution, with additional records following the alluvial aquifer of the Jimawurrada-Bungaroo Creek system and into the Robe River aquifer (Section 7.1.2). It appears possible that all three species may occur further downstream on the Robe River. Sequencing data from multiple genes have also shown that the *O. candidum* specimen from drawdown extent site BC186 had a very low level of divergence from specimens at Cape Range; at the level typically seen within the same species (Foster and Humphreys 2011, Moore et al. 2018).

Quantitative predictions from hydrogeological modelling indicate that a substantial thickness of alluvial habitat between 5 and 17 m thick will remain saturated along Jimmawurrada Creek (Section 7.1.2). The species also occurs locally along the habitats of the Robe River – which will not be affected by the drawdown greater than natural water table fluctuations – and this distribution may extend downstream in the same system (with a population of apparently the same species also occurring at Cape Range). The consequences of the dewatering on that basis could therefore be assessed as a Minor impact (less than 10% of the known distribution) with Medium certainty. However, there are several factors that indicate the certainty with which impacts on *O. candidum* can be predicted differs from that for *Nedsia hurlberti* and *N. sculptilis*. These include, that:

- the species has a higher conservation status than the two amphipod species (listed at Commonwealth as well as State level); and
- the much larger body size of the species compared to the amphipods, which could affect the ability of individuals to move horizontally or vertically through cavities and interstices within saturated habitat.

These considerations suggest that additional caution is warranted regarding the confidence with which impacts can be predicted for *O. candidum*. A more precautionary position might be to assume that the same species only occurs within the local habitat extent within the Robe River valley (as shown in Figure 7.5) and that the quality and availability of this habitat would be reduced. Hydrogeological modelling suggests this scenario is unlikely, but this conservatism provides some balance to the uncertainties in predictions listed above. Within this framework then, the impact on *O. candidum* would be significant, amounting to a Moderate impact with High certainty.

8.1.3 Ecological Community Receptors

The impacts on both the Stygofaunal Community of the Bungaroo Aquifer PEC would not be considered significant within the framework used here (Minor (<10%); with a maximum impact on the PEC of 3.1% by area, with much of the drawdown being relatively minor compared to the scale of the aquifer).

8.2 Troglofauna

8.2.1 Species Receptors

A total of 33 troglofauna species are known from the development envelope. Six of these have been recorded from outside of the development envelope and have demonstrated wider distributions in at least the Robe River valley (Hubbardiidae sp. ‘SCH011’, Hubbardiidae sp. ‘SCH015/SCH016’, Armadillidae sp. ‘ISA056/ISA057’, ?*Nocticola* sp. 'West Pilbara Complex', Ptilidae sp. 1/'CP003' and Ptilidae sp. 'Robe Valley'/’CP002’; Section 5.2.2.2). At 751.5 ha in extent, the direct impact of the mine pits on these six taxa would not be significant at the species level (<10% of known distribution with a High degree of certainty).

The remaining 27 key receptor species have currently only been recorded from within the development envelope and their distributions cannot be assumed to extend beyond the habitat mapped at Mesa H. The consequence of the direct impact of the mine pits on these species can

be assessed on the basis of their record locations within Mesa H and the proportional habitat loss predicted for the proposal. Based on current data there are no records of 22 of the 27 species recorded at Mesa H from within the mine pit areas. Taken at face value, this would indicate a Negligible impact but it is also likely that the species actually occur more widely within the landform; including within the mine pit boundaries. Thus at present, those 22 species would not be significantly impacted by the proposal, but a more precautionary assessment may treat them as equivalent to the remaining seven species known to occur within the mine pits. Six of these latter species confirmed within the pits also have records within the MEZ or other habitat that will remain intact post-mining. While the direct impact of habitat removal for the mine pits on these species would still be considered significant (Moderate at 10-50% of their known distributions with a High degree of certainty), 1,745.8 ha of mapped troglofauna habitat, and more than 50% of the pre-mining volume, remaining unmined on completion of the project, which would include known records of 32 of the 33 troglofauna species known from Mesa H.

Only one of the 33 development envelope species has thus far been recorded solely from within proposed pits: the dipluran Japygidae sp. 'DJA011' (Section 5.2.2.2). It is possible that this species only occurs within these direct impact areas, which would represent a Major impact on this species (loss of more than 50% of the known or inferred distributional extent) and thereby a significant impact following EPA (2016a).

However, available biological and physical connectivity evidence indicates that it is far more likely that the species is distributed to at least the scale of the troglofauna habitat mapped for Mesa H and the impacts on it at taxon level is likely to be equivalent to the other key receptor species known only from the development envelope (remaining as a significant impact, but at the Moderate consequence level rather than Major).

8.2.2 Ecological Community Receptors

The cumulative and incremental impact of the proposal on the 'Subterranean invertebrate communities of mesas in the Robe Valley region' PEC is very minor at 0.07% of its original extent and would not be significant under the framework used in this assessment.

The cumulative and incremental loss of habitat from the 'Subterranean invertebrate community of pisolitic hills in the Pilbara' PEC is greater at 7.96% of its original extent, but this would still not be assessed as a significant impact following the framework here (>10% of known distribution with a High degree of certainty).

8.3 Summary of Significant Impacts

8.3.1 Stygofauna

While all stygofauna species and ecological community receptors occurring within the drawdown extent will be impacted to some degree, impacts on five of the 16 stygofauna species present have been identified here as being potentially significant. As discussed in Section 8.1.1 and 8.1.2, impacts on four of these five species would only be considered significant if a precautionary position is adopted to the assessment, which is the context within which these final conclusions are presented. The species in question comprise:

1. Paramelitidae sp. 'AMP003' and Paramelitidae sp. 'AMP037' (Moderate or Major impact with High certainty);
2. the Schedule 3 amphipods *Nedsia hurlberti* and *N. sculptilis* (a Minor impact with High certainty, but still considered significant given the species Schedule listing); and
3. Schedule 3 Blind Cave Eel *Ophisternon candidum* (Moderate impact with High certainty).

8.3.2 Troglofauna

There are 27 species of troglofauna currently known only from the development envelope and 22 of these do not have any records from within the mine pit areas, which, taken on the basis of existing data, would indicate they would not be significantly impacted (Section 8.2.1).

However, again in the interests of providing a precautionary assessment, all 27 could be considered likely to occur more widely within Mesa H, as the 22 species possibly also occur within habitat inside the mine pit boundaries. The troglofauna species and ecological community receptors that would be significantly impacted within this precautionary context then comprise:

1. 26 potential SRE troglofauna species known only from within the development envelope but with confirmed records outside of the mine pits (Moderate impact with High certainty); and
2. a single potential SRE troglofauna species known only from within the mine pits: the dipluran Japygidae sp. 'DJA011' (Major impact with High certainty).

8.3.3 Conclusions

While Section 8.3.1 and Section 8.3.2 above present precautionary assessments (consistent with EPA (2018)), a more realistic assessment is provided here in closing. These conclusions adopt a balanced appraisal based on the combined survey and desktop data sets, and the body of biological and physical evidence collated in this assessment for both ecological groups.

That more realistic context would suggest that for:

- Stygofauna: Impacts 1, 2 and 5 above should be revisited, with impacts on four of the stygal species; Paramelitidae sp. 'AMP003', Paramelitidae sp. 'AMP037', *Nedsia hurlberti* and *N. sculptilis* (points 1 and 2 of Section 8.3.1) no longer assessed as significant (Minor impacts with High certainty); and
- Troglofauna: the impact on the troglofauna species known only from within the mine pits; Japygidae sp. 'DJA011' (point 5 of Section 8.3.2) should still be considered significant, but should be consolidated with the other 26 troglofauna taxa considered under point 4 of Section 8.3.2 as a Moderate impact with High certainty.

In closing then, the significant impacts on subterranean fauna from the Mesa H proposal comprise:

- the impact of groundwater drawdown arising from the dewatering on the Schedule 3 Blind Cave Eel *Ophisternon candidum* (a Moderate impact with High certainty); and
- the impact of habitat removal for mine pits on 27 potential SRE troglofauna species known only from within the development envelope but with confirmed records outside of the mine pits (Moderate impact with High certainty).

While these impacts would be considered significant (after EPA (2016a)), neither of the impacts would be assessed as Major under the framework used here (Loss of more than 50% of the known or inferred distribution and habitat extent and/or change in conservation status of the species), and both *Ophisternon candidum* and the 27 species of troglofauna will remain represented in subterranean fauna habitat outside of the proposal's impact footprint after the closure of the Mesa H operations.

9.0 Glossary

Congener	Belonging to the same genus.
Development envelope	The predicted maximum ground disturbance area for the proposed development.
EIA	Environmental Impact Assessment.
EPA	Environmental Protection Authority of Western Australia.
GIS	Geographical Information System.
Ground disturbance	Any construction or operational ground disturbing activity that results in the removal of native vegetation, landforms and/or the disturbance of topsoil.
Indicative arrangement	The current conceptual design for proposed pit locations and boundaries, overburden storage areas and infrastructure.
Interstices	An opening or space, especially a small or narrow one between mineral grains in a rock or within sediments or soil.
Receptor	A subterranean fauna species, ecological community or habitat occurring or likely to occur within the development envelope that may be impacted by the proposal.
Locality	The area encompassed within a 40 km buffer on the development envelope.
Short-Range Endemic (SRE)	A species that has a naturally small distribution and is often characterised by having poor dispersal capabilities, confinement to disjunct habitats and low fecundity.
Stygobite / Stygofauna	Obligate groundwater fauna.
Taxon	A group of organisms identified as comprising a taxonomic unit (e.g. a species) (“taxa” = plural).
Taxonomy	Theory and practice of biological classification.
Troglobite / Troglofauna	Species living obligatory in caves; also blind, depigmented and often having an elongate body morphology.
Troglomorphic	Pertaining to morphological, behavioural and physiological characters that are convergent in subterranean populations (Christiansen 1962).
Troglophilic / Troglophile	Species able to live and reproduce underground as well as in the surface environment (Wilkens et al. 2000).
Vug	A small cavity in a rock or vein, often with a mineral lining of different composition from that of the surrounding rock.

This page intentionally blank.

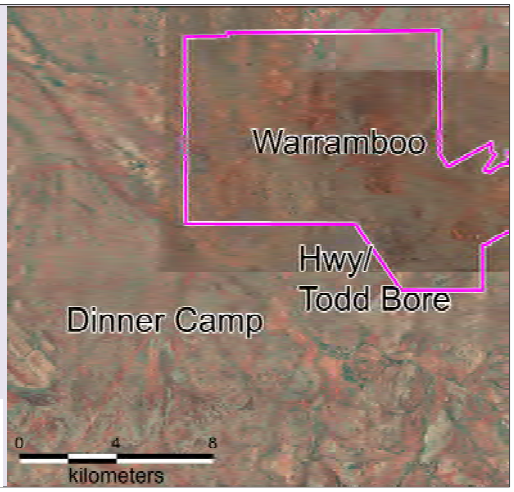
Appendix 1

Conceptual Flowchart of Troglofauna Habitat CID Modelling

Conceptual Methodology for Subterranean Fauna Habitat Modelling

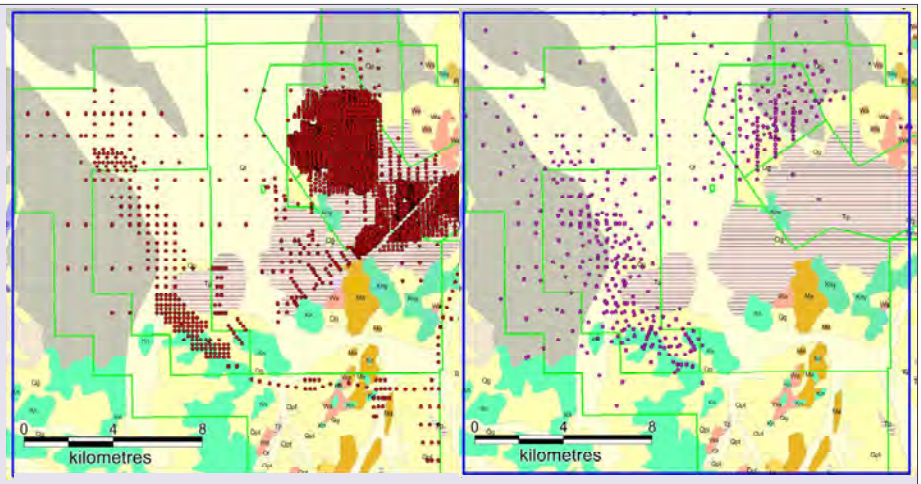
Warramboo/Highway/Tod Bore, Q1 2018

1. Define the location



2. Collate available data sources

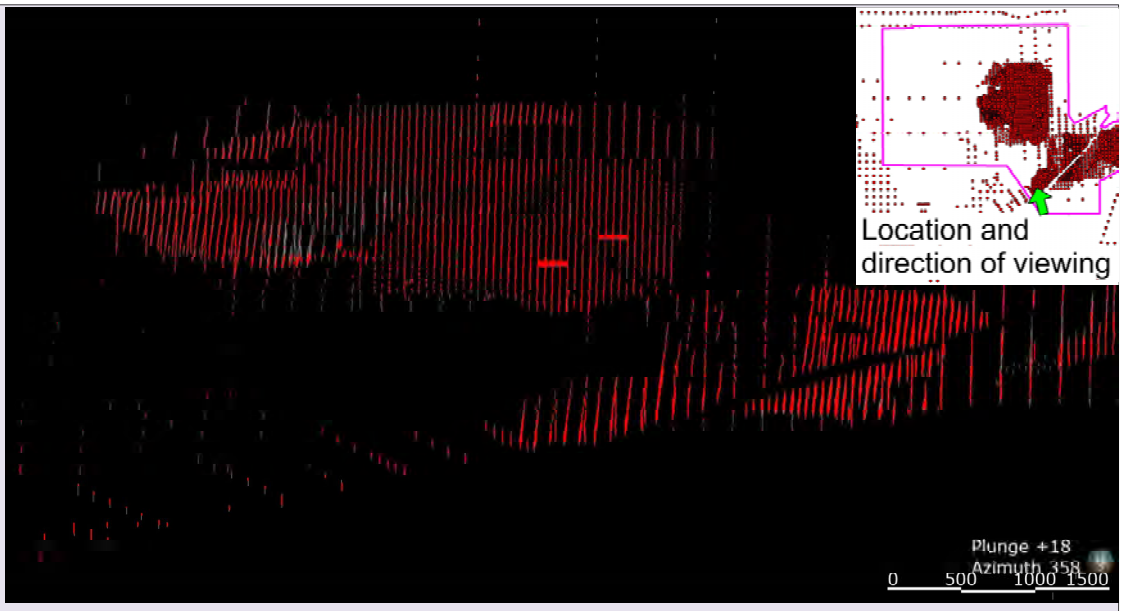
- geological mapping
- geophysical mapping
- downhole drilling information
- geotechnical information
- core data (if available), including photos



Red dots = geological drill logs available Historical publicly available data (DMIRS)

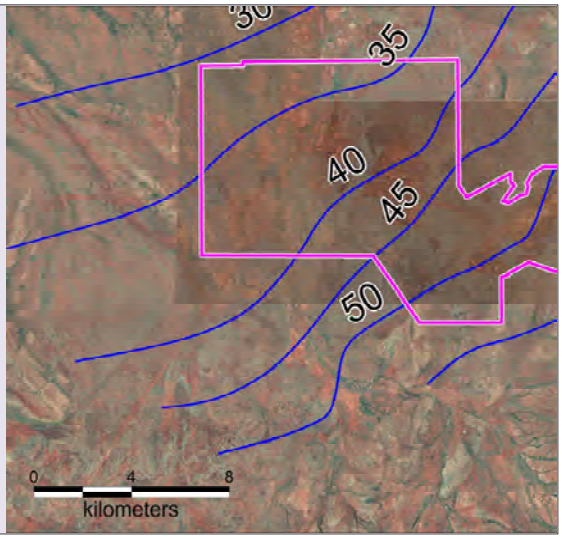
3. Calculate habitat thickness at each data point (drillhole)

In this case habitat was channel iron deposits (CID)



Cross section shows a 3D tilted image of CID thickness in each hole (red bars)

4. Establish water table levels using groundwater contour data

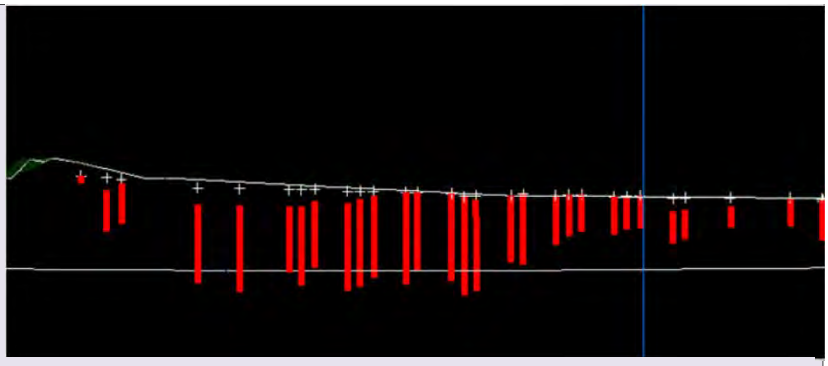


Mesa A Hub proposed Part IV boundary

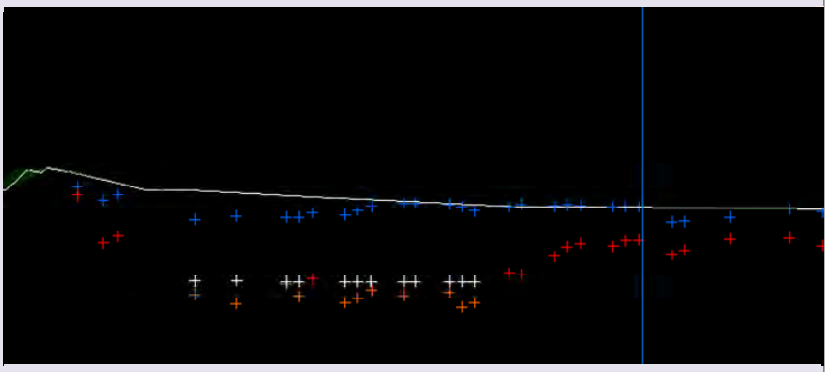
pre-mining water contours

5. Calculate thickness of above water table CID

Troglofauna don't reside below the water table



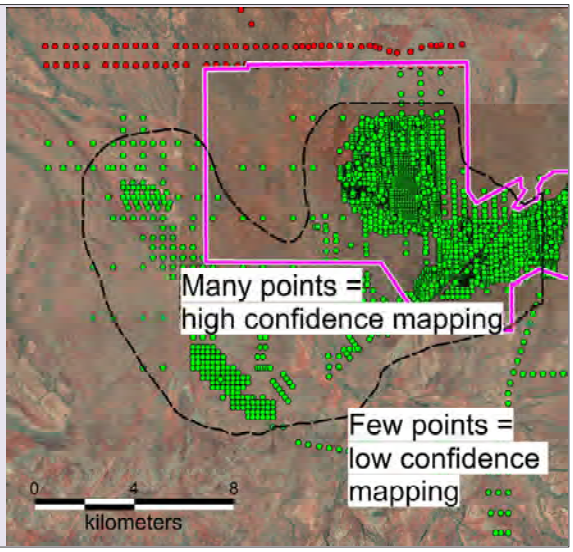
Cross section showing CID depth (red bars) in relation to the water table (lower white line)



Resulting above water table CID depth once below water table is removed. Top of CID interval (blue), bottom of CID interval (red) and water table (white).

6. Determine high and low confidence areas

Based on drill hole density



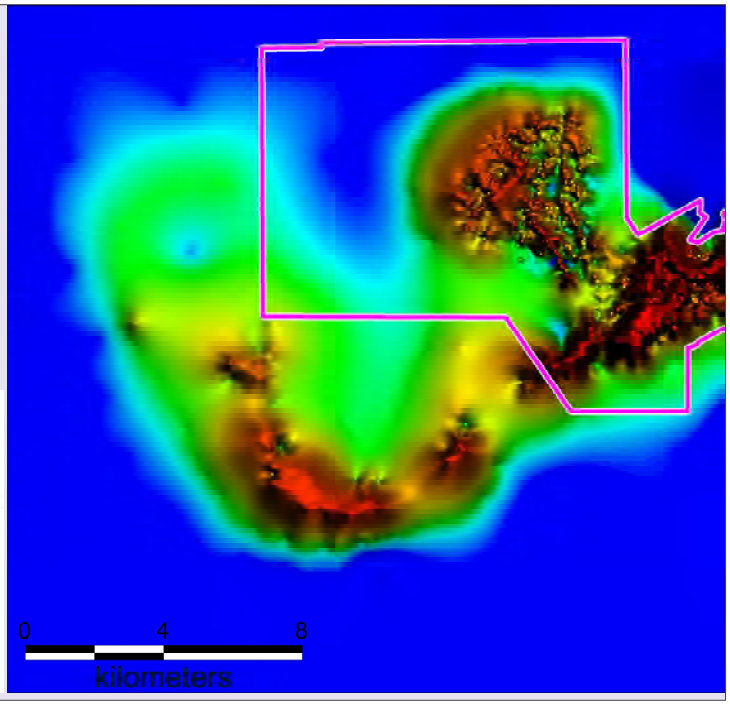
high confidence interval

Mesa A Hub proposed Part IV boundary

Drill holes

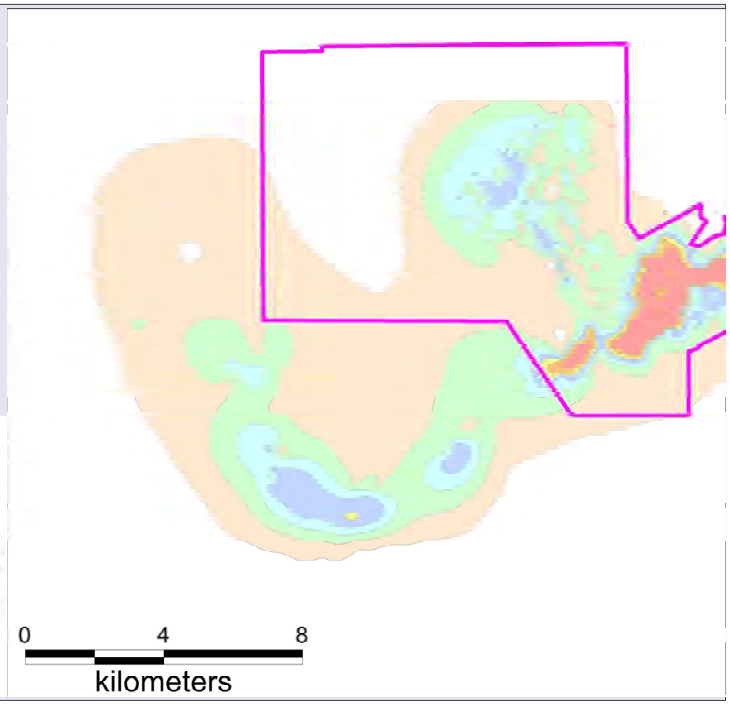
7. Create 3D surface/ raster map of above water table CID thickness

Use spatial interpolation of point data combined with confidence information



8. Produce CID contour map

Use pre-defined categories to split the 3D surface/ raster image into sections

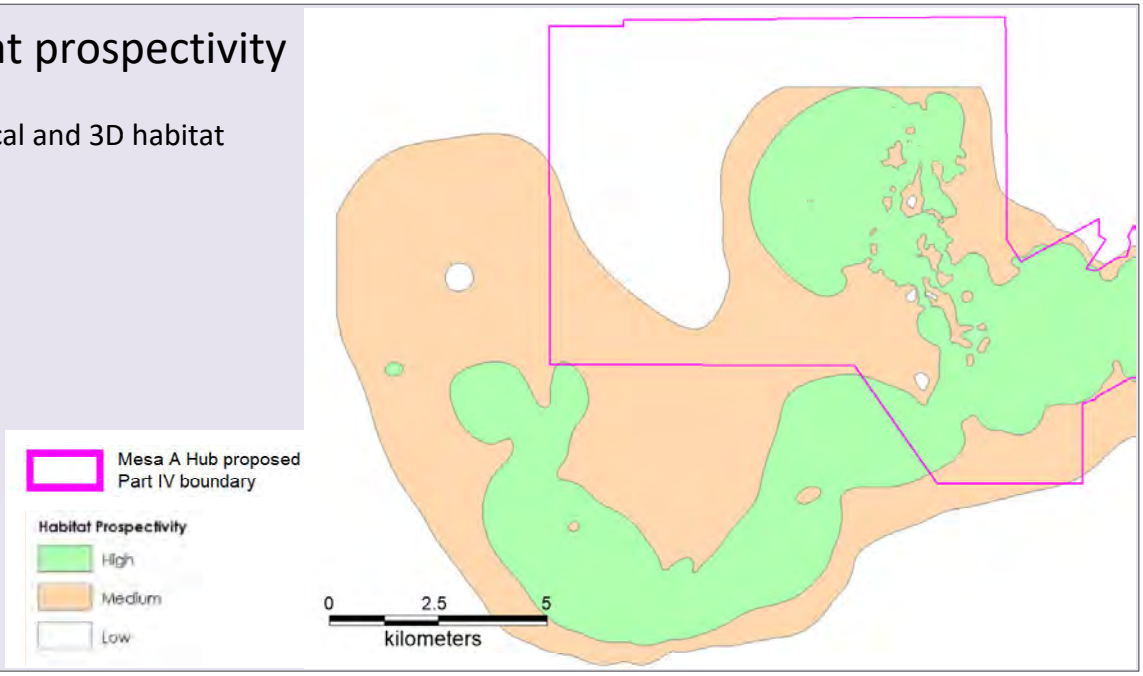


10. Determine habitat prospectivity categories

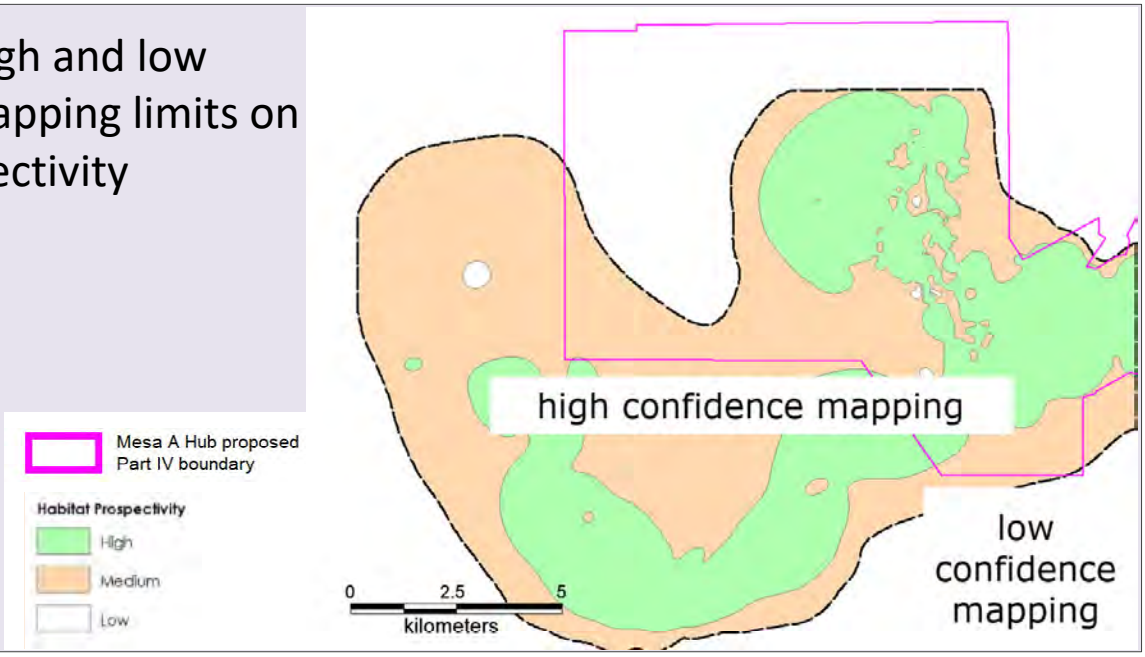
Habitat prospectivity	Geological Unit
High	Robe Pisolite (TP; >5m thickness)
Medium	Robe Pisolite (TP; 1-5m thickness)
Low	Robe Pisolite (TP; <1m thickness)

11.Map habitat prospectivity

Amalgamate geological and 3D habitat thickness maps



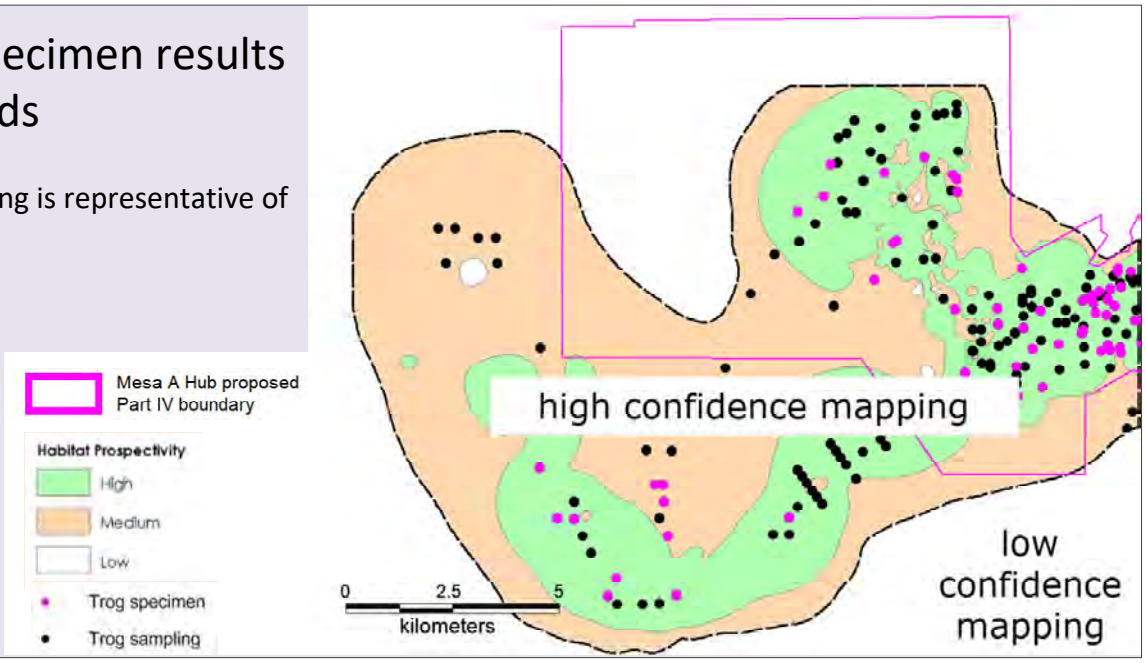
12. Overlay high and low confidence mapping limits on habitat prospectivity mapping



13. Overlay specimen results and null records

Validate that modelling is representative of actual results

*Note that troglofauna records outside the high confidence interval are located in a different geological habitat which requires a separate modelling analysis.



eDNA Metabarcoding Preliminary Report: Blind Cave Eel survey in the Pilbara WA

Prepared for

Rio Tinto
Level 24, 152-158 St Georges Terrace
Perth, WA, 6000

Prepared by

Trace and Environmental DNA (TrEnD) Laboratory

Curtin University

21st March 2018

Report Authors: Dr Nicole White and Prof. Michael Bunce (TrEnD laboratory)

Executive Summary:

Overall Project objective:

The aim of this pilot project was to use an environmental DNA (eDNA) metabarcoding approach to determine presence/absence of Blind Cave Eel (*Ophisternon candidum*) from within and outside the Mesa H project area in the Pilbara region of Western Australia. The data was to be incorporated into an environmental impact statement (EIS) by Rio Tinto. This interim report documents the results to date and will be superseded by the final report on the project which involves replication of data and design of new assays for eel detection.

Outputs:

- Two collection trips in 2017 were conducted (i) June 2017: 91 water samples from 18 bores were collected and filtered by Michelle Guzik (University of Adelaide. (ii) December 2017: 85 water samples were collected and filtered by Jason Alexander (Biota) from 16 bores and one open surface water sample from the Robe River (5x 1 liter replicates). The TrEnD lab at Curtin University successfully isolated DNA from 122 of these samples.
  .
- As a preliminary first-pass to determine the presence of Blind Cave Eel (*O. candidum*) from 122 water membranes the TrEnD labs Fish 16S assay was used. Although this DNA assay (Fish 16S) isn't specific for Blind Cave Eel our previous research has demonstrated successful amplification of eel DNA.

- The June 2017 water membranes detected the possibility of Blind Cave Eel (*O. candidum*) from bore JW021. The December 2017 water membranes detected the possibility of Blind Cave Eel (*Ophisternon candidum*) from bore 25 and bore RR1. This result is preliminary in nature – detections are currently un-replicated. Additional sites could yield eel signatures as assays are repeated and modified.

- Blind Cave Eel (*O.candidum*) tissue was sourced from the Western Australia Museum (WAM) for comparative purposes. We have sequenced the 16S barcode from this sample.

- Comparisons of the potential Blind Cave Eel (*O. candidum*) DNA sequences from bore JW021 with the National Centre for Biotechnology Information (NCBI) database showed an 85.9% match to *O. bengalense*, an eel-like fish found in northern Australia and 85.9% match to *Synbranchid* sp., a freshwater eel-like fish.

- Comparisons of the potential Blind Cave Eel (*O. candidum*) DNA sequences from bore 25 and RR1 with the NCBI database showed an 87.7%% match to *O. bengalense* and 87.1% match to *Synbranchid* sp.

- Comparisons of the potential Blind Cave Eel (*O. candidum*) DNA sequences from bore JW021, 25 and RR1 with the reference sample obtained from the WAM showed 100% match to the DNA sequences obtained from bore JW021 and 97% match to the DNA sequences from bore 25 and RR1. The genetic sequences in bores 25 and RR1 are 100% similar to each other but distinctly different from the WAM reference or the JW021 sequence. The significance of this genetic difference is unknown.

Recommendations:

- An eDNA approach using a Fish 16S assay has successfully detected Blind Cave Eel from three bores within and outside the Mesa H project area. The sensitivity and reproducibility of these findings still need to be confirmed by the ongoing research program. The successful detection of Blind eel from a non-invasive sample speaks to the promise of eDNA approaches for the detection of taxa in subterranean environments.

1. Introduction

eDNA refers to all genetic material that is recovered from environmental substrates (such as water or sediment). DNA directly from an organism (e.g. microorganisms) as well as trace amounts of DNA that are shed by all organisms is collectively termed eDNA. This preserved, but often degraded, genetic material provides a means to audit species composition and communities at a given location. When combined with recently developed DNA sequencing technologies (termed 'next generation' or 'high-throughput' sequencing), eDNA can provide a wealth of information for studies of introduced marine pests (IMP), biodiversity surveys, food web dynamics, and diet analysis.

Potential applications for monitoring using eDNA include:

- Biosecurity: to detect the presence/absence of introduced species
- Environmental Impact Assessment: baseline/ongoing monitoring and assessment; audit
- Conservation: to detect the presence/absence of threatened species

Rio Tinto has partnered with the Trace and Environmental DNA (TrEnD) Laboratory at Curtin University to develop eDNA tools for Blind Cave Eel (*Ophisternon candidum*) as a means to use DNA-based bio surveys in groundwater monitoring and management.

eDNA sampling has benefits over other traditional survey methods including:

- highly cost-effective monitoring compared to traditional survey methods
- rapid sample collection that is non destructive to habitats, flora and fauna
- non-reliance on individuals with taxonomic expertise, provision of consistent results between monitoring programs, independent of surveyors

The objectives of this project, albeit preliminary, were to use an environmental DNA (eDNA) metabarcoding approach to determine the presence/absence of Blind Cave Eel (*Ophisternon candidum*) a threatened species within the groundwater systems of the Pilbara in Western Australia, specifically the Mesa H area (Rio Tinto). The data was to be incorporated into an environmental impact statement.

2. Methods and Samples

Water samples were collected by Michelle Guzik (University of Adelaide; June 2017) and Jason Alexander (Biota; December 2017) and filtered using a Sentino pump (Pall corporation) as outlined in TrEnD standard operating procedures (available upon request). Turbidity in the water resulted in varying volumes of water that could be filtered between the bores and replicates (see table 1 below and attached electronic data file).

eDNA was extracted using Qiagen Blood & Tissue DNeasy kits in the TrEnD laboratory at Curtin University in dedicated facilities (inclusive of laboratory clean rooms) suited for eDNA workflows. eDNA derived from the Fish 16S assay was amplified using PCR, followed by sequencing on an Illumina MiSeq in the TrEnD Laboratory. Negative laboratory controls were included (and sequenced if identified as positive) to control for environmental laboratory contamination.

The 16S DNA sequences recovered were compared to the National Centre for Biotechnology Information (NCBI) database for taxonomic identification and to reference Blind Cave Eel (*Ophisternon candidum*) obtained from the WAM (P.34817-001).

3. Results and Discussion

The following table outlines the taxonomic assignments from each bore water sample for which suspected Blind Cave Eel (*Ophisternon candidum*) was amplified and sequenced. Taxonomic assignments are to genera and species with the per cent match genetic similarity to the DNA sequences contained on the reference database (NCBI). At the time of this report, the taxonomic assignments for the DNA sequences obtained from the bore water samples (i.e. DNA 'barcodes') are listed in the table below and the electronic file accompanying this report. The environmental laboratory controls for this work were identified as negative and not included in the Table.

Table 2

Taxonomic Assignments			
AWFS ID	**Bore**	**% match (NCBI)**	**Species**
AWFS-I17-107B	JW021	85.9	Synbranchid sp. VietNam-TC-2002 haplotype 1
		85.9	Ophisternon bengalense voucher MRS haplotype OB1
AWFS-I18-001A	25	87.1	Synbranchid sp. VietNam-TC-2002 haplotype 1
		87.1	Ophisternon bengalense voucher MRS haplotype OB1
AWFS-I18-013A	RR1	87.1	Synbranchid sp. VietNam-TC-2002 haplotype 1
		87.1	Ophisternon bengalense voucher MRS haplotype OB1
AWFS-I18-013C	RR1	87.1	Synbranchid sp. VietNam-TC-2002 haplotype 1
		87.1	Ophisternon bengalense voucher MRS haplotype OB1
AWFS-F18-005 BlindEel_WAM P.34817-001		85.9	Synbranchid sp. VietNam-TC-2002 haplotype 1
		85.9	Ophisternon bengalense voucher MRS haplotype OB1

Fish DNA was detected in a number of sampling locations. This preliminary report is only reporting on, and presenting data from, those bores that yielded eel DNA.

Comparisons of the potential Blind Cave Eel (*O. candidum*) DNA sequences from bore JW021 with the NCBI database showed an 85.9% match to *O. bengalense*, an eel-like fish found in northern Australia and 85.9% match to *Synbranchid* sp., a freshwater eel-like fish (see Table 2). The DNA barcode recovered from JW021 was a 100% match to the reference DNA sequence from the WAM Blind Cave Eel (*O. candidum*) sample. Eel DNA was recovered in one of two replicates from bore JW021

Comparisons of the potential Blind Cave Eel (*O. candidum*) DNA sequences from bore 25 and RR1 with the NCBI database showed an 87.7%% match to *O. bengalense* and 87.1% match to Synbranchid sp. (see table 2). The DNA barcode recovered from bore RR1 and bore 25 was a 97% match to the reference DNA sequence from the WAM Blind Cave Eel (*O. candidum*) sample. Eel DNA was recovered in two of the five replicates from bore RR1 and one of five replicates from bore 25.

The genetic sequences in bores 25 and RR1 are 100% similar to each other but distinctly different from the WAM reference or the JW021 sequence. The significance of this genetic difference is

unknown it may represent variation within the species or a distinct lineage. There is a distinctive DNA 'insertion' in the sequences obtained from JW021 and the WAM reference that is the major distinguishing feature (see Figure 1)

Figure 1: 16S DNA sequences from bore JW021, RR1, 25 and *O. candidum* (WAM P.34817-001)

4. Findings, Recommendations and Concluding remarks

The Fish 16S metabarcoding assay utilised on the bore water samples collected in June and December 2017 detected the potential Blind Cave Eel (*O. candidum*) in three of 34 bores. To our knowledge this represents the first time an eDNA based approach has been used in the ground water system(s) in the Pilbara for the detection of a restricted species. The gaps in the reference databases often prevent definitive assignments to genus and/or species at the time of this report. Although comparisons of the suspected Blind Cave Eel (*O. candidum*) DNA sequences with the DNA sequences obtained from a tissue sample of Blind Cave Eel (*O. candidum*) from the WAM indicate the strong likelihood of Blind Cave Eel (*O. candidum*). Current laboratory work is underway to sequence the complete mitochondrial genome from the WAM reference sample and develop a metabarcoding assay specific for Blind Cave Eel (*O. candidum*). Once completed, the Blind Cave Eel (*Ophisternon candidum*) metabarcoding assay will be used to re-screen the 122 water samples to validate the findings from the Fish 16S assay and potentially find additional bores that may contain Blind Cave Eel (*O. candidum*).

The DNA yields recovered from the bores was low and, as expected, not every replicate from positive wells yielded a positive detection. The sensitivity of the assays and the level of replication appropriate is yet to be determined for bores in the Pilbara. The development of additional assays and optimisation of existing assays (and sampling protocols) is ongoing and will likely enhance the likelihood of detections.

5. Appendices and additional information

- An electronic file titled; Appendix_BlindCaveEel_March2018.xlsx is attached to this report.

- Additional information on sampling and methods are available from TrEnD upon request however the exact nature of the assays and workflow are proprietary.

- Below is a list of acronyms, abbreviations and definitions that may apply to aspects of this report.

% value in data	Represents the percentage similarity of a DNA sequence recovered from a sample compared to reference sequences in a database (e.g. compared to DNA databases such as GenBank or references generated in-house)
(x) value in data	Represents the frequency the % value was recorded in the dataset
16S rRNA	The 16S rRNA refers to a conserved gene region of mitochondrial DNA, which codes for a subunit of the ribosome. 16S rRNA is found in all eukaryotes making it a good candidate for DNA barcoding and is used extensively to detect vertebrate taxa such as fish and mammals.
18S rRNA	The 18S rRNA refers to a conserved gene region of nuclear DNA, which codes for a subunit of the ribosome. 18S rRNA is found in all eukaryotes making it a good candidate for DNA barcoding
18S IMS reference database	Reference 18S rRNA sequences of invasive marine species that are available in DNA databases
Assay	In the context of metabarcoding an assay is a molecular test (using PCR) that is implemented to target a group of taxa within a mixed biological substrate. It is akin to using a magnet to selective enrich for needles (the target) in the context of a haystack (the total DNA from a sample).
COI	The gene region that is being used as the standard barcode for almost all animal groups is a 648 base-pair region of the mitochondrial cytochrome c oxidase 1 gene ("CO1"). COI is proving highly effective in identifying birds, butterflies, fish, flies and many other animal groups. COI is not an effective barcode region in plants because it evolves too slowly, but two gene regions in the chloroplast, matK and rbcL, have been approved as the barcode regions for plants
CO1 IMS reference database	Reference COI sequences of invasive marine species that are available in DNA databases
DNA	Deoxyribonucleic Acid (DNA) is the hereditary material that contains the genetic information of an organism
DNA metabarcoding	Is a genetic technique that simultaneously amplifies and sequences barcode regions

	(e.g. COI, 18S, 16S) of many different species in parallel
eDNA	Environmental DNA (eDNA) refers to genetic material that is recovered from an environmental substrate (e.g. water, sediment, air)
eukaryotes	An organism where cells contain a nucleus surrounded by a membrane and has the DNA bound together by proteins (histones) into chromosomes. The cells of eukaryotes also contain an endoplasmic reticulum and numerous specialised organelles not present in prokaryotes, especially mitochondria, golgi bodies, and lysosomes
Fisheries	Department of Primary Industries and Regional Development, Fisheries Division, Aquatic Biosecurity Section
GenBank	Publically available repository of genetic information. Contains the barcode information of genes that have previously been sequenced
Genome	A genome is all the genetic material of an organism. It consists of DNA (or RNA in RNA viruses). The genome includes both the genes (the coding regions) and the noncoding DNA. In eukaryotes it refers to the genomes of the nucleus, mitochondria and chloroplasts. In prokaryotes, there is a single genome (as they do not contain mitochondria or chloroplasts)
Illumina MiSeq	Next generation sequencing platform developed by the company Illumina
IMP	Introduced marine pests
IMS	Introduced marine species
Metabarcoding assay	A PCR reaction using a specific set of primers that simultaneously amplifies the same gene target from multiple species
Mitochondria	The mitochondrion (plural mitochondria) is a double membrane-bound organelle found in all eukaryotic organisms, although some cells in some organisms may lack them (e.g. Red blood cells). It contains its own genome
Mitogenomes	Refers to the mitochondrial genome
NGS	Next generation sequencing or second generation sequencing refers to massively parallel sequencing technology, as opposed to first generation sequencing or sanger sequencing where only a single template is sequenced at one time
Nucleotide	A compound consisting of a nucleoside linked to a phosphate group. Nucleotides form the basic structural unit of nucleic acids such as DNA
PCR	Polymerase chain reaction (PCR) is the technique that is used to amplify (akin to photocopying DNA) specific regions of the genome from specific groups of taxa
Primer	A short DNA strand (≈20bp in size) used in PCR to target particular groups of organisms and genes. Two of them are required for PCR (a forward and a reverse)
Primer binding site	A primer-binding site is the target region of a genome where the primer attaches to start replication. The primer binding site is on one of the two complementary strands of a double-stranded nucleotide polymer, in the strand which is to be copied, or is within a single-stranded nucleotide polymer sequence
prokaryote	Any of the typically unicellular microorganisms that lack a distinct nucleus and

	membrane-bound organelles and that are classified as a kingdom (Prokaryotae syn. Monera) or into two domains (Bacteria and Archaea)
RNA	Ribonucleic acid (RNA) is a polymeric molecule implicated in various biological roles in coding, decoding, regulation, and expression of genes
rRNA	ribosomal ribonucleic acid is the RNA component of the ribosome, and is essential for protein synthesis in all living organisms
Sequence	DNA sequencing is the process of determining the precise order of nucleotides within a DNA molecule. It includes any method or technology that is used to determine the order of the four bases—adenine, guanine, cytosine, and thymine—in a strand of DNA
Shotgun sequencing	Refers to randomly sequencing short pieces of DNA (≈150bp in size) after shearing or cutting DNA (e.g. fragmenting a genome)

Executive Summary:

Overall Project objective:

The aim of this pilot project was to use an environmental DNA (eDNA) metabarcoding approach to determine presence/absence of Blind Cave Eel (*Ophisternon candidum*) from within and outside the Mesa H project area in the Pilbara region of Western Australia. The data was to be incorporated into an environmental impact statement (EIS) by Rio Tinto.

Outputs:

- This report is a follow-up of the results from the EelFishCOI 'molecular magnet' designed for Blind Cave Eel (*Ophisternon candidum*) detection. This report presents the eDNA results following on from the report issued to RioTinto on the 13th July 2018 by the TrEnD lab.

- The presence of Blind Cave Eel (*Ophisternon candidum*) DNA was confirmed from two sample sites of the Robe River and bores JW021, JW024, BC186, 25, RR1 and MB17MEH0015. Blind Cave Eel DNA was not previously detected from MB17MEH0015 with the EelFish16S assay reported on 13th July 2018. Re-screening all 122 eDNA water membranes collected in June and December 2017 with Fish16S and EelFishCOI 'molecular magnets' confirms the presence of *O. candidum* from this additional bore.

Recommendations:

- This is the first time eDNA metabarcoding methods have been implemented in the Pilbara groundwater systems. The Fish16S, EelFish16S and EelFishCOI metabarcoding assays designed by the TrEnD lab indicates that an eDNA approach is able to detected Blind Cave Eel (*Ophisternon candidum*) from the survey area as a non-invasive method. Blind Cave Eel (*Ophisternon candidum*) DNA was isolated and DNA sequenced from 6 bores sampled, in addition to two open surface water samples collected from the Robe River, which indicates eDNA metabarcoding is capable of detecting threatened species. Finally it is worth noting that these eDNA assays are performing at the limits of detection and further gains in sensitivity may be achievable with optimised sampling.
-

1. Introduction

eDNA refers to all genetic material that is recovered from environmental substrates (such as water or sediment). DNA directly from an organism (e.g. microorganisms) as well as trace amounts of DNA that are shed by all organisms is collectively termed eDNA. This preserved, but often degraded, genetic material provides a means to audit species composition and communities at a given location. When combined with recently developed DNA sequencing technologies (termed 'next generation' or 'high-throughput' sequencing), eDNA can provide a wealth of information for studies of introduced marine pests (IMP), biodiversity surveys, food web dynamics, and diet analysis.

Potential applications for monitoring using eDNA include:

- Biosecurity: to detect the presence/absence of introduced species
- Environmental Impact Assessment: baseline/ongoing monitoring and assessment; audit
- Conservation: to detect the presence/absence of threatened species

Rio Tinto has partnered with the Trace and Environmental DNA (TrEnD) Laboratory at Curtin University to develop eDNA tools for Blind Cave Eel (*Ophisternon candidum*) as a means to use DNA-based bio surveys in groundwater monitoring and management.

eDNA sampling has benefits over other traditional survey methods including:

- highly cost-effective monitoring compared to traditional survey methods
- rapid sample collection that is non destructive to habitats, flora and fauna
- non-reliance on individuals with taxonomic expertise, provision of consistent results between monitoring programs, independent of surveyors

The objectives of this project were to use an environmental DNA (eDNA) metabarcoding approach to determine the presence/absence of Blind Cave Eel (*Ophisternon candidum*) a threatened species within the groundwater systems of the Pilbara in Western Australia, specifically the Mesa H area (Rio Tinto). The data is to be incorporated into an environmental impact statement.

2. Methods and Samples

Please refer to report "**eDNA Metabarcoding Report: Blind Cave Eel survey in the Pilbara WA**" issued to RioTinto by the TrEnD lab on 13th July 2018.

3. Results and Discussion

Table 1 list the water samples from each bore and those for which Blind Cave Eel (*Ophisternon candidum*) were detected with the Fish16S, EelFish16S and EelFishCOI metabarcoding assays. DNA sequences obtained for *O. candidum* can be found in the Supplementary Information accompanying this report.

Table 1: Results of eDNA metabarcoding (Fish16S, EelFish16S, EelFishCOI) from groundwater for Blind Cave Eel (*Ophisternon candidum*) detection.

TrEnD Sample ID	Site (bore code)	Field Trip	Ophisternon candidum DNA detected?

4. Findings, Recommendations and Concluding remarks

At the time of report "**eDNA Metabarcoding Report: Blind Cave Eel survey in the Pilbara WA**" issued to RioTinto by the TrEnD lab on 13th July 2018, the water samples identified as positive from the EelFishCOI and Fish16S metabarcoding assays had not been DNA sequenced and bioinformatically processed.

The Fish16S, EelFish16S and EelFishCOI assays utilised on bore water samples collected in June and December 2017 detected Blind Cave Eel (*Ophisternon candidum*) from two sample locations of the Robe River, in addition to bores JW021, JW024, BC186, 25, RR1 and MB17MEH0015. To our knowledge this represents the first time an eDNA based metabarcoding approach, specific for *Ophisternon candidum*, has been applied to samples from ground water system(s) in the Pilbara, Western Australia. Sequencing the mitochondrial genome of *Ophisternon candidum* (WAM P.34817-001) has provided definitive assignments of DNA sequences from eDNA groundwater samples to genus and species.

5. Appendices and additional information

- An electronic file titled; SupplementaryInformation_EelFish16SandCOI_August2018.xlsx is attached to this report.

- Additional information on sampling and methods are available from TrEnD upon request however the exact nature of the assays and workflow are proprietary.

- Below is a list of acronyms, abbreviations and definitions that may apply to aspects of this report.

% value in data	Represents the percentage similarity of a DNA sequence recovered from a sample compared to reference sequences in a database (e.g. compared to DNA databases such as GenBank or references generated in-house)
(x) value in data	Represents the frequency the % value was recorded in the dataset
18S rRNA	The 18S rRNA refers to a conserved gene region of nuclear DNA, which codes for a subunit of the ribosome. 18S rRNA is found in all eukaryotes making it a good candidate for DNA barcoding
18S IMS reference database	Reference 18S rRNA sequences of invasive marine species that are available in DNA databases
Assay	In the context of metabarcoding an assay is a molecular test (using PCR) that is implemented to target a group of taxa within a mixed biological substrate. It is akin to using a magnet to selective enrich for needles (the target) in the context of a haystack (the total DNA from a sample).
COI	The gene region that is being used as the standard barcode for almost all animal groups is a 648 base-pair region of the mitochondrial cytochrome c oxidase 1 gene ("CO1"). COI is proving highly effective in identifying birds, butterflies, fish, flies and many other animal groups. COI is not an effective barcode region in plants because it evolves too slowly, but two gene regions in the chloroplast, matK and rbcL, have been approved as the barcode regions for plants
CO1 IMS reference database	Reference COI sequences of invasive marine species that are available in DNA databases
DNA	Deoxyribonucleic Acid (DNA) is the hereditary material that contains the genetic information of an organism
DNA metabarcoding	Is a genetic technique that simultaneously amplifies and sequences barcode regions (e.g. COI, 18S, 16S) of many different species in parallel
eDNA	Environmental DNA (eDNA) refers to genetic material that is recovered from an environmental substrate (e.g. water, sediment, air)

eukaryotes	An organism where cells contain a nucleus surrounded by a membrane and has the DNA bound together by proteins (histones) into chromosomes. The cells of eukaryotes also contain an endoplasmic reticulum and numerous specialised organelles not present in prokaryotes, especially mitochondria, golgi bodies, and lysosomes
Fisheries	Department of Primary Industries and Regional Development, Fisheries Division, Aquatic Biosecurity Section
GenBank	Publically available repository of genetic information. Contains the barcode information of genes that have previously been sequenced
Genome	A genome is all the genetic material of an organism. It consists of DNA (or RNA in RNA viruses). The genome includes both the genes (the coding regions) and the noncoding DNA. In eukaryotes it refers to the genomes of the nucleus, mitochondria and chloroplasts. In prokaryotes, there is a single genome (as they do not contain mitochondria or chloroplasts)
Illumina MiSeq	Next generation sequencing platform developed by the company Illumina
IMP	Introduced marine pests
IMS	Introduced marine species
Metabarcoding assay	A PCR reaction using a specific set of primers that simultaneously amplifies the same gene target from multiple species
Mitochondria	The mitochondrion (plural mitochondria) is a double membrane-bound organelle found in all eukaryotic organisms, although some cells in some organisms may lack them (e.g. Red blood cells). It contains its own genome
Mitogenomes	Refers to the mitochondrial genome
NGS	Next generation sequencing or second generation sequencing refers to massively parallel sequencing technology, as opposed to first generation sequencing or sanger sequencing where only a single template is sequenced at one time
Nucleotide	A compound consisting of a nucleoside linked to a phosphate group. Nucleotides form the basic structural unit of nucleic acids such as DNA
PCR	Polymerase chain reaction (PCR) is the technique that is used to amplify (akin to photocopying DNA) specific regions of the genome from specific groups of taxa
Primer	A short DNA strand (≈20bp in size) used in PCR to target particular groups of organisms and genes. Two of them are required for PCR (a forward and a reverse)
Primer binding site	A primer-binding site is the target region of a genome where the primer attaches to start replication. The primer binding site is on one of the two complementary strands of a double-stranded nucleotide polymer, in the strand which is to be copied, or is within a single-stranded nucleotide polymer sequence
prokaryote	Any of the typically unicellular microorganisms that lack a distinct nucleus and membrane-bound organelles and that are classified as a kingdom (Prokaryotae syn. Monera) or into two domains (Bacteria and Archaea)
RNA	Ribonucleic acid (RNA) is a polymeric molecule implicated in various biological roles in coding, decoding, regulation, and expression of genes

rRNA	ribosomal ribonucleic acid is the RNA component of the ribosome, and is essential for protein synthesis in all living organisms
Sequence	DNA sequencing is the process of determining the precise order of nucleotides within a DNA molecule. It includes any method or technology that is used to determine the order of the four bases—adenine, guanine, cytosine, and thymine—in a strand of DNA
Shotgun sequencing	Refers to randomly sequencing short pieces of DNA (≈150bp in size) after shearing or cutting DNA (e.g. fragmenting a genome)

Dear Melinda,

Re: Mesa H – Targeted Night Parrot Fauna Assessment, September 2017

1 Introduction

Rio Tinto Iron Ore Pty Ltd (Rio Tinto), on behalf of Robe River Mining Co. Pty. Ltd, is evaluating the potential development of the Mesa H deposit (survey area) located adjacent to the Mesa J Operation and approximately 13 km to the south-west of Pannawonica. Key components of the pre-feasibility and feasibility studies being undertaken are environmental surveys which are required to inform the environmental assessment process for the potential development of the Mesa H deposit. Due to the recent publication of the *Interim guideline for preliminary surveys of Night Parrot* (*Pezoporus occidentalis*) (Department of Parks and Wildlife 2017) and to ensure all fauna surveys meet current guidelines, Astron was commissioned to undertake a targeted Night Parrot fauna survey in the survey area (Figure A.1, Attachment A).

The possible occurrence of this Matters of National Environmental Significance species within the survey area presents a potential management issue to ground disturbance activities for the development of the Mesa H deposit. In order to gain a comprehensive understanding of Night Parrot occurrence, habitat utilisation and resident population estimates, a more intensive survey was required within the survey area.

2 Scope of Work

The scope of work was to conduct a targeted Night Parrot fauna survey within the survey area in accordance with the scope of works provided by Rio Tinto (dated 17/07/2017), regulatory guidelines (Department of Parks and Wildlife 2017) and industry best practice. Specifically, the following was undertaken:

- a desktop literature review to assess the potential occurrence of the Night Parrot within the local and regional vicinity of the survey area
- a systematic field survey to:
    - verify the results of the desktop study and previous Night Parrot records
    - record potential Night Parrot observations or records and assess the potential for the survey area to support a resident population of this species.

This report details the findings of the desktop and field studies.

3 Night Parrot (*Pezoporus occidentalis*)

3.1 Distribution and Conservation Status

The Night Parrot is listed as Endangered under the *Environmental Protection and Biodiversity Conservation Act 1999* (EPBC Act) and Critically Endangered (Scheduled 1) under the *Wildlife Conservation Act 1950*. Conservation category listings are detailed in Table B.1 and B.2 (Attachment B). The Night Parrot has long been thought extinct in Australia, with only sporadic and sometimes unconfirmed sightings recorded. However the focus on this species has amplified due to a recent sighting near Wiluna in Western Australia (Jones 2017) and from the rediscovery of this species in Queensland near the Pullen Pullen Reserve and at Goneaway and Diamantina National Parks (Palaszczuk and Miles 2017).

The Night Parrot has long been elusive and due to its highly cryptic behaviour has largely gone unnoticed and undetected. Now with the release of the vocal calls made by this species from Queensland, a more informed and targeted survey effort can be undertaken.

3.2 Ecology

Little is known on the ecological requirements of the Night Parrot due to the cryptic behaviour this species has previously shown. With the recent sightings of the Night Parrot and records from certain areas, ecologists have been able to better understand the species' habitat requirements.

Roosting habitat is thought to be long unburnt stands of spinifex hummocks (*Triodia* spp.) particularly large hummocks that are ring forming that would form a certain level of protection from predators. The hummocks that are < 50 cm in height and collapsed are thought not likely to provide enough shelter and/or protection from predators (Department of Parks and Wildlife 2017). Some systematic acoustic monitoring from Murphy (2015, 2016) has shown that Night Parrots in south-western Queensland regularly roosted in the same location even despite exceptionally dry conditions when no *Triodia* seed was available. However, Higgins (1999) reported that the species may be nomadic, have very large home ranges and may only be sedentary under suitable conditions, such as during mass times of seeding and flowering of *Triodia* seed.

Foraging habitat requirements are also largely unknown; however, some favoured sites, particularly in Western Australia, seem to be in close association of chenopod communities, principally the succulents of *Sclerolaena*. These succulents are possibly a source of moisture for the Night Parrot given their preference for the arid regions of Australia and the probable lack of free standing water. Murphy (2016) suggested that Night Parrots may not rely on surface water, and instead may derive sufficient metabolic water from foraging on succulent plants, such as *Sclerolaena*. This indicates that access to water may not be required in some circumstances. It is also assumed that *Triodia* spp. would provide foraging potential particularly during times of mass seeding and flowering (Department of Parks and Wildlife 2017).

It is evident that Night Parrots have a preference for highly selective habitat and this probably explains the low level of records to date.

4 Methodology

The field survey was completed according to the relevant state and federal survey guidelines, particularly the guidelines set out by the state Environmental Protection Authority (EPA) and Parks and Wildlife Service of the Department of Biodiversity, Conservation and Attractions (DBCA):

- EPA Position Statement No. 3, Terrestrial Biological Surveys as an Element of Biodiversity Protection (Environmental Protection Authority 2002)
- Survey Guidelines for Australia's Threatened Birds: Guidelines for Detecting Birds Listed as Threatened Under the EPBC Act (Department of Environment 2010).
- Technical Guidance - Sampling Methods for Terrestrial Fauna (Environmental Protection Authority 2016a)
- Technical Guidance - Terrestrial Fauna Surveys (Environmental Protection Authority 2016b)
- Interim Guideline for Preliminary Surveys of Night Parrot (*Pezoporus occidentalis*) in Western Australia, May 2017 (Department of Parks and Wildlife 2017).

4.1 Desktop Literature Review

Prior to the field assessment a review of publically available databases was conducted. In particular, the desktop review included an examination of the previous Night Parrot records on DBCA's *NatureMap* database. The review focussed on the locations of recent survey records to help obtain an understanding on the distribution of this species from the current literature available.

4.2 Targeted Field Survey

The targeted field survey was conducted by Astron Zoologists Matthew Love and John Trainer on the 14 and 18 September 2017. Matthew and John both have over five years of experience conducting Level 2 vertebrate fauna surveys. The survey was conducted under a "Licence to Take Fauna for Scientific Purposes" (Permit 08-000566-2).

Weather conditions were hot during the survey period. Maximum temperatures recorded at Pannawonica (approximately 13 km north-east of the survey area) ranged from 37.0°C to 39.4°C with minimum temperatures in the mid to upper twenties. As a result of low rainfall prior to the survey, no surface water was present in the vicinity of the survey area, except where dewatering from the Mesa J mine site was occurring.

Conditions were considered to be dry with no seeding spinifex and very little seed remaining in the seed-heads of spinifex and other grasses, indicating that it had been many months since grasses had flowered. No rain-fed surface water was observed within the Robe River and in the immediate vicinity of the survey area. Yerra Bluff (located on the western margin of the survey area), a permanent water pool of the Robe River, was full and was likely to be the only natural source of water in the area at the time of the survey.

Rainfall received (based on Pannawonica weather station 005069) in three months preceding the survey was 0.3 mm, 58.9 mm less than the mean rainfall for the same three months (Bureau of Meteorology 2018). Rainfall was received earlier in the year, with a total of 602.7 mm of rainfall received in the nine months preceding the survey, 208.7 mm more than the mean rainfall for the same nine months (Bureau of Meteorology 2018). These factors are not optimal for Night Parrot occurrence, however, they are not considered to be a major limitation given that:

- this species is generally accepted as an arid and semi-arid specialist and would be adapted to long periods of drought
- habitat assessment is a critical component of a survey, as no available survey technique can irrefutably demonstrate that Night Parrots are absent from a site (Department of Parks and Wildlife 2017).

4.2.1 Habitat Assessment

Previously, Astron conducted a flora, vegetation and fauna assessment within the survey area (Astron Environmental Services 2016a, 2016b). The fauna survey conducted in November 2016 (Astron Environmental Services 2016a) mapped the fauna habitats of the survey area that helped refine the survey effort for potential Night Parrot habitat.

Two fauna habitat assessments were conducted within the survey area (Table C.1, Attachment C). The locations are shown in Figure A.2 (Attachment A) and the following information was collected at each site:

- location – coordinates measured using a handheld GPS (GDA94)
- recorder and date – personnel involved in undertaking the fauna habitat assessment and the survey date
- vegetation type – a broad description of vegetation type and structure
- soils – a brief description of soil type
- microhabitat pertinent to the Night Parrot – potential roosting habitat such as the presence of primarily old large spinifex hummocks (>50 cm), especially hummocks that are ring forming or presence of foraging habitat such as the presence of samphire communities and/or seeding spinifex hummocks, and the presence of permanent or semi-permanent water
- condition – habitat condition was assessed based on the presence of anthropogenic (human-induced) disturbances, and using the condition ratings suggested by Thompson and Thompson (2010) (Table B.3, Attachment B)
- fire age – recorded as either recent (<2 years); young (2 to 5 years); moderate (5 to 10 years); old (>10 years); very old (>50 years)
- disturbance – any disturbance such as clearing, weeds, flooding, vehicular, machinery, tracks or grazing
- photographs – a representative photograph was taken of each habitat assessment site.

The information derived from the fauna habitat assessments, as well as the previous fauna habitat mapping (Astron Environmental Services 2016a) and vegetation mapping (Astron Environmental Services 2016b) from within the survey area, was used to assess the suitability of habitat for the Night Parrot. The habitat was ranked according to the criteria listed in Table 1 and the likelihood of occurrence in the survey area utilising the criteria in Table B.4 (Attachment B).

Table 1: Suitability of habitat ranking criteria for the Night Parrot (*Pezoporus occidentalis*) within the survey area.

Species	Potential shelter and foraging habitat (a)	Suitable foraging and dispersal habitat (b)	Limited foraging and dispersal habitat (c)
Night Parrot (*Pezoporus occidentalis*)	Isolated habitat not subjected to predation pressure, fire pressure, and altered habitat from pastoralism and mining activities. Generally roosting habitat that contains old and large spinifex clumps (>50 years unburnt), particularly ring-forming hummocks **OR** Areas highly suitable for foraging in close association (<10 km) to potential roosting habitat, including Triodia (particularly at times of mass flowering and seeding) and chenopod communities dominated by Sclerolaena	Very little is known on the foraging requirements of the Night Parrot. Habitat within 40 km of potential roosting and nesting sites, potentially important for foraging, including chenopod communities (particularly those dominated by Sclerolaena), Triodia and areas rich in herbs, including forbs, grasses and grass-like plants.	Habitat that has limited roosting and foraging potential for the Night Parrot.

4.2.2 Autonomous Recording Units

Autonomous Recording Units (ARUs) were used to record the potential presence of the Night Parrot by recording the species' vocal call. Two acoustic recording devices (Song Meter 2, SM2BAT+) were positioned in four locations (Figure A.2, Attachment A and Table C.1, Attachment C). The detectors were set for three nights, resulting in a total of 12 recording nights. The ARUs were set to record from 1 hour pre-sunset to 1 hour post-dawn. The recordings were recorded at 44.1 k bits and covered the frequency range 100 kHz to 21,000 kHz that brackets the Night Parrot call frequency range of 1,500 kHz to 3,500 kHz.

The data collected on the SM2BAT+ detectors in the field were analysed by Robert Bullen (Bat Call WA 2017). The reference calls for the Night Parrot were available from Bat Call WA's library and compared against any potential calls made from the survey area (Bat Call WA 2017).

4.2.3 Motion Sensitive Cameras

Two motion sensitive cameras were used during the survey (Moultrie, Reconyx). Cameras were set for four nights each with a combined trapping effort of eight camera trap nights (Figure A.2, Attachment A and Table C.1, Attachment C). The cameras were placed in prospective/suitable habitat aimed at targeting potential foraging Night Parrots in or near prospective roosting habitat.

4.2.4 Aural Listening Surveys/Nocturnal Searching

Two nights (12 person hours) of targeted nocturnal searching was conducted within the survey area. This included six locations of aural listening surveys (Figure A.2, Attachment A and Table C.1, Attachment C). The fauna team targeted the search effort in long unburnt spinifex hummocks and sat and listened for the distinct audio call of the Night Parrot. It is thought that the species' peak calling period is two hours after sunset and two hours before sunrise (Department of Parks and Wildlife 2017). Due to concerns with health, safety and fatigue only the post-sunset calling period was targeted during the fauna assessment.

5 Results

5.1 Desktop Assessment

A review of the DBCA *NatureMap* database in October 2017 for previous records of the Night Parrot reported 15 records within Western Australia. Of these, five records were made within the Interim Biogeographic Regionalisation for Australia Pilbara bioregion and only one record was reported recently or post-2000.

In April 2005 three individuals of the Night Parrot were recorded at the onset of dusk near standing water at Minga Well adjacent to the Fortescue Marsh (Davis and Metcalf 2008). Minga Well is 320 km to the east of the survey area, situated on Mulga Downs pastoral station. Two birds were observed moving towards the water's edge and then drinking; the third bird was only seen briefly and was not resighted (Davis and Metcalf 2008). No vocalisations or noises from their wings were recorded when the individuals departed the site (Davis and Metcalf 2008). The habitat was described as a pastoral bore; however, Minga Well is situated 2 km from the edge of the Fortescue Marsh (a known priority ecological community) where succulents such as *Sclerolaena* are found.

5.2 Targeted Field Survey

No individual sightings, vocal calls or any other signs of the Night Parrot were recorded during the current targeted survey. The Night Parrot was not detected from the 12 nights of ARU recordings (Attachment D). No Night Parrots were recorded on any of the motion sensitive cameras from the combined trapping effort of eight camera trap nights.

Two habitat assessments in the survey area determined the fire ages to range from young (2 to 5 years) to moderate (5 to 10 years) (Attachment C).

6 Discussion

The survey area is located in the western extent of the Pilbara region of Western Australia, located within an area deemed as 'species or species habitat may occur' by the Department of the Environment and Energy (Department of the Environment and Energy 2017). No individual sightings and/or vocal calls were recorded, nor any prospective calls made on the ARUs set within the survey area. Astron is of the belief that the survey area is not suitable for the Night Parrot as there is limited preferred habitat present and the impacts of regular fire would be too great. The current knowledge of habitat preference of the Night Parrot is limited, with some sources believing a matrix of long unburnt spinifex stands (>50 years) in close association with chenopod communities (samphire) is a key habitat preference. The only recent discovery of the Night Parrot within the Pilbara region was in 2005 in which three individuals were sighted at a pastoral bore close to the Fortescue Marsh, supporting the theory that samphire is of some importance (Davis and Metcalf 2008). Recently the Night Parrot was discovered in March 2017 in the arid region of the Mid-west in which the habitat was also described as long unburnt spinifex in association with a chenopod community (Jones 2017). Given these habitats do not occur in the survey area, the likely predation pressure from cats and dingos (sighted during the survey) and the proximity to active mining infrastructure, the chance of this species being present is considered very low.

This report was prepared by Senior Scientist Matthew Love and technically reviewed by Senior Scientist Dr Jessica Johnston. Should you have any further queries regarding this information, please do not hesitate to contact Melissa Ford (Project Coordinator) on 9421 9600.

Attachment B: Conservation Fauna Categories, Habitat Condition Scales and Likelihood Criteria

This page has been left blank intentionally.

Table B.1: Categories and definitions for EPBC Act listed fauna species.

Conservation category	Definition
Extinct	Taxa with no reasonable doubt that the last member of the species has died.
Extinct in the wild	Taxa known to survive only in cultivation, in captivity or as a naturalized population well outside its past range; or it has not been recorded in its known and/or expected habitat, at appropriated seasons, anywhere in its past range, despite exhaustive surveys over a time frame appropriate to its life cycle and form.
Critically endangered (CR)	Taxa facing an extremely high risk of extinction in the wild in the immediate future, as determined in accordance with the prescribed criteria.
Endangered (E)	Taxa are not critically endangered; and are facing a very high risk of extinction in the wild in the near future, as determined in accordance with the prescribed criteria.
Vulnerable (V)	Taxa are not critically endangered or endangered; and are facing a high risk of extinction in the wild in the medium-term future, as determined in accordance with the prescribed criteria.
Conservation dependent (CD)	Taxa are the focus of a specific conservation program the cessation of which would result in the species becoming vulnerable, endangered or critically endangered; or the following subparagraphs are satisfied: i) the taxa is a species of fish; ii) the taxa is the focus of a management plan that provides management actions necessary to stop the decline of, and support the recovery of, the taxa so that its chances of long term survival in nature are maximized; iii) the management plan is in force under a law of the Commonwealth or of a State or Territory; iv) Cessation of the management plan would adversely affect the conservation status of the taxa Fish includes all taxa of bony fish, sharks, rays, crustaceans, molluscs and other marine organisms, but does not include marine mammals/reptiles.

Table B.2: Conservation codes for Western Australian fauna (Department of Parks and Wildlife 2015).

Code	Conservation category	Definition
CR	Schedule 1 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Fauna that is rare or likely to become extinct, as critically endangered fauna.
EN	Schedule 2 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Fauna that is rare or likely to become extinct, as endangered fauna.
VU	Schedule 3 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Fauna that is rare or likely to become extinct, as vulnerable fauna.
EX	Schedule 4 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Fauna that is presumed to be extinct.
IA	Schedule 5 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Birds that are subject to international agreements relating to the protection of migratory birds.
CD	Schedule 6 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Fauna that are of special conservation need being species dependent on ongoing conservation intervention.
OS	Schedule 7 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Declared to be fauna that is in need of special protection, otherwise than for the reasons mentioned.

Reference: Department of Parks and Wildlife 2015, *Conservation Codes For Western Australian flora and fauna*, The Government of Western Australia.

Table B.3: Fauna habitat condition scale (Thompson and Thompson 2010).

Habitat condition	Condition description
High Quality Fauna Habitat (1.0)	These areas closely approximate the vegetation mix and quality that would have been in the area prior to any human induced disturbance. The habitat has connectivity with other habitats and is likely to support the most natural vertebrate fauna assemblage.
Very Good Fauna Habitat (0.8)	These areas show minimal signs of human induced disturbance (e.g. grazing, clearing, fragmentation, weeds) and retain almost all of the characteristics of the habitat had it not been disturbed. The habitat has connectivity with other habitats, and fauna assemblages in these areas are likely to be minimally effected by disturbance.
Good Fauna Habitat (0.6)	These areas show signs of human induced disturbance (e.g. grazing, clearing, fragmentation, weeds) but generally retain many of the characteristics of the habitat had it not been disturbed. The habitat still retains some connectivity with other habitats but fauna assemblages in these areas are likely to be affected by disturbance. Fauna assemblages in these areas are likely to be similar to what might be expected in this habitat.
Disturbed Fauna Habitat (0.4)	These areas show signs of human induced significant disturbance (e.g. mining, clearing, tracks and roads). Many of the trees, shrubs and undergrowth have died or have been cleared. These areas may be in the early succession and regeneration stages. Areas may show signs of significant grazing, contain an abundance of weeds or have been damaged by vehicles or machinery. Habitats are fragmented or have limited connectivity with other fauna habitats. Fauna assemblages in these areas are likely to differ significantly from what might be expected in the area had the disturbance not occurred.
Highly Degraded Fauna Habitat (<0.2)	These areas often have a significant human induced loss of vegetation, and / or a large number of vehicle tracks and / or have been completely cleared, and / or areas have been heavily grazed or farmed. There is limited or no fauna habitat connectivity. Fauna assemblages in these areas are likely to differ significantly from what existed prior to the disturbance, and are often depleted compared to what existed prior to the disturbance.

Table B.4: Criteria used to define likelihood occurrence of conservation significant fauna species.

Likelihood of occurrence	Pre-survey	Post-survey
Recorded	N/A	Species or evidence of species recorded during survey.
High	Species has been recorded within the survey area or within 20 km of the survey area and preferred habitat appears to be present.	Core or preferred habitats present in the survey area which are abundant and/or high quality condition. OR Species is known to be cryptic and may not have been detected despite adequate survey effort and suitable habitat present within the survey area. OR Species or evidence of species recorded within the survey area however doubt remains over the taxonomic identification, validity of record.
Moderate	Species has not been recorded from within the survey area, however species has been recorded within 20 km of the survey area and suitable habitat appears to be present.	Core or highly suitable habitats present in the survey area, however, non-cryptic species that was not detected despite adequate survey effort. OR Core or preferred habitats present in the survey area are mainly in poor or modified condition.
Low	Species recorded within 20 km of the survey area but suitable habitat does not appear to be present.	Species has not been recorded in the survey area despite adequate survey effort. OR Species dependent on specific habitats that do not occur in the survey area. OR Species considered locally extinct.

Rio Tinto Mesa A and H targeted Night Parrot survey

Astron Environmental Services has provided Bat Call with a series of audio recordings made at Mesa A and Mesa H in September 2017. These recordings were made at eight locations, four at each mesa, and targeted Night Parrot (*Pezoporus occidentalis*) presence. They were made using Songmeter SM2 audio detectors fitted with SMX-II microphones. Reference calls for the Night Parrot for comparison were available from Bat Call's library.

The recoding data and results for each site are summarised in the following tables.

Mesa A	Date	Recording Time & SM2 unit	Easting	Northing	Night Parrot presence detected
SM002468A	13 to 16 September	Detector failed to record	381293	7599064	No
SM002468B	17 to 20 September	Detector failed to record	381262	7599212	No
SM007982A	13 to 16 September	Four overnight recordings using SM2 SN 7982	380088	7608911	No
SM007982B	17 to 19 September	Three overnight recordings using SM2 SN 7982	391731	7602261	No

Mesa H	Date	Recording Time & SM2 unit	Easting	Northing	Night Parrot presence detected
SM004685A	15 to 17 September	Three overnight recordings using SM2 SN 4685	421585	7591008	No
SM004685B	18 to 20 September	Three overnight recordings using SM2 SN 4685	415745	7598784	No
SM004698A	15 to 17 September	Three overnight recordings using SM2 SN 4698	422451	7591151	No

Executive Summary

Astron was commissioned by Robe River Mining Co Pty Ltd to undertake a contextual analysis for the conservation significant Ghost Bat (*Macroderma gigas*) within the vicinity of the Mesa H survey area. The Ghost Bat has recently been upgraded to Vulnerable under the *Environment Protection and Biodiversity Conservation Act 1999* and Schedule 3 under the *Wildlife Conservation Act 1950*. The Mesa H survey area is approximately 4,930 ha and encompasses potential future mine and infrastructure. The contextual survey area is approximately 94,582 ha and encompasses areas west of Mesa H through to the Mesa A Operation. The purpose of this assessment is to identify significant habitats for the Ghost Bat in the vicinity of the Mesa H survey area and to discuss this habitat in a local and regional context.

The first stage of the assessment involved a desktop review. This review combined data from database searches and previous surveys from within a 30 km radius of the Mesa H survey area. The review indicated that 79 Ghost Bat records, including six diurnal roosts (five confirmed and one potential) and three maternal roosts (one confirmed and two potential) have been recorded within 30 km of the Mesa H survey area (the desktop survey area). This includes two diurnal roost sites that have been previously identified within the Mesa H survey area.

The second stage of the assessment was a field survey involving mapping of potential habitat and targeted survey for the Ghost Bat within the contextual survey area. Survey effort was concentrated to the west of Mesa H, specifically along the Robe Valley, as this area lacked recent Ghost Bat records/data and the Robe Valley to the east of Mesa H had been recently surveyed. Habitats of the contextual survey area were assessed and mapped on their ability to support Ghost Bats, in particular the presence of roosting sites, feed cave sites and quality foraging sites. Habitats were mapped as:

- High quality habitat: potential/confirmed roosting habitat.
- Moderate quality habitat: potential/confirmed nocturnal feeding roosts and quality foraging habitat.
- Low quality habitat: widespread foraging habitat.

The vast majority of the contextual survey area (90,425.3 ha and 95.6%) contains habitat considered as being of low quality habitat for Ghost Bats, including approximately 4,716.1 ha within the Mesa H survey area. A total of 2,531.1 ha (2.7%) of the contextual survey area contains habitat considered as being of moderate quality habitat for Ghost Bats, including approximately 270.4 ha within the Mesa H survey area. A total of 256 ha (0.3%) of the contextual survey area contains habitat considered as being of high quality habitat for Ghost Bats, including only 4.1 ha within the Mesa H survey area.

During the field survey an additional 26 nocturnal feeding roosts, four diurnal roosts and two potential maternal roosts were recorded in the contextual survey area; however, no new roost sites were located in the Mesa H survey area. Since the field survey was completed, further targeted cave assessments have reassessed some of theses caves and it is considered that only four diurnal roosts (three confirmed and one potential) and one potential maternal roost occurs within the contextual survey area. No new roosts were recorded within the Mesa H survey area.

Although high quality habitat is present within the Mesa H survey area, the majority of the high quality habitat (98.4%) and roost sites are located in areas outside the Mesa H survey area. The most significant Ghost Bat habitats in the contextual survey area are located within the gorges on the

lower Robe Valley Mesas, Mesa G and the gorge system along the Buckland Hills to the south of Mesa H, although the only confirmed maternal roost occurs at Mesa F. The gorge to the south of Mesa H was too large to properly survey within the scope of this assessment and only received a preliminary assessment. A maternal roost and two diurnal roosts were identified, however based on the geology and size of the gorge system, more roost sites are expected.

The land systems mapping for the contextual survey area shows relationships between the Robe and Newman systems and the presence of both diurnal and maternal roost sites. Within the contextual survey area approximately 96% of the Newman system and 75% of the Robe system are located outside of the Mesa H survey area, indicating that both of these land systems are well represented locally and are widespread throughout the Pilbara.

The number of Ghost Bat records from the desktop assessment and field survey suggest that the Ghost Bat is common and widespread in small numbers within the Robe Valley and the vicinity of Mesa H. The contextual survey area occurs in the Hamersley subregion where Ghost Bats are widespread but occur in small numbers (approximately 350 individuals) and relatively few breeding records exist. Little is known about this species' roost site fidelity, seasonal movements or local population estimates in the Pilbara, let alone in the contextual survey area or the roost sites identified in this assessment.

Appendix C: Summary of Ghost Bat Records

1 Introduction

1.1 Project Background

Robe River Mining Co. Pty. Ltd (the Proponent), is evaluating the potential development of the Mesa H deposit (Mesa H) located adjacent to the Mesa J Operation and approximately 13 km to the southwest of the town of Pannawonica. A key component of the pre-feasibility and feasibility studies being undertaken is the environmental surveys which are required to inform the environmental assessment process for the potential development of the Mesa H deposit (Figure 1). Astron Environmental Services (Astron) has been commissioned to undertake a number of these environmental surveys.

This report presents the outcome of a contextual analysis of conservation significant fauna, specifically the Matter of National Environmental Significance (MNES) species the Ghost Bat (*Macroderma gigas*), within the vicinity of the Mesa H survey area. The status of the Ghost Bat has recently been upgraded to Vulnerable under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) and Schedule 3 under the *Wildlife Conservation Act 1950* (WC Act).

1.2 Scope and Objectives

The purpose of this assessment is to identify significant habitats for the Ghost Bat in the vicinity of the Mesa H survey area and to discuss this habitat in a local and regional context.

To obtain a contextual overview of this species within the vicinity of the Mesa H survey area, Astron undertook a desktop review and targeted fauna survey for the Ghost Bat. The desktop assessment combined data from database searches and previous surveys from within a 30 km radius of the Mesa H survey area (desktop survey area; Figure 1).

A number of recent biological surveys have been completed within the Robe Valley, in particular at Mesa H and areas to the east (Bungaroo, Middle Robe). These assessments have provided data on the Ghost Bats presence and habitat within these areas. The field component of this survey concentrated on the Robe Valley to the west of Mesa H (contextual survey area) where recent Ghost Bat specific data were lacking. The contextual survey area is approximately 94,582 ha and covers the Robe Valley between the Mesa A Operation (Mesa A) and Mesa H (Figure 1).

Astron conducted the contextual study in accordance with the following:

- Position Statement No. 3 (Environmental Protection Authority 2002)
- Guidance Statement No. 56 (Environmental Protection Authority 2004)
- Technical Guide – Terrestrial Vertebrate Fauna Surveys for Environmental Impact Assessment (Environmental Protection Authority and Department of Environment and Conservation 2010)
- Survey Guidelines for Australia's Threatened Bats (Department of the Environment, Water, Heritage and the Arts 2010).

2 Environmental Context

2.1 Geology and Soils

The contextual survey area occurs on the Hamersley Basin which overlies the Archaean Pilbara Craton and comprises of mafic and felsic volcanics, shale, siltstone, sandstone and conglomerate, as well as dolomite and banded iron formation. The area is extensively deformed with the rocks being folded and faulted (van Vreeswyk et al. 2004). The surface geology of the contextual survey area comprises 13 different geological units (Stewart et al. 2008) (Table 1). Geological mapping of the contextual survey area and surrounds is presented in Figure A.1 (Appendix A).

Table 1: Geological units of the contextual survey area.

Geological name	Label	Area (ha) within the contextual survey area
Marra Mamba Iron Formation: chert, ferruginous chert, jaspilite, banded iron formation, minor shale, siltstone, mudstone	Achm	2,419
Mount McRae Shale and Mount Sylvia Formation: interbedded shale, chert, banded iron-formation	Ashm	4,640
Jeerinah Formation: shale, sandstone, siltstone, mudstone, dolomite, local microbanded chert, jaspilite, conglomerate; fine-grained massive rhyolite; mafic tuff with local accretionary lapilli and agglomerate; thin basalt/dolerite and andesitic basalt flows	Awfj	476
Robe Pisolite: pisolitic, oolitic and massive limonite, goethite and hematite deposits containing fossil wood fragments; iron ore	Czlr	9,777
Nanutarra Formation: shale, ferruginous and glauconitic quartz sandstone, siltstone, micaceous siltstone; poorly sorted conglomerate	Kswn	9,345
Boolgeeda Iron Formation: fine-grained, finely laminated, dark grey-brown to black flaggy iron-formation, minor chert, jaspilite, shale	Lchb	1,445
Brockman Iron Formation: banded iron-formation, chert, mudstone and siltstone	Lchk	7,437
Weeli Wolli Formation: banded iron-formation (commonly jaspilitic), mudstone, siltstone; common interlayered metadoleritic sills	Lchw	87
Woongarra Rhyolite: rhyolite, rhyodacite, rhyolitic volcaniclastic breccia and banded iron formation	Lfhw	1,581
Wyloo Group: shale, sandstone, greywacke, dolomite, phyllite, quartz-mica schist, felsic volcanic rocks, chert, chert breccia, mudstone, siltstone, conglomerate	Lsy	8,449
Ashburton Formation: mudstone interbedded with sandstone and dolomite; intruded by sills	Lsya	1,049
Alluvium 38485: channel and flood plain alluvium; gravel, sand, silt, clay, locally calcreted	Qa	14,524
Colluvium 38491: colluvium, sheetwash, talus; gravel piedmonts and aprons over and around bedrock; clay-silt-sand with sheet and nodular kankar; alluvial and aeolian sand-silt-gravel in depressions and broad valleys in Canning Basin; local calcrete, reworked laterite	Qrc	33,352

Soils of the contextual survey area are typically shallow and of poor quality; soils in the area of the Mesa A Operation are pisolitic limonite gravels, whilst the river landform is characterised by sand, gravel, pebbles and stones. The drainage zones surrounding are red shallow loams (van Vreeswyk et al. 2004).

2.2 Surface Water and Hydrology

The Robe River is considered a seasonal watercourse. It intersects the contextual survey area, flowing in an east-west orientation. A number of permanent pools in the river were observed within the contextual survey area. Numerous creeks and smaller drainage lines stem from the Robe River; drainage lines were also noted down the gullies of the surrounding mesas. There are no regionally significant wetlands in proximity.

2.3 Land Systems

Land systems of the Western Australian rangelands were mapped by the Department of Agriculture and Food to outline their distributions and provide comprehensive descriptions of biophysical resources, including soil and vegetation condition. A total of 102 land systems occur in the Pilbara bioregion covering 181,723 km^2, of which 12 occur in the contextual survey area (Table 2). The distribution of these land systems within the contextual survey area is shown in Figure A.2 (Appendix A).

Table 2: Distribution of land systems within the contextual survey area and Pilbara bioregion (van Vreeswyk et al. 2004).

Land system	Total area within Pilbara bioregion (ha)	Total area within the contextual survey area (ha)	Proportion within the contextual survey area (%)
Boolgeeda: Stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands and mulga shrublands	961,847	16,779	1.7%
Cane: Alluvial plains and flood plains supporting snakewood shrublands, soft and hard spinifex grasslands and tussock grasslands	81,798	496	0.6%
Capricorn: Rugged sandstone hills, ridges, stony footslopes and interfluves supporting low acacia shrublands or hard spinifex grasslands with scattered shrubs	698,396	3,508	0.5%
Marallina: Sandy surfaced alluvial plains supporting soft spinifex grasslands and minor hard spinifex and tussock grasslands	41,825	1,269	3%
McKay: Hills, ridges, plateaux remnants and breakaways of meta sedimentary and sedimentary rocks supporting hard spinifex grasslands	425,967	1,881	0.4%
Nanutarra: Low mesas and hills of sedimentary rocks supporting soft and hard spinifex shrubby grasslands	77,423	14,198	18.3%
Newman: Rugged jaspilite plateaux, ridges and mountains with hard spinifex	1,994,339	15,898	0.8%
River: Active flood plains, major rivers and banks supporting grassy eucalypt woodlands, tussock grasslands and soft spinifex grasslands	481,994	5,553	1.1%
Robe: Low limonite mesas and buttes supporting soft spinifex (and occasionally hard spinifex) grasslands	128,680	10,967	8.3%
Sherlock: Stony alluvial plains supporting snakewood shrublands with patchy tussock grasses and spinifex grasslands	38,662	10,403	26.9%
Stuart: Gently undulating stony plains supporting hard and soft spinifex grasslands and snakewood shrublands	276,800	4,146	1.5%
Urandy: Stony plains, alluvial plains and drainage lines supporting shrubby soft spinifex grasslands	132,039	9,484	7.2%
TOTAL	**5,339,770**	**94,582**	**N/A**

2.4 Vegetation and Flora

Pre-European vegetation has been mapped across the Pilbara region at a scale of 1:1,000,000 (Beard 1975). The contextual survey area is located in the Stuart Hills and Hamersley Plateau physiographic units of the Fortescue Botanical District (Figure A.3, Appendix A). These physiographic units are described as:

Hamersley: a compact unit defined by the outcropping of jaspilite and dolomite, with some shale, siltstone and volcanics. Vegetation is described as:

- ranges – tree steppe of *Eucalyptus brevifolia* (likely to represent *E. leucophloia*) over *Triodia wiseana* hummock grasslands
- valley plains – mulga (*Acacia aneura* complex) low woodlands, or tussock grasslands on cracking clay soils
- basalt hills – mosaic of mulga low woodland and *Acacia pyrifolia* and *Triodia* species shrub steppe.

Stuart Hills: this unit consists mostly of plains, gently undulating pediplains extending out from Breakaways and residuals capped by Robe pisolites, and stony hills and steeply dissected pediments on fine-grained sandstone, shale and dolomite. Vegetation is described as:

- hills and plains – *Triodia wiseana* and *T. basedowii* hummock grasslands with sparse shrubs, particularly *Acacia bivenosa*
- Drainage lines – *Corymbia hamersleyana* and *C. candida* occur occasionally, with *Senna* species and ephemerals
- major rivers – *Eucalyptus camaldulensis* and *Acacia citrinoviridis* along river and mulga low woodland on river flats and tributaries.

Nine pre-European vegetation units, 29, 82, 93, 157, 583, 603, 605, 609 and 620 (Shepherd, Beeston, and Hopkins 2002), are associated with the contextual survey area:

29: 'Sparse low woodland; mulga, discontinuous in scattered groups,

82: 'Hummock grasslands, low tree steppe; snappy gum over *Triodia wiseana*',

93: 'Hummock grasslands, shrub steppe; kanji over soft spinifex',

157: 'Hummock grasslands, grass steppe; hard spinifex, *Triodia wiseana'*,

583: 'Hummock grasslands, sparse shrub steppe; kanji and *Acacia bivenosa* over hard spinifex *Triodia basedowii* and *T. wiseana*',

603: 'Hummock grasslands, sparse shrub steppe; *Acacia bivenosa* over hard spinifex',

605: 'Hummock grasslands, shrub steppe, *Acacia pachycarpa* and waterwood over soft spinifex',

609: 'Mosaic: Hummock grasslands, open low tree steppe; bloodwood with sparse kanji shrubs over soft spinifex/Hummock grasslands, open low tree steppe; snappy gum over *Triodia wiseana*' and

620: 'Hummock grasslands, shrub steppe; snakewood over soft spinifex.

Table 3 summarises the current and pre-European extent of these nine vegetation units in the Pilbara and the contextual survey area.

Table 3: Extent of pre-European vegetation in the contextual survey area (Government of Western Australia 2014).

Vegetation association	Extent in the contextual survey area (ha)	Current extent in Pilbara bioregion (ha)
29	11,943	1,132,939
82	14,710	2,550,898
93	6,315	3,038,471
157	25	198,409
583	11,793	243,111
603	13,999	55,764
605	24,133	114,115
609	2,278	72,765
620	9,385	15,539

2.5 Ghost Bat, *Macroderma gigas*

2.5.1 Distribution and Conservation Status

The status of the Ghost Bat (*Macroderma gigas*) has been recently upgraded to Vulnerable under the Commonwealth EPBC Act and Schedule 3 under the Western Australian WC Act. This is due to the fact that the Ghost Bat has undergone a substantial decline across its distribution, including an estimated decline greater than 30% in the Pilbara population (Department of the Environment and Energy 2016).

Ghost Bats occur in the Pilbara (Armstrong and Anstee 2000; McKenzie and Bullen 2009), Kimberley including several islands (McKenzie and Bullen 2012), northern sections of the Northern Territory (including Groote Eylandt), and coastal and near coastal eastern Queensland from Cape York to near Rockhampton (Richards et al. 2008). Burbidge et al. (2009), using modern, historical and subfossil data, found that the Ghost Bat occurred in 37 of Australia's 85 bioregions, and that it was extinct in 12 bioregions.

The Pilbara Ghost bat population is estimated at 1,500 to 2,000 based on recently published estimates. This includes estimates of approximately 600 (N.L. McKenzie pers. comm. in McKenzie and Hall 2008); approximately 1,200 (Armstrong and Anstee 2000) and Robert Bullen's unpublished database summarising data from a range of surveys carried out in recent years by Pilbara mining companies, including Rio Tinto and other organisations (summarised in Department of the Environment and Energy (2016)). These recent data (estimates less than 15 years old) cover the entire Pilbara bioregion. Current population estimates in the Hamersley and Chichester subregions are approximately 350 and 1,500 respectively (author's unpublished database summarised in Department of the Environment and Energy (2016)).

Ghost bat breeding populations are known from a small number of maternal roosts in the Pilbara, the largest of these colonies are in abandoned mines in the Chichester subregion and number up to several hundred (Armstrong and Anstee 2000). There is no known large, permanent maternal roost in the Hamersley subregion (Bat Call WA 2016a). Hamersley Range populations are between 5 and 25 individuals in local groups (Bat Call WA 2016a). Multiple records including visual observations and the presence of cave middens of the Ghost bat have been detected on the various mesas within the Robe River valley (Bat Call WA 2016a).

2.5.2 Relevant Biology/Ecology

The Ghost Bat is the largest microchiropteran bat in Australia, weighing up to 150 g and having a wingspan of 60 cm. It is Australia's only carnivorous bat. Its fur is light to dark grey above and paler below (Plate 1). It has long ears which are joined together, large eyes, a simple noseleaf and no tail (Richards et al. 2008). The Ghost Bat occurs in a wide range of habitats from the arid Pilbara to tropical savanna woodlands and rainforests and has a broad diet comprising small mammals including other bats, birds, reptiles, frogs and large insects (Boles 1999; Schulz 1986; Pettigrew et al. 1986).

In the Pilbara, pregnancy in Ghost Bats has been recorded from August until September and births occurred from October until December (Armstrong and Anstee 2000). Hoyle et al. (2001), who studied the southernmost known colony in Queensland, found that female bats gave birth to a single young in late spring and females bred at age two to three years. At Mount Etna, Toop (1985) found that pregnant females congregated in the warmest caves and gave birth over a month commencing in mid-October. As caves became warmer as summer progressed, some mothers shifted the young to other caves. Juvenile bats commenced flying at seven weeks with all young capable of flight by the end of January. Ghost bats disperse widely when not breeding, but concentrate in relatively few maternal roost sites when breeding. Few of these sites are known (Worthington Wilmer 2012; Richards et al. 2008), and most are not protected or managed.

Bat Call WA (2016a) describes the roosting requirements of Ghost Bats: "For Ghost Bats to persist the bats need an 'apartment block' of roosting opportunities, at least one deep cave with characteristics of a maternal roost, multiple caves/shelters and overhangs in close proximity offering nocturnal feeding and refuge opportunities, a productive set of gullies and gorges locally, and a productive foraging area within a 5 km to 10 km radius, usually including a good quality riparian line and appropriate protection from human interference."

Ghost Bats hunt their prey in two primary ways. They hunt birds and bats at cave entrances and elsewhere "air-to-air" by swooping from above or from a perch (Bat Call WA 2016a). They also hunt ground level prey in their target food size range by dropping onto the prey from a perch, either tree branch or rock outcrop (Bat Call WA 2016a). Their diet includes small mammals such as other bats, birds, reptiles, frogs and large insects. The proportion of food items in the diet varies with availability and reported foraging areas vary from a few km to over 10 km from the roost cave (Bat Call WA 2016a).

Roost sites include caves, rock crevices and disused mine adits. In the Hamersley Range in the Pilbara, preferred roosting habitat appears to be caves beneath bluffs of low rounded hills composed of Marra Mamba geology, and larger hills of Brockman Iron Formation; in the eastern Pilbara caves beneath bluffs composed of Gorge Creek Group geology and granite rockpiles are preferred (Armstrong and Anstee 2000). Ghost Bats use three types of roost regularly, these being nocturnal roosts or feeding sites, diurnal or diurnal roosts that may be permanent or semi-permanent sites and maternal roosts that are diurnal roosts with the range of characteristics allowing regular or permanent occupancy:

- Nocturnal roosts or feeding sites are only used at night, either habitually or for transitory visits. They are typically shallow caves and shelters that are well lit during the day. They are often high in the strata and may be well or poorly insulated from the elements. They usually contain guano scatters and/or midden(s) of various sizes containing guano and food scraps.
- Diurnal roosts are generally deep, complex caves or disused mines that contain domed ceilings, fissures or passages which create a stable microclimate. They typically have one or

more large chambers at or beyond the twilight area with additional fissures or chambers at the rear in the fully dark regions. They have a minimum roof height in the chambers of 2 m to 3 m providing protection from attack by terrestrial predators. They are often at mid-levels or lower in the strata and are well insulated overhead providing a stable temperature environment (McKenzie and Bullen 2009; Armstrong and Anstee 2000; Hall et al. 1997; Leitner and Nelson 1967). They typically contain multiple scat piles and middens of guano and food remains that include feathers and skeletal materials.

- Maternal roosts are diurnal roosts that provide additional features listed above that are able to support a reproducing population. These features usually include an interior chamber that is rising toward the rear thereby trapping warmer and more humid air at the top allowing suitable conditions to form during the period when reproductive females and pups are present (Armstrong and Anstee 2000; Churchill 1991; Churchill and Helman 1990; Pettigrew et al. 1986).

2.5.3 Threats

Threats to the Ghost Bat have been outlined by Woinarski et al. (2014) and are summarised in Table 4.

Table 4: Summary of threats to the Ghost Bat (Woinarski, Burbidge, and Harrison 2014).

Threat factor	Consequence rating	Extent over which threat may operate	Evidence base
Disturbance of (human visitation at) maternal roost sites	Severe	Moderate	Ghost Bats easily disturbed and may abandon sites where disturbance occurs (K. Armstrong pers. comm., cited in. Woinarski et al. 2014).
Habitat loss: destruction of, or disturbance to, roost sites (and nearby areas) due to mining	Moderate-severe	Moderate	Mt Etna and surrounding area contains maternal roost sites; some maternal roost sites destroyed; Mt Etna now protected in a national park and visited by tourists; declines reported at Mt Etna following mining (Worthington Wilmer 2012); Mount Consider cave west of Cairns destroyed; other sites still vulnerable; most Pilbara roosts are vulnerable to iron ore mining and the deterioration and disturbance of old underground gold and copper mines.
Collision with fences, especially those with barbed wire	Moderate	Moderate	Ghost Bats have low fecundity and survival (Hoyle et al. 2001), often fly at about fence height and substantial numbers are known to be killed when colliding with fencing wire (McKenzie and Bullen 2009; Armstrong and Anstee 2000).
Collapse or reworking of old mine adits	Minor-moderate	Minor-moderate	Many of the known nursery roosts are in old mine workings that are collapsing, flooding or subject to disturbance (Armstrong 2001; Hall et al. 1997) e.g. the Pine Creek colony roosts in an adit that is in danger of collapse (Richards et al. 2008).
Contamination by mining residue at roost sites	Moderate	Moderate	Several roosting sites in old mines have high levels of pollutants.

Threat factor	Consequence rating	Extent over which threat may operate	Evidence base
Disease	Unknown	Unknown	A possible herpes type virus appears to be affecting the Mt Etna population, but pathology yet to be confirmed (J. Augusteyn pers. comm., cited in Woinarski et al. 2014).

3 Methodology

3.1 Desktop Assessment

Database searches were conducted to identify previous Ghost Bat records within the desktop survey area, a 30 km radius from Mesa H (Table 5). The 30 km radius search area was used as it encompasses all of the recent survey work completed within the Robe Valley including the contextual survey area.

Table 5: Database searches and regional literature.

3.2 Field Survey

3.2.1 Timing and Personnel

Survey effort was concentrated to the west of Mesa H, specifically along the Robe Valley, as this area lacked recent Ghost Bat records/data. The Robe Valley to the east of Mesa H was previously surveyed by Astron in 2015 as part of the Middle Robe/ East Deepdale and Bungaroo fauna surveys and the presence of Ghost Bat activity and potential roost sites assessed. The current field survey was undertaken by John Trainer and Matthew Love, both of whom have over five years of experience conducting Level 2 fauna surveys, including bat monitoring surveys. The field survey was conducted from 3 to 9 June 2016.

Daily weather observations recorded from the Mesa J Operation were used to describe local rainfall and temperatures during the survey. During the survey 39.6 mm rain was received (between 5 and 8 June, with heavy rain occurring between 5 and 7 June) and daily maximum temperatures ranged between 20.5°C and 32.5°C. Night time minimum temperatures varied greatly with warm temperatures experienced from 3 to 6 June (19.4°C to 21.8°C) and cooler temperatures from 7 to 9 June (7.7°C to 14.6°C). A total of 271 mm rainfall was recorded at Mesa J in the 12 months preceding the survey; 133 mm below the annual average of 404 mm at Pannawonica (Station 5069) (Figure 2). Rainfall in the 12 weeks preceding the survey was less than half of the long-term mean for the same period, with 56 mm recorded (Bureau of Meteorology 2016).

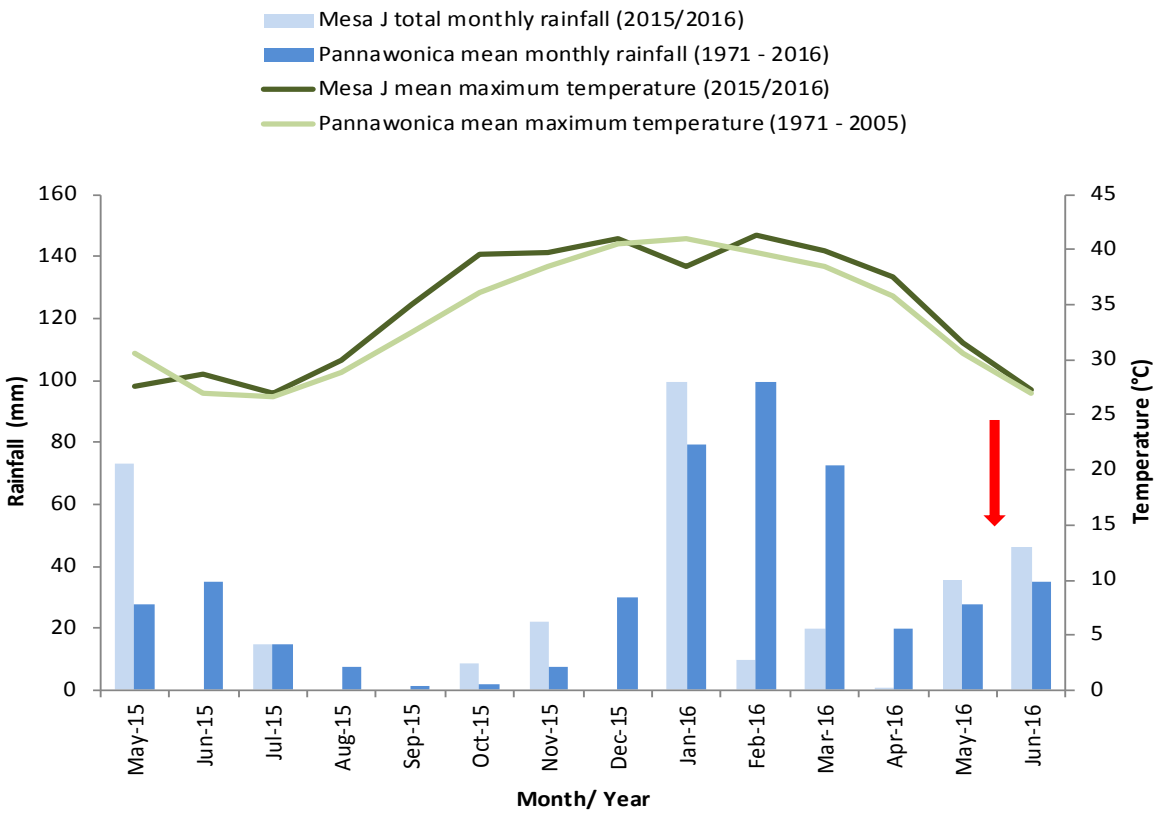

Figure 2: Pannawonica mean monthly rainfall (1971 – 2015) and Mesa J total recorded rainfall (2015/2016), and Pannawonica mean monthly maximum temperatures (1971 – 2016), and Mesa J mean monthly maximum temperatures in the 12 months preceding the survey. Red arrow indicates field survey timing. Pannawonica data from Bureau of Meteorology (2016) and Rio Tinto (2015, 2016).

3.2.2 Acoustic Bat Survey

A total of eight SM2BAT SongMeter (Wildlife Acoustics Inc USA) bat detectors were used at 12 locations completing 35 nights of overnight bat acoustic recordings. The units were situated at the entrance of caves or overhangs or permanent water sources where Ghost Bats were considered likely to forage or roost (Plate 2). One SM2 unit and the associated data for two locations was lost when the unit was crushed under a rock collapse following heavy rain, resulting in only 34 nights of bat recordings at 10 locations (Figure 3).

Due to the unique call characteristics of the Ghost Bat the SM2 units were set up to provide the best chance of recording and identifying Ghost Bat calls and reduce interference/feedback caused by the recording of Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) calls. This included the use of both ultrasonic and audio microphones to record the inaudible echolocation calls and the audible social calls used by the Ghost Bat. Analysis of recordings was undertaken by Robert Bullen (Bat Call WA 2016b, Appendix B).

3.2.3 Habitat Assessment

Habitats of the contextual survey area were assessed and mapped on their ability to support Ghost Bats, in particular the presence of roosting sites, feeding sites and quality foraging sites. In this report unless otherwise stated the term 'roost sites' is the collective term for both maternal and diurnal roosts. Significant rocky habitats such as gorges, cliffs and breakaways were identified from aerial photographs or visual inspection during the field survey. If accessible, these habitat features

were traversed by foot during the day and any caves or overhangs were inspected for signs of Ghost Bats and assessed on their suitability as roost caves or feeding sites.

Any cave or overhang that contained Ghost Bat scats and/or feeding remnants (typically feathers and small animal bones) were classified as nocturnal roosts/feeding sites and had their location recorded. The overall concentration of nocturnal roosts/feeding sites is used to indicate the key locations where Ghost Bats forage (given their methods of hunting discussed in Section 2.5.2) and their distribution through the contextual survey area. The focus of the survey was to find and assess the presence of diurnal roosts and maternal roosts. Diurnal roosts were identified by the presence of Ghost Bats (visual observation, presence of scats or low call numbers from acoustic recordings) within or at a complex cave. Maternal roosts were identified by the presence of multiple Ghost Bats (visual observation or high call numbers from acoustic recordings) within or at a complex cave. For this assessment, a complex cave is defined as one which contains domed chambers, internal passages or fissures and is deep enough to provide a different microclimate (stable temperature and elevated humidity) to the ambient.

Cave assessment datasheets were completed at each roost site to document the caves' physical characteristics and their potential to support Ghost Bats. The following details were recorded on each datasheet:

- location – coordinates measured using a handheld GPS (GDA94)
- location on slope – the position of the cave on the slope relative to the top of the slope
- local foraging habitat – broad vegetation description, approximate distance to any nearby water
- entrance description – including aspect and approximate dimensions
- internal description (if visible) – cave depth and height; presence of features such as rear passages, domed chambers
- evidence of bats
- photographs of the cave entrance.

Habitats were rated and mapped as high, moderate or low quality based on the significance each habitat has within the Ghost Bat's ecological requirements. The Ghost Bat habitats were classified according to the criteria detailed in Table 6 and a summary of survey effort is provided in Figure 3.

Table 6: Suitability/significance of habitat criteria for Ghost Bats.

Species	High quality habitat *Potential/confirmed roosting habitat*	Moderate quality habitat *Potential/confirmed feeding sites and quality foraging habitat*	Low quality habitat *Widespread foraging habitat*
Ghost Bat *Macroderma gigas*	Rocky habitats containing, or classified as likely to contain, maternal roosts and/or diurnal roosts.	Habitats containing or likely to contain shallow feeding sites/nocturnal roosts; areas of permanent water sources and gorges suitable for foraging and are likely to be used on a regular basis.	Widespread habitat providing foraging potential only.

3.3 Survey Limitations

To identify how complete the contextual survey was, it was assessed against the potential limitations suggested in Guidance Statement 56 for fauna surveys (Environmental Protection Authority 2004). Table 7 lists the key limitations of the targeted Ghost Bat survey.

Heavy rainfall was experienced on three of the six survey nights (5 to 7 June 2016) which affected the SM2 unit's ability to record Ghost Bats. The noise of the rain drowns out all frequency ranges including those where the SM2 unit record bat calls. Additionally, the heavy rain may have reduced the activity levels of Ghost Bats. The survey guidelines for Australia's threatened bats suggest that surveys not be conducted on windy, cold or rainy nights (Department of the Environment, Water, Heritage and the Arts 2010). While not preferred conditions, the rain did not fall during all post dusk and pre-dawn periods and that allowed an adequate chronology of the emergence of the bat species to be recorded (Bat Call WA 2016b).

Data was lost from two locations when the rockfall crushed one of the SM2 units. Although relative abundance data were lost, the occurrence of Ghost Bats at both sites could still be confirmed due to the presence of scats. The occurrence of Ghost Bats in the area is well documented in previous biological reports and as this survey focused on the identification of roost sites rather than the presence/absence of this species it is not deemed a significant limitation.

The heavy rain also created issues with access as many of the tracks were unable to be safely driven on for three of the survey days. As such, on these days access was limited to areas surrounding sealed roads or well used tracks. Overall, this did not impact the survey effort as it just adjusted the areas of focus to sites closer to the main tracks during those days.

Many of the roost caves could not be assessed properly due to the health and safety limitations that did not allow field personnel to enter caves. Internal dimensions were limited to what could be identified visually from the entrance of each cave. To properly assess the size and significance of each roost site, an internal assessment of each cave is required.

Although Mesa H has been extensively surveyed for fauna, only a fraction of the surrounding area has been directly assessed for Ghost Bat presence/suitability. Due to the size of the contextual survey area and the survey effort (two personnel for six survey days) not all areas could be ground-truthed. The contextual survey area was mapped based on the topography identified in the field survey and from aerial photographs and as such it provides an assessment of the likelihood of roost sites. The only way to confirm the presence of roost sites is to walk the gorge/breakaway habitats and assess each cave individually; this was outside of the designated scope for this project. The survey effort and breakaway/gorge locations assessed are displayed in Figure 3. However, the intensity of both the current survey and historical surveys undertaken in the vicinity of Mesa H was considered adequate to identify and assess potential areas of significance.

Table 7: Statement of limitations for the targeted Ghost Bat survey.

Potential limitation	Statement regarding potential limitations
(i) Competency/experience	The ecologists responsible for conducting the survey have extensive experience in conducting Level 2 vertebrate surveys, including targeted bat surveys in the Pilbara.
(ii) Scope What faunal groups were sampled and were some sampling methods not able to be employed because of constraints such as weather conditions.	The survey scope was able to be completed with a total of 35 nights of SM2 acoustic recording and cave assessments undertaken in significant habitats. Internal cave inspections could not be undertaken due to HSE issues. Harp trapping or thermal imaging was not required as part of the scope of this survey.
(iii) Proportion of fauna identified, recorded and/or collected	This was a targeted Ghost Bat survey and did not record any other species or assemblages. It is not possible to determine Ghost Bat abundance/population number from echolocation records; Ghost Bat activity levels provide a relative measure of the population within the contextual survey area.
(iv) Sources of information Previously available information (whether historic or recent) as distinct from new data.	Adequate information was available from database searches and previous studies in the Mesa H survey area and desktop survey area and region.
(v) Proportion of task achieved Further work which might be needed?	The field survey and the desktop assessment were undertaken and considered complete. Any further data required such as population estimates and numbers using each maternal roost are outside of the scope of this assessment and would require a more detailed work program.
(vi) Timing/weather/season/ cycle	The heavy rain experienced during much of the survey period limited the recording ability of the SM2 units and potentially the activity levels of the Ghost Bats. The presence of Ghost Bats in the area is well documented in previous biological reports and as this survey focused on the identification of roost sites rather than the presence/absence of this species it is not deemed a significant limitation.
(vii) Disturbances e.g. fire, flood, accidental human intervention which affected results of survey	A rockfall caused by heavy rain crushed a SM2 unit, losing four nights of data from two separate locations. The data lost were from feeding sites that contain Ghost Bat scats. Although relative abundance data was lost, the presence of Ghost Bats at both sites could still be confirmed. Therefore, the loss of the SM2 unit did not significantly affect the results of the survey.
(viii) Intensity In retrospect, was the intensity adequate?	The intensity of the surveys was considered adequate to ground-truth the desktop assessment and to assess potential areas of significance.
(xi) Completeness Was the relevant area fully surveyed?	Due to the large survey area and the fact that assessments had to be completed on foot, not all breakaways/gorges could be assessed. The points of interest identified during the desktop assessment were suitably covered with all other areas mapped via aerial photographs.
(x) Resources Degree of expertise available in animal identification to taxon level.	All personnel involved in identification have extensive experience in conducting bat monitoring surveys in the Pilbara. All bat call identifications were conducted by Robert Bullen (Bat Call WA) who is considered an expert in this field.
(xi) Remoteness and/or access problems	The majority of significant habitats were able to be accessed by vehicle or on foot. There were two areas classified as high quality

Potential limitation	Statement regarding potential limitations
	habitat that were not able to be assessed due to lack of access. Due to safety and heritage related constraints, internal inspections of caves were not permitted. Ghost Bat roost caves were assessed by external visual observation only, with the internal structure beyond visual boundaries unknown. Cave assessments were used to provide an indication as to whether Ghost Bats were recorded or may utilise the caves as habitat.
(xii) Availability of contextual information e.g. biogeographic information on the region.	Database searches and previous fauna surveys in the desktop survey area provided by Rio Tinto provided contextual information.

4 Results

4.1 Desktop Assessment

The database searches and literature review indicate that 79 Ghost Bat records (not including records from the current survey) exist within 30 km of the Mesa H survey area (Figure 4). The majority of these records (approximately 53%) are from the identification of scats (42 records) or acoustic records (15 records). These types of records provide information on the presence of this species at the location but do not provide the relative abundance or habitat context (i.e. foraging individual vs roost site).

Where Ghost Bat records were identified as occurring at a cave, but its dimensions or habitat context were not stated, some inferences were used to classify the record. Unless specifically stated, any caves that contain scats or feeding material are classified as nocturnal feeding roosts, that have a visual record of a single Ghost Bat are classified as a potential diurnal roost, and caves with visual records of multiple Ghost Bats are classified as a potential maternal roost. Only records of roost sites that are supported by cave assessments and/or visual sightings or high call readings from acoustic recordings are stated as confirmed roost locations. For many of the potential roost sites, the consultant's reports provided limited information on the cave dimensions, habitat context or use by Ghost Bats; as such, little can be inferred from these records.

From the desktop assessment (not including records from the current survey) a total of seven diurnal roost sites (six confirmed and one potential) and two maternal roost sites (one confirmed and one potential) have been previously recorded in the wider desktop survey area. A summary of the Ghost Bat records from previous ecological surveys is presented in Table 8 and the comprehensive data from the desktop assessment is detailed in Appendix C. The numbers of diurnal and maternal roosts are high for some earlier surveys; however, more recent targeted assessments have reassessed these caves, and fewer maternal and diurnal roosts have been confirmed. A summary of diurnal and maternal roosts confirmed following the current survey and more recent targeted caves assessments is presented in Table 9.

The most significant record from the desktop assessment was a potential maternal roost (reference number 11, Appendix C) on Mesa F where 24 Ghost Bats were captured in harp traps at a cave (Biota Environmental Sciences 2009). This cave was confirmed as a permanent maternal roost (MF01) in 2017 when 70 individuals were found to be present (Bat Call WA 2017a). This cave had two entrances opening into a mid-size chamber. It had multiple internal chambers between 2.5 m and 7 m high. The cave was located approximately 4 km from the Robe River.

One cave on Mesa B (MBC-05) was determined to be a diurnal roost with the ability to support a maternity colony (Bat Call WA 2016a). This cave included an internal shape adequately deep and dark along with a high domed chamber at the rear, multiple nocturnal roost opportunities, multiple daytime refuge opportunities, multiple early evening observation sites and a major productive riparian zone within 5 km (Bat Call WA 2016a).

Table 8: Summary of Ghost Bat records from biological surveys in the vicinity of Mesa H.

Report title	Company	Year of report	Distance from Mesa H	Ghost Bat records
Mesa H Level 1 Flora, Vegetation and Fauna Assessment	Astron	2014	Within Mesa H	7 diurnal roosts 4 acoustic records 2 remains

4.2 Field Survey

4.2.1 Habitat Assessments

Habitats were classified as high, moderate or low corresponding to the resources they provide to the Ghost Bat's ecological requirements (Table 10). Data collected from the cave assessments undertaken during the survey are detailed in Appendix C and the habitat mapping presented in Figure 5.

High quality habitats correspond to the locations where diurnal roosts or maternal roosts were identified or areas where aerial photography showed the topography corresponded to significant gorges or landforms likely to contain suitable caves for roost sites. High quality habitat was restricted to the gorge system located directly south of the Mesa H survey area (Plate 3), the gorges located within Mesa G (Plate 4), gorges on the western side of Mesa H, and the area surrounding the potential maternal roost in Mesa F to the south-west of the contextual survey area. A total of 248.7 ha (0.3%) of the contextual survey area and 4.1 ha (0.1%) of the Mesa H survey area contain habitat considered as being high quality habitat for Ghost Bats.

Moderate quality habitats correspond to rocky breakaways and cliffs where feeding sites were recorded or considered likely to occur and sites where permanent/semi-permanent water sources occur. These areas were mapped based on the type of geology identified in the field visit or from the topography identified from aerial photographs. The areas mapped as moderate quality habitat lack the significant gorges and gullies likely to contain suitable caves for roost sites (Plate 5). Permanent/semi-permanent water sources were classified as moderate quality habitat due to the fact they are likely to be important foraging sites used on a regular basis. A total of 2,531.1 ha (2.7%) of the contextual survey area and 270.4 ha (6.3%) of the Mesa H survey area contain habitat considered as being moderate quality habitat for Ghost Bats.

Low quality habitats correspond to areas of rocky hills, low hills, stony/clay plain and drainage lines where caves were not recorded or considered unlikely to occur. Ghost Bats forage over a variety of habitat types, as such all natural habitats within the contextual survey area provide foraging habitat for this species. Besides foraging these areas do not provide another biological function such as roosting or breeding sites. The vast majority of the contextual survey area (90,425.3 ha and 95.6%) and the Mesa H survey area (4,624.8 ha and 93.6%) contain habitat considered as being low quality habitat for Ghost Bats.

Table 10: Summary of habitat quality in the contextual survey area.

Habitat quality	Area in the contextual survey area (ha)	Proportion in the contextual survey area	Area in the Mesa H survey area (ha)	Proportion in the Mesa H survey area
High quality habitat	248.7	0.3%	4.1	0.1%
Moderate quality habitat	2,531.1	2.7%	270.4	6.3%
Low quality habitat	90,425.3	95.6%	4264.8	93.6%

4.2.2 Nocturnal Feeding Roosts

During the field survey a total of 26 nocturnal feeding roosts were identified by the presence of Ghost Bat scats and feeding debris. The nocturnal feeding roosts were typically open overhangs along breakaway habitat or in small caves. Scats and feed debris were usually concentrated on the ground under the domed sections of caves/overhangs, indicating a favoured foraging area and feeding location. Sites frequently used often have a large build-up of scats (midden) indicating prolonged use (Plate 6 and Plate 7).

Although foraging evidence is associated with rocky habitats and nocturnal feeding roosts, Ghost Bats forage over all habitat types only returning to nocturnal feeding roosts to eat their prey. Nocturnal feeding roosts were recorded across the contextual survey area in all rocky habitats surveyed indicating the foraging habitat for this species is widespread. Nocturnal feeding roosts are not mapped as part of this assessment.

4.2.3 Significant Roost Sites

During the field survey, four diurnal roosts and two potential maternal roosts were recorded (Table 11). With the exception of the diurnal roost site on the northern side of Mesa C, the roost sites were all located in either side gorges of the southern face of Mesa G or in the large gorge system located directly south of Mesa H. Both potential maternal roosts were large complex caves that were located on the southward facing sections of gorge systems. Based on observations from the field survey, the gorges with southward facing walls generally contained the most suitable geology and conditions to form complex, deep caves.

Since the field survey was completed, further targeted cave assessments have assessed one of the diurnal roosts (DRJT1) as a nocturnal feeding roost and possibly a diurnal roost (MCC02) (Bat Call WA 2017c) and one of the potential maternal roosts (MCJT1) with 12 individual Ghost Bats sighted as only a diurnal roost (G02) (Bat Call WA 2017a).

Potential maternal roost- 3 individuals sighted	A4	Gorge south of Mesa H	Open and large (20 m x 40 m)	60 m deep with 3 large domed chambers and 2 rear passages	
Potential maternal roost - 12 individuals sighted	MCJT1^	Gorge in Mesa G	Complex with multiple tight entrances	40 m deep with multiple domed caverns and rear passages	
Diurnal roost - no scats but presence expected due to cave dimensions	RCML1	Gorge in Mesa G	Open (15 m x 30 m)	25 m deep with 3 rear passages and an open domed cavern	

*since survey, roost confirmed as a nocturnal feeding roost, possible diurnal roost (MCC-02) (Bat Call WA 2017c)

^since survey, roost confirmed as a diurnal roost only (G02) (Bat Call WA 2017a)

4.3 Environmental Context and Ghost Bat Records

The habitat mapping and Ghost Bat records from both the desktop assessment and the field survey in the contextual survey area were compared against the geological mapping (Stewart et al. 2008), land systems (van Vreeswyk et al. 2004) and the pre-European vegetation mapping (Beard 1975). The mapping data that most consistently correlated to the Ghost Bat habitat mapping and records were the land systems mapping.

Land systems mapping is a comprehensive description of biophysical resources including soil and vegetation condition across the Pilbara. As the Ghost Bat requires caves for its important ecological requirements (feeding, roosting and breeding), land systems that contain critical habitat were identified and mapped. The associations of each land system with Ghost Bat habitats and records are detailed in Table 12 and mapped in Figure 6.

The Newman and Robe land systems contain the most significant Ghost Bat habitat and they coincide with the majority of the high quality habitat (99%), diurnal roosts and maternal roosts (both potential and confirmed). The Newman land system is the most important of these as it supports the high quality habitat and roost sites at Mesa B, C, G and the gorge system south of Mesa H. The only exception to this is the maternal roost (RVM04/MF01) at Mesa F (reference number 11 in Appendix C) that occurs in the Boolgeeda system. However, this site occurs only 60 m from the boundary of the Boolgeeda land system and the Robe system suggesting some association with the Robe land system.

Moderate quality Ghost Bat habitat and nocturnal feeding roosts are strongly associated with the Newman, Robe and Nanutarra land systems with 92.5% of the moderate habitat and all but three of the nocturnal feeding roosts in the contextual survey area occurring in these three land systems. The Newman, Robe and Nanutarra land systems (Van Vreeswyk et al. 2004) are described below.

Newman system: extensive high plateaux, mountains and strike ridges with vertical escarpments and steep scree slopes and more gently inclined lower slopes; moderately spaced dendritic and rectangular tributary drainage patterns of narrow valleys and gorges with narrow drainage floors and channels. The system contains iron ore deposits which are currently being mined and deposits which are likely to be mined in the future. Approximately 14,580 km² of this Land system occurs in the Pilbara and is widespread between Pannawonica and Newman.

Robe system: erosional surfaces; formed by partial dissection of old Tertiary surfaces, dissected plateaux and long lines of low mesas along present and past river valleys, indented near vertical breakaway faces and steep slopes with limonite outcrop and pisolitic gravelly mantles, restricted gravelly lower slopes and closely to moderately spaced narrow tributary drainage floors. The system contains iron deposits which are currently being mined or which may be mined in the future. Approximately 850 km² of this Land system occurs in the Pilbara and is widespread between Pannawonica, Port Hedland and Newman, with a concentration south of Pannawonica.

Nanutarra system: erosional surfaces; formed by partial dissection of an old plateau of marine sediments - low plateaux, dissected plateaux, mesas, buttes and low hills with rounded crests, short stony footslopes with parallel and radial drainage patterns, narrow dendritic drainage zones and creeklines between dissected plateaux and mesas. Approximately 697 km² of this Land system occurs in the Pilbara and is concentrated to the west of Pannawonica.

Table 12: Ghost Bat habitat compared against land system mapping within the contextual and Mesa H survey areas.

5 Discussion and Conclusions

Mesa H has been extensively surveyed with four biological surveys conducted within the last five years (the current survey; Astron Environmental Services 2014, 2016b; Bat Call WA 2017b; Biota Environmental Sciences 2011). As such, the presence and habitat for the Ghost Bat in the Mesa H survey area is well documented. The Mesa H survey area contains 22 Ghost Bat records (including caves, individuals and acoustic recordings) accounting for approximately 28% of all Ghost Bat records from the desktop survey area. Following recent targeted cave assessments, a total of two confirmed diurnal roosts occur within the Mesa H survey area. Significant habitat for Ghost Bats in the Mesa H survey area occur in the small sections of a gorge/breakaway habitat (approximately 4.1 ha mapped as high quality habitat) located along the western side of Mesa H and a small portion of a gorge system to the south (and outside) of the Mesa H survey area (Figure 5). The number of records is to be expected given the geology of the Mesa H survey area and the fact it has been extensively surveyed in recent years.

Although high quality habitat is present within the Mesa H survey area, the majority of roost sites (including the more important one maternal and two potential maternal roosts) and high quality habitat (98.4%) are located in areas outside of the Mesa H survey area boundary. The most significant Ghost Bat habitats in the contextual survey area are located within the gorges on the lower Robe Valley Mesas, Mesa G and the gorge system to the south of (and outside) Mesa H, although the only confirmed maternal roost occurs on Mesa F. The gorges on Mesa G contained one diurnal roost, one potential maternal roost on Mesa B and one potential diurnal roost on Mesa C. The gorge to the south of Mesa H was too large to properly survey in the time available and only received a preliminary assessment. One potential maternal roost and two diurnal roosts (all confirmed) were identified; however, based on the geology and size of the gorge system more roost sites are expected.

In the Chichester subregion Ghost Bats are more numerous (approximately 1,500 to 2,000 individuals) and are focused in medium to large groups around roosts in abandoned mine shafts and adits. The contextual survey area occurs in the Hamersley subregion where Ghost Bats are more widespread, occur in smaller numbers (approximately 350 individuals) and where relatively few breeding records exist (Department of the Environment and Energy 2016). Observations from the survey and the desktop components support this statement with all roost sites containing a small numbers of individuals (1 to 70 individuals).

All of the records obtained through the desktop assessment were collected by environmental consultants and were therefore biased towards mining tenements in the area, specifically along the Robe Valley. The majority of records are from scats and acoustic recordings; although a number of targeted cave assessments have been conducted in recent years, and therefore do not reflect the location of roost sites (Bat Call WA 2016a, 2017a, 2017b, 2017c). The number of Ghost Bat records from the desktop assessment and field survey suggest that the Ghost Bat is well distributed across the Robe Valley and within the vicinity of the Mesa H survey area but in small numbers.

Armstrong and Anstee (2000) stated that roost sites in the Hamersley Ranges are associated with the Marra Mamba Iron and Brockman Iron formations. In the contextual survey area, roost sites were associated with the Robe Pistolite and Brockman Iron formations but not with the Marra Mamba Iron formations. However, the geological formation mapping does not correlate as strongly with potential Ghost Bat habitat as the land systems mapping does. In the contextual survey area, the land systems mapping shows relationship between the Robe and Newman systems and the presence of both diurnal and maternal roost sites. Within the contextual survey area approximately 96% of the Newman system and 75% of the Robe system are located outside of the Mesa H survey area, indicating that both of these land systems are well represented locally and are widespread

throughout the Pilbara (Table 2). Nocturnal feeding roosts are expected to occur across all rocky habitats in all of the land systems; however, during the field survey they were not found in some land systems due to the fact that survey effort focused on likely roost locations rather than a broad scale assessment. As such, the habitat mapping gives a clearer indication of potential presence of nocturnal feeding roosts (moderate quality habitat) rather than the feeding site records.

The key threat to the Ghost Bat is the habitat loss and degradation due to mining activities (McKenzie and Hall 2008). The species' slow reproductive rate, and the lack of suitable habitat which restricts its movement, renders it vulnerable to threats and localised extinctions (Queensland Department of Environment and Heritage Protection 2015). The Pilbara population is genetically distinct at both a regional and local scale (Armstrong et al. in prep). The genetic isolation of each subpopulation suggests areas are unlikely to be recolonised if a local extinction occurs (Queensland Department of Environment and Heritage Protection 2015). In the Pilbara, most known breeding sites of the Ghost Bat are confined to underground gold/copper mines that are now collapsing or being open cut, and to caves in banded ironstone strata that may be mined out over the next 30 to 50 years. On current trends, most of its Pilbara roost sites may be destroyed over the next 30 years (Woinarski et al. 2014). Numbers are likely to decline by over 30% in Western Australia in the future with local extinction in areas such as the central and eastern Hamersley Range, with the extent of occupancy likely to decline by over 10,000 km² (Bullen pers. comm., Department of the Environment and Energy 2016). However, barbed wire fences are being replaced in crucial areas and breeding sites are being identified for protection (Department of Parks and Wildlife 2015), which may reduce the current rate of decline.

The survey was completed prior to the known breeding period of this species in the Pilbara and the survey methods employed, specifically the lack of harp trapping, mist netting or thermal tracking cameras means that maternal roosts were identified on the presence of multiple Ghost Bats rather than breeding records. Relatively little is known about this species' roost site fidelity, seasonal movements or local population estimates in the Pilbara, let alone in the contextual survey area or the roost sites identified in this assessment.

2	29 Aug 2017	Second issue incorporating client comments

Summary
Bat species presence, with an estimate of activity level, is presented for ten sites near Mesa H along the Robe River valley in the Pilbara, WA. Astron Environmental Services (Astron) carried out an echolocation based survey during June 2016. Bat Call WA has reviewed the recordings made and provided species lists for the bats present.

Nine species of echolocating bats were recorded including the two EPBC Act listed species from the Pilbara, the Orange Leaf-nosed Bat, Pilbara form (*Rhinonicteris aurantia*) (PLNb) and the Ghost bat (*Macroderma gigas*). Ghost bat calls were detected at four sites, all cave entrances or overhangs. PLNb calls were detected foraging in medium numbers at one site and in low numbers at five sites. A summary of call numbers and timing is provided. Activity levels for the common species are provided by site. No previously unidentified PLNb roost is indicated by these data

Habitats
The sites for the survey were chosen by Astron. Details of the sites are presented in Table 1. Three were in cave entrances, six under overhangs and one was on a semi-permanent pool within a gorge. The locations are shown in relation to Robe River valley features in Figure 1.

Characteristics of the calls recorded are presented in Table 2.

Bat Fauna
An assemblage of nine echolocating species was confirmed as present at the study sites, Tables 2 and 3. Species activity levels were low to high, which is expected for the study area habitat and the time of year, see criteria below.

Multiple Ghost bat calls were detected at four sites, Bat A1, ‘A4, ‘2 and ‘7 although the patterns of calls at these sites were interrupted by nights with extensive rainfall and also probably impacted by two nights with low temperatures, see below. The pattern though is adequate to show that Ghost bats are using most well defined caves and some overhangs in the district.

PLNb were detected at six of the sites. One site, Bat A4 had a medium activity level with a total of 140 calls being recorded over six nights. Five sites had low activity levels. Detections within 60 minutes of dusk civil twilight (CT) were recorded at the three southern sites. The earliest time differentials from dusk CT were at site ‘A4, 30 minutes on the 6th June (overcast night with rainfall periods), 35 minutes at ‘A2 and 50 minutes at ‘A3. The latest calls were between 25 and 45 minutes before CT, on the 6th June at ‘A4, and at sites ‘A3 and ‘A1, Figure 1. The closest call to CT at Bat 2 was 90 minutes and the single call at Bat 7 was close to midnight. These time differentials, together with the progressively increasing time differentials from south to north, indicate that the PLNb probably originated from a known roost approximately10 km south of the study area.

Taxonomy presented herein is after Reardon *et al.* (2014) and Jackson and Groves (2015).

Survey Timing, Moon Phase and Weather
The echolocation survey was conducted between 3rd and 8th June 2016.

The first four sampling evenings were warm with minimum overnight temperatures between 15 and 20^{O}C while the last two were cold with temperatures around 10^{O}C. Rain fell on the nights of 4th , 5th and 6th June. The moon in this period was new.

During the survey, sunset, sunrise, dusk and dawn CT were within two minutes of 17:39, 06:49, 18:03 and 06:25 respectively.

Survey Team
Sites were chosen and detectors placed by Astron ecologists. Bob Bullen of Bat Call WA completed analysis of echolocation recordings.

Sampling
The survey consisted of completing a total of 34 overnight bat sound recordings, beginning at twilight, at ten locations within the survey area. The recordings were "continuous" (Hyder *et al.* 2010) made using SM2BAT+ SongMeter (Wildlife Acoustics Inc., USA) detectors. The jumper and audio settings used followed the manufacturer's recommendations for bat detection contained in the user manual (Wildlife Acoustics 2010).

For the recordings, once reformatted as .wav files, COOL EDIT 2000 (now available as AUDITION from Adobe Systems Inc.) was used to display each sequence for identification. Calls were identified manually. Only good quality call sequences were used. Details of calls analysed are provided in Table 2 as recommended by Australasian Bat Society (ABS 2006). Reference data for the species identified are available in Bullen and McKenzie 2002, McKenzie and Bullen 2003 and McKenzie and Bullen 2009.

Bat activity was then characterised as "Low", "Medium" or "High" based on the rate of call sequences recorded.

- Low species activity is referred when a species is recorded with call spacing less often than ten minutes.
- Medium species activity refers to call recordings more often than 10 minutes but less often than two minutes apart for at least an hour followed by sporadic records for the remainder of the session.
- High species activity refers to call recording more often than two minutes apart for at least two hours followed by reasonably regular records for the remainder of the session.

Survey Limitations
The sites surveyed were accessible on foot and the SM2, using an omnidirectional microphone, was set on the ground with the microphone horizontal. Species are unlikely to be under-represented as a result.

Bat species density away from cave or adit entrances is impossible to estimate from echolocation records. Bat activity is therefore substituted as an approximate guide to the relative numbers of each species using the study area.

Heavy rain on three nights and cold temperatures on two nights have resulted in lower than typical bat call numbers for the time of year.

Executive Summary

Rio Tinto on behalf of Robe River Mining Co. Pty. Ltd is evaluating the potential development of the Mesa H deposit located adjacent to the Mesa J Operation and approximately 13 kilometres to the south-west of the town of Pannawonica. Astron Environmental Services has been commissioned to undertake a two-phase Level 2 vertebrate and Short Range Endemic invertebrate fauna assessment in the Mesa H survey area which is approximately 4,930 hectares in size.

Vertebrate Fauna

Seven broad fauna habitat types were recorded in the survey area: Riverine, Drainage Line, Gorge, Breakaway, Rocky Hills, Low Hills and Slopes, and Loamy/Stony Plain. Areas of disturbed habitat were prevalent in the Low Slopes and Hills habitats on the top of Mesa H and the Loamy/Stony Plains habitat in the form of drill pads and associated tracks. The Gorge, Riverine and Breakaway habitats in the survey area are considered important for fauna due to the microhabitats they provide such as caves and water pools. The Gorges and Breakaways in particular contain a high diversity of microhabitats; it represents an important site of refuge due to its location close to the Robe River and as habitat for conservation listed fauna.

There were 169 vertebrate fauna species recorded within the survey area, including two amphibian species, 55 reptile species, 85 bird species and 27 mammal species (including four introduced species). The faunal assemblage recorded is considered typical of the Hamersley Range subregion extending from near Pannawonica to Mt Brockman.

Eight conservation listed fauna species have been recorded in the survey area: Pilbara Olive Python (VU; S3) (*Liasis olivaceus barroni*), Northern Quoll (EN; S2) (*Dasyurus hallucatus*), Pilbara Leaf-nosed Bat (VU; S3) (*Rhinonicteris aurantia*), Ghost Bat (VU; S3) (*Macroderma gigas*), Rainbow Bee-eater (Mi; S5) (*Merops ornatus*), Eastern Great Egret (Mi; S5) (*Ardea modesta*), Lined Soil-crevice Skink (P4) (*Notoscincus butleri*) and Western Pebble-mound Mouse (P4) (*Pseudomys chapmani*).

Four of the eight recorded conservation listed species are classified under the *Environment Protection and Biodiversity Act 1999* as 'Matters of National Environmental Significance' species: the Pilbara Olive Python; Northern Quoll; Ghost Bat; and Pilbara Leaf-nosed Bat. A single juvenile Pilbara Olive Python was recorded within the Riverine habitat and two Pilbara Olive Python scats were recorded within the Breakaway habitat type of the survey area. The Northern Quoll was recorded 32 separate times during the survey comprising: six capture records (four confirmed individuals); 22 remote camera records from 14 different locations; and from four scats within the Breakaway, Riverine and Gorge habitat types. The Pilbara Leaf-nosed Bat was recorded at eight of the 14 SM2 bat detector locations, all at low activity levels apart from BAT 14 (located in the mouth of a Gorge) which recorded 257 calls. Further data and analysis of the BAT 14 sites suggests that the Pilbara Leaf-nosed Bats likely originated from a known roost site approximately 10 kilometres south of the survey area. No diurnal or maternal roost sites suitable for the Pilbara Leaf-nosed Bat were recorded in the survey area. The Ghost Bat was recorded twice through scat collections and acoustic recordings. Seven caves were previously identified in the Astron 2014 survey of Mesa H, two of which were deemed to be diurnal roosts (possible maternal roosts) following a targeted cave assessment conducted by Bat Call WA Pty Ltd. Another three of the caves (two caves part of one system) were determined to be nocturnal feeding roosts and the other two caves were considered to not be used. An additional seven sites identified by Bat Call WA Pty Ltd during the targeted cave assessment were deemed to be nocturnal feeding roosts.

The results from the survey suggest that the survey area supports a diverse and representative vertebrate fauna assemblage with a varied array of microhabitats for fauna species to exploit. The

microhabitats of the Gorge, Riverine and Breakaway habitat types contain ecological features important to conservation listed fauna such as the Pilbara Olive Python, Northern Quoll, Ghost Bat and Pilbara Leaf-nosed Bat.

Short Range Endemic Invertebrate Fauna

The fauna habitats most suited to Short Range Endemic species, namely the Breakaway, Gorge and Riverine habitats, did not support rich Short Range Endemic communities. Conversely, the Loamy/Stony Plains habitat supported some Short Range Endemic species but this habitat type is widespread and has little prospect to restrict dispersal in Short Range Endemic fauna. Prospective Short Range Endemic habitats within the survey area are not restricted at the local, sub-regional or regional scale.

A total of 36 specimens belonging to at least 14 invertebrate morphospecies were collected from the survey area. Scorpions were the most diverse group with six species and 12 specimens, followed by slaters (three species; 16 specimens), pseudoscorpions (two species; four specimens) and spiders (three species; four specimens). No centipedes, harvestmen, millipedes or snail specimens (aquatic or terrestrial) were collected during the current survey. No listed invertebrate species were collected during the survey. Based on these results, nine of the species (64%) were not considered to be, or are unlikely to be, Short Range Endemics. No confirmed Short Range Endemic species were collected; however, five species (36%) were classified as potential Short Range Endemic species, principally in the scorpion (two species), spider (two species) and slater (one species) faunas. These species are:

- slaters – *Buddelundia* '61'
- scorpions – *Lychas* 'sp. nov. 1' and *Lychas* 'sp. nov. 2'
- spiders – *Karaops feedtime* and *Karaops* sp. indet.

The identity and distribution of these potential Short Range Endemic species is uncertain, primarily due to a lack of taxonomic resolution. Some of the potential Short Range Endemic species are likely to be more widespread but remain poorly documented. Molecular analyses were undertaken on the arachnid specimens because they were either juvenile specimens or from complex family groups that have a cryptic morphology. The four potential Short Range Endemic arachnid species were identified using genetic data and are classified as potential Short Range Endemics in the Western Australian Museum sub-category 'Molecular Evidence'. The potential Short Range Endemic slater species was identified using morphology and was classified as a potential Short Range Endemic in the sub-category 'Data deficient'.

1 Introduction

1.1 Project Background

Rio Tinto, on behalf of Robe River Mining Co. Pty. Ltd (the Proponent), is evaluating the potential development of the Mesa H deposit located adjacent to the Mesa J Operation and approximately 13 km to the south-west of the town of Pannawonica. Key components of the pre-feasibility and feasibility studies being undertaken are the environmental surveys which are required to inform the environmental assessment process for the potential development of the Mesa H deposit. Astron Environmental Services (Astron) has been commissioned to undertake some of these environmental surveys. This report presents the outcome of the Level 2 vertebrate and Short Range Endemic (SRE) invertebrate fauna assessment at the Mesa H deposit (the survey area). The survey area is 4,930 ha (Figure 1).

1.2 Scope and Objectives

The objective of the assessment was to undertake a two-phase Level 2 assessment of vertebrate fauna and targeted SRE invertebrate fauna through a desktop assessment and field survey, and to incorporate data from previous biological surveys. The resultant data has been utilised to produce this report which is intended to support and inform the environmental assessment process in accordance with the requirements of the Environmental Protection Authority (EPA). Astron completed the first phase of the assessment in 2015 (Astron Environmental Services 2015). The scope of works was to undertake a:

- **desktop assessment**, including database searches and literature review of available resources
- **two-phase vertebrate fauna** field survey, including:
  - fauna sampling
  - targeted Matters of National Environmental Significance (MNES) species sampling and searches
  - fauna habitat mapping
- **targeted SRE field survey**, including:
  - targeted survey and searches
  - dry pitfall trap sampling
  - SRE fauna habitat mapping.

Astron conducted the fauna survey in accordance with the following:

- Position Statement No. 3 (Environmental Protection Authority 2002)
- Technical Guidance - Terrestrial Fauna Surveys (Environmental Protection Authority 2016a)
- Technical Guidance - Subterranean Fauna Surveys (Environmental Protection Authority 2016b)
- Technical Guidance - Sampling Methods for Terrestrial Fauna (Environmental Protection Authority 2016c)

- *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) referral guideline for the Endangered Northern Quoll *Dasyurus hallucatus* (Department of the Environment and Energy 2016)
- Rio Tinto data standards (Rio Tinto Iron Ore 2016a, 2016b, 2016c, 2016d, 2016e).

The scope and key limitations of the survey are outlined in Table 1. Section 3.5 of this report provides more detail on the limitations of the survey.

Table 1: Summary of Astron's vertebrate fauna and SRE invertebrate fauna assessment.

Level of survey	Survey area size	Survey timing	Relevant regulatory guidance documents	Key survey limitations
Level 2 two-phase survey	4,930.2 ha	24 September to 3 October 2015 27 April to 9 May 2016	• Position Statement No. 3 (Environmental Protection Authority 2002) • Technical Guidance - Terrestrial Fauna Surveys (Environmental Protection Authority 2016a) • Technical Guidance - Subterranean Fauna Surveys (Environmental Protection Authority 2016b) • Technical Guidance - Sampling Methods for Terrestrial Fauna (Environmental Protection Authority 2016c) • *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) referral guideline for the Endangered Northern Quoll *Dasyurus hallucatus* (Department of the Environment and Energy 2016)	• Rainfall preceding both phase 1 and phase 2 of the fauna surveys was below average. • Large portions of the Low Hills and Slopes and Loamy/Stony Plains habitat on top of Mesa H were affected by exploration drilling pads and their associated tracks. • These are classified as minor limitations only and are not expected to have a major effect on survey outcomes.

2 Environmental Context

2.1 Physical Environment

2.1.1 Climate

The climate of the Pilbara region of Western Australia is classified as arid tropical with two distinct seasons: a hot, wet summer (October – April) and a mild, dry winter (May – September) (Bureau of Meteorology 2016).

Based on long-term climatic data from the nearest Bureau of Meteorology (BOM) weather station at Pannawonica (Station 5069) (approximately 13 km north-east of the survey area) the mean annual rainfall since 1971 is 403.5 mm (Bureau of Meteorology 2016). The mean maximum daily temperatures range between 28°C and 41°C, and range above 30°C for much of the year (Bureau of Meteorology 2016) (Figure 2).

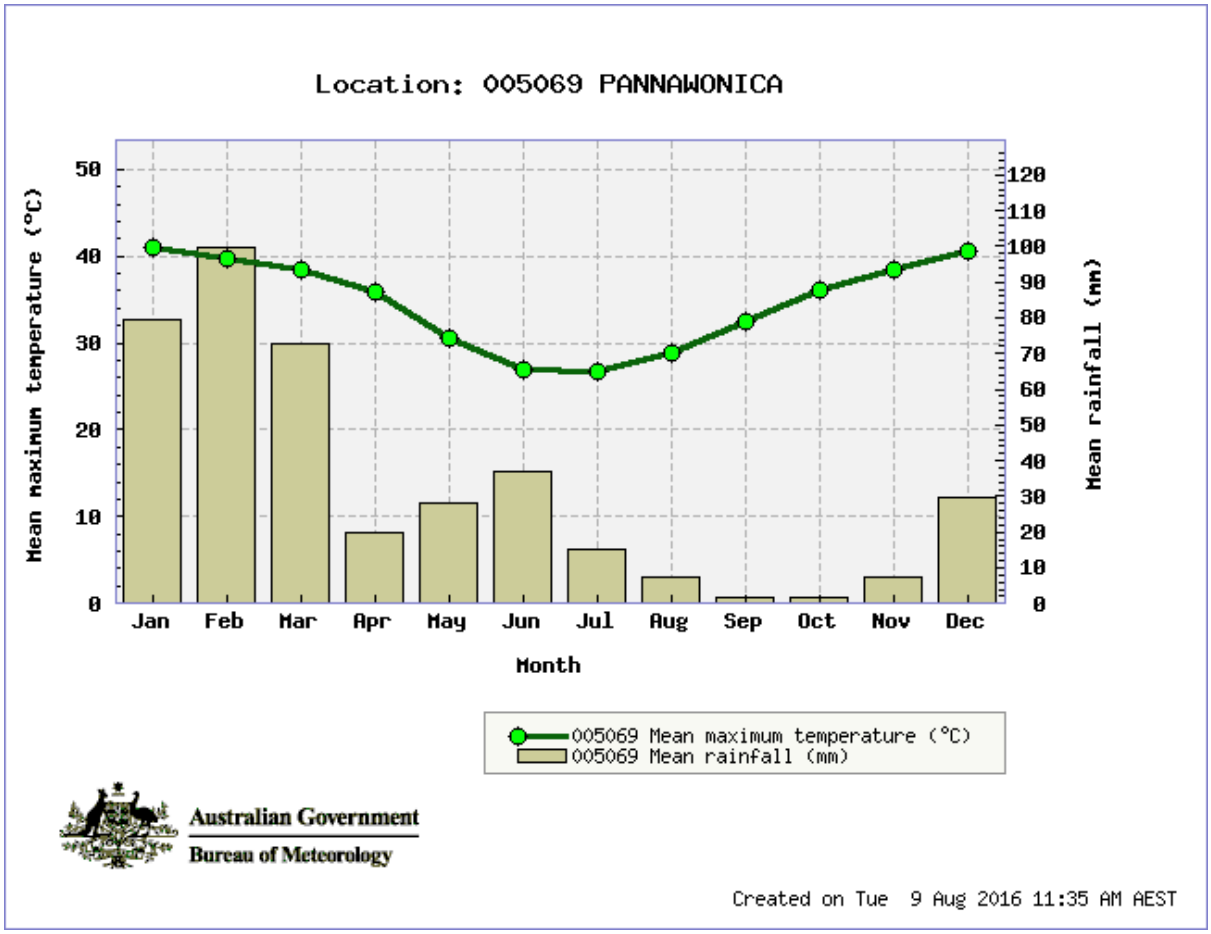

Figure 2: Climate data for Pannawonica (Station 5069). Mean annual rainfall data has been calculated from 1971 – 2016 and mean maximum temperature has been calculated from 1971 – 2005 (Bureau of Meteorology 2016).

2.1.2 Geology and Soils

The survey area occurs on the Hamersley Basin which overlies the Archaean Pilbara Craton and comprises of mafic and felsic volcanics, shale, siltstone, sandstone and conglomerate, as well as dolomite and banded iron formation. The area is extensively deformed with the rocks being folded and faulted (van Vreeswyk et al. 2004). The surface geology of the survey area is comprised of seven

units (Stewart et al. 2008), with Robe Pisolite the most dominant (Table 3). Geological mapping of the survey area and surrounds is presented in Figure A.1 (Appendix A).

Table 2: Geological units of the survey area (Stewart et al. 2008).

Geological name	Label	Area within survey area (ha)
Woongarra Rhyolite: rhyolite, rhyodacite, rhyolitic volcaniclastic breccia and banded iron formation	Lfhw	88.5
Marra Mamba Iron Formation: chert, ferruginous chert, jaspilite, banded iron formation, minor shale, siltstone, mudstone	Achm	635.9
Mount McRae Shale and Mount Sylvia Formation: interbedded shale, chert, banded iron-formation	Ashm	289.7
Brockman Iron Formation: banded iron-formation, chert, mudstone and siltstone	Lchk	114.0
Colluvium 38491: colluvium, sheetwash, talus; gravel piedmonts and aprons over and around bedrock; clay-silt-sand with sheet and nodular kankar; alluvial and aeolian sand-silt-gravel in depressions and broad valleys in Canning Basin; local calcrete, reworked laterite	Qrc	778.2
Robe Pisolite: pisolitic, oolitic and massive limonite, goethite and hematite deposits containing fossil wood fragments; iron ore	Czlr	2,261.7
Alluvium 38485: channel and flood plain alluvium; gravel, sand, silt, clay, locally calcreted	Qa	762.3

The survey area is mapped as soil landscape zone 285 – Hamersley Plateaux in the Fortescue Province and soil landscape zone 296 – Stuart Plains and Hills Zone of the Ashburton Province (Tille 2006).

The Hamersley Plateaux soil unit is described as hills and dissected plateaux with some stony plains and hardpan wash plains on volcanic and sedimentary rocks. It is comprised predominately of stony soils with red shallow loams and some red-brown non-cracking clays and red loamy earths (Tille 2006). Some drainage habitats occur and these are characterised by sand, gravel, pebbles and stones (van Vreeswyk et al. 2004).

The Stuart Plains and Hills Zone consists of hills and ranges with some floodplains and stony plains on sandstone, shale and conglomerate of the Ashburton Basin. Soils are typically stony with red loamy earth and red shallow loams (Tille 2006).

2.1.3 Surface Water and Hydrology

The Robe River is considered a seasonal watercourse and intersects the northern section of the survey area, flowing in an east-west orientation. A number of permanent pools in the river were observed within the survey area. Numerous creeks and smaller drainage lines stem from the Robe River; drainage lines also occur down the gullies of the surrounding mesas. Springs and pools of the Robe River are listed as 'Wetlands of Subregional Significance' (Kendrick 2001) and are in proximity to the survey area. These wetland ecosystems are distributed from 40 km east of Pannawonica downstream to the North West Coastal Highway. Approximately 998 ha in the south-eastern corner of the survey area is within a Public Drinking Water Source Area: the Bungaroo Water Reserve (Department of Water 2008).

2.2 Biological Environment

2.2.1 Interim Biogeographic Regionalisation of Australia

The Interim Biogeographic Regionalisation for Australia (IBRA version 7) divides the Australian continent into 89 bioregions and 419 subregions (Department of the Environment and Energy 2016a). The IBRA regions represent a landscape-based approach to classifying the land surface, including attributes of climate, geomorphology, landform, lithology, and characteristic flora and fauna. The survey area occurs in the Pilbara Bioregion, of which 5% to 10% is represented in the national reserve system (Department of the Environment and Energy 2016b).

The biodiversity of the 53 subregions recognised in Western Australia was documented as part of a national audit to provide priorities for conservation action (Department of Conservation and Land Management 2002). The survey area occurs within the Hamersley subregions of the Pilbara region. The Hamersley subregion is described in the audit as:

> Hamersley PIL3 – dissected bold plateaux and ranges of flat lying, moderately folded sandstone and quartzite with vegetation described as Mulga low woodland over tussock grasses occurring on fine textured soils in valley floors, with scattered Snappy gum (*Eucalyptus leucophloia*) over *Triodia brizoides* on skeletal soils of the ranges (Kendrick 2001).

2.2.2 Land Systems

Land systems of the Western Australian rangelands have been mapped and described by the Department of Agriculture and Food outlining the distributions and providing descriptions of biophysical resources including soil and vegetation condition. A total of 102 land systems occur in the Pilbara bioregion covering 181,723 km^2. Six land systems occur in the survey area, with Robe being the most dominant (Table 3). The layout of these land systems within the survey area is shown in Figure A.2 (Appendix A).

Table 3: Distribution of land systems within the survey area and Pilbara bioregion (van Vreeswyk et al. 2004).

Land system	Total area within Pilbara bioregion (ha)	Total area within survey area (ha)	Proportion within survey area (%)
Boolgeeda - stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands and mulga shrublands	961,847	559.8	<0.1
McKay - hills, ridges, plateaux remnants and breakaways of meta sedimentary and sedimentary rocks supporting hard spinifex grasslands	425,967	0.2	<0.1
Newman - rugged jaspilite plateaux, ridges and mountains with hard spinifex	1,994,339	673.5	<0.1
River - active flood plains, major rivers and banks supporting grassy eucalypt woodlands, tussock grasslands and soft spinifex grasslands	481,994	816.7	0.2
Robe - low limonite mesas and buttes supporting soft spinifex (and occasionally hard spinifex) grasslands	128,680	2,758	2.1
Urandy - stony plains, alluvial plains and drainage lines supporting shrubby soft spinifex grasslands	132,039	121.8	<0.1
TOTAL	**4,124,866**	**4,390**	-

2.2.3 Pre-European Vegetation

Pre-European vegetation was mapped across the Pilbara region at a scale of 1:1,000,000 (Beard 1975). The survey area is located in the Stuart Hills and Hamersley Plateau physiographic units of the Fortescue Botanical District (Figure A.3, Appendix A). These physiographic units are described as:

Hamersley: a compact unit defined by the outcropping of jaspilite and dolomite, with some shale, siltstone and volcanics. Vegetation is described as:

- ranges – tree steppe of *Eucalyptus brevifolia* (likely to represent *E. leucophloia*) over *Triodia wiseana* hummock grasslands
- valley plains – mulga (*Acacia aneura* complex) low woodlands, or tussock grasslands on cracking clay soils
- basalt hills – mosaic of mulga low woodland and *Acacia pyrifolia* and *Triodia* species shrub steppe.

Stuart Hills: this unit consists mostly of plains, gently undulating pediplains extending out from Breakaways and residuals capped by Robe pisolites, and stony hills and steeply dissected pediments on fine-grained sandstone, shale and dolomite. Vegetation is described as:

- hills and plains – *Triodia wiseana* and *T. basedowii* hummock grasslands with sparse shrubs, particularly *Acacia bivenosa*
- drainage lines – *Corymbia hamersleyana* and *C. candida* occur occasionally, with *Senna* species and ephemerals
- major rivers – *Eucalyptus camaldulensis* and *Acacia citrinoviridis* along river and mulga low woodland on river flats and tributaries.

Four pre-European vegetation units, 82, 603, 605 and 609 (Shepherd, Beeston, and Hopkins 2002), are associated with the survey area:

> 82: 'Hummock grasslands, low tree steppe; snappy gum over *Triodia wiseana*'
>
> 603: 'Hummock grasslands, sparse shrub steppe; *Acacia bivenosa* over hard spinifex'
>
> 605: 'Hummock grasslands, shrub steppe; *Acacia pachycarpa* and waterwood over soft spinifex'
>
> 609: 'Mosaic: Hummock grasslands, open low tree steppe; bloodwood with sparse kanji shrubs over soft spinifex/Hummock grasslands, open low tree steppe; snappy gum over *Triodia wiseana*'.

Table 4 summarises the current and pre-European extent of these four vegetation units in the Pilbara and the survey area.

Table 4: Extent of pre-European vegetation in the survey area (Government of Western Australia 2014).

Vegetation association	Mapping unit (Beard 1975)	Extent in survey area (ha)	Current extent in Pilbara bioregion (ha)	Pre-European extent (ha)	Proportion of pre-European extent remaining (%)
82	e16Lr t3Hi	2,023.7	2,550,898.98	2,563,583.23	99.51
603	a6Sb t3Hi	534.0	55,764.00	56,726.87	98.30
605	a5,11Sr t1Hi	965.5	114,115.85	114,115.85	100.00
609	e24Lr a2Sp t1Hi /e16Lr t3Hi	1407.0	72,765.18	74,186.11	98.08

2.3 State and Commonwealth Conservation Categories and Management

Commonwealth and State regulatory authorities maintain databases of the locations and conservation status of significant flora, fauna and ecological communities in Western Australia. The EPBC Act provides a legal framework to protect and manage MNES including listed flora, fauna and ecological communities. These listed flora, fauna and ecological communities are allocated conservation categories, which are outlined in Tables B.1-B.6 (Appendix B).

Ecological communities may be subject to processes that threaten to destroy or significantly modify it across much of its range. These communities are identified as Threatened Ecological Communities (TECs) and are listed at both the State level by the Western Australian Minister for Environment and the Commonwealth level under the EPBC Act (Tables B.1-B.2, Appendix B). The Department of Parks and Wildlife (Parks and Wildlife) maintains a list of Priority Ecological Communities (PECs), which may also be under threat and are assigned one of four priority rankings according to the criteria outlined in Table B.3 (Appendix B).

Under Western Australian legislation, all native fauna is protected and it is an offence to 'take' protected fauna. The *Wildlife Conservation Act 1950* (WC Act) also provides for native fauna species to be specially protected when they are considered rare, threatened with extinction, or have a high conservation value (Table B.4, Appendix B). In addition, due to the diversity of Western Australia's fauna, many species are known from only a few collections or locations, but have not been adequately surveyed. Such fauna may be rare or threatened, but cannot be considered for declaration as Threatened fauna until adequate surveys have been undertaken. These fauna species are included on a supplementary conservation list managed by Parks and Wildlife called the *Priority*

Fauna List. Priority fauna are categorised according to level of threat and other information and the conservation categories are described in Table B.5 (Appendix B).

2.4 Land Use and Tenure

The survey area is located within the Shire of Ashburton. The majority of the survey area is on the Yalleen Station pastoral lease, with 100 ha (<1% of the survey area) on the Yarraloola Station pastoral lease. The local area is used for pastoralism, mineral exploration and mining activity.

The Millstream-Chichester National Park is the nearest conservation reserve to the survey area, located approximately 79 km to the north-east. The Cane River Conservation Park is located approximately 48 km to the south-west, Murujuga National Park is approximately 120 km north and Karijini National Park is approximately 180 km south-east of the survey area (refer to Figure 1).

3 Methodology

3.1 Desktop Assessment

A desktop assessment was undertaken to assess whether any conservation listed vertebrate and invertebrate species, SRE invertebrate species or communities, or PECs/TECs were likely to occur within the survey area. For vertebrate species, the review focused on key habitats for conservation listed fauna and species of MNES. For SRE invertebrates, the review focused on key habitats for SRE fauna and the eight invertebrate groups with a known high proportion of SRE species (the SRE groups): centipedes (Chilopoda), harvestmen (Opiliones), millipedes (Diplopoda), non-marine snails (Gastropoda), pseudoscorpions (Pseudoscorpiones), scorpions (Scorpiones), terrestrial slaters (Isopoda) and spiders (Araneae).

3.1.1 Database Searches

A search for Environmentally Sensitive Areas (ESAs) in the vicinity of the survey area was conducted using the WA Atlas (Landgate 2015) and Register of the National Estate spatial database (Department of the Environment and Energy 2008). In addition, database searches were conducted with search details summarised in Table 5. Conservation categories for fauna are provided in Appendix B.

Table 5: Database searches requested.

Database name	Date search results received	Search focus	Search area
NatureMap (Department of Parks and Wildlife 2015a)	22/09/2015	Terrestrial fauna and fauna of conservation significance	40 km radius from an approximate survey area centre point, defined by the coordinates: 21°44’47 S, 116°12’02 E
Threatened and Priority Fauna Database (Department of Parks and Wildlife 2015b)	30/09/2015	Threatened and Priority fauna species	20 km radius from a point defined by the coordinates: -21.738899, 116.205782 (MGA50, GDA94)
Protected Matters Search Tool (Department of the Environment 2015)	21/09/2015	Threatened and Priority fauna species	40 km buffer from the central coordinates: -21.738899, 116.205782 (MGA50, GDA94)
BirdLife Australia (Birdlife Australia 2015)	30/09/2015	Bird species	1 degree from a point defined by the coordinates: -21.74617, 116.20118 (MGA50, GDA94)
Western Australian Museum Invertebrate Database (Western Australian Museum 2015)	20/04/2015	Arachnids, Myriapods, Crustaceans, and Molluscs	100 km buffer from survey area bounded by the coordinates: -21.338898, 115.636173 and -22.548142, 116.805241 (MGA50, GDA94)
Atlas of Living Australia (Atlas of Living Australia 2015)	20/04/2015	All fauna species	10 km radius from a point defined by the coordinates: 21°53’21 S, 116°22’37 E

3.1.2 Literature Review

Fauna surveys have previously been commissioned by Rio Tinto within the vicinity of the survey area and supplied to Astron for the desktop assessment. The previous survey areas in relation to the current survey area are shown in Figure 3. The reports reviewed as part of this assessment include:

- Mesa J Tail Track Extension Vegetation, Flora and Fauna Survey (Astron Environmental Services 2011)
- Mesa H Level 1 Flora, Vegetation and Fauna Assessment (Astron Environmental Services 2014)
- Mesa H Flora, Vegetation and Fauna Survey – Phase 1 Summary (Astron Environmental Services 2015)
- Bungaroo Iron Ore Mine and Infrastructure Project, Level 2 Fauna Survey (Astron Environmental Services 2016a)
- Middle Robe and East Deepdale Level 2 Fauna Assessment (Astron Environmental Services 2016b)
- Yarraloola Targeted Fauna Survey (Biologic Environmental Survey 2014)
- Fauna Habitats and Fauna Assemblage of Mesa A and G (Biota Environmental Sciences 2005)
- Fauna Habitats and Fauna Assemblage of the Mesa A Transport Corridor and Warramboo (Biota Environmental Sciences 2006)
- Bungaroo Trial Pit and Transport Corridor to Mesa J, near Pannawonica (Biota Environmental Sciences 2007)
- Mesa G Baseline Fauna Survey (Biota Environmental Sciences 2009)
- Greater Bungaroo Seasonal Fauna Survey (Biota Environmental Sciences 2010)
- Robe Valley Mesas Fauna Survey (Biota Environmental Sciences 2011)
- Middle Robe and East Deepdale Flora, Vegetation, Vertebrate and Invertebrate Fauna Survey (ecologia Environment 2013).

3.1.3 Habitat Characterisation

Using orthophotos provided by Rio Tinto and the available literature, the survey area was split into distinct landform types that were evaluated further for their likelihood of conservation listed vertebrate or SRE species occurrence. The assessment followed several criteria, such as the availability of moisture, extent of shade and shelter, and soil and vegetation types. Emphasis was given to landforms (and associated habitats) that may contain 'relict' species (surviving in sheltered and moist conditions) and those that may support habitat specialists (i.e. species restricted to rocky outcrops).

3.1.4 Conservation Assessment

Conservation listed vertebrate fauna species returned from the database searches were categorised for likelihood of occurrence within the survey area prior to the field survey, according to the criteria listed in Table B.7 (Appendix B). Post survey, the likelihood table was re-assessed utilising the information obtained during the field survey. The additional criteria used for the assessment are outlined in Table B.7 (Appendix B). The likelihood table was then updated to reflect an improved understanding of the likelihood that a species would actually occur in the survey area.

SRE invertebrates are species with distributions of less than 10,000 km^2 and their occurrence within their distribution is usually fragmented and highly localised (Harvey 2002; Ponder and Colgan 2002). However, it is often difficult to determine whether or not a species in one of the target SRE groups actually has a range < 10,000 km^2. For the purpose of desktop review, SRE status was determined by the staff of the Western Australian Museum (WAM) through providing the results of SRE filtered searches of the WAM databases. This assessment was reviewed and supplemented with information contained in previous environmental reports, the published literature and online databases. For morphospecies collected during the survey, the criteria outlined in Table B.8 (Appendix B) were used to determine SRE status. The SRE categories of the WAM (confirmed SRE, potential SRE and widespread species) were used to assess the status of species, with sub-categories applied in accordance with the WAM-TS guidelines.

3.2 Field Survey

3.2.1 Survey Timing and Personnel

The phase 1 field survey (dry season) was undertaken by Matthew Johnston and John Trainer and the phase 2 field survey (post wet season) was undertaken by Matthew Love and John Trainer. All survey personnel have over five years of experience conducting Level 2 vertebrate fauna surveys or invertebrate surveys. The survey was conducted under "Licence to Take Fauna for Scientific Purposes" Permit No. SF010530.

The phase 1 and 2 field surveys were conducted from 24 September to 3 October 2015 and 27 April to 9 May 2016, respectively. Data and trap sites previously set up in the survey area for the Robe Valley Mesas Fauna Survey (Biota Environmental Sciences 2011) was used to supplement the phase 1 data; this survey was completed by Biota from the 22 to 29 October 2010.

Daily weather observations recorded at the Mesa J Weather Station (Rio Tinto supplied data) directly adjacent to the survey area were used to identify local rainfall and temperatures preceding the survey as current data were not available from Pannawonica weather station (Figure 4).

Phase 1: Rainfall received in the 12 months preceding the phase 1 survey was 67.4 mm below the annual average. Rainfall for July, August and September 2015, the three months preceding the phase 1 survey, was almost 10 mm below the average monthly means with a total of only 14.6 mm. No rainfall was received during the phase 1 survey.

Phase 1 daily maximum temperatures averaged 38°C ± 3.0°C and daily minimum temperatures averaged 17°C ± 5.5°C. Mean maximum and minimum daily temperatures were higher during the phase 1 survey than the long-term means for September and October.

The weather conditions for the phase 1 survey conducted by Biota in 2010 included maximum temperatures from 33.4°C to 41.3°C and minimum temperatures from 18.7°C to 22°C. No rain was recorded during the survey. A total of 35.4 mm of rain fell at Mardie during the six months leading up to the survey. This is well below the average of 116.2 mm for this period (Biota Environmental Sciences 2011).

Phase 2: Rainfall received 12 months preceding the phase 2 survey was 145 mm above the annual average. However, rainfall for February, March and April 2016, the three months preceding the phase 2 survey, was almost 87 mm below the average monthly means with a total of 108.8 mm. A total of 35.4 mm was recorded across two days during the phase 2 survey.

Phase 2 daily maximum temperatures averaged 32°C ± 6.0°C and daily minimum temperatures averaged 26°C ± 5°C. Mean maximum daily temperatures were slightly lower during the phase 2 survey than the long-term means for April and May, this may be due to the high levels of cloud cover and subsequent rain. Minimum daily temperatures during the phase 2 survey were far warmer than the long term means for April and May, again attributed to the cloud cover experienced during the survey period.

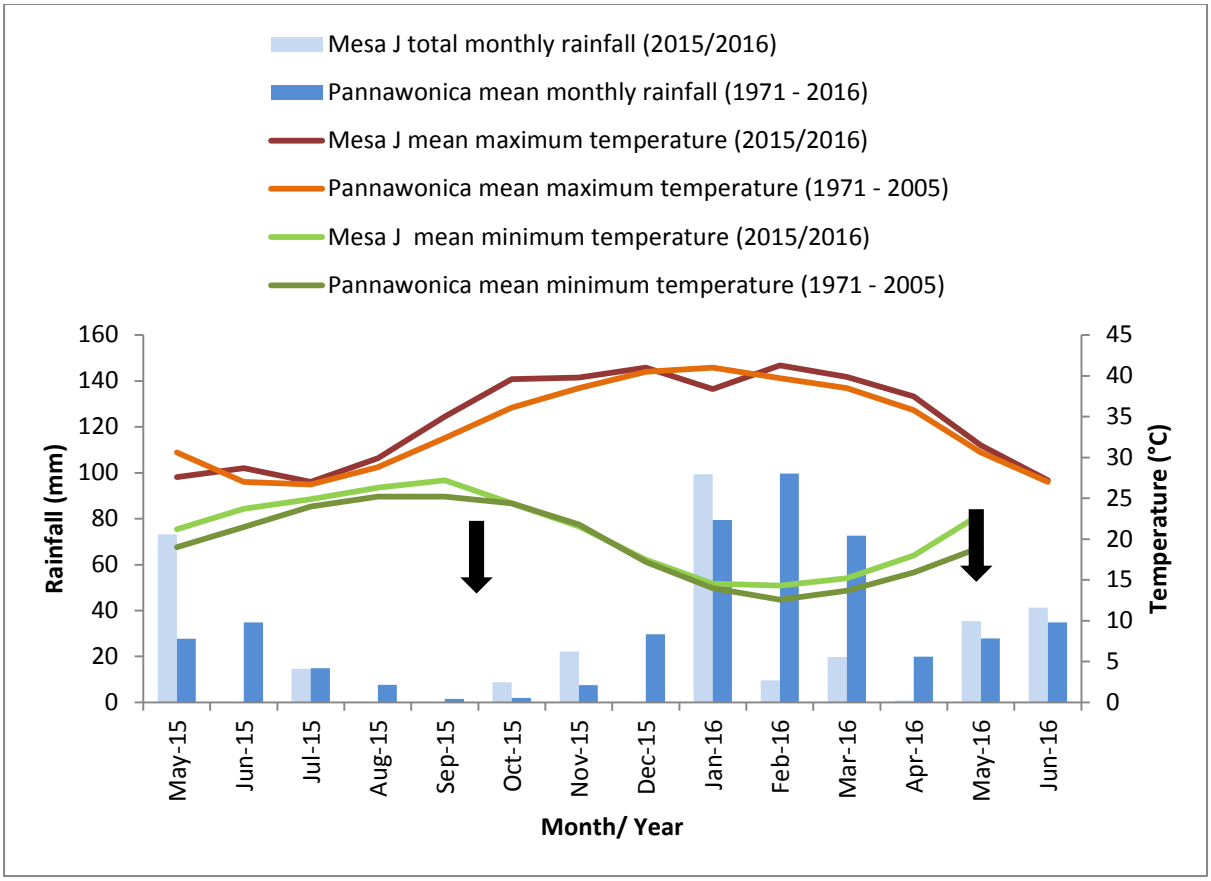

Figure 4: Pannawonica mean monthly rainfall (1971 – 2016) and Mesa J rainfall (2015 - 2016), and Pannawonica mean monthly maximum and minimum temperatures (1971 – 2005), and Mesa J mean monthly maximum and minimum temperatures, in the 12 months preceding the survey. Black arrow indicates field survey timing. Pannawonica data from Bureau of Meteorology (2016) and Mesa J data from Rio Tinto (2016f).

3.2.2 Vertebrate Fauna

3.2.2.1 Habitat Assessment

There were 24 fauna habitat assessments conducted within the seven fauna habitat types present in the survey area (Tables C.1-C.2, Appendix C). The locations are shown in Figure C.1 (Appendix C) and the following information was collected at each site:

- location – coordinates measured using a handheld GPS (GDA94)
- recorder and date – personnel involved in undertaking the fauna habitat assessment and the survey date
- habitat/landform – position in the landscape - major fauna habitat types were described based on the landform and vegetation
- vegetation type – a broad description of vegetation type and structure
- soils – a brief description of soil type
- microhabitat – presence of specific microhabitat features, e.g. leaf litter, logs, burrows, rocky outcrops, rock crevices, hollows, permanent or semi-permanent water

- condition – habitat condition was assessed based on the presence of anthropogenic (human-induced) disturbances, and using the condition ratings suggested by Thompson and Thompson (2010) (Table B.9, Appendix B)
- disturbance – any disturbance such as clearing, fire, weeds, flooding, vehicular, machinery, tracks or grazing
- photographs – a representative photograph was taken of each habitat assessment site.

The information derived from the fauna habitat assessments was used to delineate fauna habitats throughout the survey area, which were then mapped accordingly. The potential for the mapped habitats to provide suitable habitat for MNES species, Pilbara Olive Python (VU, S3), Northern Quoll (EN, S2), Ghost Bat (VU, S3) and Pilbara Leaf-nosed Bat (VU, S3) were ranked according to the criteria listed in Table B.10 (Appendix B) and then mapped for each species.

3.2.2.2 Trapping Grids

The phase 1 trapping program was a dry season survey encompassing five Biota trap sites undertaken in October 2010 (Biota Environmental Sciences 2011) and an additional three trapping sites undertaken in September/October 2015 by Astron. The phase 2 trapping program was a post wet season survey undertaken in April/May 2016 using all eight sites from phase 1 (Table 6). Sites were selected in areas of favourable micro-habitat to maximise the likelihood of fauna capture. The location of previous and current trap sites is shown in Figure C.1 (Appendix C).

Biota in phase 1 (October 2010) used the following trap design:

- three trap sites (RVM13-15) of 10 pitfall traps (20 L bucket and PVC pipes)
- one trap site (RVM12) of 12 funnel traps (fish-net style)
- one trap site (RVM16) of 50 Elliot (A) traps (aluminium box-trap).

Aston in phase 1 and phase 2 used the following trap design:

- six trap sites (MHT01-3 both phases and RVM13-15 phase 2 only) of 10 pitfall traps (20 L bucket and PVC pipes), six funnel traps, 20 Elliot traps and four cage traps (wire mesh cage trap)
- two trap sites in rocky habitats (RVM12 and RVM16 both phase 2) were established as Elliot sites, each with 20 Elliott traps and four cage traps arranged in a linear layout along the breakaway habitat. In phase 2, RVM12 was moved to a more suitable location further along the same breakaway habitat.

All pitfall and funnel traps were used in conjunction with a 100 m drift fence running over the centre of the pit, directing animal movement into the pitfall trap. The trap sites remained open for seven nights in phase 1 and phase 2. Traps were cleared each morning within three hours of sunrise to minimise the potential of trap death. The typical trap arrangement used by Astron in both the phase 1 and 2 surveys is depicted in Figure 5.

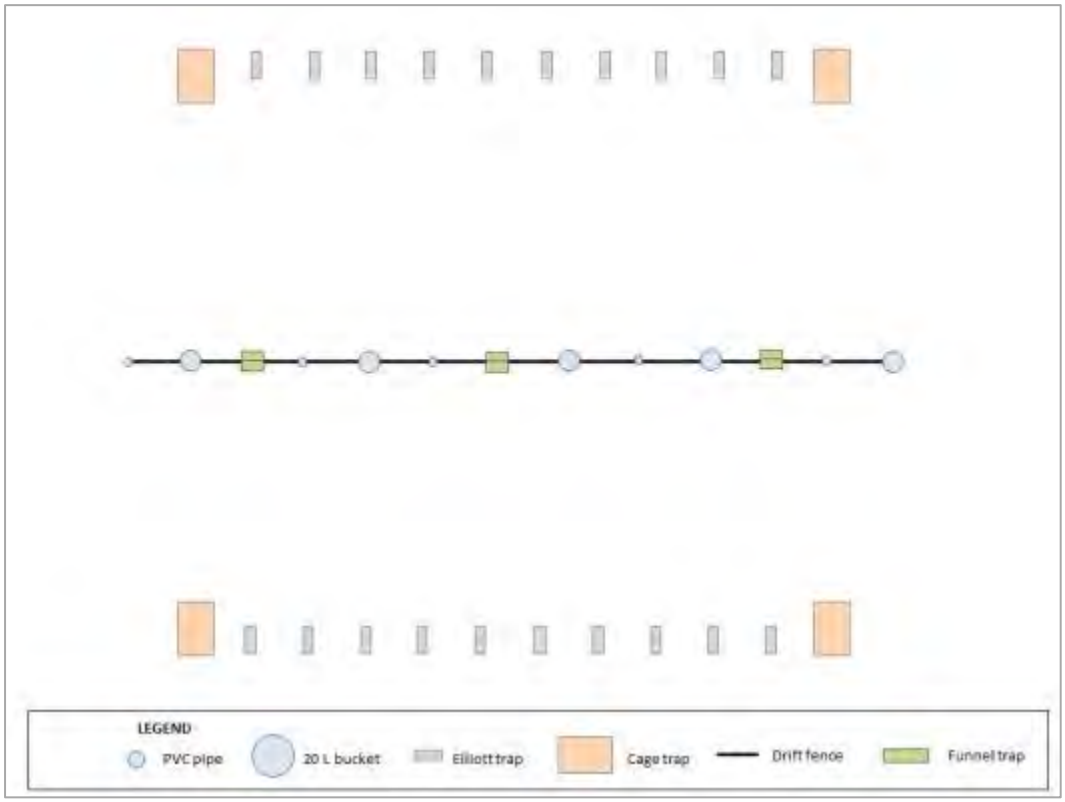

Figure 5: Diagrammatic layout of systematic trapping sites.

3.2.2.3 Avifauna Surveys

Systematic avifauna (bird) censuses were undertaken at each trapping grid for 20 minutes each day on five occasions over both survey phases, resulting in 100 minutes per person of survey effort at each site. This equates to a total of 2,200 minutes (36 hours and 40 minutes) over both phases of the survey. All species were recorded from sightings and/or from species-specific bird calls. Opportunistic records of species across the survey area were also recorded and habitats that may support species of conservation significance were targeted.

Biota (2011) undertook avifauna sampling in a similar manner at each of the trap sites. During the phase 1 survey avifauna survey, effort ranged between 40 minutes and 155 minutes at each of the sites with a total of 243 minutes avifauna sampling undertaken.

3.2.2.4 Motion Sensitive Cameras

Thirty motion sensitive cameras were used during both phases of the survey (Moultrie, Bushnell Trophy Cam infra-red, and Reconyx HC600 HyperFire). Cameras were set at 48 locations for between two and six nights with a combined trapping effort of 247 camera trap nights over both phases of the survey. The cameras were baited and placed in prospective/suitable habitat such as cave entrances and water holes aimed at targeting MNES species. Camera locations are shown in Figure C.1 and detailed in Table C.1-C.2 (Appendix C).

3.2.2.5 Acoustic Bat Surveys

Acoustic ultrahigh frequency equipment was used to record the presence of bats, in particular the Pilbara Leaf-nosed Bat and Ghost Bat. Four acoustic recording devices (Song Meter 2, SM2BAT+) were positioned in a total of 14 locations across both phases to achieve a broad coverage of the

survey area, but also distributed across the survey area to allow for an analysis of flying direction and the potential locations of any roosts. The detectors were set for one to four nights, resulting in a total of 27 recording nights. The locations are depicted in Figure C.1 and detailed in Table C.1-C.2 (Appendix C). The bat echolocation data collected on the SM2BAT+ detectors in the field was analysed by Robert Bullen (Bat Call WA 2016).

3.2.2.6 Active Foraging

Active searches were undertaken across both phases of the survey in microhabitats suitable for ground-dwelling reptiles and mammals. Active searches included the following:

- searching and recording scats, tracks and other traces
- turning over rock and logs and peeling off bark
- raking soil and leaf litter
- searching rocky habitats in cracks and caves, around water bodies and inside bore hole caps.

3.2.2.7 Targeted Searches

The aim of the targeted searches was to identify areas of potentially suitable habitat for conservation significant fauna, such as caves, and secondary signs including tracks, scats, diggings and burrows. Walked transects were undertaken throughout the survey area (Figure C.1, Appendix C). In addition, visual observation for conservation significant fauna habitat was ongoing whilst moving through the survey area. Track logs were recorded using a handheld GPS and are shown in Figure C.1 (Appendix C). Any opportunistic sightings of fauna species were recorded whilst traversing the survey area.

3.2.2.8 Nocturnal Spotlighting

Spotlighting at night was undertaken on foot and from vehicles to target fauna that are nocturnal or crepuscular, particularly conservation significant species. A total of 1,800 minutes (30 hours) of nocturnal spotlighting was undertaken in the survey area across both phases of the survey. Approximately, 1,080 minutes (18 hours) of nocturnal spotlighting was undertaken in phase 1 and 720 minutes (12 hours) of nocturnal spotlighting was undertaken in phase 2.

This page has been left blank intentionally.

3.2.3 Statistical Analyses

3.2.3.1 Sampling Effort

Sampling effort was assessed using species accumulation curves and modelled estimates of the total species pool. Species accumulation curves are created by randomly sampling an incremental number of sites while plotting the total number of species sampled. Species estimators are particular statistical models of species accumulation which estimate the total species pool available. Four species estimators were compared: Chao 2, Jackknife 1, Jackknife 2 and Bootstrap (Colwell and Coddington 1994). Species accumulation curves were created for each faunal group (mammals, birds and herpetofauna) and for the different monitoring programs (Astron phase 1, Astron phase 2, all Astron samples, and all samples including other consultant surveys). Species estimations were based on all Astron surveys. All analyses were performed in R 3.2.1 (R Development Core Team 2015) using the package "Vegan".

3.2.3.2 Site Classification

The similarity of species assemblages amongst sites was assessed using two dimensional ordinations based on Sorensen's index of similarity amongst sites. Significant groupings of sites by habitat type were identified using the ANOSIM function (Clarke, Somerfield, and Gorley 2008) within the package "Vegan". Ordinations and ANOSIM tests were performed for each faunal group.

3.2.4 SRE Invertebrates

3.2.4.1 Habitat Assessment

Fauna habitats within the survey area were mapped for their suitability to support SRE invertebrates as part of an initial desktop assessment (Section 3.1.3) and further refined following the field survey (Section 3.2.4.1).

3.2.4.2 Active Foraging

A total of 20 systematic sites (including the trapping sites) were sampled for SRE fauna across the survey area (Figure C.1, Appendix C). All sites were sampled by active foraging and litter-soil samples. The sites were selected so that they represented the landforms and vegetation associations inferred as prospective in the desktop assessment; however, some sites also targeted the less prospective habitats (e.g. Loamy/Stony Plains) to confirm the results of the initial desktop assessment. Detailed site descriptions, including associated landforms and vegetation features, are provided in Table C.1-C.2 (Appendix C). The descriptions provide qualitative information about factors influencing the macroclimate (e.g. landform, vegetation type, dominant substrate, and indicative plant species) and microclimate (e.g. amount of organic matter or existing damage).

Foraging was focused under boulders, crevices in rocky outcrops, at the base of tree logs, under loose tree bark, in moist and dry leaf litter accumulations and in *Triodia* clumps, but occurred in all habitats. The search for mygalomorph spider burrows was by visual inspections and using a leaf blower. Night-time searching for scorpions was undertaken in conjunction with the nocturnal spotlighting. Leaf litter was sifted *in situ* with a 16 mm soil sieve, and potential SRE invertebrates preserved directly in 98% ethanol. Approximately 800 minutes (13 hours and 20 minutes) were spent searching the 20 SRE sites. Any potential SRE invertebrates observed in the dry pitfall or funnel traps at each of the six relevant trapping grids were also collected.

3.3 SRE Specimen Identification

The samples were separated and sorted to morphospecies level under a dissecting microscope. Morphological identifications to species level were attempted for all collected specimens. These identifications were completed in-house and were based on the available taxonomic literature and keys, environmental reports and online databases. Compound microscopes were used to examine fine taxonomic characters not visible otherwise, e.g. trichobothria patterns in pseudoscorpions.

The identification of many invertebrates was straightforward; however, all slaters were identified by Dr Simon Judd (Edith Cowan University) and all arachnid groups were identified by Dr Erich Volschenk. Several pseudoscorpion species were compared with critical specimens from the WAM to assure species alignment whenever possible. WAM lodgement details for representative vouchers are provided in Appendix D.

DNA analyses were performed by Dr Gaynor Dolman from the WAM on representative arachnids specimens considered to represent potential SRE species. This was done because many of the specimens belong to complex family groups or were juvenile and could not be identified using morphology. In total, 10 specimens from two arachnid orders (Araneae, Scorpiones) were submitted to the WAM and the CO1 'barcoding' gene sequenced for nine specimens. Detailed results of the molecular analyses and lodgement details are available in Appendix E (Dolman 2016).

3.4 Taxonomy and Nomenclature

For species identified in the desktop assessment, every effort was made to determine the current scientific name for each taxon, including wherever there was doubt as to their true taxonomy (through subsequent name changes). In addition, some taxon names may be followed by 'sp.', meaning that the species name was not given in the original data source. Taxa that were identified as 'sp. indet.' usually belong to species complexes that are unresolved to a degree that accurate species identification is not possible. These complexes may include species that are newly recorded for a survey area or have been collected for the first time; however this cannot be determined from the data available. For named species in SRE groups, the taxonomy follows the published literature. WAM species codes were applied to unnamed species whenever possible (MYG codes for mygalomorph spiders) but alternative names applied by the taxonomic experts were used when WAM codes were unavailable (unpublished manuscript names for scorpions given as *Genus* 'name' by Dr Erich Volschenk).

The biology of many SRE species is not well known and the precise distribution and life history are poorly, if at all, documented (Harvey 2002; Harvey et al. 2011). Species identification is often very difficult because few specimens have been collected, reference collections are unavailable, the specimens are the wrong sex or life stage for identification, or they are morphologically cryptic and require DNA analyses. Taxonomic resolution can also be poor, either because there are no published taxonomic revisions for a group in question (terrestrial isopods in Western Australia), or because there is no expert actively working on one of the SRE groups.

3.5 Limitations

Following completion of the desktop assessment and field survey, a review of any limitations that may affect a complete assessment of the data collected was conducted. The limitations listed in Table 7 are based on those suggested as considerations in Technical Guidance - Terrestrial Fauna Surveys (Environmental Protection Authority 2016a).

Table 7: Statement of limitations for the vertebrate and SRE invertebrate fauna survey.

Potential limitation	Degree of limitation	Statement regarding potential limitations
(i) Competency/experience	No limitation	The ecologists responsible for conducting the survey have extensive experience in conducting Level 2 vertebrate and SRE fauna surveys in the Pilbara.
(ii) Scope What faunal groups were sampled and were some sampling methods not able to be employed because of constraints such as weather conditions.	No limitation	The survey scope employed was able to be completed and all sampling methods adequately employed. The fauna observed and identified is likely to represent a portion of the suite of species that utilise the survey area.
(iii) Proportion of fauna identified, recorded and/or collected	No limitation	The fauna observed and identified are likely to represent a portion of the suite of species that utilise the survey area. Fauna habitats were able to be adequately described and a list of species likely to be present was prepared based on this assessment. Species accumulation curves generally did not reach an asymptote, but when taking into account previous records as well as species recorded from methods other than trapping, then a large portion of the predicted assemblage was recorded. It is not possible to determine bat species abundance from echolocation records; bat activity levels provide a relative measure of the abundance of each species within the survey area.
(iv) Sources of information Previously available information (whether historic or recent) as distinct from new data.	No limitation	Adequate information was available from database searches and previous studies in the survey area and region.
(v) Proportion of task achieved. Further work which might be needed?	No limitation	The survey scope employed was able to be completed and all sampling methods adequately employed.
(vi) Timing/weather/season/ cycle	Minor limitation	Rainfall preceding the phase 1 survey was below average, however as this was the dry season survey it is not considered a limiting factor. The rainfall in the three months preceding the phase 2 survey was well below average. This was evident in the lack of surface water present specifically in the Riverine habitats. This is likely to have reduced the number of waterbirds recorded during the phase 2 survey. The temperatures during both phases 1 and 2 were above or close to the long term average. The higher than normal temperatures, especially at night may have resulted in an increased abundance of species being recorded, specifically reptiles and small mammals. The timing of the survey follows the EPA (2016b) guidelines for SRE sampling. Climatic conditions varied between the two survey periods with no climatic extremes that could affect the activity of SRE fauna.

Potential limitation	Degree of limitation	Statement regarding potential limitations
(vii) Disturbances e.g. fire, flood, accidental human intervention which affected results of survey	Minor limitation	Large portions of the Low Hills and Slopes and Loamy/Stony Plains habitat on top of Mesa H were affected by exploration drilling pads and their associated tracks. Fauna captures at trap sites RVM15 and MTH03, which were situated in the middle of disturbed areas, was comparable to other sites. No other disturbances were recorded in the survey area that would have affected the survey results.
(viii) Intensity In retrospect, was the intensity adequate?	No limitation	The intensity of the surveys was considered adequate for a Level 2 assessment.
(xi) Completeness Was the relevant area fully surveyed?	No limitation	All main habitats in the survey area were surveyed and coverage of habitat assessments and targeted surveys is considered adequate.
(x) Resources Degree of expertise available in animal identification to taxon level.	No limitation	Adequate resources were available to identify fauna species. All personnel involved in identification have extensive experience in conducting Level 2 vertebrate and SRE fauna surveys in the Pilbara. Taxonomic experts were consulted for all SRE fauna groups and DNA analyses were undertaken at the WAM to help identify the selected taxa.
(xi) Remoteness and/or access problems	Minor limitation	There were no access problems with all of the survey area able to be accessed by vehicle or on foot. Due to safety and heritage related constraints, internal inspections of caves are not permitted. The characteristics of Pilbara Leaf-nosed Bat and Ghost Bat roost caves are variable and therefore it is not possible to determine the potential for a cave to be a roost by external visual observation. The cave assessments provide an indication only as to whether Pilbara Leaf-nosed Bats or Ghost Bats may utilise the caves as habitat.
(xii) Availability of contextual information e.g. biogeographic information on the region.	No limitation	Database searches and previous fauna surveys in the survey area provided by Rio Tinto provided contextual information.

This assessment combines data collected from Biota's trapping program in 2010 with that recorded by Astron in 2015 and 2016. As such, differences in methodology of trap design (lack of Elliot traps at all Biota sites), survey effort for avian census (varying from 40 to 155 minutes per site), acoustic bat sampling (use of SM2 units versus AnaBat SD units) and their potential effect on the data are difficult to assess. Although different, the methods previously used are deemed adequate for a Level 2 survey.

EPA (2016b) recommends that assessments of SRE fauna in the Pilbara should be undertaken between November and April when there is increased activity of cryptic groups such as male mygalomorph spiders. Recent studies on millipedes and spiders suggest that adult specimens are frequently collected much later in the year (between May and October) and that SREs are not only active during the cyclone season (Car and Harvey 2013; Harvey et al. 2012; Miglio et al. 2014). The

current survey was conducted in two phases: October 2015 and late April/May 2016. The timing of survey therefore covers the period of greatest activity for SRE groups.

Most SRE species rely on moisture and are most active following periods of elevated rainfall and comparably low temperatures. Climatic conditions during the first phase of survey were relatively dry with no rainfall observed during this phase. However, there was permanent water in the Robe River and the vegetation was green and intact. Conditions were drier again in the second phase of survey and rainfall for the February-April period was almost 87 mm below the average monthly means. A total of 35 mm of rainfall was observed across two days during the second phase, potentially promoting SRE activity. Rainfall received 12 months preceding the survey was 145 mm above the annual average and climatic conditions are unlikely to have impacted on the SRE survey results. Previous surveys in the vicinity of the survey area (Astron Environmental Services 2016a, 2016b) collected a similar number of SRE species despite varying climatic conditions between these surveys.

It should be noted that some prospective SRE habitats identified in the desktop assessment were often degraded, or modified by infrastructure development. For example, site OPP38 was extensively disturbed and the vegetation had been cleared in a drainage culvert under a railway. Sites RVM14 and MTH03 were nested within drill pads and heavily disturbed through the construction of tracks and vegetation clearing. There were also signs of cattle grazing, such as site MTH02, although the level of disturbance was comparably minor.

4 Results

4.1 Desktop Assessment

4.1.1 Environmentally Sensitive Areas

There are no ESAs located within, or adjacent to the survey area (Department of the Environment and Energy 2008).

4.1.2 Vertebrate Fauna

The database searches and literature review results indicate that 322 vertebrate fauna have been previously recorded within 40 km of the survey area, including six amphibian species, 102 reptile species, 164 bird species (including one introduced bird species) and 50 mammal species (including 10 introduced mammal species) (Table F.1-F.4, Appendix F). Of these, 33 species are of conservation significance, including three reptile species, 21 bird species and nine mammal species (Table G.1, Appendix G). Of these, nine species were considered to have a 'high' likelihood (inclusive of those previously recorded within the survey area), 11 species were considered to have a 'moderate' likelihood and 13 were considered to have a 'low' likelihood of occurrence within the survey area (Table G.1, Appendix G). This is based on their respective ecology, habitats considered likely to be present and any previous records from historic survey and database records.

Previous surveys undertaken for Rio Tinto in the vicinity of the survey area recorded 12 conservation significant vertebrate fauna species: Northern Quoll (*Dasyurus hallucatus),* Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*), Ghost Bat (*Macroderma gigas*), Western Pebble-mound Mouse (*Pseudomys chapmani*), Eastern Great Egret (*Ardea modesta*) Rainbow Bee-eater (*Merops ornatus*), Wood Sandpiper (*Tringa glareola*), Common Sandpiper (*Actitis hypoleucos*), Sharp-tailed Sandpiper (*Calidris acuminata*), Pilbara Olive Python (*Liasis olivaceus barroni*), Blind Snake (*Anilios ganei*) and Lined Soil-crevice Skink (*Notoscincus butleri*) (Table 8).

4.1.3 SRE Invertebrates

4.1.3.1 Habitat Characterisation

The focus of the SRE survey was on the geology and landforms likely to support a suitable microclimate for SRE fauna, such as deep creek lines, sheltered gorges, south-facing slopes, breakaways and areas with high vegetation cover.

There are seven broad habitat types in the survey area: Riverine, Drainage Line, Gorge, Breakaway, Rocky Hills, Low Hills and Slopes, and Loamy/Stony Plains. Some sections of the survey area have been cleared or are unsuitable for SRE fauna and are not assessed further.

The Loamy/Stony Plains habitat was inferred as unlikely to support significant SRE communities because it is exposed, generally has low moisture holding capacity, a lack of topographic relief, and has uniform vegetation (primarily introduced Buffel Grass and *Triodia* steppe). The riverbeds of the Drainage Line habitat are also not ideal habitat due to the lack of organic leaf litter from flooding and washouts. Low Hills/Slopes may support some SRE species but lack significant topographic relief and shelter. These habitats are not considered a prospective landform for SRE fauna.

The Gorge, Breakaway, Riverine and Rocky Hills landforms may provide suitable habitat for relictual SRE species owing to their capacity to provide sheltered microhabitats (such as between rock boulders, at the base of outcrops or south-facing gullies), the accumulation of organic matter such as leaf litter, and permanent moisture required for many SREs (Harvey 2002). The Gorge, Breakaway and Rocky Hills habitats are also likely to support specialist SRE species, such as *Synsphyronus* pseudoscorpions and selenopid spiders that live under rocks (Crews and Harvey 2011; Crews 2013; Harvey 2010).

4.1.3.2 Species

There are 16 arachnids, 19 crustaceans, four millipedes, three insects, one polychaete and one snail species from the Pilbara currently listed as Threatened or Priority fauna species. These species are mostly subterranean and not part of this assessment, or do not occur in the vicinity of the survey area. Only the two dragonfly species, *Antipodogomphus hodgkini* and *Nosoticta pilbara*, are surface species but no specimens have ever been recorded from the vicinity of the survey area and the species are unlikely to occur locally. There are no PECs or TECs in the vicinity of the survey area on the basis of terrestrial SRE taxa.

The study of available grey and published literature revealed diverse communities of SRE group species in the western Pilbara, including the vicinity of the survey area. However, there is considerable uncertainty about the ranges of most species, either because they are known from only a few specimens or because there is a lack of taxonomic resolution. The collation of data, including results from the WAM databases, revealed at least 137 potential or confirmed SRE species belonging to eight SRE groups that have been collected in the search area (Table F.5, Appendix F). These comprised terrestrial slaters (36), mygalomorph spiders (32), and non-marine snails (19), pseudoscorpions (15), araneomorph spiders (13), scorpions (10), millipedes (eight), centipedes (three) and harvestmen (one). The proportion of confirmed SRE species was low with 21 species comprising millipedes (eight species), spiders (seven), snails (five) and pseudoscorpions (one). Most species were potential SREs with deficient data, reflecting uncertainties caused by insufficient taxonomic resolution and/or the lack of reference collections.

The likelihood of SRE species groups occurring within the survey area is detailed in Table G.2 (Appendix G). Three SRE fauna surveys were conducted recently on behalf of Rio Tinto in the vicinity

of the survey area. The level 2 fauna survey at Bungaroo collected 30 species in SRE groups and seven potential SREs: the slaters *Spherillo* sp. indet., *Buddelundia* '61' and Buddelundiinae sp. indet., pseudoscorpions *Euryolpium* sp. 'Bungaroo', *Ideoblothrus* sp. 'Bungaroo' and *Tyrannochthonius* sp. 'Bungaroo 2', a scorpion species in the *Lychas* 'hairy tail'-group and the spider *Karaops* sp. 'Bungaroo' (Astron Environmental Services 2016a). The Level 2 survey at Middle Robe and East Deepdale collected 27 species in SRE groups and six potential SREs: slater *Philosciidae* sp. indet., scorpions in the *Lychas* 'hairy-tail' and *Lychas* 'multipunctatus'-groups, the spiders *Karaops* sp. 'Middle Robe 1' and *Karaops* sp. 'Middle Robe 2', and harvestman *Dampetrus* sp. nov. 'Middle Robe' (Astron Environmental Services 2016b). A third survey at the Mesa J Mine Extension collected only one species in SRE Groups: the widespread slater *Buddelundia* '15' (Astron Environmental Services 2016c)

Biota (2011) collected two terrestrial snails *Rhagagda convicta* and *Gastrocopta* sp. and two mygalomorph spiders *Aname* sp. A and *Aname* sp. C, from within the survey area. All species were recorded in the Breakaway habitats surrounding site RVM16. All species were classified as potential SRE and with the exception of *Aname* sp. A, had been previously recorded in multiple biological surveys in the vicinity (Astron Environmental Services 2016b).

Other surveys in the surrounding area recorded similar or lower numbers of SRE invertebrates. A seasonal fauna survey at Bungaroo in 2010 collected 10 locally widespread species in SRE groups: two mygalomorph spider species, a selenopid spider, three pseudoscorpion species, two terrestrial and two aquatic snail species (Biota Environmental Sciences 2010). A previous survey in the surrounding area collected four millipede species, one mygalomorph spider, one terrestrial and two aquatic snail species, which were also locally widespread (Biota Environmental Sciences 2007). The fauna survey for the Buckland Project identified seven potential SRE species: one terrestrial snail species in the family Camaenidae, four slater species, one selenopid spider species, and one species of centipede (Phoenix Environmental Sciences 2012). The fauna assessment for the Balla Balla Railway Project, located north-east of the Bungaroo survey area, collected 13 potential SRE invertebrates, comprising three arachnids, two centipedes, seven isopods and one terrestrial snail (Phoenix Environmental Sciences 2014b). Additional surveys across the Mesa A Transport Corridor (Biota Environmental Sciences 2006) and Middle Robe (ecologia Environment 2013) also collected millipedes, mygalomorph spiders and snail species, all more widespread in the area.

Overall, no confirmed SREs or listed invertebrate species have ever been recorded from the vicinity of the survey area or have been collected in previous surveys. None of the potential SRE species collected have ever been assessed as potentially threatened by economic development.

Based on the desktop assessment data, the SRE fauna in the vicinity of the survey area comprises primarily isopods, mygalomorph spiders, pseudoscorpions, scorpions, and terrestrial snails. Potential SRE millipedes, centipedes and harvestmen are less likely to occur. Although no confirmed SRE species have been recorded from the survey area, potential SRE species are most likely to belong to the slater, spider, snail and pseudoscorpion groups. However, such species are likely to be more widespread locally with total ranges of at least several square kilometres and ranges that mirror the wider distribution of landforms (Astron Environmental Services 2016a, 2016b; Biota Environmental Sciences 2007; ecologia Environment 2012).

4.2 Field Survey

4.2.1 Vertebrate Fauna Habitat

4.2.1.1 Fauna Habitats

Seven broad fauna habitat types were recorded in the survey area: Riverine, Drainage Line, Gorge, Breakaway, Rocky Hills, Low Hills and Slopes, and Loamy/Stony Plain. Areas of disturbed habitat were prevalent in the Low Slopes and Hills habitats on the top of Mesa H and the Loamy/Stony Plains habitat in the form of drill pads and the associated tracks. The habitats are described in Table 9 and mapping is presented in Figure H.1 (Appendix H). Habitat assessments undertaken during the survey are detailed in Table C.1-C.2 (Appendix C).

There was no record of recent or past fires in the survey area. The majority of Loamy/Stony Plain and Drainage Line habitats were generally in 'disturbed' to 'very good' condition. Some areas were heavily affected by cattle grazing and Buffel Grass. All other habitats were generally in 'good' to 'high quality' condition depending on the level of grazing, weeds and the presence of tracks. The Rocky Hills, Breakaway and Gorge habitats were generally in 'high quality' condition.

As stated in Section 3.5 a significant level of disturbance was recorded during the fauna survey, including drill tracks and pads, pastoralism and weed infestation. The majority of Drainage Line and Riverine habitats were generally in 'poor' to 'very good' condition due to weed infestation spread through pastoral activities; some areas were also heavily impacted from cattle grazing and therefore the introduction and spread of Buffel Grass (Thompson and Thompson 2010). All other habitats were generally in 'good' to 'high quality' condition depending on the level of grazing and weeds. The Rocky Hills, Gorges and Breakaway habitats generally had the highest quality fauna habitat condition due to isolation from threatening processes such as grazing.

Table 9: Vertebrate fauna habitat types recorded in the survey area.

Habitat type	Extent in survey area (proportion)	Broad habitat description	Vegetation description	Microhabitats	Sites	Habitat condition	Value (broad faunal assemblage and MNES species)	Representative photos	
Riverine	143 ha (2.9%)	Densely vegetated riparian zones of the Robe River often with permanent and semi-permanent water bodies on stony soils	*Eucalyptus camaldulensis* and *Melaleuca argentea* open forest over *Acacia* tall open shrubland over mixed open herbland and open hummock grassland.	Surface water (permanent and semi-permanent) Dense and varied leaf litter Hollow bearing trees and logs	BAT 11, BAT 12, CAM03, CAM06, CAM14, CAM15, CAM17, CAM18, CAM32, CAM33, CAM34, CAM37, HA01, HA02, HA04, HA13, HA15, MHT01, RVM13, SRE10, SRE11	Good to High Quality	High value to a wide spectrum of fauna species that are likely to reside in Riverine habitats. Moderate value to target MNES species as they are likely to traverse and forage within this habitat type.		
Drainage Line	589 ha (11.9%)	Broad open valley floor of the Robe River on stony soils	*Eucalyptus camaldulensis* or *Corymbia hamersleyana* low woodland over *Acacia* tall open shrubland over mixed open herbland and *Triodia wiseana* hummock grassland.	Sparse isolated vegetation Minimal leaf litter	BAT02, CAM05, CAM30, CAM43, CAM44, HA05, HA12 HA20, HA22, HA23, SRE08 SRE09	Disturbed to Good Quality	Moderate value to a wide spectrum of fauna species that are likely to reside in Drainage habitats. Low value to target MNES species as they do not provide significant refugia or shelter.		
Gorge	17 ha (0.3%)	Deep often rocky gorges, sometimes with ephemeral, semi-permanent or permanent pools	*Eucalyptus leucophloia* scattered low trees over *Triodia* hummock grassland.	Overhangs, crevices, caves, tree hollows, ephemeral, semi-permanent and permanent water	BAT08, BAT09, BAT10, CAM10, CAM11, CAM12, CAM13, CAM19, CAM20, CAM31, CAM35, CAM38, CAM39, HA14, HA21, SRE06, SRE07, SRE12, BAT14, HA06	High Quality	Primary high value habitat for target MNES species. Provides significant refugia/shelter sites and supports a diversity of fauna species.		
Breakaway	84 ha (1.7%)	Breakaway or ridge line, falling away to steep scree slope or drainage line	*Eucalyptus leucophloia* scattered low trees over *Acacia* open shrubland over *Triodia wiseana* open hummock grassland and *Eriachne mucronata* open tussock grassland.	Caves (roost/feed caves) Cracks and crevices Sheltered leaf litter	BAT13, CAM04, CAM07, CAM16, CAM21, CAM22, CAM23, CAM24, CAM26, CAM27, CAM28, CAM36, CAM40, CAM41, CAM42, HA10, HA17, RVM12, RVM16	High Quality	High value to a low diversity of fauna species that are likely to reside in Breakaway habitats. High value to target MNES species as they are likely to roost and den within this habitat type.		
Rocky Hills	66 ha (1.3%)	Stony hills on high ranges with dissected valleys and gorges	*Eucalyptus leucophloia* low open woodland over *Acacia inaequilatera* scattered tall shrubs over *Triodia* open hummock grassland.	Termite mounds, tree hollows, crevices	BAT07, HA03	High Quality	Moderate value for target MNES species as they are likely to traverse and forage within these habitats. Moderate value to a low diversity of fauna species that are rocky habitat specialists.		

Habitat type	Extent in survey area (proportion)	Broad habitat description	Vegetation description	Microhabitats	Sites	Habitat condition	Value (broad faunal assemblage and MNES species)	Representative photos	
Low Hills and Slopes	1,897 ha (38.5%)	Low stony hills and slopes with dissected valleys and drainage on stony soils	*Acacia inaequilatera* scattered tall shrubs over *A. bivenosa* scattered shrubs over *Triodia wiseana* open hummock grassland.	Termite mounds Large *Triodia* hummocks Minimal leaf litter	BAT01, BAT03, BAT04, CAM01, CAM02, CAM08, CAM09, CAM29, HA08, HA09, HA11, HA16, HA18, HA24, RVM14, RVM15, SRE01, SRE04, SRE05	Disturbed to High Quality	Low value to a wide spectrum of fauna species that are likely to reside in Stony Hills and Slopes habitats. Low value to target MNES species as this habitat type offers minimal ecological value to these species.		
Loamy/ Stony Plain	1,762 ha (35.8%)	Low-lying undulating loamy to stony plain within Robe valley floor	*Corymbia hamersleyana* scattered low trees over *Acacia* scattered shrubs over *Triodia wiseana* hummock grassland.	Termite mounds	CAM25, HA07, MHT02, MHT03, SRE02, SRE03	Disturbed to High Quality	Low value to a wide spectrum of fauna species. Low value to target MNES species as they do not provide significant refugia or shelter.		
Disturbed	372 ha (7.6%)	Cleared areas from mining and pastoralism activities	N/A	None	None	Highly Degraded	Little value as fauna habitat.		

Key: Cam - camera (active) site/location; HA - habitat assessment site/location; MTH/RVM- trapping grid site/location; BAT - SM2 acoustic bat recording site/location; SRE – Short Range Endemic sample site

Riverine habitat is considered to be of high importance to fauna species providing a range of ecological values to a wide suite of species. This habitat type in the survey area was often narrow linear isolated pockets of riparian vegetation which is usually denser, taller and more diverse than the adjacent Drainage Line habitat. The vegetation was complex and provided a range of micro niches for fauna species to exploit, such as for shelter and foraging. There were also a significant number of permanent and semi-permanent water bodies that provide drinking opportunities for a range of species and attract prey for predators. This habitat supports conservation listed fauna species such as the Rainbow Bee-eater and provides foraging sites for Ghost Bats and Pilbara Leaf-nosed Bats. In addition a female Northern Quoll was trapped within this habitat suggesting that this individual was using the habitat as a foraging site or an ecological corridor traversing different habitats across the landscape.

Drainage Line habitat is a commonly recorded habitat for the Pilbara region and considered to be of low to moderate value to a wide spectrum of fauna species. The Drainage Line habitat typically exhibits a moderate diversity of microhabitats, with some tree hollows and woody debris (logs and leaf litter). Within the survey area this habitat was generally devoid of vegetation when compared to Riverine habitat, with less dense and less complex vegetation. There were some locations with water bodies, albeit less significant and less permanent, which would likely be seasonally inundated during large rainfall events only. Conservation listed species including the Rainbow Bee-eater and Lined Soil-crevice Skink may occur in this habitat.

Gorge habitat is the most restricted habitat in the survey area. Gorges are a common feature of the Pilbara; however, as they tend to be narrow, linear features, gorges represent a small proportion of the total land area. In addition, they represent important shelter or roosting habitat for a number of MNES species, including the Pilbara Olive Python, Ghost Bat, Pilbara Leaf-nosed Bat and Northern Quoll. They may also support Priority listed species such as *Anilios ganei*. Deep caves and semi-permanent rock pools were recorded in this habitat type; these habitat features can provide refuge for fauna during harsher drier seasonal conditions. This habitat is considered of high value as it contains a complexity of microhabitats and supports conservation significant fauna species.

Breakaway habitat is a common feature of the Pilbara but because they tend to be narrow, linear features, they represent a small proportion of the total land area. The breakaways of the survey area were often associated with the Mesa habitat. Breakaway habitat contained microhabitats such as crevices, overhangs and caves that provide shelter opportunities for MNES species, including the Pilbara Olive Python and Northern Quoll. A number of caves were being used as diurnal roosts and nocturnal feeding roosts for the Ghost Bat, potential den sites for the Northern Quoll and for the Pilbara Olive Python. The Breakaway habitat provides critical habitat values to a number of conservation listed species including MNES, therefore it is considered of high importance for fauna.

Rocky Hills are common and widespread throughout the Pilbara. This habitat generally has low vegetation complexity and low diversity of microhabitats; however, MNES species (such as the Northern Quoll) are likely to traverse and forage within these habitats. Other conservation significant species such as the Western Pebble-mound Mouse and *Anilios ganei* may also utilise this habitat. Therefore this habitat is considered of moderate value for fauna.

Low Hills and Slopes habitat was the most common habitat within the survey area. The Low Hills and Slopes habitat is widespread and common throughout the Pilbara region and although there are a few conservation listed species that may utilise this habitat, they are unlikely to be restricted to it, with the possible exception of the Western Pebble-mound Mouse. This habitat generally has low vegetation complexity and low diversity of microhabitats available for fauna species to exploit. The soils are generally stony and compact, reducing the potential opportunities for burrowing species. This habitat is considered to be of low value to a broad spectrum of fauna species.

Loamy/Stony Plain habitat was the second most common habitat within the survey area. It is also widespread and common throughout the Pilbara region and although there are a few species of conservation significance that may utilise it, they are not restricted to this habitat type. Conservation significant fauna likely to occur in this habitat type include the Western Pebble-mound Mouse and Rainbow Bee-Eater. This habitat generally had low vegetation complexity and microhabitat diversity as well as areas that were heavily affected by grazing and Buffel Grass; therefore, it is considered to be of low value for fauna.

4.2.1.2 Significant Habitat Areas

Several significant habitat features were recorded throughout the survey area. This includes five permanent pools (8.5 ha) that were located within the Robe River (Figure H.1 and Table H.1, Appendix H).

No significant bat roosts or other significant areas were identified during the current survey. However, seven Ghost Bat caves were identified by Astron (2014) during a previous survey, two of which were deemed to be diurnal roosts (and possible maternal roosts), three (two that were part of one system) were deemed to be nocturnal feeding roosts and two caves were determined to not be used, following a targeted cave assessment by Bat Call WA Pty Ltd (2017) (Figure H.1 and Table H.1, Appendix H). An additional seven caves identified during the targeted cave assessment were deemed to be nocturnal feeding roosts (Bat Call WA 2017) (Figure H.1 and Table H.1, Appendix H).

None of the fauna habitats were considered to be synonymous with any TECs or PECs relating to terrestrial fauna listed in the Pilbara region (Department of Parks and Wildlife 2015c). It should be noted however, that two PECs relating to subterranean invertebrates overlap the survey area - '*Subterranean invertebrate communities of mesas in the Robe valley*' (P1) and '*Stygofaunal Community of the Bungaroo Aquifer'* (P1). These have not been addressed in this report as they relate to subterranean habitats.

4.2.1.3 Habitat Suitability for MNES Species

Northern Quoll

Approximately 101 ha (2%) of the survey area, comprising Gorge and Breakaway habitats, was considered potential shelter and foraging habitat for the Northern Quoll (Table B.10, Appendix B; Figure H.2, Appendix H). The Gorge and Breakaway habitats contain rocky environments of high relief that are particularly important for Northern Quolls in the Pilbara as they provide denning sites for breeding and shelter and diverse microhabitats for foraging.

Approximately 209 ha (4%) of the survey area was considered suitable foraging and dispersal habitat, which mostly consisted of Riverine and Rocky Hills habitats, particularly where these habitats were in close association with the Gorge and Breakaway habitats as they provided microhabitats such as crevices and cracks for foraging (Figure H.2, Appendix H). The remaining 4,620 ha (94%) of the survey area was considered to provide limited foraging and dispersal habitat, consisting of Drainage Line, Loamy/Stony Plain and Low Hills and Slopes habitats (Figure H.2, Appendix H).

Ghost Bat

Approximately 101 ha (2%) of the survey area, comprising the Gorge and Breakaway habitat, was considered potential shelter and foraging habitat (Table B.10, Appendix B; Figure H.3, Appendix H), due to the presence of two diurnal roosts and a number of nocturnal feeding roosts.. One of the diurnal roosts (possible maternal roost) was found in Gorge habitat and the other diurnal roost (possible occasional use as a maternal roost) was found within Breakaway habitat. Both Gorge and Breakaway habitats contained caves and deep shelters used as nocturnal feeding roosts. Both habitats contain complex vegetation structures and microhabitats that support prey species and foraging sites for the Ghost Bat.

Approximately 798 ha (16%) of the survey area, which consisted of Riverine, Drainage Line and Rocky Hills habitat, was considered suitable foraging and dispersal habitat (Figure H.3, Appendix H). The tall trees found in the Riverine and Drainage Line habitats provide ideal foraging/hunting perches particularly in areas that contain permanent surface water or thick vegetation. The Rocky Hills habitat contains microhabitats such as boulder piles, crack and crevices that support a wide range of prey species for the Ghost Bat.

The remaining 4,031 ha (82%) of the survey area, comprising the Loamy/Stony Plain and Low Hills and Slopes habitats, was considered to provide limited foraging and dispersal habitat (Figure H.3, Appendix H).

Pilbara Leaf-nosed Bat

Approximately 17 ha (0.3%) of the survey area, comprising the Gorge habitat, was considered potential shelter and foraging habitat for this species (Table B.10, Appendix B; Figure H.4, Appendix H), due to the presence of nocturnal refuge caves. The Pilbara Leaf-nosed Bat requires deep, humid, climatically stable caves for diurnal and maternal roost sites. The caves located in the Gorge habitat of the survey area do not fit these criteria; however, they can be classified as nocturnal refuge caves (Department of the Environment 2017) that are occupied or entered at night for resting or feeding.

Approximately 816 ha (16.7%) of the survey area, which consisted of Riverine, Drainage Line and Breakaway habitat, was considered suitable foraging and dispersal habitat (Figure H.4, Appendix H). The complex vegetation structure, in particular surrounding areas of permeant water, of the Riverine and Drainage Line habitats provide ideal foraging habitat for this species.

The remaining 4,097 ha (83%) of the survey area, comprising the Loamy/Stony Plain, Rocky Hills and Low Hills and Slopes habitats, was considered to provide limited foraging and dispersal habitat (Figure H.4, Appendix H).

Pilbara Olive Python

Approximately 244 ha (5%) of the survey area, comprising the Gorge, Breakaway and Riverine habitats, was considered as potential shelter and foraging habitat for the Pilbara Olive Python (Table B.10, Appendix B; Figure H.5, Appendix H). The caves and overhangs of the Gorge and Breakaway habitats provide denning sites and ambush locations frequented by this species. The thick vegetation and log piles/flood refuse provide shelter and ambush locations within the Riverine habitat, especially in areas containing permanent or semi-permanent water sources.

Approximately 655 ha (13%) of the survey area was considered suitable foraging and dispersal habitat, which consisted of Rocky Hills and Drainage Line habitats (Figure H.5, Appendix H). These

habitats are often adjacent to the more suitable Gorge and Riverine habitats and provide dispersal opportunities for the Pilbara Olive Python.

The remaining 4,031 ha (82%) of the survey area was considered to provide limited foraging and dispersal habitat, consisting of Loamy/Stony Plain and Low Hills and Slopes habitats (Figure H.5, Appendix H).

4.2.2 Vertebrate Fauna Species

There were 169 vertebrate fauna species recorded within the survey area during the survey (Table 10). A complete list of recorded species is provided in Tables F.6-F.10 (Appendix F). The following sections provide detailed results for each major taxonomic group sampled.

Table 10: Number of vertebrate fauna species recorded during the survey.

Fauna taxonomic group	No. of native species recorded	No. of conservation significant species recorded	No. of introduced species recorded
Amphibians	2	0	0
Reptiles	55	2	0
Birds	85	2	0
Mammals	27	4	4
Total	**169**	**8**	**4**

4.2.2.1 Herpetofauna

Two amphibian species were recorded during the survey: *Litoria rubella and Uperoleia saxatilis* (Table F.6, Appendix F). Frogs were either caught in pitfall traps, sighted, or heard calling during targeted searches. No conservation significant species were recorded.

Fifty-five reptile species were recorded during the survey (Table F.7, Appendix F). The most abundant groups encountered were the skinks (257 records, 63%), which was also the most speciose with 17 species, followed by the geckos (72 records, 18%) with 10 species. The most commonly recorded species were *Ctenotus grandis titan* (95 records) and *Eremiascincus isolopes* (50 records). The most speciose site was RVM15 (Low Hills and Slopes) with 20 species and MHT02, MHT03 and RVM14 (Loamy/Stony Plains and Low Hills and Slopes) each with 19 species. Six of the 55 reptile species (11%) were not captured at trapping grids, but were recorded from targeted and opportunistic records.

Two conservation significant species were recorded during the survey. The Lined Soil-crevice Skink (P4) was caught at MHT03, RVM14 and RVM15 (Loamy/Stony Plains and Low Hills and Slopes). An individual Pilbara Olive Python (S3; VU), was recorded opportunistically in the Riverine habitat during a nocturnal survey.

Species accumulation curves were beginning to asymptote during the current surveys (Figure 6), and based on estimates of total species richness, between 62% and 82% of the total species pool was recorded (Table 11). As an additional four species (7% of all species) were recorded using methods other than trapping, the survey effort recorded the majority of the herpetofauna present in the survey area.

Table 11: Total number of herpetofauna taxa sampled in comparison to estimates of the total species pool based on several models.

	Observed	Estimated			
		Chao2	Jackknife 1	Jackknife 2	Bootstrap
Number of species	51	70.9	72.6	82.1	61.6
Estimated % sampled		71.9	70.2	62.1	82.8

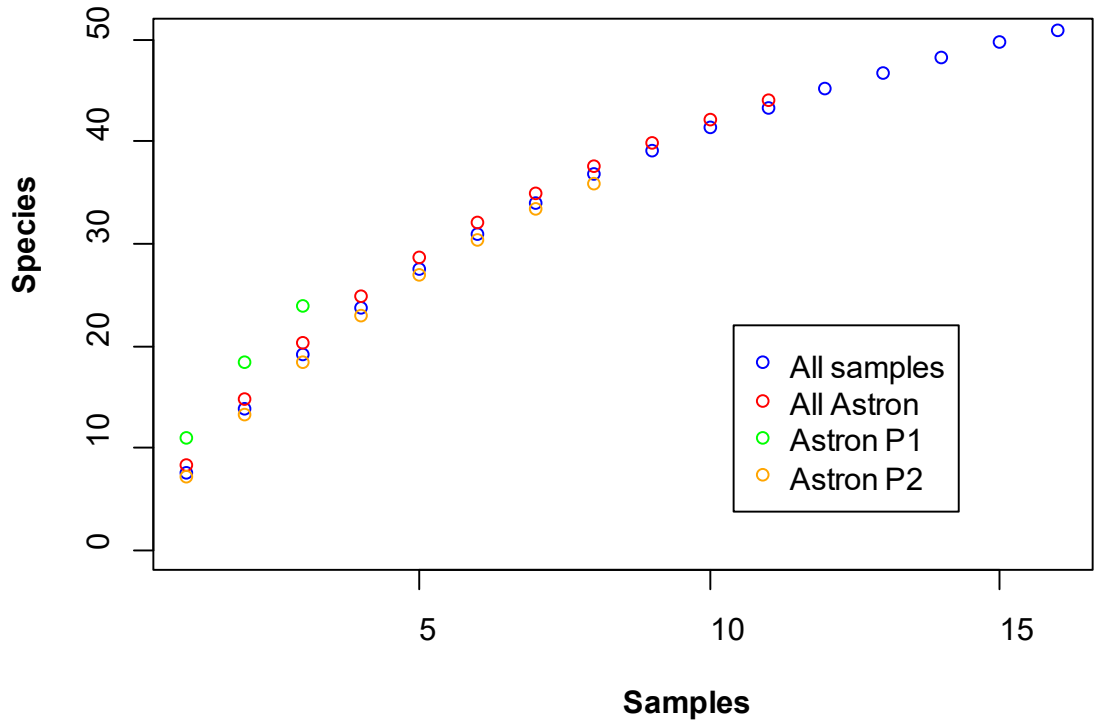

Figure 6: Species accumulation curves for herpetofauna surveys.

There was a significant difference in species composition between habitat types (ANOSIM R = 0.51, P=0.009), with each trapping site generally grouped with other trap sites in the same habitat type and showing similar species compositions. The trap sites in the Breakaway habitat were the most distinct in species composition for herpetofauna. This is likely due to the fact that the trap sites in this habitat type were comprised of Elliot traps rather than pitfall traps (owing to the lack of soil to dig pitfalls into). As such, herpetofauna captures were lower in the Breakaway habitat than the other habitats (Figure 7).

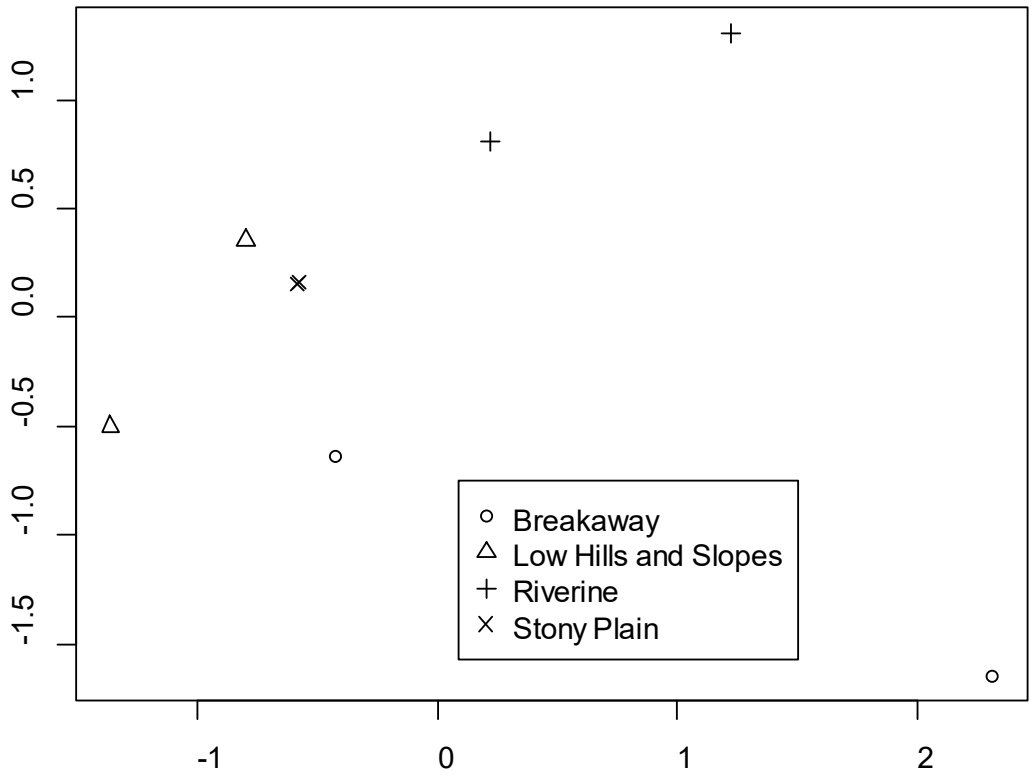

Figure 7: Two-dimensional ordination of herpetofauna species assemblages of each site.

4.2.2.2 Birds

Eighty-five bird species were recorded during the survey (Table F.8, Appendix F). The most commonly recorded species was the Painted Finch (*Emblema pictum),* with a total of 208 records and the Zebra Finch (*Taeniopygia guttata*) with 53 records. The most abundant group of birds was the Estrilidae (Finches), with 263 records accounting for 34% of all records. The most speciose families observed were the Accipitridae (Eagles, Kites and Hawks) and Meliphagidae (Honeyeaters), which comprised seven and six species, respectively. The most speciose sites were RVM13 (Riverine) with 36 species and MTH03 (Loamy/Stony Plain) with 29 species. Of the 85 bird species recorded 41 species were not recorded at trapping grids, but were recorded from targeted and opportunistic searches.

One species of conservation significance was recorded during the survey. The Rainbow Bee-eater (S5; Mi) was recorded on numerous occasions throughout the survey area in a variety of habitats including Loamy/Stony Plains, Drainage Lines and Breakaways.

Species accumulation curves appeared to asymptote during the current surveys (Figure 8), and based on estimates of total species richness, between 61% and 85% of the total species pool was recorded (Table 12). The data does not include an additional 25 bird species (29%) that were recorded opportunistically.

There was a significant difference in species composition between habitat types (ANOSIM R = 0.646, P=0.008; Figure 9) with each trapping site generally grouped with other trap sites in the same habitat type and showing similar species compositions.

Table 12: Total number of bird taxa sampled in comparison to estimates of the total species pool based on several models.

	Observed	Estimated			
		Chao2	Jackknife 1	Jackknife 2	Bootstrap
Number of species	60	94.8	83.5	98	70.9
Estimated % sampled		63.3	71.9	61.2	84.6

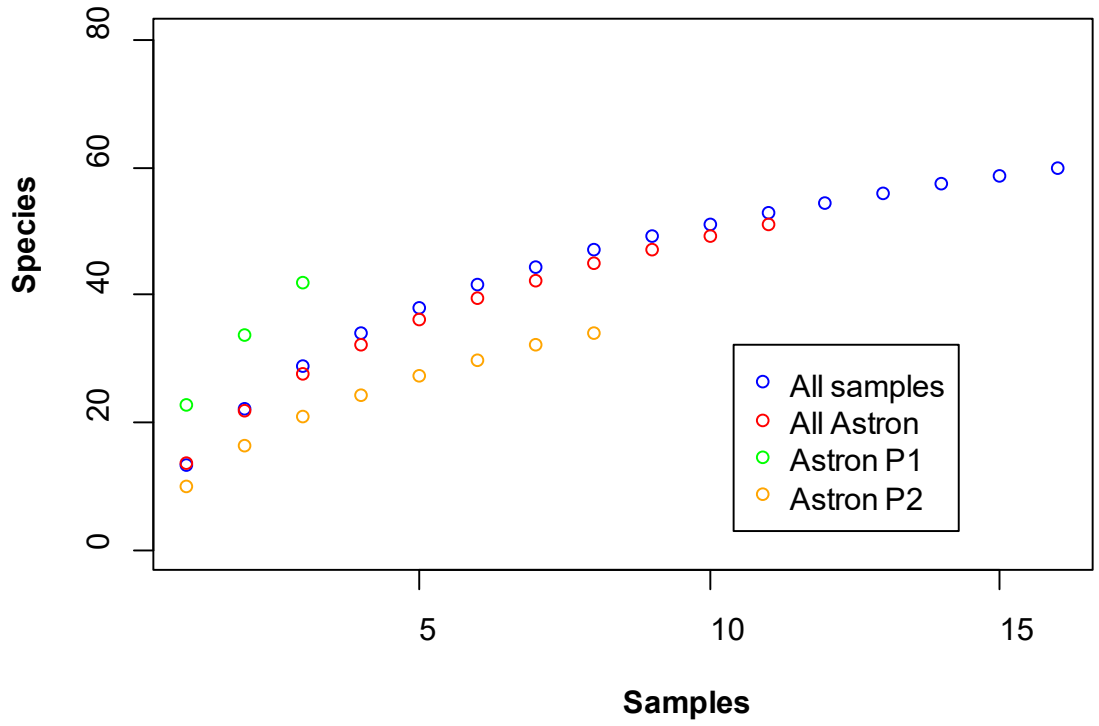

Figure 8: Species accumulation curves for bird surveys.

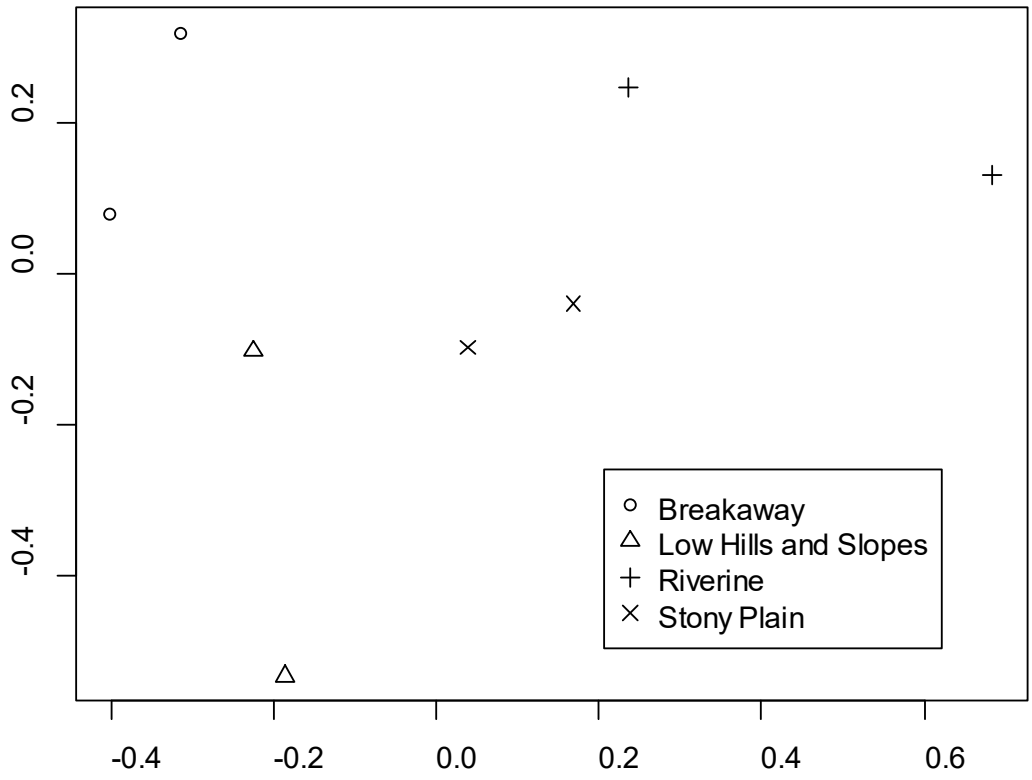

Figure 9: Two-dimensional ordination of bird species assemblages of each site.

4.2.2.3 Mammals

Twenty-seven species of mammal were recorded during the survey, including four introduced species: Cat (**Felis catus*), Dog/Dingo (**Canis familiaris*), European Cattle (**Bos taurus*) and House Mouse (**Mus musculus*) (Table F.9-F.10, Appendix F). The most commonly trapped species was the Pilbara Ningaui (*Ningaui timealeyi*) with 20 captures (23% of trap records). Also commonly encountered was Planigale (*Planigale* sp. 1) with 17 captures and the Common Rock Rat (*Zyzomys argurus*), with 14 captures. The most speciose trapping sites were MHT01 (Riverine) and MHT03 (Loamy/Stony Plain) with six species each. The most commonly recorded species including targeted and opportunistic records was Northern Quoll with four individuals captured and 22 image records at 14 different sites. Nine bat species were recorded from the acoustic recording sites (Table F.10, Appendix F).

Four species of conservation significance were recorded during the survey: Northern Quoll (S2; EN), Pilbara Leaf-nosed Bat (S3; VU), Ghost Bat (S3; VU) and Western Pebble-mound Mouse (P4).

Species accumulation curves reached an asymptote during the current surveys (Figure 10), and based on estimates of total species richness, between 81% and 90% of the total species pool were recorded (Table 13). The data does not include any bat species, which make up 33% of the mammal species, as well as an additional six species that were recorded opportunistically.

There was no significant difference in species composition between habitat types, although the two Loamy/Stony Plain sites were very similar in composition (ANOSIM R = 0.313, P=0.129, Figure 11).

Table 13: Total number of mammal taxa sampled in comparison to estimates of the total species pool based on several models.

	Observed	Estimated			
		Chao2	Jackknife 1	Jackknife 2	Bootstrap
Number of species	12	13.5	14.9	13.4	14.3
Estimated % sampled		88.9	80.5	89.6	83.9

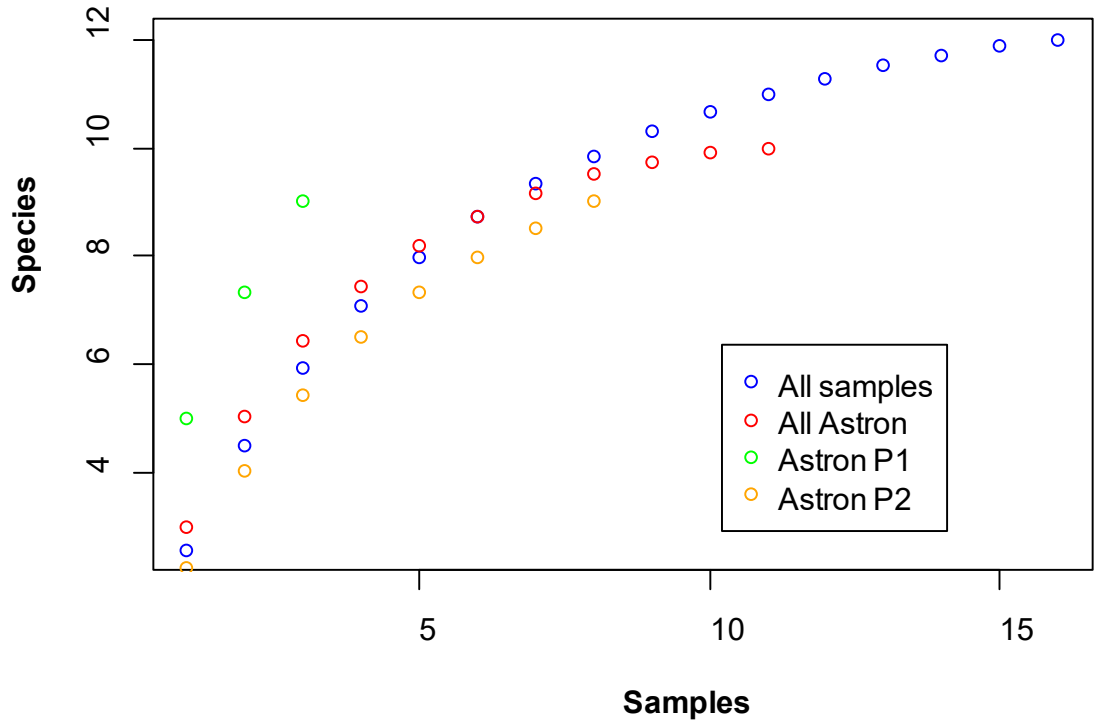

Figure 10: Species accumulation curves for mammal surveys.

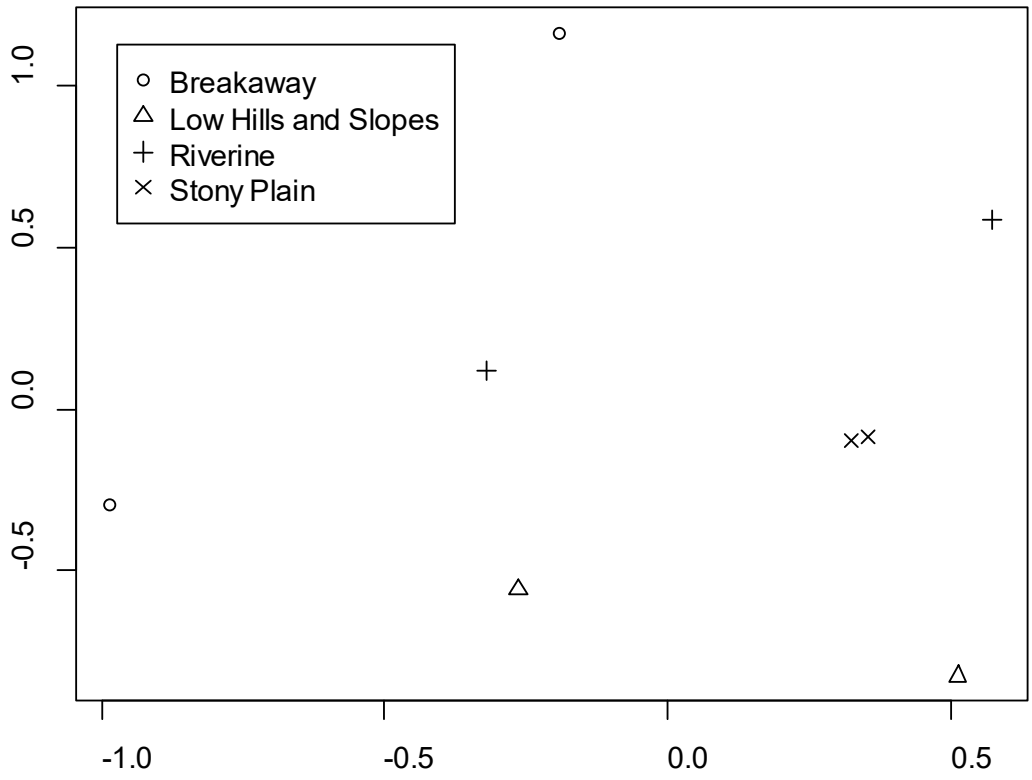

Figure 11: Two-dimensional ordination of mammal species assemblages of each site.

4.2.2.4 Conservation Listed Species Recorded

Eight vertebrate species of conservation significance have been recorded within the survey area. The locations of these species records from the current survey, as well as previously recorded species, are shown in Figure I.1 and detailed in Table I.1 (Appendix I).

Pilbara Olive Python (*Liasis olivaceus barroni*)

The Pilbara Olive Python (VU; S3) prefers escarpments, deep gorges, water holes and rock piles associated with permanent pools in rocky areas in the ranges of the Pilbara region (Pearson 1993; Wilson and Swan 2010). Microhabitat preferences of the Pilbara Olive Python are under rock piles, on top of rocks or under spinifex (Tutt et al. 2004). Individuals spend the cooler winter months within caves and rock crevices away from water sources. In the warmer summer months, the pythons are found to move around widely, usually in close proximity to water and rock outcrops (Wilson and Swan 2010). A population is known to exist along the Robe River near Pannawonica (Biota Environmental Sciences 2007).

A single juvenile Pilbara Olive Python was recorded within the Riverine habitat of the survey area (Figure I.1 and Table I.1, Appendix I). Additionally, the presence of this species was recorded on a further two occasions through the forms of scats within the Breakaway habitat type. This species is likely to be found within the Gorge, Breakaway and Riverine habitats particularly in the sites that contain semi-permanent and permanent water. This species has been previously recorded in the vicinity of the survey area (Astron Environmental Services 2016a, 2016b; Biologic Environmental Survey 2014).

Northern Quoll (*Dasyurus hallucatus*)

The Northern Quoll (EN; S2) occurs in a variety of habitats (Oakwood 2008) but is commonly found in open lowland savannah forest and rocky escarpments. Rocky areas are a particularly important zone for quolls in the Pilbara as these areas retain water and provide a diversity of microhabitats. These areas also tend to have greater floristic diversity and productivity resulting in greater prey density compared to non-rocky areas. These rocky areas also provide refuge from feral cats, fire and livestock (Hill and Ward 2010) and provide breeding potential (Department of the Environment 2013).

The Northern Quoll was recorded 32 times during the survey (Figure I.1 and Table I.1, Appendix I), with six capture records (four confirmed separate individuals), 22 remote camera records at 14 different locations and four scats, tracks and/or trace records. Generally the majority of these records were found in the Breakaway habitat; however some records occurred within Riverine and Gorge habitat types (Figure I.1, Appendix I).

A single Northern Quoll (sex unknown) was captured at site RVM16 (Breakaway) during phase 1 in 2010 (Biota Environmental Sciences 2011). During phase 2 a single female Northern Quoll was captured at MHT01 (Riverine) and a single male and two females were captured at RVM16 (Breakaway). As microchip PIT tags were used in the phase 2 survey these records are confirmed as separate individuals.

The Northern Quoll has previously been recorded for the survey area and within the general vicinity (Astron Environmental Services 2014, 2016a, 2016b; Biologic Environmental Survey 2014; Biota Environmental Sciences 2005, 2007, 2011; ecologia Environment 2013). Astron (2014) recorded the Northern Quoll at two locations in the survey area from scat records within the Rocky Hills habitat type. Within the survey area Biologic (2014) recorded the Northern Quoll at two locations, in the Riverine habitat type and Biota (2011) recorded this species once in the Breakaway habitat type. All previous records of this species in the survey area were from sites consistent with the preferred habitat for this species.

Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*)

Pilbara Leaf-nosed Bats (VU; S3) are known to require deep caves characterised by high levels of humidity and stable temperatures (Churchill 2008). This is a result of their limited ability to conserve heat and water (Armstrong 2001; Churchill 1991). Caves deep enough to create this environment are relatively uncommon in the Pilbara, with only 20 to 25 roost sites being known (R. Bullen 2014, pers. comm. 20 Oct 2014). Foraging habitat for the Pilbara Leaf-nosed Bat is diverse and includes riparian vegetation, hummock grassland, and sparse tree and shrub savannah (Duncan, Baker, and Montgomery 1999). Roost sites for the Pilbara Leaf-nosed Bat can be classified (Department of the Environment 2017) based on the following criteria:

- Permanent diurnal roosts—occupied year-round and likely the focus for some part of the 9-month breeding cycle; considered as critical habitat that is essential for daily.
- Non-permanent breeding (maternal) roosts—evidence of usage during some part of the 9-month breeding cycle (July–March), but not occupied year-round; considered as critical habitat that is essential for both the daily and long-term survival.
- Transitory diurnal roosts—occupied for part of the year only, outside the breeding season (i.e. April–June), and which could facilitate long distance dispersal in the region; considered as critical habitat that is essential for both the daily and long-term survival.

- Nocturnal refuge—occupied or entered at night for resting, feeding or other purposes, with perching not a requirement. Excludes overhangs. Not considered critical habitat, but are important for persistence in a local area.

Pilbara Leaf-nosed Bats have also been recorded flying over small watercourses amongst granite boulder terrain, over pools and low shrubs in ironstone gorges, and above low shrubs and around pools in gravelly watercourses with *Melaleuca leucadendron*, such as in Barlee Range Nature Reserve (Armstrong 2001). In the Pilbara, the species has been observed in *Triodia* hummock grasslands covering low rolling hills and shallow gullies, with scattered *Eucalyptus camaldulensis* along the creeks (Armstrong 2001; Churchill 1991).

The Pilbara Leaf-nosed Bat was recorded at eight of the 14 SM2 bat detector locations that were all deemed to be at low activity levels, apart from BAT 14 which recorded 257 calls, which is classified as being a site with high activity levels (Bat Call WA 2016) (Appendix J). BAT 14 was situated at the enterance to a large gorge system, of which most occurs to the south of the survey area. To identify where the Pilbara Leaf-nosed Bats were roosting, four SM2 units were placed strategically along the gorge system during 3 to 8 June 2016 (after the main survey was completed). Progressively increasing time differentials between the SM2 units in the south to the north of this gorge suggest the Pilbara Leaf-nosed Bats likely originated from a known roost site approximately 10 km south of the survey area (Bat Call WA 2016) (Appendix J).

The Pilbara Leaf-nosed Bat has previously been recorded for the survey area and within the general vicinity (Astron Environmental Services 2014, 2016a, 2016b; Biologic Environmental Survey 2014; Biota Environmental Sciences 2009, 2010; ecologia Environment 2013). This species was previously recorded within the survey area by Astron (2014). Acoustic detections were made of this species at eight separate sites within Gorge, Riverine and Low Hills and Slopes habitat types.

The caves of the survey area do not match the criteria to be classsified as roost sites for the Pilbara Leaf-nosed Bat, which is supported by the low activity levels from the SM2 units across most of the survey area. The deeper caves located in the Gorge habitat of the survey area have the dimentions to be classified as potential nocturnal refuges.

Ghost Bat (*Macroderma gigas*)

The preferred habitat of Ghost Bats (VU; S3) is considered to be rocky gorges and breakaways that support caves and crevices used as maternity roosts. The Ghost Bat uses different natural formations for various purposes and for groups to persist they generally require habitats that provide:

- a selection of roosting opportunities with night roosts or feeding sites, day roosts and at least one deep cave with characteristics of a maternity roost
- nearby gullies and gorges with vegetation of vertical complexity (diverse vegetation heights and density) and presence of water that would attract prey species
- a productive foraging area within a 5 km to 10 km radius, usually including a good quality riparian drainage line.

Transient roosts and feeding sites are used by small numbers of Ghost Bats, whereas maternity roosts are used by larger colonies (Armstrong and Anstee 2000). Night feeding roosts (feed caves) are typically shallow caves and shelters/overhangs high in the strata and poorly insulated from the elements (Armstrong and Anstee 2000). Transient day roosts are deeper and more complex, have more insulation providing a more stable temperature and typically have one or more large chambers high enough to avoid predators. Maternity roosts provide additional features to support a

reproducing population including high temperature (27°C to 33°C) and humidity (>85%) (Armstrong and Anstee 2000). The Ghost Bat can have a relatively small nightly foraging range (up to 2 km from the roost where it has been studied in Queensland) (Tidemann et al. 1985; Pettigrew et al. 1986), but has the flight capability to range widely (Bullen and McKenzie 2002), perhaps tens of kilometres in a night. This is evident from genetic markers, which suggest that males are particularly likely to disperse long distances throughout the landscape (Worthington Wilmer et al. 1994; 1999).

Ghost Bats require caves of varying shapes and sizes to fulfil each of its ecological requirements. Caves usage can be classified into three categories: feed caves, day roosts and maternal roosts.

- Feed caves are typically shallow caves or overhangs high in the strata that are poorly insulated from the elements (Armstrong and Anstee 2000). Ghost Bats hunt at night and use feed caves to consume prey they have captured in the surrounding area. Feed caves often contain Ghost Bat scats and/or feeding remnants (typically feathers and small animal bones).
- Day roosts are generally deep, complex caves or disused mines that contain domed ceilings, fissures or passages which create a stable microclimate. These caves are usually lower in the strata making them well insulated. The stable temperature and elevated humidity of these caves relative to the ambient conditions create physiologically benign conditions (McKenzie and Bullen 2009; Armstrong and Anstee 2000; Hall et al. 1997; Leitner and Nelson 1967).
- Maternal roosts like day roosts are generally deep, complex caves or disused mines that contain domed ceilings, fissures or passages which create a stable microclimate and often contain multiple entrances (McKenzie and Hall 2008). Maternal roosts have a stable temperature of 23°C to 28°C and moderate to high relative humidity of 50% to 100% (Armstrong and Anstee 2000; Churchill 1991; Churchill and Helman 1990; Pettigrew et al. 1986).

The Ghost Bat was recorded twice during the current survey through scat collections and acoustic recordings from SM2 bat detectors (Figure I.1 and Table I.1, Appendix I). This includes acoustic recordings on four separate occasions (Figure G.1, Appendix G; Bat Call WA 2016) and from scat piles within temporary feed caves. Seven caves have been previously identified in the 2014 survey of Mesa H (Astron Environmental Services 2014), two of which were deemed to be diurnal roosts (and possible maternal roosts), three (two that were part of one system) were deemed to be nocturnal feeding roosts and two caves were determined to not be used, following a targeted cave assessment (Bat Call WA 2017). An additional seven caves identified during the targeted cave assessment were deemed to be nocturnal feeding roosts (Bat Call WA 2017) (Figure H.1 and Table H.1, Appendix H).

The Ghost Bat has been previously recorded within the vicinity of the survey area (Figure I.1, Appendix I) from past fauna surveys (Astron Environmental Services 2014, 2016a, 2016b; Biologic Environmental Survey 2014; Biota Environmental Sciences 2005, 2006, 2009, 2010, 2011). Within the survey area Astron (2014) has previously recorded the presence of Ghost Bats at 12 locations (six scat locations and six acoustic records).

Rainbow Bee-eater (*Merops ornatus*)

The Rainbow Bee-eater (Mi; S5) is one of the most common and widespread birds in Australia and was a commonly recorded species during bioregional surveys in the Pilbara (Burbidge, Johnstone, and Pearson 2010). The species winters from the Gascoyne north to Indonesia, moving south mainly in late September and early October and north from February to April (Johnstone and Storr 1998). Rainbow Bee-eaters tend to prefer lightly wooded, preferably sandy country near water (Johnstone and Storr 1998).

The Rainbow Bee-eater was recorded on numerous occasions throughout the survey area during both phases of the fauna survey in all habitats including Riverine, Drainage Line, Loamy/Stony Plains, Low Hills and Slopes, Gorge and Breakaway (Figure I.1 and Table I.1, Appendix I). Nine previous records of this species were made within the survey area (Astron Environmental Services 2014; Biota Environmental Sciences 2011; ecologia Environment 2013) and numerous records exist in the vicinity of the survey area (Astron Environmental Services 2011, 2016a, 2016b; Biologic Environmental Survey 2014; Biota Environmental Sciences 2010; ecologia Environment 2013).

Eastern Great Egret (*Ardea modesta*)

The Eastern Great Egret (Mi; S5) is an inland wetland specialist often seen wading in a range of wetlands from lakes, rivers and swamps to estuaries (Johnstone and Storr 1998). Eastern Great Egrets can be seen alone or in small flocks, often with other egret species, and roost at night in small groups. This species has been recorded within the survey area in the Riverine habitat (Astron Environmental Services 2014) and in the vicinity of the survey area (Astron Environmental Services 2014, 2016b; ecologia Environment 2013). The Eastern Great Egret is likely to be present at permanent pools within the Riverine and Drainage Line habitats of the survey area.

Lined Soil-crevice Skink (*Notoscincus butleri*)

The Lined Soil-crevice Skink (P4) is endemic to Western Australia and restricted to the arid north-west of the Pilbara bioregion (Storr, Smith, and Johnstone 1999). This species has been associated with spinifex-dominated areas near creek and river margins (Wilson and Swan 2010).

The Lined Soil-crevice Skink was captured on five occasions during the survey at three trapping grids (MHT03, RVM14 and RVM15); all within the Loamy/Stony Plains and the Low Hills and Slopes habitat types (Figure I.1 and Table I.1, Appendix I). Four previous records of this species were made within the survey area (Biota Environmental Sciences 2006, 2011; ecologia Environment 2013) and the vicinity of the survey area (Astron Environmental Services 2016a, 2016b; Biota Environmental Sciences 2006, 2007, 2010, 2011).

Western Pebble-mound Mouse (*Pseudomys chapmani*)

Although suitable habitat is patchy, extant Western Pebble-mound Mouse (P4) populations are widespread in the extensive ranges of the central and southern Pilbara region (Start 2008). The persistence of abandoned mounds in the Gascoyne and Murchison regions and small, isolated, coastal ranges in the Pilbara indicates considerable recent decline (Start 2008). Colonies occur on the gentler slopes of rocky ranges where the ground is covered by stony mulch and vegetated by hard spinifex, often with a sparse overstorey of eucalypts and scattered shrubs, typically *Senna, Acacia* and *Ptilotus* (Start 2008). Mounds are also sited close to narrow ribbons of *Acacia* dominated scrub along incised drainage lines (Start 2008).

Five inactive mounds were recorded within the Low Hills and Slopes habitat type during the survey (Figure I.1 and Table I.1, Appendix I). This species has been previously recorded in the survey area; Astron (2014) recorded one inactive pebble-mound and Biota (2006) captured one individual from the Low Hills and Slopes habitat type. Numerous records of this species exist from the vicinity of the survey area (Astron Environmental Services 2014, 2016a, 2016b; Biologic Environmental Survey 2014; Biota Environmental Sciences 2006, 2007).

4.2.2.5 Conservation Listed Species Potentially Occurring in the Survey Area

One species, the Blind Snake, *Anilios ganei* (P1), was not recorded in the survey area but was considered to have a high likelihood of occurring (Table G.1, Appendix G).

The Blind Snake *Anilios ganei*, is often poorly collected in vertebrate fauna surveys, but is known from the Pannawonica local area. This species has been associated with moist gorges and gullies (Wilson and Swan 2010) but potentially occurs over a wide range of other stony habitats. Given its cryptic fossorial habit this species is rarely encountered. Little is known of this species' ecology but like most other blind snakes, it is insectivorous, feeding on termites and their eggs, and larvae and pupae of ants (Wilson and Swan 2010). This species has been recorded within the vicinity of the survey area (Astron Environmental Services 2016a) and is likely to be present within suitable habitats, including the Gorge, Breakaway and Rocky Hills habitat types of the survey area.

Eleven species were not found in the survey area but were all considered to have a moderate likelihood of occurrence: Fork-tailed Swift (Mi; S5), Cattle Egret (Mi; S5), Letter-winged Kite (P4), Australian Painted Snipe (EN; S2), Common Sandpiper (Mi; S5), Sharp-tailed Sandpiper (Mi; S5), Wood Sandpiper (Mi; S5), Common Greenshank (Mi; S5), Oriental Pratincole (Mi; S5), Long-tailed Dunnart (P4) and Short-tailed Mouse (P4) (Table G.1, Appendix G). Although suitable habitat is present within the survey area, these species are either seasonal migrants only present at certain times of the year or they are cryptic species such as Australian Painted Snipe and Oriental Pratincole, making individuals difficult to record during fauna surveys.

An additional 13 species not found in the survey area were considered to have a low likelihood of occurrence due to lack of suitable habitats (Table G.1, Appendix G).

4.2.3 Invertebrate Fauna Species

4.2.3.1 Invertebrate Habitats

Seven potential SRE habitat types were identified differing in their prospectivity for SRE fauna. The most prospective habitats were Breakaway and Gorge habitats, followed by Rocky Hills, Riverine habitats and Drainage Line habitats. Breakaway and Gorge habitats were also the least common landforms, which together comprised only 2% of the survey area. The most common habitat types, that together account for more than 74.3% of the survey area, were assessed as not suitable or having low suitability for supporting SREs in the desktop assessment. The fauna habitats' suitability to support SRE species are detailed in Table 14 and mapping is presented in Figure H.1.

Table 14: Suitability of habitat types for SRE fauna within the survey area.

Landform/habitat	Total area (ha)	Total area (%)	Suitability for SRE fauna
Riverine	143 ha	2.9%	Moderate
Drainage Lines	589 ha	11.9%	Moderate
Gorge	17 ha	0.3%	High
Breakaway	84 ha	1.7%	High
Rocky Hills	66 ha	1.3%	Moderate
Low Hills and Slopes	1,897 ha	38.5%	Low-Moderate
Loamy/Stony Plains	1,762 ha	35.8%	Low
Disturbed	372 ha	7.6%	N/A
TOTAL	**4,930 ha**		

Riverine habitats of the Robe River valley in the survey area comprised linear isolated pockets of riparian vegetation and associated woodlands which are denser, taller and more diverse than the adjacent Drainage Line habitat. The vegetation was complex and provided a range of micro-niches for SRE fauna. Permanent pools of water were present during the survey and the area generally had more moisture than adjacent habitat types. This habitat was sampled as sites MTH01, SRE10, SRE11 and RVM13 and the potential SRE scorpion *Lychas* 'sp. nov. 1' (MHT01, RVM13) was collected. This species was identified using molecular methods and its actual range is currently not clear. Overall, the survey data confirmed the desktop assessment that this is moderately suitable habitat for SRE fauna.

Drainage Line habitats are open riverbeds of the Robe River that runs through the survey area from east to west. Although some portions of this habitat are well-vegetated, the majority of the Drainage Line habitat in the survey area is open, exposed riverbeds with little leaf litter. The Drainage Line habitat associated with the Low Hills and Slopes or Breakaway habitats have an elevated capacity to hold moisture and complex vegetation associations providing a more suitable environment for SRE species. Site SRE09 represented this habitat type. The collected *Indolpium* pseudoscorpions, are widespread species that have been collected during previous fauna surveys in the surrounding area (Astron Environmental Services 2016a, 2016b). This habitat is considered to have moderate suitability for SRE fauna but it appears that the species in SRE groups are locally widespread.

Gorge habitat is associated with the Rocky Hills or Breakaway habitats, where deeply carved rock incisions and minor drainage lines provide shade and diverse microhabitats. Minor creek lines and water run-offs lead to higher moisture availability compared to the surrounding areas. Most of the Gorge habitat in the survey area was open and exposed, therefore limiting the amount of moist microhabitats available for SRE species. This is a relatively rare habitat type in the survey area and was represented by sites SRE06, SRE07 and SRE12. The potential SRE slater *Buddelundia* '61' was collected in the Gorge habitat but is also known from the Bungaroo area (Astron Environmental Services 2016a). No other potential SREs were collected in this habitat type. The Gorge habitat is generally considered as having high suitability for SRE habitat but was surprisingly poor in the survey area for unknown reasons. Site-specific characteristics such as sun exposition and hydrogeology may account for this.

Breakaway habitat contains exposed rock faces with accumulations of rock boulders and scree. It differs from the geologically similar Low Hills and Slopes habitat in that the rock strata are not compacted and without a weathered zone near the surface. It provides shelter for SRE fauna and diverse microhabitats for both habitat specialists and moisture-dependent SRE fauna. This habitat type was sampled as sites SRE08, RVM12, RVM16 and OPP37. The collected fauna comprised both widespread (*Buddelundia* '14hr') and potential SRE (*Buddelundia* '61') species. Similar results were acquired for the arachnid fauna, with two of the collected species (*Indolpium* sp. indet. and *Beierolpium* 8/4) widespread and the third (spider *Karaops* sp. indet.) representing a potential SRE. All sampled SRE groups are typical representatives of Breakaway habitats and specialist species that live under rocks and gravel. The distribution of the species present will mirror the degree of connectivity for these habitats.

Rocky Hills habitat denotes the high-elevation rock features isolated to the south-west of the survey area. This habitat type is deeply incised by creek lines and valleys. No SRE sampling was undertaken within this habitat type. Based on its rocky microhabitats it is expected to provide habitat for specialist species that live under rocks and gravel, similar to those found in the Breakaway habitats. This habitat type represents a small portion of the survey area and is the dominant habitat/landform to the south of the survey area.

Low Hills and Slopes habitat is widespread in the survey area and was sampled by sites SRE01, SRE04, SRE05, RVM14 and RVM15. Both sites RVM14 and RVM15 were generally well-vegetated with *Triodia* and some emergent *Eucalyptus leucopholia* over a stony surface. The collected invertebrates comprised widespread species (scorpions *Lychas* 'pilbara1' and *Lychas* 'harveyi' and spider *Aname mellosa*) and no potential SRE species were collected. Although there is some potential for SRE fauna to be present in this habitat, most species are clearly widespread in the western Pilbara and have also been recorded in previous fauna surveys from other habitat types (Astron Environmental Services 2016a, 2016b). Overall, this confirms the general assessment that this habitat has low to moderate suitability for SRE fauna.

Loamy/Stony Plains habitat is the most widespread habitat type in the survey area and was sampled by sites MHT02, MHT03, SRE02 and SRE03. Although soil types differ, this habitat type is generally exposed and has low microhabitat diversity compared to other landforms. It is therefore surprising that a moderately diverse SRE community was recorded in this habitat, including the potential SRE scorpion *Lychas* 'sp. nov. 2' and the more widespread *Lychas* 'multipunctatus'. However, both species were identified from genetic data and range estimates are conservative because no comparative genetic data is available for morphologically similar specimens from other areas in the Pilbara. Both species may actually have been sampled during previous surveys in this region (Astron Environmental Services 2016a, 2016b) but more sequencing work would be required to test this. Certainly, it appears that there is a high degree of connectivity in this habitat type over wide areas.

Overall, none of the habitat types sampled in the survey area were inferred as having a very high prospect for SRE fauna. The Loamy/Stony Plains habitat had a higher suitability than suggested by the desktop review, which may reflect site-specific characteristics or survey design. Other habitat types that are usually considered highly prospective (Gorge habitat) did not have a very diverse SRE fauna. No individual sites were overly rich and there were no local 'hotspots' of SRE biodiversity. The two habitat types that are highly localised and have the potential to restrict dispersal in SRE fauna (Gorge and Breakaway habitats) were not overly rich in SRE fauna.

4.2.3.2 Invertebrate Species

A total of 36 specimens belonging to at least 14 invertebrate morphospecies were collected from the survey area. Scorpions were the most diverse group with seven species and 12 specimens, followed by slaters (three species; 16 specimens), pseudoscorpions (two species; four specimens) and spiders (two species; four specimens). No centipedes, harvestmen, millipedes and snail specimens (aquatic or terrestrial) were collected. No listed invertebrate species were collected during the survey.

Based on these results, eight species (64%) were not considered to be, or unlikely to be, SREs. No confirmed SRE species were collected; however, five species (36%) were classified as potential SRE species, principally in the scorpion (two species), spider (two species) and slater (one species) faunas (Table 15 and Figure I.2, Table I.2, Appendix I). These species are:

- slaters – *Buddelundia* '61'
- scorpions – *Lychas* 'sp. nov. 1' and *Lychas* 'sp. nov. 2'
- spiders – *Karaops feedtime* and *Karaops* sp. indet.

Of these potential species, the slater *Buddelundia* '61' was collected from multiple habitats that extend far beyond the survey area. The scorpions *Lychas* 'sp. nov. 1' and *Lychas* 'sp. nov. 2' were identified using DNA sequence data and are treated here as potential SREs primarily because there were no matching sequences in the databases of the WAM and the distribution ranges cannot be inferred at present. It is likely that both species are more widespread and future genetic work is

likely to show a wider distribution. Morphologically similar specimens have been collected from other areas of the western Pilbara but genetic work still has to be undertaken on these samples. The two spider-species were collected from juveniles and also identified using DNA sequence data. *Karaops feedtime* is a potential SRE but has been collected from a disturbed site and is certainly more widespread, as has been suggested by the genetic data. *Karaops* sp. indet. is also a potential SRE and has been collected from the Breakaway habitat. However, genetically similar specimens have been collected from localities outside the Mesa H survey area and the species is clearly more widespread. *Karaops* specimens have also been collected previously during fauna surveys at Bungaroo and Middle Robe/East Deepdale (Astron Environmental Services 2016a, 2016b) and they may belong to this species.

Overall, only a relatively small number of potential SRE species were collected in the survey area. The status of the potential SREs is also often unclear and the data available is not sufficient to establish SRE status with certainty (WAM sub-categories 'Data Deficient' or 'Molecular Evidence' for SRE species). Four of the potential SREs were collected from Loamy/Stony Plains, Low Hills and Slopes or Riverine habitats that are widespread habitat types extending far beyond the survey area, with no obvious barriers for the dispersal of fauna within these habitats. Only one spider species (*Karaops* sp. indet.) occurs in a habitat type that may be more restricted but additional specimens of this species are known from outside the survey area. It should also be noted that no species of *Karaops* have ever been shown to have ranges smaller than the survey area.

Many species known from the desktop assessment to potentially occur within the survey area were not collected. For example, no mygalomorph spider species of the genera *Missulena* (Actinopodidae) and *Synothele* (Barychelidae) were collected, although they occur in similar habitats nearby (Biota Environmental Sciences 2007, 2010, 2011), indicating they are likely to be absent from the survey area. Most species identified in the desktop assessment occur in the wider search area and outside the survey area. They may be absent locally, were not collected, or have ranges that do not coincide with the survey area.

Disturbance factors, such as the presence of weeds, were unlikely to have affected the survey results. The potential impact of these factors is discussed in more detail in Section 3.5. Importantly, sampling for SRE invertebrates is principally opportunistic because most SREs have patchy distributions and can be very difficult to sample, especially when habitat preferences of particular species are unknown, they occur at low abundance, or sampling is outside their narrow activity period.

Table 15: Summary of the potential SRE species within the survey area.

Species / SRE category	WAM SRE category	No. of specimens	Site(s)	Landform	Linear range	Status	Habitat surrogates
Slaters							
Buddelundia '61'	Potential SRE – Research and Expertise	5	OPP37 SRE12	Breakaway Gorge	6.0 km	Also known from Bungaroo	Available
Scorpiones							
Lychas 'sp. nov. 1'	Potential SRE – Molecular Evidence	2	MHT01 RVM13	Loamy/Stony Plains	7.0 km	Probably more widespread	Available
Lychas 'sp. nov. 2'	Potential SRE – Molecular Evidence	3	MHT02 MHT03	Loamy/Stony Plains	Unknown	Sequenced for the first time. Possibly conspecific with the more widespread *Lychas* 'gracilimanus'	Available
Spiders							
Karaops feedtime	Potential SRE – Data Deficient	1	OPP38	Disturbed Areas	Unknown	Unresolved taxonomy, additional records from outside the survey area	Available
Karaops sp. indet.	Potential SRE – Molecular Evidence	1	SRE08	Breakaway	5.7 km	Unresolved taxonomy, additional records from outside the survey area	Available

A summary of the SRE groups recorded and the six potential SRE species identified is provided below.

4.2.3.3 Slaters

Three slater species (and 16 specimens) were collected in this survey. They all belong to *Buddelundia*, a genus that is highly diverse and comprises more than 100 species of which almost all are currently undescribed. All species collected in this survey are widespread.

***Buddelundia* '10bf'**

Thirteen specimens of this morphospecies were collected from site MHT02 in the Loamy/Stony Plains habitat. This species is widespread in the northern Pilbara (Simon Judd, pers. comm. 2016) and was collected from a habitat type that extends well beyond the survey area. This species is not of conservation significance.

***Buddelundia* '14hr'**

This species was collected from the Breakaway habitat at site SRE08 and Riverine habitat at site MHT01. This morphospecies is widespread in the northern Hamersley Range and is commonly collected during fauna surveys (Simon Judd, pers. comm. 2016). This species is not of conservation significance.

***Buddelundia* '61'**

This species was collected from sites SRE12 and OPP37 in the Breakaway habitat and Gorge Habitat. It was collected by Astron during a previous fauna survey at Bungaroo (Astron Environmental Services 2016a) adjacent to the survey area and is a **potential SRE** in the WAM category 'Research and Expertise'. As in the Bungaroo fauna survey, it has been collected from multiple habitat types and seems to be a habitat generalist. The areas located north and west of the Mesa H survey area have not yet been surveyed for slaters and it is possible that the species also occurs in the wider area surrounding Mesa H (Simon Judd, pers. comm. 2016). The notion that the species was collected in habitat types extending beyond the survey area makes a wider distribution likely.

4.2.3.4 Pseudoscorpions

Four specimens of pseudoscorpions were collected in the current survey. They all belong to the arid-adapted family Olpiidae that is diverse in north-western Australia.

***Beierolpium* sp. 8/4**

A single male of this morphotype was collected from Breakaway habitat at site SRE08. There is no taxonomic framework for species in this group of *Beierolpium* but these pseudoscorpions are commonly collected in fauna surveys, often very abundant, and currently considered widespread fauna.

***Indolpium* sp. indet.**

Three specimens of *Indolpium* were collected from Drainage Line habitat (site SRE09) and Breakaway habitat (site SRE08). *Indolpium* is the most commonly collected pseudoscorpion genus in the Pilbara and are currently understood to comprise widespread species. This species of pseudoscorpion is not considered SRE fauna.

4.2.3.5 Scorpions

Six scorpion species were collected in the current survey. Five species belong to the genus *Lychas* and one species belongs to the genus *Urodacus*. Two species of *Lychas* are potential SRE species in the WAM category 'Molecular Evidence' (Dolman 2016) whereas the remaining four species are widespread.

***Lychas* 'sp. nov. 1'**

Two specimens of this species were collected from sites MHT01 and RVM13 and tentatively assigned to *Lychas* 'multipunctatus' by Erich Volschenk based on morphology. Both specimens were sequenced by WAM staff and do in fact represent a currently undescribed species that differs from *Lychas* 'multipunctatus' and other commonly collected species of *Lychas* in the Pilbara, such as *Lychas* 'hairy-tail'. It is currently not possible to estimate the distribution range of *Lychas* 'sp. nov. 1' and the species is classified a **potential SRE** in the sub-category 'Molecular Evidence'. The specimens

were collected from Riverine habitat that extends beyond the survey area. This may indicate a wider distribution of the species and future field work may establish a wider distribution.

***Lychas* 'sp. nov. 2'**

Three specimens of this species were collected from the Loamy/Stony Plains habitat at sites MHT02 and MHT03 (Plate 1c). One specimen (WAM T141172) was sequenced but there are no genetic matches in the databases of the WAM. As such, it is not possible to estimate the distribution range of this species based on molecular data. Using a precautionary approach, the species is classified as a **potential SRE** in the sub-category 'Molecular Evidence'. Based on morphology, the specimens could possibly be conspecific with *Lychas* 'gracilimanus' which is an informally described species by Erich Volschenk but no DNA sequences are available in the WAM database for this species. *Lychas* 'gracilimanus' is also considered a potential SRE by Erich Volschenk but has been previously collected during fauna surveys in the Pilbara, including a location north-east of Mile Camp and Bonney Downs Homestead (290 km east of the survey area) (Phoenix Environmental Sciences 2014a).

***Lychas* 'harveyi'**

This is a widespread and commonly collected species with a distribution that encompasses most of arid Western Australia. A single specimen was collected from the Low Hills and Slopes habitat at site RVM15. This species is not of conservation concern.

***Lychas* 'multipunctatus'-group**

Lychas 'multipunctatus' was long considered a widespread morphological species but recent molecular work at the WAM has shown that it comprises several genetically distinct lineages that may represent separate species (Plate 1d). Two specimens of *Lychas* 'multipunctatus' were sequenced by WAM for this project (T141176 and TT141177) and they indeed belong to *Lychas* 'multipunctatus' as recognised by Erich Volschenk, with genetic divergences from other sequenced specimens < 3.6% (Dolman 2016). *Lychas* 'multipuncatus' is an undescribed species and there is some uncertainty about its distribution range because the taxonomy has yet to be formalised. However, a corroborated approach of both morphology and molecular data suggests that the distribution of this species may be wider than 10,000 km^2. The two specimens collected here are from the Loamy/Stony Plains habitat (site MHT02); a habitat type that extends beyond the survey area. Morphologically similar specimens have also been collected during the Middle Robe/East Deepdale survey (Astron Environmental Services 2016b), supporting the idea of a widespread distribution.

***Lychas* 'pilbara 1'**

This undescribed species is widespread in the Pilbara bioregion and not of conservation significance (Erich Volschenk, pers. comm. 2016). Two specimens were collected from the Low Hills and Slopes habitat at site RVM15.

Urodacus megamastigus

Two specimens of this rather large species were collected from Loamy/Stony Plains habitat at site MHT02. This species is widespread in arid Western Australia (Atlas of Living Australia 2015) and not of conservation significance.

4.2.3.6 Spiders

Three spider species belonging to SRE groups were collected in the current survey: the mygalomorph spider *Aname mellosa*, and the selenopid spider species *Karaops feedtime* (Crews 2013) *and Karaops* sp. indet.

Aname mellosa

Two specimens of wishbone spiders (genus *Aname*) were collected from sites MHT02 and RVM14 in the Loamy Stony Plains and Low Hills and Slopes habitats respectively. These specimens were juvenile and DNA sequencing was undertaken by WAM staff to clarify their status. One of these specimens was identified as *Aname mellosa* whereas the DNA amplification for the second specimen failed. However, given that both specimens share an almost identical morphology we also consider this to belong to *Aname mellosa*. A recent review of the genus *Aname* in the Pilbara (Harvey et al. 2012) suggests that *Aname mellosa* is a widespread species despite high genetic divergences between populations that may indicate some degree of population isolation (Dolman 2016). This species is not of conservation concern and widespread in the Pilbara. It is possible that the specimens collected by Biota Environmental Sciences (Biota Environmental Sciences 2011) during the Rove Valley Mesas fauna survey in this area also belong to *Aname mellosa* but additional genetic analyses would be required to test this.

***Karaops feedtime* and *Karaopos* sp. indet.**

Two juvenile specimens of selenopid spiders (genus *Karaops*) were collected from Breakaway habitat and a drainage culvert (Plate 1a). DNA analyses indicate these specimens belong to two distinct species. Specimen T141164 from site Opp38 most likely belongs to the more widespread *Karaops feedtime* (Crews 2013) but the genetic data are somewhat inconclusive and the specimen may also represent a new species that is genetically and morphologically similar to *Karaops feedtime* (Dolman 2016). Considering this uncertainty, this sample is conservatively classified as a **potential SRE** species in the WAM sub-category 'Data Deficient' but referred to as *Karaops feedtime* throughout this report to avoid confusion. We note that this specimen was collected from a disturbed site and may be more generalist in habitat choice. The second sequenced specimen T141165 from Site SRE8 belongs to currently undescribed species of *Karaops* with an unknown distribution (Dolman 2016). All other sequenced specimens of this species are from an area < 10,000 km^2 from Mesa H and *Karaop*s sp. indet. is therefore classified as a **potential SRE** in the 'Data Deficient' sub-category. This species was collected from Breakaway habitat, which is the preferred habitat of selenopid spiders.

Plate 1: Examples of species in SRE groups collected within the survey area. A, *Karaops feedtime* (T141164); B, *Kwonkan* sp. (T141166); C, *Lychas* 'sp. nov 2' (T141172); D, *Lychas* 'multipunctatus' (T141176); E, *Lychas* 'sp. nov. 1' (T141171); F, *Lychas* 'pilbara1'. Scale Bars = 2mm.

5 Discussion

5.1 Vertebrate Fauna

5.1.1 Habitats

Habitats within the survey area are not restricted at the local, sub-regional or regional scale and no restricted or uncommon geological units or land systems occur within the survey area. The Gorge and Breakaway habitats in the survey area are considered significant for fauna. Deeply incised gorges, characteristic of the Hamersley subregion, generally have high levels of species endemism and diversity, and are considered important as refugia in a local context (Kendrick 2001). This is due to the microhabitats they provide such as caves and semi-permanent water pools, which were recorded during the current survey. Gorge and Breakaway habitats are considered suitable for several MNES species including the Pilbara Olive Python, Northern Quoll, Ghost Bat and Pilbara Leaf-nosed Bat (for foraging) that were all recorded during this survey. Two caves classified as diurnal roosts for Ghost Bats were recorded in the survey area, one of which was considered a possible maternal roost and the other considered possible occasional use as a maternal roost although no current evidence of use was observed (Bat Call WA 2017). In a regional context, the Gorge and Breakaway habitats in the Pilbara are restricted to the Chichester and Hamersley Ranges but they are well represented in these areas.

The Riverine habitat in the survey area is considered significant for fauna. The deep pools and shallow spring fed pools provide an important permanent water source for drinking and a refuge for amphibians and waterfowl that occur in a wide area up and downstream of the survey area. This habitat contains microhabitats not common in other habitat types such as large tree hollows, hollow logs and moist leaf litter which provide a productive ecosystem attracting and supporting a range of predators and prey. This habitat supports conservation listed fauna species such as the Rainbow Bee-eater and Pilbara Olive Python and acts as foraging sites for Northern Quolls, Ghost Bats and Pilbara Leaf-nosed Bats. The survey area contains some of the most significant pools in the area (such as Yerra Bluff) that are significant ecological features to the local fauna both up and downstream. The springs and pools of the Robe River that occur in the survey area are considered wetlands of sub-regional significance (Kendrick 2001).

The gullies and valleys of the Rocky Hills habitat type also contain caves and rock crevices and are likely to be utilised by a range of species, including those of conservation significance. This habitat type has a distinct herpetofauna assemblage due to the presence of a number of rocky habitat specialists, including *Varanus pilbarensis, Egernia cygnitos, Ctenotus rubicundus* and *Anilios ganei*. The Rocky Hills habitat is widespread and common throughout the Pilbara bioregion and is not restricted to the Chichester and Hamersley Ranges.

The Drainage Line habitats within the survey area are mainly the broad valley of the Robe River or minor ephemeral drainage lines that are not likely to provide significant refugia for species. Drainage Line habitats, although not necessarily large in terms of area, are common habitats within the Pilbara region and immediate surrounds, e.g. the Robe River.

The Low Hills and Slopes and Loamy/Stony Plains in the survey area provide fewer microhabitat opportunities for terrestrial fauna and are also more widespread in the immediate vicinity as well as the Hamersley subregion and wider Pilbara bioregion.

5.1.2 Species

5.1.2.1 General Assemblage

There were 169 vertebrate fauna species, comprising two amphibians, 55 reptiles, 85 birds and 27 mammals (including four introduced species) recorded within the survey area during the current surveys. This compares to 151, 204, 181, 148 and 147 species recorded from the wider Pannawonica area (Astron Environmental Services 2016a, 2016b; Biota Environmental Sciences 2006, 2007, 2010), respectively. The fauna species assemblage recorded during the current survey is considered typical of the Hamersley Range subregion extending from near Pannawonica to Mt Brockman as well as a subset of typical fauna assemblages across the Pilbara bioregion.

The number of reptile and amphibian species recorded (57 species) is consistent with that recorded during other dual phase surveys in the vicinity (47 to 64 species in comparable surveys) (Astron Environmental Services 2016a, 2016b; Biota Environmental Sciences 2006, 2007, 2010). Again the number of bird species recorded during the survey (85 species) is consistent with other dual season surveys conducted in the area (70 to 107 species) (Astron Environmental Services 2016a, 2016b; Biota Environmental Sciences 2007, 2010). However, this number is slightly lower than expected given the large water pools recorded within the survey area. Many species of waterfowl recorded elsewhere were not recorded during the current survey (phase 1 and 2). This may be because the survey area received poor rainfall preceding the phase 2 survey and the amount of surface water during the post wet season survey was relatively lower than normal. The current surveys (phase 1 and 2) recorded a comparatively high number of mammal species (27 species) compared to other dual season surveys in the vicinity (16 to 31 species). This was mainly due to the high number of bat species recorded; nine species were recorded in the current survey using acoustic recordings, whereas only two bat species were previously recorded by Biota Environmental Sciences (2007) using harp nets.

5.1.2.2 Conservation Significant Species

Of the 33 conservation significant species identified in the literature review, eight species have been previously recorded or were recorded during the current survey. An additional species *Anilios ganei* was considered to have a 'high' likelihood of occurrence, 11 species to have a 'moderate' likelihood and 13 species to have a 'low' likelihood.

Target MNES Species

The Gorge and Breakaway habitats within the survey area were considered suitable for the target MNES species: Pilbara Olive Python, Ghost Bat, Pilbara Leaf-nosed Bat and Northern Quoll. The current survey included a targeted search for these species. The majority of the survey area was mapped as low habitat suitability for the target MNES species; Northern Quoll, Ghost Bat, Pilbara Leaf-nosed Bat and Pilbara Olive Python (94%, 82%, 83% and 82% of the survey area classified as low habitat suitability, respectively). Low potential habitat for all four species generally comprised areas of disturbed habitat, Loamy/Stony Plain and Low Hills and Slopes habitats. These habitats contained no significant refugia or shelter, or semi-permanent or permanent water.

A single juvenile Pilbara Olive Python was recorded within the Riverine habitat and two scats were recorded within the Breakaway habitat type during the survey. This species is likely to be found within the Gorge, Breakaway and Riverine habitats particularly in the locations that contain semi-permanent and permanent water, which has been defined as their preferred habitat (Pearson 1993). The Rocky Hills and Drainage Line habitats (particularly those that contain permanent or semi-permanent pools) are considered suitable foraging and dispersal habitat for the Pilbara Olive Python.

All other habitats were considered to provide limited foraging and dispersal habitat for the Pilbara Olive Python.

The Northern Quoll was one of the more commonly recorded mammals within the survey area and was recorded 32 separate times during the survey. The majority of these records occurred in Breakaway habitats, but some records occurred within Riverine and Gorge habitat types. The Gorge and Breakaway habitats are considered potential shelter and foraging habitat for the Northern Quoll. The Riverine and Rocky Hills are also considered suitable foraging and dispersal habitats for the Northern Quoll.

In the Pilbara, Northern Quolls are generally associated with rocky habitats, although records of this species in the Riverine habitats and the presence of permanent water close to rocky habitats, suggest that it is an important foraging site for this species. All other habitats were considered to provide limited foraging and dispersal habitat for the Northern Quoll. Based on the high number of camera triggers and captures (Department of the Environment and Energy 2016) the survey area (specifically the Gorge and Breakaway habitats) supports a permanent, high density population of Northern Quolls.

The Ghost Bat was recorded twice during the current survey through scat collections and acoustic recordings from SM2 bat detectors. This includes acoustic recordings on four separate occasions and from scat piles (Figure I.1 and Table I.1, Appendix I). Seven caves have been previously identified in the 2014 survey of Mesa H (Astron Environmental Services 2014); two of which were deemed to be diurnal roosts (possible maternal roosts) (Bat Call WA 2017). Another three of the caves (two caves part of one system) were determined to be nocturnal feeding roosts and the other two caves were considered to not be used (Bat Call WA 2017). An additional seven sites identified during a targeted cave assessment were deemed to be nocturnal feeding roosts (Bat Call WA 2017).. The Gorge and Breakaway habitat was categorised as providing foraging and shelter habitat due to the presence of diurnal roost caves and nocturnal feeding roost caves.

The Pilbara Leaf-nosed Bat was recorded at eight of the 14 SM2 bat detector locations that were all deemed to be at low activity levels, apart from BAT 14 which recorded 257 calls (which is classified as having high call activity levels) (Bat Call WA 2016). Further data and analysis of the BAT 14 site suggests that the Pilbara Leaf-nosed Bats likely originated from a known roost site approximately 10 km south of the survey area (Bat Call WA 2016).

Pilbara Leaf-nosed Bat calls were recorded infrequently from a variety of habitats throughout the survey area, including Low Hills and Slopes, Gorge and Riverine habitats. The timing of calls from acoustic recordings suggests that the Pilbara Leaf-nosed Bats within the survey area originate from a known roost outside the survey (Bat Call WA 2016). The occurrence of Pilbara Leaf-nosed Bats within the survey area is likely to be influenced by the presence of water pools (typically persisting within deeply incised, shaded gorges) and major drainage lines with dense vegetation (Specialised Zoological 2010). The Pilbara Leaf-nosed Bat requires deep, humid, climatically stable caves for diurnal and maternal roost sites. The caves located in the Gorge habitat of the survey area do not fit these criteria however they can be classified as nocturnal refuge caves (Department of the Environment 2017) that are occupied or entered at night for resting or feeding.

Other Conservation Significant Species

Other conservation significant species recorded from within the survey area include the Western Pebble-mound Mouse, Eastern Great Egret, Rainbow Bee-eater and Lined Soil-crevice Skink.

Five inactive mounds from the Western Pebble-mound Mouse (P4) were recorded all within the Low Hills and Slopes habitat type during the fauna survey (Figure I.1 and Table I.1, Appendix I). Generally this species prefer gentle rocky slopes, hills and spurs. As such, the Low Hills and Slopes and Rocky Hills habitats of the survey area are likely to support this species. These habitats that are suitable for the Western Pebble-mound Mouse are also widespread and common adjacent to the survey area.

The Rainbow Bee-eater was recorded on numerous occasions throughout the survey area during both phases of the fauna survey in almost all habitats including Riverine, Drainage Line, Loamy/Stony Plains, Low Hills and Slopes, Gorge and Breakaway habitats. This species is highly mobile and generally less reliant on specific habitats.

This species has been recorded within the survey area in the Riverine habitat and in the vicinity of the survey area and is likely to be present at permanent pools within the Riverine and Drainage Line habitats of the survey area.

The Lined Soil-crevice Skink was captured on five occasions during the survey at three trapping grids (MHT03, RVM14 and RVM15); both within the Loamy/Stony Plains and the Low Hills and Slopes habitat types (Figure I.1 and Table I.1, Appendix I). Suitable habitats also exist adjacent to the survey area and are common within the wider region.

5.2 SRE Invertebrates

5.2.1 Habitats

Prospective SRE habitats within the survey area are not restricted at the local, sub-regional or regional scale. Gorge habitats are islands of high moisture retention and usually refugia for moisture-dependent SRE fauna, with some potential for dispersal-restriction in species present. Breakaway habitats are also expected to be rich in microrefugia and offer potential for specialist SRE fauna. Together, these habitats comprise only 2% of the survey area. Neither Breakaway nor Gorge habitats were found to support rich SRE communities with only two potential SREs collected in these habitats. Riverine habitat was also not overly rich in SRE fauna with only one potential SRE species recorded.

Although there is a variety of a potential SRE habitat types, the diversity of SRE fauna is comparatively low. The survey area has as many habitat types as Bungaroo (Astron Environmental Services 2016a) and Middle Robe/East Deepdale (Astron Environmental Services 2016b) but it appears to support less diverse SRE communities and fewer potential SRE species.

Overall, the habitat assessment indicates that potential SRE species in the survey area should be widespread due to the wider occurrence of similar habitats within the Hamersley subregion and Pilbara bioregion. The Bungaroo and Middle Robe/East Deepdale surveys (Astron Environmental Services 2016a, 2016b) contained similar habitats to the survey area and many species in SRE groups, including some potential SRE species, have ranges that encompass all these different survey areas. There are no habitat types unique to the survey area and the habitat types and landforms are common in the vicinity of the Mesa H survey area.

5.2.2 Species

A total of 36 specimens belonging to at least 14 invertebrate morphospecies were collected from the survey area, with six potential SRE species identified. Scorpions were the most diverse group with seven species and 12 specimens, followed by slaters (three species; 16 specimens), spiders (three species; four specimens) and pseudoscorpions (two species; four specimens). This is comparable to the six potential SRE species collected at Middle Robe/East Deepdale and the eight species collected at Bungaroo in 2015. This number is much lower than the 19 potential SRE species collected during earlier fauna surveys at Bungaroo South (Phoenix Environmental Sciences 2014b) and the 10 potential SRE species collected in the wider Bungaroo area (Biota Environmental Sciences 2010). The deviation between the 2015/16 surveys and the earlier surveys may reflect differences in sampling design, survey timing and also an increased knowledge of species taxonomy and distributions of Pilbara invertebrate fauna. Certainly, the diversity of landforms in the survey area is lower than in some of the previously surveyed areas and may account for some of the differences.

None of the species recorded within the survey area are listed as Threatened or Priority species under State or Federal legislation. The two listed dragonfly species were not seen or collected and are unlikely to occur in the survey area. Based on the survey results, the majority of the species were not considered to be, or are unlikely to be, SREs. No confirmed SRE species were collected but five species were considered potential SRE species:

- slaters: *Buddelundia* '61'
- scorpions: *Lychas* 'sp. nov. 1' and *Lychas* 'sp. nov. 2'
- spiders: *Karaops feedtime* and *Karaops* sp. indet.

The potential SRE slater *Buddelundia* '61' was collected from multiple habitat types that extend far beyond the survey area. This species has been collected during previous fauna surveys in the surrounding area (Astron Environmental Services 2016a) and clearly has a range that is much wider than the survey area.

The scorpions *Lychas* 'sp. nov. 1' and *Lychas* 'sp. nov. 2' were identified using DNA sequence data and are treated here as potential SREs primarily because there were no matching sequences in the databases of the WAM. As such, the distribution ranges cannot be inferred from the data available. It is likely that both species are more widespread and future genetic work is likely to show a wider distribution, following the more widespread nature of the habitat types in which the species were collected. Morphologically similar specimens have been collected from other areas of the western Pilbara (Astron Environmental Services 2016a, 2016b) but genetic work still needs to be undertaken on these samples.

The two spider-species were collected from juveniles and identified using DNA sequence data. *Karaops feedtime* is classified as a potential SRE. As this species was collected from a disturbed site it is certainly more widespread, as has been suggested by the genetic data. *Karaops* sp. indet. is also classified as a potential SRE and was collected from the Breakaway habitat. However, genetically similar specimens have been collected from localities outside the Mesa H survey area and the species is clearly more widespread. Specimens of *Karaops* have also been collected previously during fauna surveys at Bungaroo and Middle Robe/East Deepdale (Astron Environmental Services 2016a, 2016b) that may also belong to these species.

Overall, the survey data indicated that species richness for SREs was lower in the survey area than in other areas of the western Pilbara. All but one potential SRE species were collected from habitat types that extend far beyond the survey area. Three of the five potential SREs have also been

collected during previous fauna surveys (Astron Environmental Services 2016a, 2016b) and have established ranges that are much wider than the survey area. The habitat types that are usually considered prospective for SRE fauna (Gorges and Breakaways) did not support rich SRE communities and no habitat type was unique to the survey area.

Appendix B: Conservation Fauna Categories, Habitat Condition Scales and Likelihood Criteria

This page has been left blank intentionally.

Table B.1: Categories of Threatened Ecological Communities (Department of Environment and Conservation 2013).

PD: Presumed Destroyed
An ecological community that has been adequately searched for but for which no representative occurrences have been located. The community has been found to be totally destroyed or so extensively modified throughout its range that no occurrence of it is likely to recover its species composition and/or structure in the foreseeable future. An ecological community will be listed as presumed totally destroyed if there are no recent records of the community being extant **and either** of the following applies (A or B): A) Records within the last 50 years have not been confirmed despite thorough searches of known or likely habitats **or** B) All occurrences recorded within the last 50 years have since been destroyed.
CR : Critically Endangered
An ecological community that has been adequately surveyed and found to have been subject to a major contraction in area and/or that was originally of limited distribution and is facing severe modification or destruction throughout its range in the immediate future, or is already severely degraded throughout its range but capable of being substantially restored or rehabilitated. An ecological community will be listed as **Critically Endangered** when it has been adequately surveyed and is found to be facing an extremely high risk of total destruction in the immediate future. This will be determined on the basis of the best available information, by it meeting **any one or more of** the following criteria (A, B or C): A) The estimated geographic range, and/or total area occupied, and/or number of discrete occurrences since European settlement have been reduced by at least 90% **and either or both** of the following apply (i or ii): i) geographic range, and/or total area occupied and/or number of discrete occurrences are continuing to decline such that total destruction of the community is imminent (within approximately 10 years); ii) modification throughout its range is continuing such that in the immediate future (within approximately 10 years) the community is unlikely to be capable of being substantially rehabilitated. B) Current distribution is limited, **and one or more** of the following apply (i, ii or iii): i) geographic range and/or number of discrete occurrences, and/or area occupied is highly restricted and the community is currently subject to known threatening processes which are likely to result in total destruction throughout its range in the immediate future (within approximately 10 years); ii) there are very few occurrences, each of which is small and/or isolated and extremely vulnerable to known threatening processes; iii) there may be many occurrences but total area is very small and each occurrence is small and/or isolated and extremely vulnerable to known threatening processes. C) The ecological community exists only as highly modified occurrences that may be capable of being rehabilitated if such work begins in the immediate future (within approximately 10 years).

En: Endangered

An ecological community that has been adequately surveyed and found to have been subject to a major contraction in area and/or was originally of limited distribution and is in danger of significant modification throughout its range or severe modification or destruction over most of its range in the near future.

An ecological community will be listed as **Endangered** when it has been adequately surveyed and is not Critically Endangered but is facing a very high risk of total destruction in the near future. This will be determined on the basis of the best available information by it meeting **any one or more** of the following criteria (A, B, or C):

A) The geographic range, and/or total area occupied, and/or number of discrete occurrences have been reduced by at least 70% since European settlement **and either or both** of the following apply (i or ii):

i) the estimated geographic range, and/or total area occupied and/or number of discrete occurrences are continuing to decline such that total destruction of the community is likely in the short term future (within approximately 20 years);

ii) modification throughout its range is continuing such that in the short term future (within approximately 20 years) the community is unlikely to be capable of being substantially restored or rehabilitated.

B) Current distribution is limited, **and one or more** of the following apply (i, ii or iii):

i) geographic range and/or number of discrete occurrences, and/or area occupied is highly restricted and the community is currently subject to known threatening processes which are likely to result in total destruction throughout its range in the short term future (within approximately 20 years);

ii) there are few occurrences, each of which is small and/or isolated and all or most occurrences are very vulnerable to known threatening processes;

iii) there may be many occurrences but total area is small and all or most occurrences are small and/or isolated and very vulnerable to known threatening processes.

C) The ecological community exists only as very modified occurrences that may be capable of being substantially restored or rehabilitated if such work begins in the short-term future (within approximately 20 years).

VU: Vulnerable

An ecological community that has been adequately surveyed and is found to be declining and/or has declined in distribution and/or condition and whose ultimate security has not yet been assured and/or a community that is still widespread but is believed likely to move into a category of higher threat in the near future if threatening processes continue or begin operating throughout its range.

An ecological community will be listed as **Vulnerable** when it has been adequately surveyed and is not Critically Endangered or Endangered but is facing a high risk of total destruction or significant modification in the medium to long-term future. This will be determined on the basis of the best available information by it meeting **any one or more of** the following criteria (A, B or C):

A) The ecological community exists largely as modified occurrences that are likely to be capable of being substantially restored or rehabilitated.

B) The ecological community may already be modified and would be vulnerable to threatening processes, is restricted in area and/or range and/or is only found at a few locations.

C) The ecological community may be still widespread but is believed likely to move into a category of higher threat in the medium to long term future because of existing or impending threatening processes.

Reference: Department of Environment and Conservation 2013, Definitions, Categories and Criteria for Threatened and Priority Ecological Communities DEC (Parks and Wildlife), <https://www.dpaw.wa.gov.au/images/plants-animals/threatened-species/definitions_categories_and_criteria_for_threatened_and_priority_ecological_communities.pdf.>

Table B.2: Definitions and criteria for Threatened Ecological Communities (Department of Environment and Conservation 2013).

Three categories exist for listing Threatened Ecological Communities under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act). An ecological community may be categorised as:

Categories of ecological communities	
Critically endangered	If, at that time, it is facing an extremely high risk of extinction in the wild in the immediate future.
Endangered	If, at that time, it is not critically endangered and is facing a very high risk of extinction in the wild in the near future.
Vulnerable	If, at that time, it is not critically endangered or endangered, and is facing a high risk of extinction in the wild in the medium-term future.

Reference: Department of Environment and Conservation 2013, Definitions, Categories and Criteria for Threatened and Priority Ecological Communities DEC (Parks and Wildlife), <https://www.dpaw.wa.gov.au/images/plants-animals/threatened-species/definitions_categories_and_criteria_for_threatened_and_priority_ecological_communities.pdf.>

Table B.3: Definitions and criteria for Priority Ecological Communities (Department of Environment and Conservation 2013).

Possible Threatened Ecological Communities that do not meet survey criteria or that are not adequately defined are added to the Priority Ecological Community Lists under Priorities 1, 2 and 3. Ecological communities that are adequately known, and are rare but not threatened or meet criteria for Near Threatened, or that have been recently removed from the threatened list, are placed in Priority 4. These ecological communities require regular monitoring. Conservation Dependent ecological communities are placed in Priority 5.

P1: Priority One – Poorly-known ecological communities
Ecological communities that are known from very few occurrences with a very restricted distribution (generally ≤5 occurrences or a total area of ≤ 100ha). Occurrences are believed to be under threat either due to limited extent, or being on lands under immediate threat (e.g. within agricultural or pastoral lands, urban areas, active mineral leases) or for which current threats exist. May include communities with occurrences on protected lands. Communities may be included if they are comparatively well-known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under immediate threat from known threatening processes across their range.
P2: Priority Two – Poorly-known ecological communities
Communities that are known from few occurrences with a restricted distribution (generally ≤10 occurrences or a total area of ≤200ha). At least some occurrences are not believed to be under immediate threat of destruction or degradation. Communities may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under threat from known threatening processes.
P3: Priority Three – Poorly-known ecological communities
(i) Communities that are known from several to many occurrences, a significant number or area of which are not under threat of habitat destruction or degradation or: (ii) communities known from a few widespread occurrences, which are either large or with significant remaining areas of habitat in which other occurrences may occur, much of it not under imminent threat, or; (iii) communities made up of large, and/or widespread occurrences, that may or may not be represented in the reserve system, but are under threat of modification across much of their range from processes such as grazing by domestic and/or feral stock, and inappropriate fire regimes. Communities may be included if they are comparatively well known from several localities but do not meet adequacy of survey requirements and/or are not well defined, and known threatening processes exist that could affect them.
P4: Priority Four
Ecological communities that are adequately known, rare but not threatened or meet criteria for Near Threatened, or that have been recently removed from the threatened list. These communities require regular monitoring. (i) Rare. Ecological communities known from few occurrences that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These communities are usually represented on conservation lands. (ii) Near Threatened. Ecological communities that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable. (iii) Ecological communities that have been removed from the list of threatened communities during the past five years.
P5: Priority Five – Conservation dependent ecological communities
Ecological communities that are not threatened but are subject to a specific conservation program, the cessation of which would result in the community becoming threatened within five years.

Reference: Department of Environment and Conservation 2013, Definitions, Categories and Criteria for Threatened and Priority Ecological Communities DEC (Parks and Wildlife), <https://www.dpaw.wa.gov.au/images/plants-animals/threatened-species/definitions_categories_and_criteria_for_threatened_and_priority_ecological_communities.pdf.>

Table B.4: Conservation codes for Western Australian fauna (Department of Parks and Wildlife 2015).

Code	Conservation category	Definition
S1	Schedule 1 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Fauna that is rare or likely to become extinct, as critically endangered fauna.
S2	Schedule 2 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Fauna that is rare or likely to become extinct, as endangered fauna.
S3	Schedule 3 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Fauna that is rare or likely to become extinct, as vulnerable fauna.
S4	Schedule 4 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Fauna that is presumed to be extinct.
S5	Schedule 5 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Birds that are subject to international agreements relating to the protection of migratory birds.
S6	Schedule 6 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Fauna that are of special conservation need being species dependent on ongoing conservation intervention.
S7	Schedule 7 of the Wildlife Conservation (Specially Protected Fauna) Notice under the Wildlife Conservation Act 1950.	Declared to be fauna that is in need of special protection, otherwise than for the reasons mentioned.

Reference: Department of Parks and Wildlife 2015, *Conservation Codes For Western Australian flora and fauna*, The Government of Western Australia.

Table B.5: Priority species under Western Australian Wildlife Conservation Act 1950 (Department of Parks and Wildlife 2015).

Taxa that have not yet been adequately surveyed to be listed under Schedule 1 or 2 are added to the Priority Flora and Priority Fauna Lists under Priorities 1, 2 or 3. These three categories are ranked in order of priority for survey and evaluation of conservation status so that consideration can be given to their declaration as threatened flora or fauna. Taxa that are adequately known, are rare but not threatened, or meet criteria for Near Threatened, or that have been recently removed from the threatened list for other than taxonomic reasons, are placed in Priority 4. These taxa require regular monitoring. Conservation Dependent species are placed in Priority 5.

P1: Priority One – Poorly known taxa
Taxa that are known from one or a few collections or sight records (generally less than five), all on lands not managed for conservation, e.g. agricultural or pastoral lands, urban areas, Shire, Westrail and Main Roads WA road, gravel and soil reserves, and active mineral leases and under threat of habitat destruction or degradation. Taxa may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements and appear to be under immediate threat from known threatening processes.
P2: Priority Two – Poorly known taxa
Taxa that are known from one or a few collections or sight records, some of which are on lands not under imminent threat of habitat destruction or degradation, e.g. national parks, conservation parks, nature reserves, State forest, vacant Crown land, water reserves, etc. Taxa may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements and appear to be under threat from known threatening processes.
P3: Priority Three – Poorly known taxa
Taxa that are known from collections or sight records from several localities not under imminent threat, or from few but widespread localities with either large population size or significant remaining areas of apparently suitable habitat, much of it not under imminent threat. Taxa may be included if they are comparatively well known from several localities but do not meet adequacy of survey requirements and known threatening processes exist that could affect them.
P4: Priority Four: Rare, near threatened and other taxa in need of monitoring
(a) Rare. Taxa that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These taxa are usually represented on conservation lands. (b) Near Threatened. Taxa that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable. (c) Taxa that have been removed from the list of threatened species during the past five years for reasons other than taxonomy.
P5: Priority Five: Conservation dependent taxa
Taxa that are not threatened but are subject to a specific conservation program, the cessation of which would result in the taxa becoming threatened within five years.

Reference: Department of Parks and Wildlife 2015, *Conservation Codes For Western Australian flora and fauna*, The Government of Western Australia.

Table B.6: Categories and definitions for EPBC Act listed fauna species.

Conservation category	Definition
Extinct	Taxa with no reasonable doubt that the last member of the species has died.
Extinct in the wild	Taxa known to survive only in cultivation, in captivity or as a naturalized population well outside its past range; or it has not been recorded in its known and/or expected habitat, at appropriated seasons, anywhere in its past range, despite exhaustive surveys over a time frame appropriate to its life cycle and form.
Critically endangered (CR)	Taxa facing an extremely high risk of extinction in the wild in the immediate future, as determined in accordance with the prescribed criteria.
Endangered (E)	Taxa are not critically endangered; and are facing a very high risk of extinction in the wild in the near future, as determined in accordance with the prescribed criteria.
Vulnerable (V)	Taxa are not critically endangered or endangered; and are facing a high risk of extinction in the wild in the medium-term future, as determined in accordance with the prescribed criteria.
Conservation dependent (CD)	Taxa are the focus of a specific conservation program the cessation of which would result in the species becoming vulnerable, endangered or critically endangered; or the following subparagraphs are satisfied: i) the taxa is a species of fish; ii) the taxa is the focus of a management plan that provides management actions necessary to stop the decline of, and support the recovery of, the taxa so that its chances of long term survival in nature are maximized; iii) the management plan is in force under a law of the Commonwealth or of a State or Territory; iv) Cessation of the management plan would adversely affect the conservation status of the taxa Fish includes all taxa of bony fish, sharks, rays, crustaceans, molluscs and other marine organisms, but does not include marine mammals/reptiles.

Table B.7: Criteria used to define likelihood occurrence of conservation significant fauna species.

Likelihood of occurrence	Pre-survey	Post-survey
Recorded	N/A	Species or evidence of species recorded during survey.
High	Species has been recorded within the survey area or within 20 km of the survey area and preferred habitat appears to be present.	Core or preferred habitats present in the survey area which are abundant and/or high quality condition. OR Species is known to be cryptic and may not have been detected despite adequate survey effort and suitable habitat present within the survey area. OR Species or evidence of species recorded within the survey area however doubt remains over the taxonomic identification, validity of record.
Moderate	Species has not been recorded from within the survey area, however species has been recorded within 20 km of the survey area and suitable habitat appears to be present.	Core or highly suitable habitats present in the survey area, however, non-cryptic species that was not detected despite adequate survey effort. OR Core or preferred habitats present in the survey area are mainly in poor or modified condition.
Low	Species recorded within 20 km of the survey area but suitable habitat does not appear to be present.	Species has not been recorded in the survey area despite adequate survey effort. OR Species dependent on specific habitats that do not occur in the survey area. OR Species considered locally extinct.

Table B.8: Criteria used to determine SRE status of invertebrates.

Status	Criteria
Confirmed	This species has a high probability of being an SRE based on expert opinion, reference databases or the scientific literature. Usually, this species belongs to a group that is well known taxonomically and contains a high proportion of SRE species. Example: Millipedes belonging to the genus *Boreohesperus* (Car and Harvey 2013).
Potential	This species has a moderate probability of being an SRE because it belongs to a group with a high proportion of SRE species, has specific biological and/or ecological attributes that may indicate range restriction, or has been collected from a single microhabitat type. Usually, this species will belong to a group with a poorly or moderately resolved taxonomy. Example: Many trapdoor spiders in the infraorder Mygalomorphae (Castalanelli *et al.* 2014). The WAM recognises the uncertainty involved with this category and lists five sub-categories that may help elucidating this status: i) data deficient because there is insufficient information; ii) habitat indicators that are associated with potential SRE status; iii) morphological indicators; iv) molecular evidence; and v) research and expert knowledge held within the WAM (WAMTS staff 2013). These sub-categories are implicitly addressed as part of the species assessments.

Castalanelli, MA, Teale, RJ, Rix, MG, Kennington, WJ & Harvey, MS 2013, 'Barcoding of mygalomorph spiders (Araneae: Mygalomorphae) in the Pilbara bioregion of Western Australia reveals a highly diverse biota', *Invertebrate Systematics*, vol. 28, pp. 375-85.

Table B.9: Fauna habitat condition scale (Thompson and Thompson 2010).

Habitat condition	Condition description
High Quality Fauna Habitat (1.0)	These areas closely approximate the vegetation mix and quality that would have been in the area prior to any human induced disturbance. The habitat has connectivity with other habitats and is likely to support the most natural vertebrate fauna assemblage.
Very Good Fauna Habitat (0.8)	These areas show minimal signs of human induced disturbance (e.g. grazing, clearing, fragmentation, weeds) and retain almost all of the characteristics of the habitat had it not been disturbed. The habitat has connectivity with other habitats, and fauna assemblages in these areas are likely to be minimally effected by disturbance.
Good Fauna Habitat (0.6)	These areas show signs of human induced disturbance (e.g. grazing, clearing, fragmentation, weeds) but generally retain many of the characteristics of the habitat had it not been disturbed. The habitat still retains some connectivity with other habitats but fauna assemblages in these areas are likely to be affected by disturbance. Fauna assemblages in these areas are likely to be similar to what might be expected in this habitat.
Disturbed Fauna Habitat (0.4)	These areas show signs of human induced significant disturbance (e.g. mining, clearing, tracks and roads). Many of the trees, shrubs and undergrowth have died or have been cleared. These areas may be in the early succession and regeneration stages. Areas may show signs of significant grazing, contain an abundance of weeds or have been damaged by vehicles or machinery. Habitats are fragmented or have limited connectivity with other fauna habitats. Fauna assemblages in these areas are likely to differ significantly from what might be expected in the area had the disturbance not occurred.
Highly Degraded Fauna Habitat (<0.2)	These areas often have a significant human induced loss of vegetation, and / or a large number of vehicle tracks and / or have been completely cleared, and / or areas have been heavily grazed or farmed. There is limited or no fauna habitat connectivity. Fauna assemblages in these areas are likely to differ significantly from what existed prior to the disturbance, and are often depleted compared to what existed prior to the disturbance.

Table B.10: Suitability/significance of habitat ranking criteria for the three target Matters of National Environmental Significance (MNES) species.

Species	Potential shelter and foraging habitat (a)	Suitable foraging and dispersal habitat (b)	Limited foraging and dispersal habitat (c)
Pilbara Olive Python (*Liasis olivaceus barroni*)	Rocky habitat such as gorges, escarpments and Breakaways along with Drainage lines including or in close proximity to permanent or semi-permanent water holes.	Drainage lines with dense vegetation enabling transitory behaviours and/or providing foraging potential. Rocky habitats that are not in close proximity to water.	Habitat that has limited sheltering and foraging capacity with no permanent or semi-permanent water.
Northern Quoll *(Dasyurus hallucatus)*	Rocky habitats such as ranges, escarpments, mesas, ranges, gorges, Breakaways and boulder fields. Also major Drainage lines or tree-lined drainage systems that are structurally diverse and contain large diameter trees, termite mounds or hollow logs.	Habitat important for foraging, dispersal and buffering of the species including moderate to small sized Drainage lines and native vegetation in close proximity (within 2 km) denning or shelter habitat.	Habitat that has limited sheltering and foraging capacity and not connected to potential denning/shelter and foraging habitat.
Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) and Ghost Bat (*Macroderma gigas*)	Rocky habitat that contains caves suitable as diurnal or maternity roosts sites, or potentially contains these caves and has not adequately surveyed; OR Areas highly suitable for foraging that are likely to be used on a regular basis.	Habitat important for foraging including diverse rocky terrain, moderately sized Drainage lines and dense complex vegetation stands.	Habitat that has limited ecological value but may provide capacity for transitory movement across the landscape and/or limited foraging potential.

Appendix E: Western Australian Museum Molecular Identification of Arachnids Report

This page has been left blank intentionally.

Molecular Identification of Arachnids (Selenopidae, Nemesiidae, Buthidae) from Mesa H, WSW, SW and SSW of Pannawonica (12.5-19 km), Western Australia

Report to *Astron* 19 August 2016

Amended 30 January 2016

Gaynor Dolman

Department of Terrestrial Zoology, Western Australian Museum,
Locked Bag 49, Welshpool DC, Western Australia 6986, Australia

Although identifications in this report were consistent with the best available information and current scientific thinking at the time of identification the use of this report is at the risk of the user. Any liability to users of this report for loss of any kind arising out of the use of this report or the information and identifications it contains is expressly disclaimed.

Summary

Ten specimens from two Orders (Araneae, Scorpiones) and three Families (Selenopidae, Nemisiidae and Buthidae) were among those collected from Mesa H, WSW, SW and SSW of Pannawonica (12.5-19 km), Western Australia, and were lodged into the Western Australian Museum collection by E.S. Volschenk from *Alacran Environmental Science* (see Appendix 1 for specimen details). DNA-based identifications were sought. The main objectives of the WA Museum's Molecular Systematics Unit (MSU) were to use COI DNA barcoding to compare DNA sequences to the WAM and published DNA databases to: 1) determine the taxonomic identity of the arachnid specimens where possible; and 2) determine the distribution and thus SRE status of the queried specimens.

A summary of specimen identifications together with their SRE status may be found in Table 1. A full explanation of the SRE categories used by the Western Australian Museum may be found in Appendix 2.

Table 1. Summary of WAMTS440 specimen identifications and SRE status

FAMILY	GENUS	SPECIES	# OF SPECIMENS	SRE SUB-CATEGORY
Selenopidae	*Karaops*	*feedtime*	1	Potential SRE- (A) Data Deficient
Selenopidae	*Karaops*	'sp. Indet'	1	Potential SRE- (D) Molecular Evidence
Nemesiidae	*Aname*	*mellosa*	1	Widespread (not an SRE)
Buthidae	*Lychus*	*'multipunctatus'*	2	Widespread (not an SRE) (morph* and DNA)/ Potential SRE- (D) Molecular Evidence
Buthidae	*Lychus*	*'sp. nov 1'*	2	Potential SRE- (D) Molecular Evidence
Buthidae	*Lychus*	*'sp. nov 2'*	1	Potential SRE- (D) Molecular Evidence

*Rigour of the morphology cannot be assured (identified by consultant- not confirmed by WAM arachnologists)

Methods and Results

DNA was extracted from a leg or half leg of each of the ten arachnid specimens using a Qiagen DNA extraction kit. The Folmer's primers, LCO1490 and HCO2198 were used to amplify COI DNA barcodes. COI DNA barcodes were successfully amplified and sequenced from nine of the ten specimens. PCR conditions were altered for the remaining specimen, but amplification remained unsuccessful. Barcodes from eight of the nine specimens represented the mitochondrial COI sequences being targeted. However one sequence contained two copies of the COI and the copies that could be clearly identified from chromatograms contained numerous stop codons signifying dysfunctional copies of the gene (pseudogene). Pseudogenes cannot be used to accurately identify species. A summary of the comparison (BLAST/phylogenetic results) for the nine successful specimens is provided in Table 2. Details of museum specimens that were identified in BLAST searches and contextualise the status of the queried species are provided in Table 3. Simple Neighbour-Joining (distance based) tree is provided in Appendix 3 for visualisation of genetic relationships. DNA sequences of queried specimens are provided in Appendix 4.

Options for Future Resolution of Pseudogene Problem for this study

The barcoding gene, Cytochrome Oxidase I, is a protein-coding mitochondrial gene. Mitochondrial genes can sometimes be copied to the nucleus and become dysfunctional. These genes are called pseudogenes. The protein coding DNA sequence in pseudogenes often contain stop-codons, making them readily detectable in DNA analyses, but this is not always the case. For the one specimen where a pseudogene was amplified in this study it is possible to perform a technique that will improve chances of obtaining the correct target COI gene. I can perform limiting dilution on these samples. This method is based on the fact that there is only one nucleus in each cell but many more mitochondria. The idea is to dilute the sample to the extent where the nuclear copies are removed and there are only mitochondrial copies left. Success is not guaranteed, but the likelihood of getting only the mitochondrial copy of the gene is improved. I am happy to negotiate cost of this method if required.

Table 2. Summary of BLAST analysis

REGNO	SPECIES	SUMMARY OF BLAST RESULTS
T141164	*Karaops feedtime*	This specimen was 6.42% divergent from a lineage that contains the holotype of *Karaops feedtime* (T111456; Crews 2013) and a juvenile presumed to be *K. feedtime* (T123838). According to currently available data it is unclear whether the queried specimen (T141164) and another specimen related to *K. feedtime* (T122639) represent a single widespread species or multiple species.
T141165	*Karaops sp. indet*	T141165 was 0.86% divergent from a lineage containing five specimens of juveniles (species indetermined). According to the COI barcoding data, these specimens represent a distinct and undescribed species.
T141166	*Aname mellosa*	T141166 is 7.29% divergent from its nearest two specimens which are in the *Aname mellosa* lineage. *Aname mellosa* is recognised as an unusually genetically diverse and widespread lineage of Nemesiidae. For this reason and phylogenetic placement, the current evidence suggests T141166 is *A. mellosa*.
T141167	(Nemesidae)	No PCR amplification
T141171 T141174	*Lychus 'sp. nov 1'*	T141171 and T141174 are 99.54% genetically similar. T141171, T141174 are 8.32% divergent from *Lychus 'hairytail'* and 7.75% divergent from *L. 'sp. indet*'.
T171172	*Lychus 'sp. nov 2'*	T141172 is 11.04% divergent from *Lychus 'pilbara 1'* and 9.26% divergent from *Lychus 'multipunctatus'*.
T171176 T171177	*Lychus 'multipunctatus'*	T141176 and T141177 are 99.85% genetically similar. T141176 and T141177 are 3.59% divergent to *Lychus 'multipunctatus'* and according to current evidence are most likely are members of this species.

Table 3. Details of registered WAM specimens in related lineages to the queried specimens according to DNA barcoding (see Table 2, Conclusion and Neighbour-joining trees in Appendix 3 for details of relatedness).

Conclusions

The main objectives were to use DNA barcoding to: 1) determine the taxonomic identity of the arachnid specimens where possible; and 2) determine the distribution and thus SRE status of the queried specimens.

1) Selenopidae

DNA barcoding (COI) data identify two distinct species in the two queried specimens of Selenopidae. The barcoding results for the first specimen are inconclusive. According to currently available data it is unclear whether the queried specimen (T141164) and another specimen (T122639) related to *K. feedtime* (Crews: Zootaxa, 2013) represent a single widespread species or multiple potentially short range species. More genetic sampling/ adult morphological analyses are required to test the species status of T141164 in relation to *K. feedtime* and T122639 and relatives.

The second specimen of Selenopidae (T141165) aligns with other specimens that have not officially been described yet (Karaops 'sp. indet'). As specimens within this undescribed species are all located within <10,000 km^2, *Karaops 'sp. indet*.' (including T141165) represents a potential SRE (Potential SRE- D Molecular Evidence).

2) Nemesiidae

According to currently available data, and the COI data generated in this study, one of the queried Nemesiidae specimens (T141166) is identified as *Aname mellosa*, an unusually widespread and genetically diverse genus of Mygalomorph spiders (not an SRE). The second of the two Nemesiidae specimens was unable to be amplified so its taxonomic status could not be determined.

3) Buthidae

In six queried scorpion specimens, three distinct species were recognised; two of the three species have been sequenced for the first time.

One of these two new species (*L. sp. nov 1*) is represented by two specimens (T141171, T141174). They are distinct from but related to *Lychus 'hairytail'* and Lychus '*sp. indet'*, two species that have not been formally described in the literature, one previously recognised by E.S. Volschenk (*L. 'hairytail'*). Given the low average genetic distances within all other *L. 'hairytail'* and *L. 'indet*.' compared to the large divergence to the queried specimens: T141171 and T141174 should be recognised as representatives of a distinct species. Being the only two known specimens from this species, according to currently available evidence they are recognised as potential SREs (D-Molecular Evidence).

The second new species, *L. 'sp. nov 2'*, represented by T141172, is a distinct species but related to *Lychus 'multipunctatus' and Lychus 'pilbara 1'*, two species that have not been formally described in the literature yet, but have previously been recognised by E.S. Volschenk. *Lychus 'sp. nov. 2'* could possibly represent *L. `gracilimanus`* another species informally described by E.S. Volschenk, but we have no DNA sequences for this morpho-type and we have no other specimens in the database recognised by

this informal name. As *L. 'sp. nov 2'* is the only specimen that can be assigned to this species, it must currently be considered a potential SRE (D- Molecular Evidence).

According to currently available barcoding data and data generated in this study, two specimens (T141176, T141177) are identified as *Lychus 'multipunctatus'*. This species has not been formally described in the literature, but has previously been recognised by E.S. Volschenk. If all barcoding sequenced *L. 'multipunctatus'* were included in a distribution analysis, *L. 'multipunctatus'* would be within 10,000 km^2 and would represent a potential SRE (D- Molecular Evidence). If all specimens, morphologically identified and molecularly identified are included in a distribution analysis, *L. 'multipunctatus'* occupies an area greater than $10,000^2$ km and therefore is not be considered an SRE. The rigour of this taxonomy is yet to be determined. Other specimens are available for sequencing if rigorous confirmation is required.

Appendix 2. WAM Short-Range Endemic Categories

	Taxonomic Certainty	Taxonomic Uncertainty
Distribution < 10 000km^2	**Confirmed SRE** • *A known distribution of < 10 000km².* • *The taxonomy is well known.* • *The group is well represented in collections and/ or via comprehensive sampling.*	**Potential SRE** • *Patchy sampling has resulted in incomplete knowledge of the geographic distribution of the group.* • *We have incomplete taxonomic knowledge.* • *The group is not well represented in collections.* • *This category is most applicable to situations where there are gaps in our knowledge of the taxon.* **Sub-categories for this SRE designation are outlined below**
Distribution > 10 000km^2	**Widespread (not an SRE)** • *A known distribution of > 10 000km².* • *The taxonomy is well known.* • *The group is well represented in collections and/ or via comprehensive sampling.*	

SRE SUB-CATEGORIES

If a taxon is determined to be a "Potential SRE", the following sub-categories will further elucidate this status.

A. <u>*Data Deficient:*</u>
- There is insufficient data available to determine SRE status.
- Factors that fall under this category include:
  - Lack of geographic information.
  - Lack of taxonomic information.
  - The group may be poorly represented in collections.
  - The individuals sampled (e.g. juveniles) may prevent identification to species level.

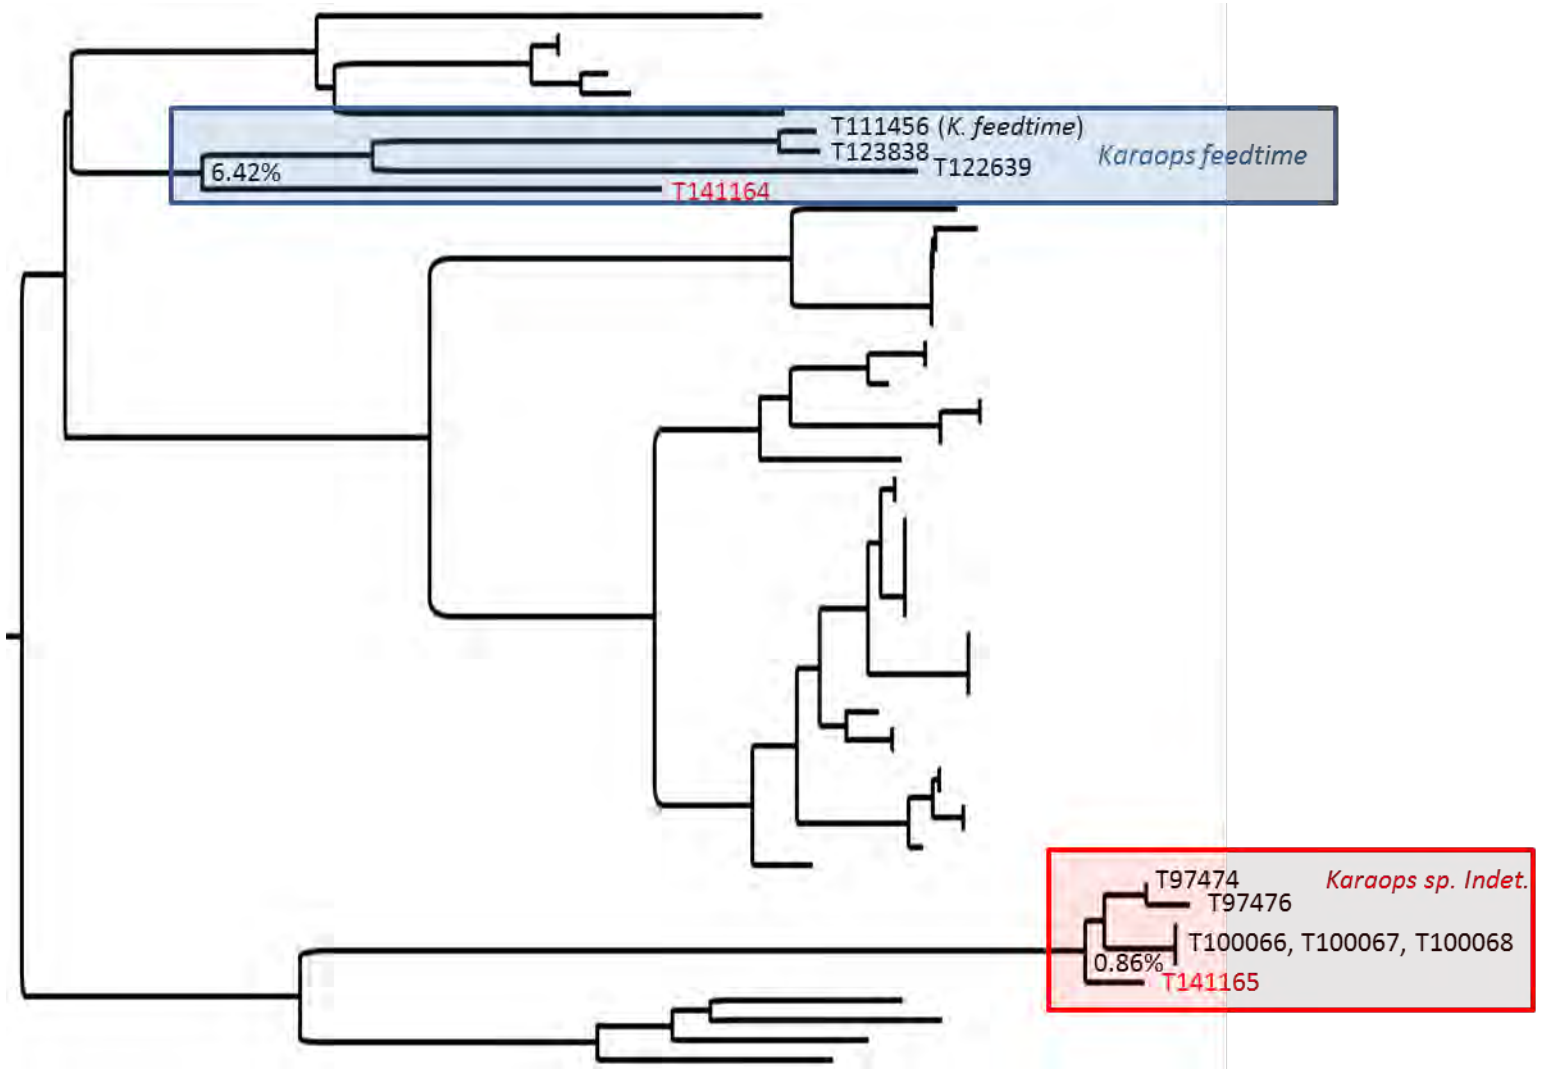
B. <u>*Habitat Indicators:*</u>
- It is becoming increasingly clear that habitat data can elucidate SRE status.
  - Below are some examples of habitats that are currently known to be associated with SRE taxa and vice versa.

C. <u>*Morphology Indicators:*</u>
- A suite of morphological characters are characteristic of SRE taxa.
- Below are some examples of morphological characters associated with SRE taxa and vice-versa.

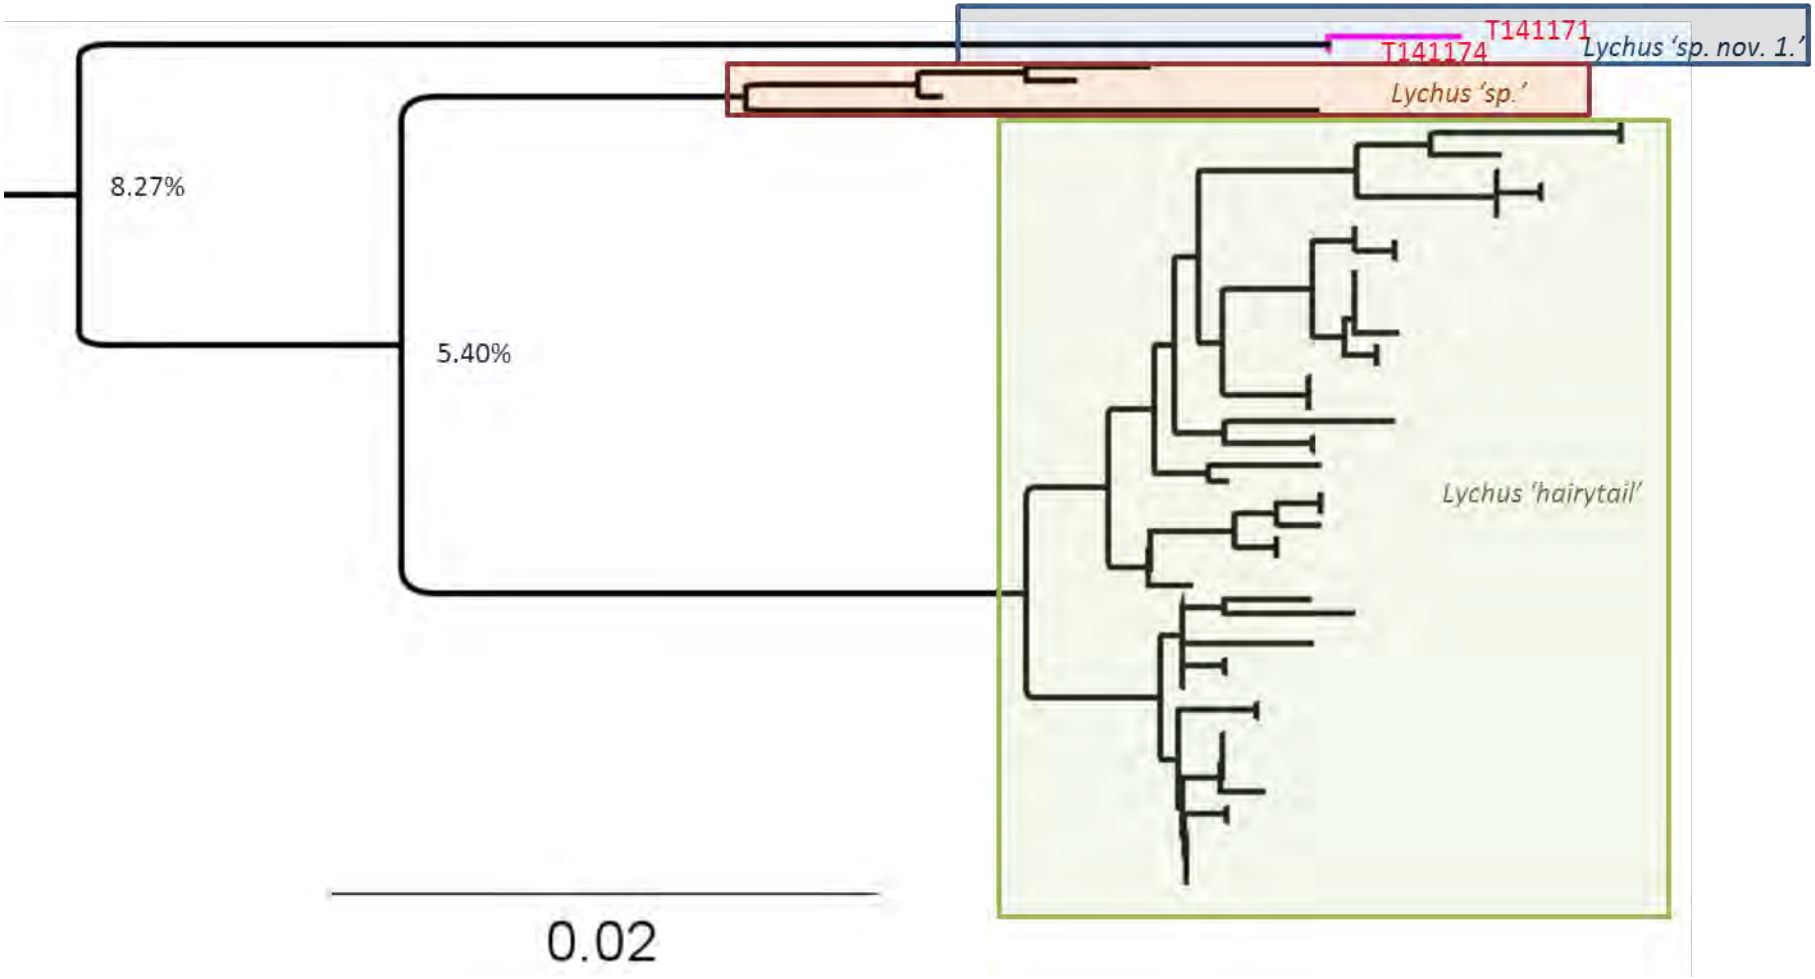
D. <u>*Molecular Evidence:*</u>
- If molecular work has been done on this taxon (or a close relative), it may reveal patterns congruent or incongruent with SRE status.
- Below are some examples of phylogenetic patterns associated with SRE taxa and vice-versa.

E. <u>*Research & Expertise:*</u>
- Previous research and/ or WAM expertise elucidates taxon SRE status.
- This category takes into account the expert knowledge held within the WAM.

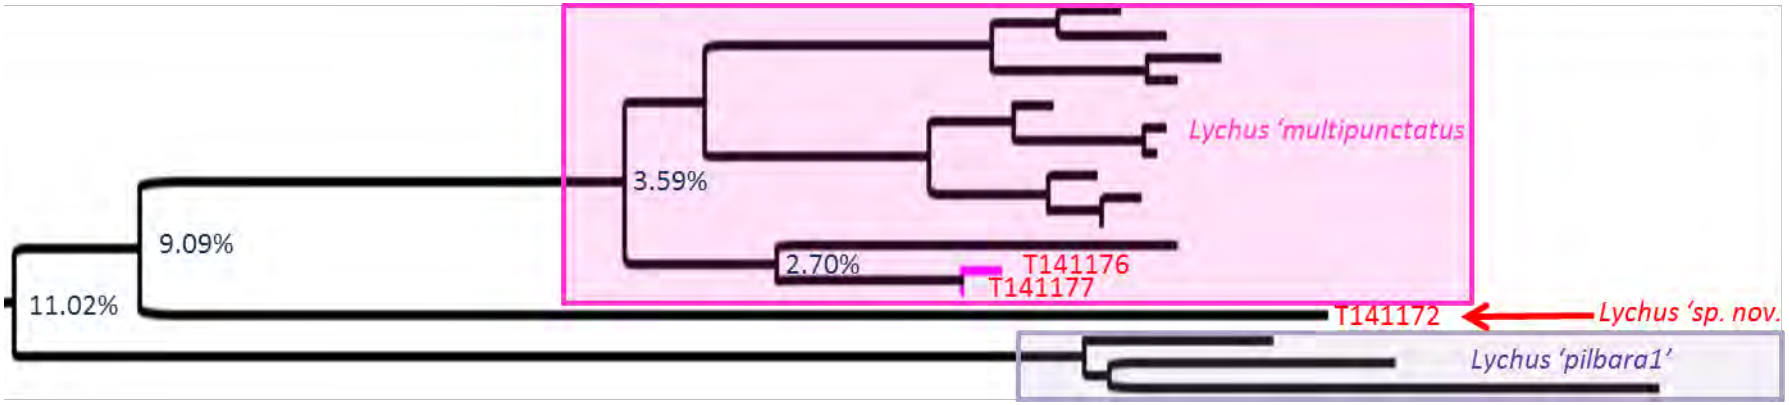
Appendix 3. Simple Neighbour-Joining (distance based) tree to be used *ONLY* for visualisation of genetic distance relationships (not a comprehensive analysis using appropriate molecular models and search algorithms).



a) Selenopidae



b) Scorpiones (T141171, T141174)



c) Scorpiones (T141172, T141176, T141177)

Appendix F: Fauna Species Lists

This page has been left blank intentionally.

Table F.1: Amphibian species list – results of database searches, literature reviews and Astron survey results.

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
HYLIDAE										
Cyclorana maini	Sheep Frog					x			x	
Litoria rubella	Little Red Tree Frog					x			x	x
MYOBATRACHIDAE										
Pseudophryne douglasi	Gorge Toadlet								x	
Uperoleia russelli	Northwest Toadlet					x			x	
Uperoleia saxatilis	Pilbara Toadlet					x			x	x
BUFONIDAE										
Platyplectrum spenceri	Centralian Burrowing Frog					x				

Table F.2: Reptile species list – results of database searches, literature reviews and Astron survey results.

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
AGAMIDAE										
Amphibolurus longirostris	Long-Nosed Dragon					x			x	x
Ctenophorus caudicinctus	Ring-tailed Rock Dragon					x			x	x
Ctenophorus femoralis	Dune Dragon					x				
Ctenophorus isolepis isolepis	Military Sand Dragon					x			x	x
Ctenophorus nuchalis	Central Netted Dragon					x			x	
Ctenophorus reticulatus	Western Netted Dragon					x				
Pogona minor minor	Bearded Dragon					x			x	
DIPLODACTYLIDAE										
Crenadactylus ocellatus	Clawless Gecko					x			x	
Diplodactylus bilybara	Western Fat-tailed Gecko					x			x	x
Diplodactylus galaxias						x			x	
Diplodactylus mitchelli						x				
Diplodactylus savagei						x			x	
Lucasium stenodactylum	Pale-snouted Ground Gecko					x			x	x
Lucasium wombeyi						x			x	
Oedura marmorata	Marbled Velvet Gecko					x			x	x
Rhynchoedura ornata	Beaked Gecko					x			x	x
Strophurus ciliaris						x				
Strophurus elderi	Jewelled Gecko					x			x	x
Strophurus wellingtonae						x				
CARPHODACTYLIDAE										
Nephrurus levis pilbarensis									x	
Nephrurus wheeleri cinctus	Banded Knob-tailed Gecko					x			x	x
Nephrurus wheeleri wheeleri	Banded Knob-tailed Gecko					x			x	
GEKKONIDAE										
Gehyra pilbara						x			x	x
Gehyra punctata	Spotted Rock Dtella					x			x	x

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Gehyra variegata	Variegated Tree Dtella					x			x	x
Hemidactylus frenatus	Asian House Gecko	*				x			x	
Heteronotia binoei	Bynoe's Gecko					x			x	x
Heteronotia spelea	Pilbara Cave Gecko					x			x	
PYGOPODIDAE										
Delma butleri									x	x
Delma elegans						x			x	
Delma nasuta						x			x	x
Delma pax						x			x	x
Delma tincta						x			x	
Lialis burtonis	Burrton's Legless Lizard					x			x	x
Pygopus nigiceps						x			x	x
EUGONGYLIDAE										
Carlia munda						x			x	x
Carlia triacantha						x				
Cryptoblepharus plagiocephalus									x	
Cryptoblepharus buchananii						x				
Cryptoblepharus ustulatus						x			x	x
Menetia greyii						x			x	x
Menetia surda surda						x			x	
Morethia ruficauda exquisita	Fire-tailed Skink					x			x	x
AGAMIDAE										
Ctenotus brooksi						x				
Ctenotus calurus						x				
Ctenotus duricola						x			x	
Ctenotus grandis titan						x			x	x
Ctenotus hanloni						x			x	
Ctenotus helenae						x			x	
Ctenotus pantherinus	Leopard Ctenotus					x			x	x
Ctenotus rubicundus						x			x	

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Ctenotus quattuordecimlineatus						x				
Ctenotus saxatilis	Rock Ctenotus					x			x	x
Ctenotus schomburgkii						x			x	
Ctenotus serventyi						x			x	x
Eremiascincus fasciolatus										x
Eremiascincus isolepis						x			x	x
Lerista bipes						x			x	
Lerista flammicauda						x			x	
Lerista ips						x				
Lerista muelleri						x			x	x
Lerista verhmens						x				
Notoscincus butleri	Lined Soil-crevice Skink				P4	x			x	x
Notoscincus ornatus						x			x	
EGERNIIDAE										
Cyclodomorphus melanops	Slender Blue-tongue					x			x	
Egernia cygnitos						x				
Ergenia depressa						x				
Ergenia formosa						x			x	x
Ergenia pilbarensis	Pilbara Skink					x			x	x
Tiliqua multifasciata	Central Blue-tongue					x			x	x
VARANIDAE										
Varanus acanthurus	Spiny-tailed Monitor					x			x	x
Varanus brevicauda	Short-tailed Pygmy Monitor					x			x	x
Varanus bushi	Pilbara Mulga Monitor					x			x	
Varanus caudolineatus						x				
Varanus eremius	Pygmy Desert Monitor					x			x	
Varanus giganteus	Perentie					x			x	x
Varanus gouldii	Bungarra					x			x	

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Varanus hamersleyensis	Southern Pilbara Rock Monitor					x			x	x
Varanus panoptes panoptes						x			x	x
Varanus pilbarensis										x
Varanus tristis tristis	Racehorse Monitor					x			x	x
TYPHLOPIDAE										
Anilios ammodytes						x			x	x
Anilios ganei					P1	x			x	
Anilios grypus	Beaked Blind snake					x			x	x
Anilios hamatus									x	x
Anilios pilbarensis						x			x	x
BOIDAE										
Antaresia perthensis	Pygmy Python					x			x	
Antaresia stimsoni stimsoni	Stimson's Python					x			x	x
Aspidites melanocephalus	Black-headed python					x			x	
Liasis olivaceus barroni	Pilbara Olive Python		VU	S3		x	x		x	x
ELAPIDAE										
Acanthopis wellsi	Pilbara Death Adder					x			x	x
Brachyurophis approximans						x			x	x
Demansia psammophis cupreiceps	Yellow-faced Whipsnake					x			x	x
Demansia rufescens	Rufous Whipsnake					x			x	
Furina ornata	Moon Snake					x			x	
Parasuta monachus						x			x	
Pseudechis australis	Mulga Snake					x			x	x
Pseudonaja mengdeni	Western Brown Snake					x			x	
Pseudonaja modesta	Ringed Brown Snake					x			x	x
Pseudonaja nuchalis	Gwardar; Northern Brown Snake					x				
Simoselaps anomalus	Desert Banded Snake					x				
Suta fasciata	Rosen's Snake					x			x	
Suta punctata	Spotted Snake					x				

Table F.3: Bird species list – results of database searches, literature reviews and Astron survey results.

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
DROMAIIDAE										
Dromaius novaehollandiae	Emu					x		x	x	
PHASIANIDAE										
Coturnix ypsilophora	Brown Quail					x			x	x
ANATIDAE										
Anas gracilis	Grey Teal					x		x	x	
Anas superciliosa	Pacific Black Duck					x		x	x	x
Aytha australis	Hardhead					x		x		
Cygnus atratus	Black Swan					x		x	x	
Chenonetta jubata	Australian Wood Duck					x			x	
Dendrocygna eytoni	Plumed Whistling Duck					x				
Dendrocygna arcuata	Wandering Whistling Duck								x	x
Nettapus pulchellus	Green Pygmy Goose								x	
PODICIPEDIDAE										
Tachybaptus novaehollandiae	Australasian Grebe					x		x	x	x
Poliocephalus poliocephalus	Hoary-headed Grebe					x		x	x	
COLUMBIDAE										
Columba livia	Domestic Pigeon	*				x	x			
Geopelia cuneata	Diamond Dove					x		x	x	x
Geopelia striata placida	Peaceful Dove					x		x	x	x
Geophaps plumifera	Spinifex Pigeon					x		x	x	x
Ocyphaps lophotes	Crested Pigeon					x		x	x	x
Phaps chalcoptera	Common Bronzewing					x		x	x	x
Phaps histrionica	Flock Bronzewing					x				
PODARGIDAE										
Podargus strigoides	Tawny Frogmouth					x		x	x	
CAPRIMULGIDAE										
Eurostopodus argus	Spotted Nightjar					x			x	x

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
AEGOTHELIDAE										
Aegotheles cristatus	Australian Owlet-nightjar					x			x	x
APOPDIDAE										
Apus pacificus	Fork-tailed Swift		Mi	S5			x		x	
ANHINGIDAE										
Anhinga novaehollandiae	Darter					x		x	x	
PHALACROCORACIDAE										
Phalacrocorax melanoleucos	Little Pied Cormorant							x	x	x
Phalacrocorax varius	Pied Cormorant							x	x	x
Phalacrocorax sulcirostris	Little Black Cormorant								x	
PELECANIDAE										
Pelecanus conspicillatus	Australian Pelican					x		x	x	x
CICONIIDAE										
Ephippiorhynchus asiaticus	Black-necked stork								x	
ARDEIDAE										
Ardea ibis	Cattle Egret		Mi	S5			x		x	
Ardea intermedia	Intermediate Egret					x	x		x	x
Ardea modesta	Eastern Great Egret		Mi	S5		x	x	x	x	
Ardea garzetta	Little Egret					x			x	
Ardea novaehollandiae	White-faced Heron					x		x	x	x
Ardea pacifica	White-necked Heron					x		x	x	x
Butorides striata	Striated Heron							x		
Nycticorax caledonicus	Nankeen Night-heron					x		x	x	x
THRESKIORNITHIDAE										
Platalea flavipes	Yellow-billed Spoonbill								x	
Threskiornis spinicollis	Straw-necked Ibis					x		x	x	x
ACCIPITRIDAE										
Accipiter cirrocephalus	Collared Sparrowhawk					x			x	
Accipiter fasciatus fasciatus	Brown Goshawk					x		x	x	x
Aquila audax	Wedge-tailed Eagle					x		x	x	x

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Circus approximans	Swamp Harrier					x				
Circus assimilis	Spotted Harrier					x		x	x	x
Elanus scriptus	Letter-winged Kite				P4	x				
Elanus caeruleus	Black-shouldered Kite					x			x	x
Lophoictinia isura	Square-tailed Kite					x		x		
Haliaeetus leucogaster	White-bellied Sea Eagle						x	x	x	
Haliastur sphenurus	Whistling Kite					x		x	x	x
Haliastur indus	Brahminy Kite							x		
Hieraaetus morphnoides	Little Eagle					x		x	x	x
Milvus migrans	Black Kite					x		x	x	x
Panidon haliaetus	Eastern Osprey		Mi	S5			x			
FALCONIDAE										
Falco cenchroides cenchroides	Australian Kestrel					x		x	x	x
Falco berigora berigora	Brown Falcon					x		x	x	x
Falco longipennis	Australian Hobby					x		x	x	
RALLIDAE										
Gallirallus philippensis	Buff-banded Rail					x				
Fulica atra	Eurasian Coot					x		x	x	
Porzana tabuensis	Spotless Crake					x				x
Tribonyx ventralis	Black-tailed Native-hen								x	x
OTIDIDAE										
Ardeotis australis	Australian Bustard					x		x	x	
BURHINIDAE										
Burhinus grallarius	Bush Stone-curlew					x			x	x
RECURVIROSTRIDAE										
Himantopus himantopus	Black-winged Stilt					x			x	
CHARADRIIDAE										
Charadrius veredus	Oriental Plover		Mi	S5			x			
Charadrius ruficapillus	Red-capped Plover							x		
Charadrius leschenaultii	Greater Sand Plover		Mi	S5				x		

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Elseyornis melanops	Black-fronted Dotterel					x		x	x	x
Erythrogonys cinctus	Red-kneed Dotterel								x	
Vanellus tricolor	Banded Lapwing					x		x		
CINCLOSOMATIDAE										
Psophodes occidentalis	Chiming Wedgebill					x				
ROSTRATULIDAE										
Rostratula benghalensis australis	Australian Painted Snipe		EN	S2			x			
SCOLOPACIDAE										
Actitis hypoleucos	Common Sandpiper					x		x		
Calidris acuminata	Sharp-tailed Sandpiper			S5		x				
Calidris ferruginea	Curlew Sandpiper		CR/Mi	S3/S5			x			
Numenius madagascariensis	Eastern Curlew		CR	S3/S5			x			
Numenius phaeopus	Whimbrel			S5				x		
Tringa glareola	Wood Sandpiper			S5		x		x	x	
Tringa nebularia	Common Greenshank			S5				x		
TURNICIDAE										
Turnix velox	Little Button-quail					x		x	x	x
GLAREOLIDAE										
Glareola maldivarum	Oriental Pratincole		Mi	S5			x			
PSITTACIDAE										
Platycercus zonarius zonarius	Australian Ringneck					x		x	x	x
Melopsittacus undulatus	Budgerigar					x		x	x	x
Nymphicus hollandicus	Cockatiel					x		x	x	x
Pezoporus occidentalis	Night Parrot		EN	S1		x	x			
CACATUIDAE										
Cacatua sanguinea	Little Corella					x		x	x	x
Cacatua roseicapilla	Galah					x		x	x	x
CUCULIDAE										
Cacomantis pallidus	Pallid Cuckoo					x		x	x	x
Chrysococcyxs basalis	Horsfield's Bronze Cuckoo					x		x	x	x

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Chrysococcyxs osculans	Black-eared Cuckoo								x	
Centropus phasianinus	Pheasant Coucal							x	x	
STRIGIDAE										
Ninox connivens	Barking Owl					x				x
Ninox boobook boobook	Southern Boobook Owl					x		x	x	x
TYTONIDAE										
Tyto javanica	Eastern Barn Owl					x				
ACLEDINIDAE										
Dacelo leachii leachii	Blue-winged Kookaburra					x		x	x	x
Todiramphus pyrrhopygia	Red-backed Kingfisher					x		x	x	x
Todiramphus sanctus	Sacred Kingfisher					x		x	x	x
MEROPIDAE										
Merops ornatus	Rainbow Bee-eater		Mi	S5		x	x	x	x	x
PTILONORHYNCHIDAE										
Ptilonorhynchus maculatus guttatus	Western Bowerbird					x			x	x
MALURIDAE										
Amytornis striatus	Striated Grasswren					x		x	x	x
Malurus lamberti assimilis	Variegated Fairy-wren					x		x	x	x
Malurus leucopterus	White-winged Fairy-wren					x		x	x	x
Stipiturus ruficeps	Rufous Crowned Emu-wren								x	
ACANTHIZIDAE										
Acanthiza apicalis	Inland Thornbill					x			x	
Acanthiza uropygialis	Chestnut-rumped Thornbill					x			x	
Gerygone fusca	Western Gerygone					x			x	
Gerygone tenebrosa	Dusky Gerygone							x		
Smicrornis brevirostris	Weebill					x		x	x	x
PARDALOTIDAE										
Pardalotus punctatus	Spotted Pardalote					x				
Pardalotus rubricatus	Red-browed Pardalote					x		x	x	x

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Pardalotus striatus	Striated Pardalote					x			x	x
MELIPHAGIDAE										
Acanthagenys rufogularis	Spiny-cheeked Honeyeater					x		x	x	x
Certhionyx variegatus	Pied Honeyeater					x			x	
Epthianura tricolor	Crimson Chat					x			x	
Ptilotula keartlandi	Grey-headed Honeyeater							x	x	x
Ptilotula penicillatus	White-plumed Honeyeater							x	x	x
Gavicalis virescens	Singing Honeyeater							x	x	x
Lichmera indistincta	Brown Honeyeater					x		x	x	x
Manorina flavigula	Yellow-throated Miner					x		x	x	x
Melithreptus gularis	Black-chinned Honeyeater					x			x	
Sugomel niger	Black Honeyeater					x			x	
POMATOSTOMIDAE										
Pomatostomus supercilious	White-browed Babbler					x				
Pomatostomus temporalis	Grey-crowned Babbler					x		x	x	x
CAMPEPHAGIDAE										
Coracina maxima	Ground Cuckoo-shrike					x				
Coracina novaehollandiae	Black-faced Cuckoo-shrike					x		x	x	x
Lalage tricolor	White-winged Triller					x		x	x	x
PACHYCEPHALIDAE										
Colluricincla harmonica	Grey Shrike-thrush					x		x	x	x
Oreoica gutturalis	Crested Bellbird					x		x	x	x
Pachycephala melanura	Mangrove Golden Whistler							x		
Pachycephala lanioides	White-breasted Whistler							x		
Pachycephala rufiventris	Rufous Whistler					x		x	x	x
Cincloramphus cruralis	Brown Songlark					x		x	x	
Cincloramphus mathewsi	Rufous Songlark					x		x	x	
ARTAMIDAE										
Artamus cinereus melanops	Black-faced Woodswallow					x		x	x	x

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Artamus leucorynchus	White-breasted Woodswallow							x	x	x
Artamus minor	Little Woodswallow					x			x	x
Artamus personatus	Masked Woodswallow					x			x	x
CRACTICIDAE										
Cracticus torquatus	Grey Butcherbird								x	
Cracticus nigrogularis	Pied Butcherbird					x		x	x	X
Cracticus tibicen	Australian Magpie					x		x	x	x
DICRURIDAE										
Rhipidura albiscapa	Grey Fantail					x			x	x
Rhipidura phasiana	Mangrove Grey Fantail							x		
Rhipidura leucophrys leucophrys	Willie Wagtail					x		x	x	x
Grallina cyanoleuca	Magpie-lark					x		x	x	x
CORVIDAE										
Corvus bennetti	Little Crow					x		x	x	
Corvus orru	Torresian Crow					x		x	x	x
PETROICIDAE										
Melanodryas cucullata	Hooded Robin					x			x	x
Petroicas goodenovii	Red-capped Robin					x			x	
ALAUDIDAE										
Mirafra javanica	Horsfield's Bushlark					x		x	x	
Mirafra cantillans	Singing Bushlark									x
ACROCEPHALIDAE										
Acrocephalus australis	Australian Reed Warbler								x	x
LOCUSTELLIDAE										
Eremiornis carteri	Spinifex-bird					x		x	x	x
TIMALIIDAE										
Zosterops luteus	Yellow White-eye							x		
HIRUNDINIDAE										
Cheramoeca leucosternus	White-backed swallow					x				

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
Hirundo neoxena	Welcome Swallow							x	x	
Hirundo rustica	Barn Swallow		Mi	S5			x			
Petrochelidon ariel	Fairy Martin					x		x	x	x
Petrochelidon nigricans	Tree Martin					x		x	x	x
DICAEIDAE										
Dicaeum hirundinaceum	Mistletoebird					x		x	x	x
ESTRILDIDAE										
Emblema pictum	Painted Finch					x		x	x	x
Neochmia ruficauda subclarescens	Star Finch (Western)					x		x	x	X
Taeniopygia guttata	Zebra Finch					x		x	x	x
MOTACILLIDAE										
Anthus australis	Australian Pipit					x		x	x	
Motacilla cinerea	Grey Wagtail		Mi	S5			x			
Motacilla flava	Yellow Wagtail		Mi	S5			x			

Table F.4: Mammal species list – results of database searches, literature reviews and Astron survey results.

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey
			EPBC Act	WC Act	Parks and Wildlife					
TACHYGLOSSIDAE										
Tachyglossus aculeatus	Short-beaked Echidna					x			x	x
DASYURIDAE										
Dasycercus blythi	Brush-tailed Mulgara				P4	x				
Dasykaluta rosamondae	Little Red Kaluta					x			x	x
Dasyurus hallucatus	Northern Quoll		EN	S2		x	x		x	x
Ningaui ridei	Wongai Ningaui					x				
Ningaui timealeyi	Pilbara Ningaui					x			x	x
Planigale ingrami	Long-tailed Planigale					x			x	
Planigale maculata	Common Planigale					x				
Planigale 'species 1'	Pilbara Planigale								x	x
Pseudantechinus roryi	Rory's Pseudantechinus								x	
Pseudantechinus woolleyae	Woolley's Pseudantechinus					x			x	
Pseudantechinus sp.										x
Sminthopsis longicaudata	Long-tailed Dunnart				P4	x				
Sminthopsis macroura	Stripe-faced Dunnart					x			x	x
Sminthopsis youngsoni	Lesser Hairy-footed Dunnart					x			x	
THYLACOMYIDAE										
Macrotis lagotis	Greater Bilby, Dalgyte		VU	S3		x	x			
NOTORYCTIDAE										
Notoryctes caurinus	Northern Marsupial Mole		EN				x			
MACROPODIDAE										
Osphranter robustus erubescens	Euro, Biggada					x			x	x
Osphranter rufus	Red Kangaroo, Marlu					x			x	x
Petrogale rothschildi	Rothschild's Rock-wallaby					x			x	x
PHALANGERIDAE										
Trichosurus vulpecula arnhemensis	Northern Brushtail Possum					x				

Scientific name	Common name	Introduced	Conservation codes			Nature Map	EPBC Protected Matters Search	Birdlife	Previous surveys	Current survey

Table F.5: Potential and confirmed SRE species list – results of database searches and literature review.

Taxonomic group	Species [1]	Records	SRE category	Source	Remarks
ARACHNIDA					
Araneae: Mygalomorphae (Trapdoor Spiders and Allies)					
Actinopodidae	*Missulena* 'MYG040'	Warramboo	Potential	WA Museum; Biota 2006; Harms and Framenau 2013	
	Missulena 'MYG110'	Millstream-Chichester NP	Potential	WA Museum; Phoenix 2014	
	Missulena sp. indet.	Robe Valley (Mesa A), Warramboo, Delphine, Eliwana-Flying Fish, Bungaroo Trial Pit	Potential	WA Museum; Biota 2007; Phoenix 2012, 2014; Harms and Framenau 2013	Probably multiple species
Barychelidae	*Aurecocrypta* 'Barrow sp. 1'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.
	Aurecocrypta 'MYG057'	South-west of Pannawonica	Potential	WA Museum	
	Aurecocrypta 'MYG319-DNA'	Aquila Onslow, south-east of Onslow	Potential	WA Museum; Castalanelli et al. 2014	
	Aurecocrypta 'po3'	12 km north-east of Mardie	Potential	WA Museum	
	Idiommata 'MYG110'	Cane River Conservation Park	Potential	WA Museum	
	Synothele butleri	Barrow Island	Confirmed	WA Museum, Raven 1994	Endemic to Barrow Is.
	Synothele 'MYG313-DNA'	Aquila, south-south-west of Pannawonica	Potential	WA Museum	
	Synothele 'preston'	18 km south-east of Mardie	Potential	WA Museum	
	Synothele sp. 'pseudidiommata'	Warramboo	Potential	WA Museum; Biota 2006	
	Synothele sp. indet.	Bungaroo Valley, Bungaroo South, Robe Valley (Mesa G), Delphine, Eliwana-Flying Fish, Mardie Station	Potential	WA Museum; Biota 2010; Phoenix 2012, 2014	Probably multiple species; listed as Barychelidae in Biota 2006
Ctenizidae	*Conothele* sp. 'Barrow 1'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.
	Conothele sp. 'Barrow 2'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.
	Conothele sp. 'Barrow 3'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.
	Conothele '295-DNA'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.
	Conothele '297-DNA'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.

Taxonomic group	Species [1]	Records	SRE category	Source	Remarks
Ctenizidae	*Conothele* sp. indet.	Robe Valley (Mesa G), Balla Balla, Eliwana-Flying Fish, Emu Siding, Zebra Hill	Potential	WA Museum; Phoenix 2012, 2014	Probably multiple species
Idiopidae	*Aganippe* sp. 'MYG302-DNA'	Robe Valley (Mesa K)	Potential	WA Museum	
	Aganippe sp. indet.	Warramboo	Potential	Biota 2006	May belong to *Aganippe* sp. 'MYG302-DNA'
	Eucyrtops sp. indet.	Robe Valley	Potential	Phoenix 2012	Not lodged with the WAM
	Euoplos 'MYG082'	Mt Minnie	Potential	WA Museum	
	Euoplos 'MYG218'	Barrow Island	Potential	WA Museum	Maybe endemic to Barrow Is.
	Euoplos 'MYG307-DNA'	Mesa A Transport Corridor	Potential	WA Museum	
Nemesiidae	*Aname* 'MYG079'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.
	Aname 'MYG093'	Mt Elvire, Mt Florance, Serenity Valley	Potential	WA Museum	
	Aname 'MYG102'	Aquila Onslow, south-east of Onslow	Potential	WA Museum	
	Aname 'MYG271-DNA'	Aquila, south-west of Pannawonica	Potential	WA Museum	
	Aname 'MYG275'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.
	Aname 'MYG328-DNA'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.
	Aname 'MYG369-DNA'	Aquila, south-south-east of Pannawonica	Potential	WA Museum	
	Aname sp. indet.	Aquila, Onslow, Bungaroo Valley, Bungaroo South, Cane River, Robe Valley, Mt Amy, Mt Brockman, Mt Farquhar, Warramboo, Delphine, Eliwana-Flying Fish	Potential	WA Museum; Phoenix 2014	Probably multiple species
	Chenistonia 'MYG090'	21 km south-east of Onslow	Potential	WA Museum	Pilbara Survey
	Kwonkan 'MYG274'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.
	Kwonkan 'po2'	Mardie Station	Potential	WA Museum; Main 1983; Phoenix 2014	
	Yilgarnia sp. indet.	Brickwood Reserve, Robe Valley, Delphine, Eliwana-Flying Fish, Mt Farquhar, Barrow Island	Potential	WA Museum; Main 1986; Phoenix 2012, 2014	
Araneae: Araneomorphae ("Modern" Spiders)					
Oonopidae	*Grymeus* sp. indet.	Mt Elvire, Barrow Island	Potential	WA Museum	Likely multiple species

Taxonomic group	Species [1]	Records	SRE category	Source	Remarks
Oonopidae	*Myrmopopaea* spp.	Barrow Island	Potential	WA Museum	Probably multiple species
	Opopaea callani	Barrow Island	Confirmed	Baehr and Harvey 2013	
	Opopaea harmsi	Barrow Island	Confirmed	WA Museum; Baehr and Harvey 2013	Endemic to Barrow Is.
	Opopaea johannae	Barrow Island, Whim Creek Hotel, Marda Pool, Bandicoot Bay	Confirmed	WA Museum; Baehr and Harvey 2013	Barrow Island and Pilbara
	Opopaea rugosa	Barrow Island	Confirmed	Baehr and Harvey 2013	Endemic to Barrow Is.
	Orchestina spp.	Barrow Island	Potential	WA Museum	Probably multiple species
	Pelicinus saaristoi	Barrow Island	Confirmed	Ott and Harvey 2008	Endemic to Barrow Is.
	Xestaspis 'inconspiqua'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.
Selenopidae	*Karaops burbidgei*	Varanus Island	Confirmed	Crews and Harvey 2011;Crews 2013	Endemic to Varanus Is.
	Karaops sp. 'Bungaroo'	Bungaroo Creek Valley	Potential	Astron 2016a	Known from Juveniles only
	Karaops sp. 'Middle Robe 1'	Robe River Valley	Potential	Astron 2016b	Known from Juveniles only
	Karaops sp. 'Middle Robe 2'	South-east and south-west of Pannawonica	Potential	Astron 2016b	Known from Juveniles only
	Karaops sp. indet.	Bungaroo South, Red Hill Station, Karratha, Middle Robe (Mesa G), Mt Edith, Millstream-Chichester NP, Python Pool, Cane River CP	Potential	WA Museum; Biota 2010; Crews and Harvey 2011; Crews 2013; Phoenix 2014	Listed as Selenopidae in Biota 2010; includes multiple genetic species (see Astron 2015b)
Pseudoscorpiones (Pseudoscorpions)					
Cheiridiidae	*Apocheiridium* 'Barrow 1'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.
	Apocheiridium 'Barrow 2'	Barrow Island	Potential	WA Museum	Probably endemic to Barrow Is.
Chthoniidae	*Lagynochthonius* sp. indet.	West Pilbara	Potential	WA Museum	Known from juveniles only
	Tyrannochthonius sp. nov. 'Bungaroo 2'	Bungaroo Creek Valley	Potential	Astron 2016a	Known from a single specimen only
Garypidae	*Anagarypus heatwolei*	Barrow Island	Confirmed	WA Museum; Muchmore 1982	Endemic to Barrow Is.
	Synsphyronus 'PSE032'	Barrow Island	Potential	WA Museum	Likely endemic to Barrow Is.
	Synsphyronus sp. nov. 'CR1'	Cane River Conservation Park	Potential	WA Museum	

Taxonomic group	Species [1]	Records	SRE category	Source	Remarks
Garypinidae	*Synsphyronus* sp. nov. 'CR2'	Cane River Conservation Park	Potential	WA Museum	
	Synsphyronus sp. indet.	Bungaroo Valley, Cane River, Robe Valley	Potential	WA Museum; Biota 2010; Harvey 1987, 2010	Listed as *Synsphyronus* sp. in Biota 2010
	Solinus sp. indet.	Bungaroo Valley	Potential	WA Museum, Biota 2010	Listed as *Solanus* sp. in Biota 2010
Hyidae	*Indohya* sp. indet.	Bungaroo Valley, Exmouth Limestone, Learmonth, Robe Valley	Potential	WA Museum	Known from subterranean and epigean habitats
	Indohya sp. 'PSE002'	South-east and south-west of Pannawonica, Mt Delphine, Bungaroo Creek Valley	Potential	WA Museum; Harvey and Volschenk 2007; Astron 2016a	Probably unresolved species-complex
Olpiidae	*Austrohorus* sp. indet.	Barrow Island, Marra Mamba	Potential	Biota 2013	Listed as *Austrohorus* sp. in Biota 2010
	Austrohorus 'Barrow sp. 1'	Barrow Island, Site 105	Potential	WA Museum	Probably endemic to Barrow Is.
	Austrohorus 'Barrow sp. 2'	Barrow Island, Gorgon Project Footprint	Potential	WA Museum	Probably endemic to Barrow Is.
	Euryolpium sp. 'Bungaroo'	Bungaroo Creek Valley	Potential	Astron 2016a	Known from a single specimen
	Euryolpium sp. indet.	Barrow Island	Potential		
Sternophoridae	*Afrosternophorus* sp. indet.	Cane River Conservation Park	Potential	WA Museum	Multiple species
Syarinidae	*Ideoblothrus* sp. 'Bungaroo'	Bungaroo Creek Valley	Potential	Astron 2016a	
	Ideoblothrus sp. indet.	Robe Valley (Mesas A, B, K), Congo, Cane River, Millstream-Chichester National Park	Potential	WA Museum; Edward & Harvey 2010	Probably represent multiple species
Opiliones (Harvestmen)					
Assamiidae	*Dampetus* sp. 'Middle Robe'	Robe River Valley	Potential	Astron 2016b	Known from a single specimen
	Dampetus sp. indet.	Balla Balla Railway Project, Delphine, Eliwana-Flying Fish, Mt Herbert, Robe Valley (Mesas A, G, and J)	Potential	Phoenix 2014	Unresolved species-complex (see Astron 2015b)
Scorpiones (Scorpions)					
Buthidae	*Isometroides* 'barrow'	Barrow Island	Potential	WA Museum	Potentially endemic to Barrow Is.
	Isometroides sp. indet.	Mesa G	Potential	WA Museum	Known from a single specimen

Taxonomic group	Species [1]	Records	SRE category	Source	Remarks
Buthidae	*Lychas* 'Barrow 2'	Barrow Island	Potential	WA Museum	Potentially endemic to Barrow Is.
	Lychas 'hairy tail'-group	Robe River Valley, East Deepdale, Bungaroo Creek Valley, Bungaroo South	Potential	Phoenix 2012; Astron 2016a, 2016b	Cryptic species-complex
	Lychas 'multipunctatus'-group	Balla Balla, Robe River Valley, East Deepdale, Bungaroo South	Potential	Phoenix 2012, 2014; Astron 2016b	Cryptic species-complex
	Lychas 'nubby'	South-west of Karratha	Potential	WA Museum	
	Lychas 'scottae'	63 km south of Pannawonica	Potential	WA Museum	
	Lychas 'warramboo 1'	Warramboo	Potential	WA Museum; Phoenix 2012	
	Lychas sp. nov.	Middle Robe and East Deepdale	Potential	ecologia Environment 2013	
Urodacidae	*Urodacus* 'saipem1'	Alinta Dampier-Bunbury Natural Gas Pipeline	Potential	WA Museum	Known from several localities
	Urodacus 'sp. 7'	North-north-east of Whim Creek Hotel, Marda Pool	Potential	WA Museum	
	Urodacus 'waramboo'	Waramboo, 50 km west of Pannawonica	Potential	WA Museum	
CRUSTACEA					
Armadillidae	*Acanthodillo* sp. indet.	Eliwana-Flying Fish	Potential	Phoenix 2012,	
	Acanthodillo sp. 6	Karratha to Millstream-Chichester National Park	Potential	Phoenix 2014	
	Armadillidae genus 1 sp. 1	Barrow Island	Potential	Judd and Perina 2013	
	Armadillidae genus 2 sp. 1	Barrow Island	Potential	Judd and Perina 2013	
	Armadillidae genus 3 sp. 1	Barrow Island	Potential	Judd and Perina 2013	
	Armadillidae genus 3 sp. 2	Barrow Island	Potential	Judd and Perina 2013	
	Armadillidae genus 4 sp. 2	Barrow Island	Potential	Judd and Perina 2013	
	Barrowdillo pseudopyrgoniscus	Barrow Island	Confirmed	Judd and Perina 2013	
	Barrowdillo sp. nov. 5	Middle Robe	Potential	ecologia Environment 2013	
	cf. *Barrowdillo* sp. 3	Karratha to Millstream-Chichester National Park	Potential	Phoenix 2014	
	cf. *Barrowdillo* sp. 9	Central Pilbara	Potential	Phoenix 2014	
	cf. *Barrowdillo* sp. 10	Central Pilbara	Potential	Phoenix 2014	

Taxonomic group	Species [1]	Records	SRE category	Source	Remarks
Armadillidae	cf. *Barrowdillo* sp. 11	Central Pilbara	Potential	Phoenix 2014	
	Buddelundia hirsuta	Barrow Island	Confirmed	Judd and Perina 2013	Collected at a cave entrance, may be subterranean fauna
	Buddelundia '10'	Central Pilbara	Potential	Phoenix 2014	
	Buddelundia '10 1016a'	Balla Balla Railway Project	Potential	Phoenix 2014	
	Buddelundia '17'	Central Pilbara	Potential	Phoenix 2014	
	Buddelundia '19'	Central Pilbara	Potential	Phoenix 2014	
	Buddelundia '30'	Bungaroo South, Middle Robe	Potential	ecologia Environment 2013; Phoenix 2012, 2014	
	Buddelundia '33'	Central Pilbara, Karratha to Millstream-Chichester National Park	Potential	Phoenix 2014	
	Buddelundia '54'	Central Pilbara	Potential	Phoenix 2014	
	Buddelundia '61'	Bungaroo Iron ore Mine, Bungaroo South	Potential	Phoenix 2014; Astron 2016a	
	Buddelundia '64'	Mt Farquhar, Nammuldi, Mt Brockman	Potential	Phoenix 2014	
	Buddelundia '66'	Mt Farquhar	Potential	Phoenix 2014	
	Buddelundia '76'	Central Pilbara	Potential	Phoenix 2014	
	Buddelundia '92'	Balla Balla Railway Project	Potential	Phoenix 2014	
	Buddelundia '93'	Balla Balla Railway Project	Potential	Phoenix 2014	
	Buddelundia '94'	Balla Balla Railway Project	Potential	Phoenix 2014	
	Buddelundia '95'	Balla Balla Railway Project	Potential	Phoenix 2014	
	Buddelundia sp. indet.	Bungaroo South, Eliwana-Flying Fish, Delphine, Mt Brockman, Mt Farquhar	Potential	Phoenix 2012	Probably multiple species
	Buddelundia sp. 2	Barrow Island	Potential	Judd and Perina 2013	
	Buddelundiinae sp. indet.	Bungaroo Creek Valley	Potential	Astron 2015a	
	Cubaris sp. 999	Eliwana-Flying Fish, Delphine	Potential	Phoenix 2012, 2014	
	Spherillo sp. indet.	Bungaroo Creek Valley	Potential	Astron 2016a	
	Spherillo '999'	Mt Farquhar, Delphine	Potential	Phoenix 2012, 2014	

Taxonomic group	Species [1]	Records	SRE category	Source	Remarks
Philosciidae	Philosciidae sp. indet.	Middle Robe and East Deepdale	Potential	Astron 2016b	Probably distinct from Philosciidae 'unknown genus'
	Philosciidae 'unknown genus'	Middle Robe and East Deepdale	Potential	Ecologia 2013	
	Philosciidae 'pannawonica'	Pannawonica	Potential	Phoenix 2014	
DIPLOPODA (Millipedes)					
Paradoxosomatidae	*Antichiropus* sp. 'DIP009'	Mt Minnie	Confirmed	WA Museum; Car et al. 2013; Car and Harvey 2014	
	Antichiropus sp. 'DIP024'	Millstream-Chichester National Park	Confirmed	WA Museum; Car et al. 2013; Car and Harvey 2014	
	Antichiropus sp. 'DIP041'	Mt Elvire	Confirmed	WAM; Car et al. 2013; Car and Harvey 2014	
	Antichiropus sp. indet.	Bungaroo South, Cane River Reserve, Marda Pool, Karratha and Mardie Stations, Pannawonica Road	Potential	WA Museum; Car et al. 2013, Car and Harvey 2014; Biota 2006; Phoenix 2014	Almost certainly multiple species
	Boreohesperus delicatus	Marda Pool	Confirmed	Car and Harvey 2013	
	Boreohesperus dubitalis	Barrow Island	Confirmed	Car and Harvey 2013	Endemic to Barrow Is.
	Boreohesperus furcosus	Mt Minnie	Confirmed	Car and Harvey 2013	
	Boreohesperus undulatus	Karratha Station, Mt Minnie	Confirmed	Car and Harvey 2013	
Siphonotidae	*Siphonotidae* sp. indet.	Bungaroo South, near Tom Price (White Quartz Road)	Confirmed	Biota 2007; Phoenix 2014	
CHILOPODA (Centipedes)					
Chilenophilidae	*Sepedonophilus* sp. indet.	Balla Balla, Mt Farquhar	Potential	WA Museum; Phoenix 2014	
Cryptopidae	*Cryptops* sp. indet	Balla Balla, Bungaroo South, Robe Valley (Mesas A and K), Delphine, Eliwana-Flying Fish, Mt Farquhar	Potential	WA Museum; Phoenix 2014	Probably multiple species
Mecistocephalidae	*Mecistocephalus* sp. indet.	Barrow Island, Bungaroo South, Delphine, Eliwana-Flying Fish, Mt Farquhar	Potential	WA Museum; Phoenix 2012	Probably multiple species
Family indet.	Gen indet.	Barrow Island	Potential	WA Museum	At least four morphospecies; taxonomic status of samples unclear

Taxonomic group	Species [1]	Records	SRE category	Source	Remarks
GASTROPODA (Snails)					
Bothriembryontidae	Bothriembryontidae 'Pilbara'-complex	Hamersley Range, Mt Farquhar, Millstream, Tom Price, Wodgina	Potential	WA Museum; Phoenix 2014	Likely multiple species
Camaenidae	New genus cf. 'Mt Robinson'	Bungaroo South, Delphine	Potential	Phoenix 2012, 2014	
	Plectorhagada meilgana	Florrie Station, Minnie Springs, East of Exmouth Road	Confirmed	Solem 1997; Phoenix 2014	
	Rhagada sp. 'Beasley'[#]	Beasley River, Tom Price	Previously listed but not SRE	Biota 2006, 2013	Genetic species; probably same species as *Rhagada* sp. 'Tom Price' (Biota 2013)
	Rhagada barrowensis	Barrow and Boodie Islands	Confirmed	Johnson et al. 2013	
	Rhagada cf. *radleyi*	Millstream, Mt Hebert, Deep Reach Pool, Coolawanyah Station	Previously listed but not SRE	Biota 2006; Ecologia 2013	Widespread in the Western Pilbara; *Rhagada* ?*radleyi* in Biota 2006
	Rhagada plicata	Barrow Island, Lowendal and Montebello Islands	Confirmed	Johnson et al. 2013	
	Rhagada sp. indet.	Millstream-Chichester National Park, Mardie Homestead, Mt Brockman, Mt Hebert, Mt Price, Mt Turner, Pannawonica Road, Whim Creek	Potential	Whisson and Kirkendale 2014	Known mostly from dead-taken shells; may be multiple species
	Rhagada sp. 'Pannawonica'[#]	Pannawonica, Marra Mamba	Previously listed but not SRE	Biota 2006, 2010, 2013, 2010; Hamilton and Johnson 2015	Genetic species; clearly distinct from *Rhagada* sp. 'Beasley' and *R.* 'Tom Price' (Biota 2013)
	Rhagada sp. 'Tom Price'[#]	Beasley River, Tom Price	Previously listed but not SRE	Biota 2013	Genetic species; probably same species as *Rhagada* sp. 'Beasley' (Biota 2013)
	Rhagada sp. indet.	Buckland Hills	Potential	WA Museum	May belong to one of the other listed species
	Quistrachia barrowensis	Barrow Island, Lowendal and Montebello Islands	Confirmed	Johnson et al. 2013	
	Quistrachia cf. 'Barlee Range'	Tom Price, Mt Farquhar	Potential	WA Museum	
	Quistrachia herberti	Bilanoo Hill, Millstream-Chichester National Park, Karratha, Mt Farquhar, Mt Herbert, Fortescue River	Confirmed	Solem 1997; Whisson and Kirkendale 2014	

Taxonomic group	Species [1]	Records	SRE category	Source	Remarks
Camaenidae	*Quistrachia* sp. indet.	Balla Balla, Delphine, Marra Mamba, Mt Hebert, Millstream-Chichester National Park	Potential	Biota 2013; Phoenix 2012, 2014	Known mostly from dead-taken shells; likely multiple species
	Quistrachia 'X'	Cape Preston	Potential	WA Museum	
Glacidorbidae	*Glacidorbis* sp. indet.	Mardie Station	Potential	WA Museum	Aquatic mollusc and probably more widespread
Hydrobiidae	Hydrobiidae sp. indet.	Bungaroo Creek	Potential	WA Museum	Aquatic mollusc and probably more widespread
Hyriidae	*Velesunio* sp.	Millstream-Chichester National Park	Potential	WA Museum	Aquatic mollusc
Lymnaeidae	*Bayardella* cf. johni	Tom Price	Potential	WA Museum	
	Isidorella cf. *egregia*	Middle Robe, Tom Price	Potential	WA Museum	Probably unresolved species complex
Succineidae	*Succinea* sp.	Pannawonica	Potential	WA Museum	

[#] previously referred to as *Rhagada* 'small banded' and thought to be a potential SRE species (WAM data); however recent molecular analyses by Biota Environmental Sciences (2013) have shown that this morphospecies consists of three distinct genetic lineages, all with ranges > 10,000 km^2 (Biota 2013).

Appendix G: Threatened and Priority Fauna Species Likelihood of Occurrence within the Survey Area

This page has been left blank intentionally.

Table G.1: Likelihood of occurrence of conservation listed vertebrate fauna species listed as potentially occurring in the vicinity of the survey area.

Scientific name (common name)	Conservation codes			Preferred habitat	Likelihood of occurrence	
	EPBC Act	WC Act	Parks and Wildlife		Pre-survey	Post-survey
Reptiles						
Notoscincus butleri (Lined Soil-crevice Skink)			P4	Arid, rocky, near coastal Pilbara regions. Associated with spinifex-dominated areas near creeks and river margins.	High – previously recorded	Recorded
Anilios ganei (Blindsnake)			P1	Little information is available on this species but it is believed to be associated with moist gorges and gullies.	High	High
Liasis olivaceus barroni (Pilbara Olive Python)	VU	S3		Generally rocky habitats in close association to permanent and semi-permanent water sources.	High	Recorded
Birds						
Apus pacificus (Fork-tailed Swift)	Mi	S5		Largely aerial species independent of the terrestrial environment.	Moderate	Moderate
Ardea ibis (Cattle Egret)	Mi	S5		Largely wetland species however can exploit drier open habitats more than other heron species.	Moderate	Moderate
Ardea modesta (Eastern Great Egret)	Mi	S5		Wide range of wetland habitats (for example inland and coastal, freshwater and saline, permanent and ephemeral).	High – previously recorded	High
Elanus scriptus (Letter-winged Kite)			P4	The Letter-winged Kite is a bird of open country and grasslands in arid and semi-arid Australia, where there are tree-lined streams or water courses.	Moderate	Moderate
Panidon haliaetus (Eastern Osprey)	Mi	S5		Favours coastal areas, especially the mouths of large rivers, lagoons and lakes.	Low	Low
Charadrius veredus (Oriental Plover)	Mi	S5		Breeding habitat includes arid grasslands, saltpans; non-breeding habitat includes grasslands, salt-fields, and coastal regions.	Low	Low

Scientific name (common name)	Conservation codes			Preferred habitat	Likelihood of occurrence	
	EPBC Act	WC Act	Parks and Wildlife		Pre-survey	Post-survey
Charadrius leschenaultii (Greater Sand Plover)	Mi	S5		This species is almost entirely coastal, inhabiting littoral and estuarine habitats. They mainly occur on sheltered sandy, shelly or muddy beaches with large intertidal mudflats or sandbanks, as well as sandy estuarine lagoons.	Low	Low
Rostratula benghalensis (sensu lato) (Australian Painted Snipe)	EN	S2		Shallow terrestrial freshwater wetlands, temporary/permanent lakes, swamps and claypans with emergent grass, sedges, rushes and samphire.	Moderate	Moderate
Actitis hypoleucos (Common Sandpiper)	Mi	S5		Non-breeding migrant to a wide variety of habitats, such as riverbanks, estuaries, freshwater seeps on coastal shores, tidal creeks, mangrove swamps and saltmarshes.	Moderate	Moderate
Calidris acuminata (Sharp-tailed Sandpiper)	Mi	S5		Muddy edges of shallow fresh/brackish wetlands with emergent sedges, saltmarsh, grass and low vegetation.	Moderate	Moderate
Calidris ferruginea (Curlew Sandpiper)	CR/Mi	S3/S5		This species mainly occurs on intertidal mudflats in sheltered coastal areas and also around non-tidal swamps, lakes and lagoons near the coast.	Moderate	Low
Numenius madagascariensis (Eastern Curlew)	CR	S3/S5		This species is most commonly associated with sheltered coasts, especially estuaries, bays, harbours, inlets and coastal lagoons, with large intertidal mudflats or sandflats, often with beds of seagrass.	Low	Low
Numenius phaeopus (Whimbrel)	Mi	S5		Primarily found in coastal habitats such as beaches, dunes, mudflats and mangroves however there are also scattered inland records.	Low	Low

Scientific name (common name)	Conservation codes			Preferred habitat	Likelihood of occurrence	
	EPBC Act	WC Act	Parks and Wildlife		Pre-survey	Post-survey
Tringa glareola (Wood Sandpiper)	Mi	S5		Occurs mainly on freshwater wetlands of the inland interior and arid regions.	Moderate	Moderate
Tringa nebularia (Common Greenshank)	Mi	S5		Inland wetlands and coastal habitats of varying salinity. Typically large mudflats, saltmarsh, mangroves and seagrass	Moderate	Moderate
Glareola maldivarum (Oriental Pratincole)	Mi	S5		Feeds in the air and roosts on bare ground besides water	Moderate	Moderate
Pezoporus occidentalis (Night Parrot)	EN	S1		Most habitat records are from *Triodia* grasslands and/or chenopod shrublands in the arid and semi-arid zones. *Astrebla* spp. (Mitchell grass), shrubby samphire and chenopod associations, scattered trees and shrubs, *Acacia aneura* (Mulga) woodland, treeless areas and bare gibber as associated with sightings of the species.	Low	Low
Merops ornatus (Rainbow Bee-eater)	Mi	S5		Lightly wooded, preferably sandy soil, near drainage channels and creek lines.	High – previously recorded	Recorded
Hirundo rustica (Barn Swallow)	Mi	S5		Coastal open country generally, especially near surface water and man-made structures such as bridges and power wires.	Low	Low
Motacilla cinerea (Grey Wagtail)	Mi	S5		Damp short-grass flats, rice stubbles and edge of swamps, sewage ponds, bore overflows, grazed or mowed grass and irrigated areas.	Low	Low
Motacilla flava (Yellow Wagtail)	Mi	S5		Mainly banks and rocks in fast-running freshwater habitats such as rivers, creeks, streams and around waterfalls.	Low	Low
Mammals						

Scientific name (common name)	Conservation codes			Preferred habitat	Likelihood of occurrence	
	EPBC Act	WC Act	Parks and Wildlife		Pre-survey	Post-survey
Dasycercus blythi (Brush-tailed Mulgara)			P4	Triodia hummock and Acacia shrublands of sand or sandy-loam.	Low	Low
Dasyurus hallucatus (Northern Quoll)	EN	S2		Dissected rocky escarpments and rocky eucalypt woodland.	High – previously recorded	Recorded
Sminthopis longicaudata (Long-tailed Dunnart)			P4	Common in rocky screes with hummock grassland and Acacia shrubs, tall open shrubland and woodlands.	Moderate	Moderate
Macrotis lagotis (Greater Bilby, Dalgyte)	VU	S3		Sand or sandy-loam in hummock grassland (Triodia species) and or Acacia shrublands.	Low	Low
Notoryctes caurinus (Northern Marsupial Mole)	EN			Lives primarily underground of sand dunes and sandy soils along river flats.	Low	Low
Macroderma gigas (Ghost Bat)	VU	S3		A wide range from rainforest, monsoon and vine scrub in the tropics to open woodlands and arid areas.	High – previously recorded	Recorded
Rhinonicteris aurantia (Pilbara form) (Pilbara Leaf-nosed Bat)	VU	S3		Deep warm, humid caves or rock cracks.	High – previously recorded	Recorded
Leggadina lakedownensis (Short-tailed Mouse, Karekanga)			P4	Open tussock and hummock grassland, Acacia shrubland and savannah woodland on alluvial clay / sandy soils.	Moderate	Moderate - previous records from surrounding areas
Pseudomys chapmani (Western Pebble-mound Mouse)			P4	Gentle rocky slopes, hills and spurs with small pebble surface cover and sparse vegetation.	High – previously recorded	Recorded

Table G.2: Likelihood of SRE groups occurring in the vicinity of the survey area.

SRE group	Likelihood of occurrence
Mygalomorph Spiders	The desktop review identified a diverse mygalomorph spider fauna (trapdoor spiders and allies), with at least 33 species in five families. Of these, the wishbone spiders (family Nemesiidae) were most diverse in the western Pilbara with at least 11 species followed by the brush-footed trapdoor spiders (family Barychelidae; 9 species), ctenizid trapdoor spiders (family Ctenizidae; 5) and true trapdoor spiders (family Idiopidae; 5). Mygalomorph spiders generally have a high proportion of SRE species (Castalanelli *et al.* 2013; Harms and Framenau 2013; Harvey *et al.* 2012) but all species that were collected previously near the survey area (*Aname* sp. 'Pannawonica 1', *Aurecocrypta* 'MYG057', Barychelidae indet., and *Missulena* sp. 'Pannawonica 1') were widespread (Biota 2006, ecologia Environment 2013). The most recent fauna survey at Middle Robe and East Deepdale, an area very close to Mesa H, collected only one species of mygalomorph spider: *Aname mellosa*. This species is very widespread in the western Pilbara and genetically very similar specimens are known from elsewhere in the area (Harvey *et al.* 2012; Astron 2016b). The two *Aname* species (*Aname* sp. A and *Aname* sp. C) that were collected during a previous fauna survey at Mesa H (Biota 2011) may also belong to this species but this is not certain. It is possible that *Aname mellosa* and additional mygalomorph spiders occur in the survey area although this fauna is not expected to be rich at a species level.
Araneomoprh Spiders	Two spider families with potential SRE species have been recorded: wall crab spiders (family Selenopidae) and goblin spiders (Oonopidae). Wall crab spiders are habitat specialists that live under rocks and have limited abilities of dispersal (Crews and Harvey 2011, Crews 2013). Two named species, *Karaops yindjibarndi* and *K. yurlburr*, are currently known only from their type locality in the desktop search area and may not occur elsewhere (Crews 2013). Additional selenopid spiders were collected in past surveys at Middle Robe and East Deepdale but could not be identified to species level because they were juveniles. The most recent fauna surveys by Astron at Bungaroo and Middle Robe (Astron 2016 a,b) collected three species of selenopid spdiers that were identified through DNA barcoding because adults were unavailable: *Karaops* sp. 'Bungaroo', *K.* sp. 'Middle Robe 1' and *K.* sp. 'Middle Robe 2'. All three species were assessed as potential SREs but not threatened by economic development because they occurred in habitats that are more widespread in the western Pilbara. Oonopid spiders are very small in body length, usually < 0.4 cm, and live in leaf litter. Some confirmed SRE species in the genus *Opopaea* and one potential SRE *Grymeus* species are known from the wider region and there is a remote possibility that additional species may occur at in the survey area.
Harvestmen	The harvestmen fauna of the western Pilbara region is comparably depauperate but the genus *Dampetrus* (family Assamiidae) is sometimes collected during fauna surveys and almost certainly contains SRE species (e.g. Phoenix 2014). Most specimens were taken from moist leaf litter in relict habitats (e.g. gorges or between large rock boulders) and are likely to be restricted to specific habitats (Shear 2001). One undescribed species of *Dampetrus* was recently collected during a fauna survey at Middle Robe and East Deepdale and assessed as a potential SRE species (Astron 2016b). It was collected from Breakaway habitat similar to those at Mesa H; hence there is a high likelihood that *Dampetrus* also occurs in the survey area.

SRE group	Likelihood of occurrence
Pseudoscorpions	The pseudoscorpion fauna in the desktop search area was moderately diverse with several potential SRE species in six families: Chthoniidae, Garypidae, Garypinidae, Hyidae, Sternophoridae, and Syarinidae. The family Chthoniidae includes species that are usually collected in moist leaf litter and these species may have short ranges. This family has been recorded from subterranean habitats at Middle Robe and additional records from surface habitats in the Bungaroo Valley have recently been established (Astron 2016a,b). *Synsphyronus* species in the family Garypidae are habitat specialists that live under rocks and have been collected previously from the hills and breakaways at Bungaroo (Biota 2010). *Ideoblothrus* and *Indohya* species are known from moist leaf litter in the search area and the available taxonomic literature points to high regional endemism and range restriction in this fauna (Harvey 1993; Harvey and Edward 2007; Harvey and Volschenk 2007). Recent surveys at the Bungaroo Iron Ore Mine collected a moderately diverse fauna of pseudoscorpions and three potential SRE species (Astron 2016a). Two pseudoscorpion species were collected during the survey at Middle Robe and East Deepdale but both species were widespread (Astron 2016b). No pseudoscorpion species were collected at Mesa J (Astron 2016c). It is very likely that pseudoscorpions occur in the survey area but the assessment of ranges is principally on a case-by-case basis.
Scorpions	Two genera of scorpions, *Lychas* and *Urodacus*, have been recorded in the desktop search area. Most scorpions are arid-adapted and considered widespread across the Pilbara (e.g. ecologia Environment 2013). The Pilbara Biodiversity Survey recorded ten morphospecies of *Lychas* but the taxonomic resolution is currently poor and there are likely many more species (Volschenk *et al.* 2010), some of these with short ranges. Ongoing genetic research at the Western Australian Museum has also shown that there are some morphologically cryptic but genetically distinct species of *Lychas* that may have ranges below the current SRE threshold of 10,000 km^2. The recent fauna survey at Middle Robe and East Deepdale collected two potential SRE scorpions in the *Lychas* 'hairy tail' and *Lychas* 'multipunctatus' species complexes (Astron 2016b). These were collected from Breakaway, Riverine and Rocky Hills habitat. All these habitat types are present at Mesa H and there is a high likelihood that a diverse scorpion fauna occurs in the survey area that may contain some SREs.
Terrestrial Slaters	This group is extremely diverse but taxonomically unrevised and species identification is extremely difficult. The desktop review identified a rich and diverse fauna of terrestrial slaters in the survey area with more than 20 potential SRE species. The slater family Armadillidae, slaters that roll up as a ball when disturbed, includes most of the species and includes many potential SREs. Other groups, such as the Philoscidiidae, also occur but seem to be less diverse at a species level, although almost nothing is known about species boundaries and distributions. Slaters were not assessed in a fauna survey at Mesa H (Biota 2011) but more recent surveys at the Bungaroo Iron Mine Project (Astron 2016a), Middle Robe and Deepdale (Astron 2016b) and Mesa J (Astron 2016c) collected several species of slaters. Of these, the four species *Buddelundia* '61', Buddelundiinae sp. indet., Philoscidiidae sp. indet. and *Spherillo* sp. indet. were assessed as potential SRE species. They were collected from habitats that are similar to those at Mesa H. Based on the data available, the presence of potentially range-restricted isopods in the survey area is almost certain.
Millipedes	This group is taxonomically diverse but almost all species in the genera *Antichiropus* and *Boreohesperus* (family Paradoxosomatidae) are confirmed SREs. Three species of *Boreohesperus* have recently been described (Car and Harvey 2013) from the wider search area but their ranges do not overlap with the survey area. At least five species in the genus *Antichiropus* are also known and there are numerous additional records of unidentified juveniles in the search area. However, none of the most recent fauna surveys in the area (Astron 2016a, b, c) recorded millipedes in the survey area or its vicinity, despite favourable climatic conditions and suitable collecting techniques. From the data available, it is unlikely that millipedes are diverse in the survey area and occur with range-restricted species.

SRE group	Likelihood of occurrence
Centipedes	Almost nothing is known about the centipede fauna of the Pilbara but three families, Chilenophilidae, Cryptopidae and Mecistocephalidae, have been recorded and are likely to include SRE species. The records of *Cryptops* sp. indet., *Mecistocephalus* sp. indet. and *Sependophilus* sp. indet. in the search area are likely to represent several range-restricted species. However, none of the recent surveys by Astron (2016a, b, c) in the vicinity of the survey area have provided evidence for the occurrence of centipedes. It is considered unlikely that a diverse centipede community occurs locally.
Snails	Three families of terrestrial snails occur in the search area: the Bothriembryontidae, Camaenidae and Pupillidae. The Pupillidae comprise widespread species but the Camaenidae include some potential and confirmed SREs species. The camaenid genus *Quistrachia* is present in the search area with at least two potential SRE species and a second genus, *Rhagada*, is common and frequently collected during environmental surveys. Species identification in *Rhagada* is often difficult because species are morphologically cryptic, have variable shell morphology, occur in sympatry, and hybridize (Hamilton and Johnson 2015). However, two well-diagnosed morphospecies have been collected from Middle Robe and East Deepdale in a recent SRE survey (*Rhagada convicta* and *R. radleyi*) and one of these (*R. convicta*) has been collected previously from Mesa H (Biota 2011). Both species are widespread (Astron 2016b). A third species of *Rhagada* (*R*. sp. 'Pannawonica') is known from the Bungaroo Creek Valley and this species is also widespread (Astron 2016a). Aquatic snail families in the search area belong to the families Glacidorbidae, Hydrobiidae, Lymnaeidae and Planorbidae and these families include few SRE species. All aquatic snails collected from the Bungaroo Creek Valley in the recent SRE survey (Astron 2016a) were assessed as widespread. In summary, there is a potential for both aquatic snails and terrestrial snails to occur in the survey area but the species present are expected to be widespread.

Summary
Bat species presence, with an estimate of activity level, is presented for seventeen sites at Mesa H near Pannawonica in the Pilbara, WA. Astron Environmental Services (Astron) carried out an echolocation based survey in two phases during September-October 2015 and May-June 2016. Bat Call WA has reviewed the recordings made and provided species lists for the bats present.

Ten species of echolocating bats were recorded including the two EPBC Act listed species in the Pilbara, the Orange Leaf-nosed Bat, Pilbara form (*Rhinonicteris aurantia*) (PLNb) and the Ghost bat (*Macroderma gigas*). PLNb calls were detected foraging in high numbers at site Bat 14, in medium numbers at Bat A4 and in low numbers at ten sites. A summary of call numbers and timing is provided. Ghost bat calls were detected at three sites. Activity levels for the common species are provided by site.

Habitats
The sites for the survey were chosen by Astron. Details of the sites are presented in Table 1. All sites are in the vicinity of Mesa H deposit. Five are on low stony hills or plains, four are in gorges, two are in cave entrances, two are under overhangs, two are within the Robe River riparian zone, two are in drainage lines and two are on breakaways. The locations are shown in relation to Mesa H features in Figure 1. This range of sites is adequate to provide an accurate species list for the area and to indicate the probable direction toward the originating PLNb roost.

Characteristics of the calls recorded are presented in Table 2.

Bat Fauna
An assemblage of ten echolocating species was confirmed as present at the study sites including the PLNb and the Ghost bat, Tables 2 and 3. Species activity levels were low to high, which is expected for the study area habitat and the time of year, see criteria below.

PLNb were detected at twelve of the nineteen sites. One, site Bat 14, had a high activity level with 257 calls recorded in spite of the night receiving heavy rainfall. The majority of these calls were recorded during the period of light rainfall after midnight, see below. Site ‘A4 had a medium activity level with a total of 140 calls being recorded over six nights. Ten sites had low activity levels.

Detections within 60 minutes of dusk civil twilight were recorded at four sites. The earliest call differentials from dusk civil twilight (CT) were at site Bat A4, 30 minutes on the 6th June (an overcast night with rainfall periods), 35 minutes at ‘14 and ‘A2, and 50 minutes at ‘A3. The latest calls were between 25 and 45 minutes before dawn CT, on the 6th June at ‘A4, and at sites ‘A3 and ‘A1, Figure 1. These time differentials, including that of 25 minutes at ‘A4 and 35 minutes at ’14 (both during overcast conditions) together with the progressively increasing time differentials from south to north indicates that the PLNb probably originate from a known roost approximately10 km south of the study area.

Multiple Ghost bat calls were detected at one site, Bat 10, on all four nights of the survey at that location. Calls were also detected at sites Bat ‘A1 and ‘A4 although the pattern of calls at these two sites were interrupted by nights with extensive rainfall and also probably impacted by the two cold nights in June, see below.

Taxonomy presented herein is after Reardon *et al.* (2014) and Jackson and Groves (2015).

Survey Timing, Moon Phase and Weather
The echolocation survey was conducted between 26th September and 1st October 2015, between 1st and 5th May 2016 and between 3rd and 8th June 2016.

In September-October 2015, sampling evenings were warm and dry with minimum overnight temperatures around 15^{O}C. The moon in this period was full. In May 2016, the first four sampling evenings were also warm and dry with minimum overnight temperatures between 20 and 25^{O}C. Heavy rain was experienced on the 5th May beginning at approximately 19:00 and continuing until dawn with a period of light rainfall between midnight and 02:00. The moon was between third quarter and new. In June 2016, the first four sampling evenings were warm with minimum overnight temperatures between 15 and 20^{O}C while the last two were cold with temperatures around 10^{O}C. Rain fell on the nights of 4th , 5th and 6th June. The moon in this period was new. On the warm nights, other than the four wet nights, these conditions correspond to typical levels of bat echolocation detection for the season. Activity levels are expected to be low on the two cold nights.

During the September-October survey, sunset, sunrise, dusk and dawn civil twilight times were within two minutes of 18:13, 06:00, 18:35 and 05:37. During May the respective times were 17:50, 06:54, 18:13 and 06:11. During June the respective times were 17:39, 06:49, 18:03 and 06:25.

Survey Team
Sites were chosen and detectors placed by Astron ecologists. Bob Bullen of Bat Call WA completed analysis of echolocation recordings.

Sampling
The survey consisted of completing a total of 47 overnight bat sound recordings, beginning at twilight, at seventeen locations within the survey area. Detectors were deployed but failed to record at two additional locations. The recordings were "continuous" (Hyder *et al.* 2010) made using SM2BAT+ SongMeter (Wildlife Acoustics Inc, USA) detectors. The jumper and audio settings used followed the manufacturer's recommendations for bat detection contained in the user manual (Wildlife Acoustics 2010).

For the recordings, once reformatted as .wav files, COOL EDIT 2000 (now available as AUDITION from Adobe Systems Inc.) was used to display each sequence for identification. Calls were identified manually. Only good quality call sequences were used. Details of calls analysed are provided in Table 2 as recommended by Australasian Bat Society (ABS 2006). Reference data for the species identified are available in Bullen and McKenzie 2002, McKenzie and Bullen 2003 and McKenzie and Bullen 2009.

Bat activity was then characterised as "Low", "Medium" or "High" based on the rate of call sequences recorded.

- Low species activity is referred when a species is recorded with call spacing less often than ten minutes,
- Medium species activity refers to call recordings more often than 10 minutes but less often than two minutes apart for a at least an hour followed by sporadic records for the remainder of the session.
- High species activity refers to call recording more often than two minutes apart for at least two hours followed by reasonably regular records for the remainder of the session.

Survey Limitations

The sites surveyed were accessible on foot and the SM2, using an omnidirectional microphone, was set on the ground with the microphone horizontal. Species are unlikely to be under-represented as a result.

Bat species density away from cave or adit entrances is impossible to estimate from echolocation records. Bat activity is therefore substituted as an approximate guide to the relative numbers of each species using the study area.

No data was collected from two Phase 1sites (due to battery failure) but seventeen sites remained functional.

Attachment A. Characteristics of caves examined during this survey

Executive Summary

Rio Tinto commissioned Bat Call WA (Bat Call) to undertake a targeted assessment of bat conservation values of caves at Mesa H. This resource is located in the Robe River valley 17 km south west of Pannawonica, in the Pilbara region of Western Australia. This assessment was completed in parallel with a broader assessment of bat conservation values across the entire Robe River that is the subject of a separate report.

Level one and two fauna surveys have been conducted in the area previously, most recently by Astron Environmental Services in 2015/16. Two bat species of conservation significance have been recorded within the area, namely Pilbara leaf-nosed bat (*Rhinonicteris aurantia*) (Pilbara form of the Orange leaf-nosed bat) (PLNb) and Ghost bat (*Macroderma gigas*), both listed as Vulnerable under Federal and State legislation. PLNb have been assessed as using Mesa H for foraging while originating from a yet to be discovered roost further to the south or east (e.g. Bat Call 2016, 2017). Multiple Ghost bat records including echolocation recordings, visual observations and cave middens have been detected within and adjacent to the study area (e.g. Biota 2009; Astron 2016; Astron 2017).

This survey was designed to provide an assessment of the conservation value of caves associated with the presence of Ghost bats at Mesa H. A visual assessment of cave environments and an extensive search for Ghost bat presence, including roosting bats, was carried out. Ghost bat presence on Mesa H was determined to be irregular with the mesa being used for nocturnal foraging and occasional diurnal roosting. Ghost bat presence, in the form of guano and middens, was recorded across all of the different areas inspected. Eleven of twenty four sites were found to be used or suitable for use by the species. No colonies of diurnally roosting Ghost bats were found. Two caves on Mesa H (MH16-34 and AC04) were found to have the characteristics of diurnal roosts for the species with the possibility of occasional use as maternity roosts. Eight sites on Mesa H were assessed to be nocturnal feeding sites. One site south of Mesa H in the nearby Buckland Hills was also assessed to be a nocturnal feeding site. Thirteen sites on Mesa H were determined to be not currently used by Ghost bats and not suitable for regular occupancy. A number of additional overhangs nearby the caves and shelters were also assessed for signs of Ghost bat use but none were found.

The caves and surrounding environments at Mesa H were found to be supporting foraging Ghost bats originating from either the Buckland Hills to the south, Yeera Bluff between mesas G and H or the Three Peak Hills to the north-west. Two diurnal roost caves with maternity cave potential

have been confirmed. These are located in productive gullies and are associated with a number of near-by caves and shelters providing a series of escape and nocturnal foraging opportunities, including the presence of the Robe River riparian zone, required by the species for successful reproduction.

1.0 Introduction.

1.1 Project Background

Rio Tinto commissioned Bat Call to undertake a targeted assessment of bat conservation values at the Mesa H deposit located approximately 17 kilometres (km) south-west of Pannawonica in the Robe River valley, in the Pilbara region of Western Australia (WA), figure 1. Rio Tinto is considering sustaining its Robe Valley operations by including additional deposits to replace ore supply from the Mesa J operations as it nears the end of its mine life. In summary, the planned mining operation would involve the following main components and activities in addition to the existing approved operations:

- progressive open pit mining of ore and overburden from Mesa H using similar open pit mining techniques to those currently used at Mesa J. These operations are planned to remove the inner core of the mesa while leaving the rocky face of the perimeter intact to a width of at least 20m at the mesa surface,
- placement of overburden in out-of-pit waste dumps adjacent to the mesa, and
- construction and use of haul and access roads to the mine areas within the mesa.

Recent surveys have identified that two species of cave roosting bat of conservation significance are present in the area, the Ghost bat (*Macroderma gigas*) and the Pilbara leaf-nosed bat (*Rhinonicteris aurantia*) (PLNb). PLNb have been assessed as using the Mesas for foraging while originating from a yet to be discovered roost further to the south or east (Bat Call 2016, 2017). Multiple Ghost bat records including echolocation recordings, visual observations and cave middens have been detected within and adjacent to the study area (Biota 2009; Astron 2016; Astron 2017).

The purpose of this survey was to assess the conservation values of caves potentially associated with Ghost bats at Mesa H that had been previously identified by both external and internal resources. This involved a visual assessment of cave geometry and environments and an extensive search for Ghost bat presence, including bat colonies and/or middens. The study area is shown in figure 1. It includes the perimeter of Mesa H including its major central gully.

1.2 Existing Environment at Robe Valley Mesas and Surrounds

Topography

The Robe River Valley mesas cover an extensive area beginning at Mesa A and running approximately 100 km upstream. Mesa H lies immediately adjacent to that river riparian zone. It is roughly circular and is 3.5 km in diameter and stands approximately 50 m higher than a flat plain that is crossed by the river. It is bisected by a major gully running south to north toward the Robe River riparian zone.

Geology

Mesa H is a tertiary Robe Pisolite iron ore deposit, also known as a Channel Iron Deposit (CID), incised with deep gullies around the perimeter. It has overhangs, shelters and caves along extensive lengths of the perimeter and the central gully, e.g. plate 1.

Overhangs, shelters and caves are defined herein as:

- Overhangs are shallow hollows in a rock wall with a distinct roof structure. Their shape is such that they are fully lit by sunlight to their back wall. Their depth is typically 2 to 5 m.
- Shelters are deeper hollows or shallow caves in the rock wall that have ceiling structures from 1.0 to >5 m. They offer significant protection from predators and the weather, are typically 5 to 15 m deep and have dark twilight conditions at their rear extremities. Some have domed areas in their ceilings offering nocturnal roosting and feeding opportunities to Ghost bats. Some are occasionally used diurnally.
- Caves are defined as deep structures of various heights, widths and depths that are very dark in their deeper recesses. They often have additional rear chamber(s) separated from the entrance by a constriction point(s). Those chambers that have ceiling heights of over 2.5m offer excellent roosting opportunities for Ghost bats.
- All three can have cracks or voids that continue back from their rear walls that may lead to additional internal cavities within the rock strata behind or above. If these cavities are almost fully enclosed, have entrance cracks large enough, and can retain high levels of humidity, they provide roosting opportunities for PLNb and Ghost bats.

Overhang and shelter density is high along the majority of the mesa perimeters with the rock strata forming numerous shallow shelters in mid and higher levels of the walls. There are a

number of deeper caves formed in the Pisolite at mid and higher levels of the mesa walls but these rarely extend beyond 15 m in depth. Most shelters and caves were found on the mesa's cliff walls at or just above the top of the talus slope.

Land Systems (after Van Vreeswyk *et al.* 2004)

Mesas H including the gullies and the surrounding gravelly plains are elements of the Robe Land System. It is a low limonite mesa that support spinifex grasslands and scattered Snappy Gums. The lower slopes and adjacent gravelly plains support spinifex grasslands with sparse Acacia and Eucalypt shrubs with low trees that sometimes form thickets.

The adjacent Robe River is a very complex and productive linear river channel and flood plain with a Eucalyptus and Melaleuca woodland over tall Acacia and Petalostylis shrubland. It is an element of the Pilbara's River Land System

The Buckland Hills to the south of Mesa H and Yeera Bluff to the west are rugged jaspilite ridges and mountains of the Newman Land System supporting open shrublands and open low woodlands of Grevillia and Eucalypt over hummock grasses.

Climate

The climate in the district is semi-desert tropical. Mean monthly minimum and maximum temperatures in the lower Robe Valley range from 12 to 41 degrees Celsius (^{o}C). Annual rainfall is extremely variable and averages 400 mm, usually in cyclonic or thunderstorm events during the northern wet season. The northern dry season lasts from May to November and winter rainfall is uncommon.

Water Sources

Drainage systems in the immediate area are associated with ephemeral gullies on the perimeters of the mesas that run into the Robe River drainage system. That riparian zone has a number of permanent and ephemeral pools along its length such as Gnieraoora Pool at the base of Yeera Bluff.

Plate 1. Example of the presence of overhangs and shelters along the perimeters and within the incised gullies on Mesa H. This view is of the Cave H18, H19 complex.

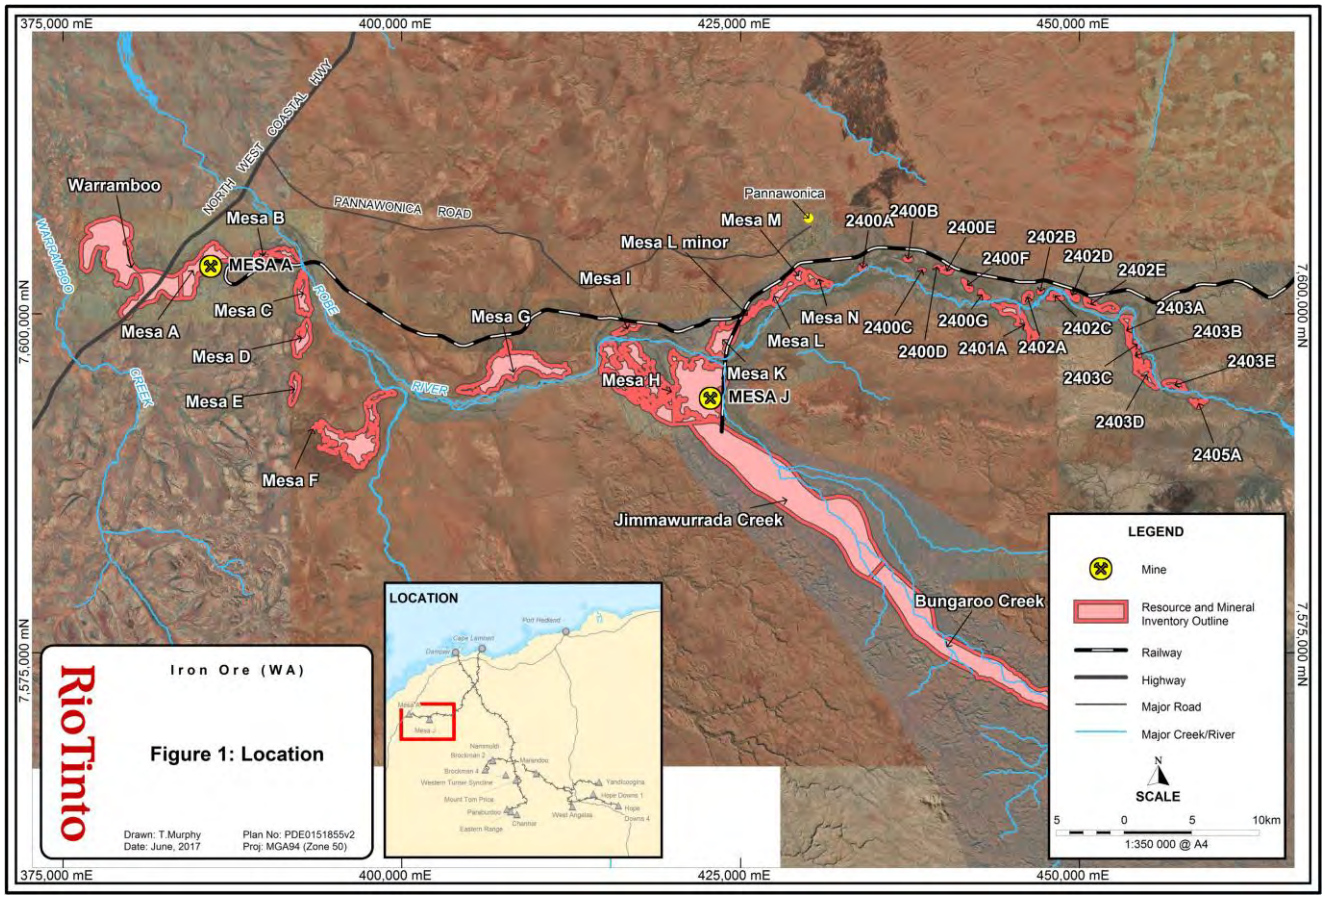

Figure 1. General Arrangement of Robe River valley mining area.

1.3 Bats of Conservation Significance

The Pilbara region contains 17 species of microbat, and of these, 13 have the potential to be found in the Mesa G-H vicinity (Van Dyke and Strahan 2008, McKenzie and Bullen 2009). A number of fauna surveys including targeted bat surveys have been previously conducted in the area, most recently by Astron in 2015 and 2016 and internal Rio Tinto ecologists in 2016-17, see table 1. Two Pilbara bat species of conservation significance have been recorded in the area, the Ghost bat (*Macroderma gigas*) and the PLNb (*Rhinonicteris aurantia*).

The Ghost bat is a large (130 g) carnivorous predator and the PLNb is a small (10 g) insectivore. Both are endemic to northern Australia and are obligate cave roosting species requiring specific cave environments for permanent roosting especially for their maternity colonies. The Ghost bat's foraging strategy and high trophic niche, as a top night-time carnivorous predator, is unique in Australian microbats. The Pilbara's Ghost bat and PLNb populations are isolated from Australia's other populations that are extant across the mesic tropics by the uninhabitable arid zone of the Great Sandy Desert to the north and east. Both species are "conservation significant" as they are semi-desert adapted populations that have specific roosting requirements. The Ghost bat has suffered significant range loss in historical times. The reasons for the range contraction are open to speculation but it is known that the species is sensitive to disturbance (e.g. Richards *et al*. 2008, Woinarski *et al.* 2014)).

The PLNb has been detected foraging across the mesas in the Middle Robe valley. A roost has not been identified on Mesa H and echolocation records indicate that it lies to the south or east of Mesa H or J.

The Ghost bat has also been detected within the study area.

1.3.1 Ghost bat (*Macroderma gigas*)

The Ghost bat is listed as Vulnerable under the commonwealth *Environment Protection and Biodiversity Act 1999* (EPBC Act), Vulnerable under the Western Australian *Wildlife Conservation Act* (1950) and Vulnerable C1 (a vulnerable species numbering less than 10,000 and in decline) under the IUCN Redlist (IUCN 2017). The listing is on the basis of the impact of loss of suitable roost opportunities. The Pilbara Ghost bat population is estimated at 1500-2000 based on recently published estimates (approximately 600, N.L. McKenzie pers. comm. in IUCN 2016; approximately 1200, Armstrong and Anstee 2000; "more common than previously supposed", McKenzie and Bullen 2009) and author's unpublished database summarising data from a range of surveys carried out in recent years by Pilbara mining companies, including Rio

Tinto and other organisations, supplemented by author's own data (summarised in Threatened Species Scientific Committee (TSSC 2016). These recent data (estimates less than 15 years old) cover the entire Pilbara bioregion. Current population estimates in the Hamersley and Chichester subregions are approximately 350 and 1500 respectively (author's unpublished database summarised in TSSC (2016)).

Ghost bats hunt their prey in two primary ways. They hunt birds and bats "air-to-air" at cave entrances and elsewhere by swooping from above or from a perch. They also hunt ground level prey in their target food size range by dropping onto the prey from a perch, either tree branch or rock outcrop. Their diet includes small mammals including other bats, birds, reptiles, frogs and large insects. The proportion of food items in the diet varies with availability and reported foraging areas vary from a few to 10 km from the roost cave. One Ghost bat carcass was found recently entangled in a barbed wire fence in the Fortescue Marsh over 12 km from the nearest cave forming rocky strata suitable for roosting (Stephen Van Leeuwen pers. comm.).

Along the lower Robe River valley multiple Ghost bat records including visual observations and the presence of cave middens have been detected on the various mesas within and adjacent to the study area (table 1).

Ghost bat breeding colonies are known from a small number of maternity roosts in the Pilbara and reproduce during the northern wet season. The largest of these colonies are in abandoned mines in the Chichester subregion and number up to several hundred (Armstrong and Anstee 2000). Hamersley Range populations are typically between 5 and 25 individuals in local groups (author's unpublished database). There is one known large, permanent maternity roost (unpublished assessment by the author) numbering over 70 bats in the lower Robe River valley of the Hamersley subregion. For these groups to persist the bats need an "apartment block" of roosting opportunities, at least one deep cave with characteristics of a maternity roost, multiple caves/shelters and overhangs in close proximity offering nocturnal feeding and refuge opportunities, a productive set of gullies and gorges locally, a productive foraging area within 5 to 10 km radius, usually including a good quality riparian corridor or ephemeral fresh water lake bed and appropriate protection from human interference (author's unpublished data base). These groups are known to reproduce in good years using suitable natural roost caves. Examples are a group numbering 5 to 10 including reproducing females at West Angeles caves in 1980 (Dr Nic Dunlop pers. comm.), a small group including reproducing females at caves at Nammuldi/Silvergrass area (Hamersley Iron 1999), observation of a heavily pregnant female at a cave near Mt Robinson by the author in 2013 and a group numbering 14 including four juveniles

at another cave near Mt Robinson in 2015 (Mr. Morgan O'Connell pers. comm.). The Ghost bat is also known to spread great distances on an annual cycle from these locations depending upon seasonal weather conditions and availability of suitable day roosts. Sporadic records of Pilbara Ghost bats have been identified in the Gascoyne (author's unpublished data) and the Little Sandy Desert (sightings by W.H. Butler at Durba Spring in 1971 and others since). Genetic work by Worthington Wilmer and Armstrong (summarised in Woinarski *et al.* 2014) suggests that the females remain or return to their birthplace and that the males can move between districts.

Ghost bats use three types of roost regularly, these being nocturnal roosts or feeding sites, diurnal or day roosts that may be permanent or semi-permanent sites and maternity roosts that are diurnal roosts with the range of characteristics allowing regular or permanent occupancy.

Nocturnal roosts or feeding sites are only used at night, either habitually or for transitory visits. They are typically shallow caves and shelters that are well lit during the day. They are often high in the strata and may be well or poorly insulated from the elements. They often contain guano scatters and/or midden(s) of various sizes containing guano and food scraps but these remains are sometimes removed by rainfall and/or varieties of "dung beetle" that are known to forage on the scats (author's unpublished observations).

Diurnal roosts are caves and mine adits that are deeper and more complex. They typically have one or more large chambers at or beyond the twilight area with additional fissures or chambers at the rear in the fully dark regions. They have a minimum roof height in the chambers of 2 to 3 m providing protection from attack by terrestrial predators. They are often at mid-levels or lower in the strata and are well insulated overhead providing a stable temperature environment. They typically contain multiple scat piles and middens of guano and food remains that include feathers and skeletal material.

Maternity roosts are diurnal roosts that provide additional features to those listed above that are able to support a reproducing population. These features usually include an interior chamber that is rising toward the rear thereby trapping warmer and more humid air at the top allowing suitable conditions to form during the period when reproductive females and pups are present.

Being predators, during a night's foraging they may also hang for short periods in any deep overhang, shelter or cave with a high enough ceiling or tree branch above a cleared patch of ground for feeding or resting on an opportunistic basis. These sites are not routinely visited and usually show no evidence of Ghost bat presence.

1.3.2 Pilbara leaf-nosed bat (*Rhinonicteris aurantia*)

The PLNb is listed as 'Vulnerable' under the federal *Environment Protection and Biodiversity Act 1999* (EPBC Act) and by the Western Australian *Wildlife Conservation Act* (1950). This listing is on the basis of the impact on its population of the loss of suitable roosts with the correct microclimate.

The PLNb requires roosts with very specific requirements of high temperature and humidity for survival in the Pilbara. These are warm deep and humid caves and historical underground mines. The humidity required is higher than the Ghost bat, approaching 100%. The species is subject to rapid dehydration and death within a day if removed from its roost. It is known to have a usual foraging range up to 20 km from its primary roost caves (Bullen 2013). It also appears to spread from these roosts to satellite roosts when wet season conditions allow and to consolidate back to permanent sites during dry periods.

1.4 Summary of Previous Bat Surveys

Prior to 2017, a number of the fauna surveys commissioned by Rio Tinto in the lower Robe River valley have included microbat species listings. These indicated the presence of both significant species foraging across the area (e.g. Bat Call 2010). More recent surveys carried out since 2015, summarised in table 1 below, indicated that the Ghost bat may be roosting locally and may include a maternity colony at Mesa H and that the PLNb was foraging generally across all Robe valley mesas but not roosting on Mesa H.

Table 1. Summary of Fauna Surveys that Include Ghost Bat records in the Mesa H District

Date	Reference	Ghost bat activity detected.
2009	Biota (2009)	• Ghost bats harp trapped at Mesa G
2015	Astron (2016)	• Ghost bat echolocation calls detected at Mesa H and a number of shelters/caves with scats recorded
2016	Astron (2017)	• Ghost bat echolocation calls detected at Mesa G and a number of shelters/caves with scats recorded
2017	RTIO internal ecologists	• Ghost bat seen at cave H27on Mesa H.

2.0 Survey and Assessment Methods

A survey consisting of three days field work was completed in April 2017 (9th to 11th April) on Mesa H. Twenty four sites were assessed plus nearby overhangs and shallow shelters.

The fieldwork focussed on the assessment of potential roosting habitat of Ghost bat that previous surveys had indicated were important for this species. Eight sites listed as Ghost bat habitat were assessed. In addition, 13 caves/shelters on Mesa H that the Rio Tinto heritage surveys had recorded with depths greater than 10m were also included in the survey. Three previously unrecorded deep shelters suitable for Ghost bat use were also found and assessed.

On an opportunistic basis, a secondary set of overhangs and shelters recorded by the heritage surveys (often within 100m of the primary caves) were also searched.

2.1 Survey Team, Timing and Weather

The survey team consisted of two experienced ecologists. Ms Tenielle Brown (Rio Tinto) was team leader and Mr Robert Bullen (Bat Call) acted as principal ecologist.

The northern wet season of 2016-17 was wetter than average in the Pilbara region. Heavy rain fell in the district in the three months prior to the survey with 535 mm being recorded at the Bureau of Meteorology station at Pannawonica (Bureau of Meteorology station No 5069) between January and March. This rain continued until a week prior to the survey. The weather during the assessment was typical late wet season conditions being hot and dry with temperatures between 20 and 40^{O}C.

Sunset and sunrise were at 18:09 and 06:26 during the survey while dusk and dawn civil twilight were at 18:31 and 06:04 respectively. The moon phase was full.

2.2 Survey Techniques

The survey was designed to assess all Ghost bat (and any PLNb) roost cave candidates, to review cave morphology, geology and cave conditions, and to narrow down the list of potential Ghost bat maternity and/or PLNb roost caves. These visits were completed during daylight hours. Caves and shelters were entered after a rigorous safety inspection that assessed potential hazardous rock structures. Each was then measured for height, width and depth using a hand held laser (Bosch model PLR-50). Some caves and gorges had been surveyed earlier by Astron, for evidence of Ghost bat activity including the presence of middens and scats. Along the perimeter of Mesa H, twenty four sites were visited and were assessed by their attributes as probable night

feeding locations, seasonal day roost candidates or permanent day/maternity roost candidates. Numerous overhangs and shallow shelters identified by the Rio Tinto heritage surveyors near these sites were also assessed. These combined totals constituted all potential Ghost bat roost caves and shelters previously known or identified during the survey on the two mesas.

The presence of Ghost bat was confirmed by either of the following observations:

- Visual observation of a large pale bat entering or departing the cave. Note that the Ghost bat is distinctive in being much larger than any other cave dwelling bat in the region; or
- Detection of Ghost bat scats or middens on the floor of the caves or shelters entered, plate 2.

Plate 2. Typical Ghost bat midden containing scats and feathers on the floor of a cave

Caves and Shelters were then classified as maternal, diurnal, nocturnal or "not used" based on the cave characteristics and evidence found. The "not used" classification was applied when there is unsuitable characteristics such as low ceilings (typically <1.5m) and/or shallow depth (typically < 5m) with no physical evidence or other record such as a sighting or echolocation recording.

Observations of bat species other than the two conservation significant species were not recorded during this assessment.

2.3 Survey Effort

Sites previously identified were approached from either the top rim or from the plain below and scanned visually for the presence of caves. Caves were assessed for safe entry and sections of the perimeter that showed cave forming strata were then walked at the height of the top of the talus slope where the caves were most common. Twenty four caves and shelters were visited, see figure 2, and assessed for Ghost bat presence. One ecologist entered each cave following agreed Rio Tinto health and safety guidelines covering personal protective equipment (PPE), access limitations and communication strategies. The cave interior was searched for evidence of Ghost bat roosting including the presence of middens and adult Ghost bats. The team's second member remained at the entrance to observe any Ghost bat that might depart the cave behind the observer inside, a common behaviour of this species. Any Ghost bats that departed and/or entered the caves or were seen flying close to the entrance were thereby recorded visually. Any that departed could be tracked visually to record the alternative cave or shelter that they re-entered.

Figure 2 Mesa H with locations of caves and shelters assessed during the survey.

2.4 Survey Limitations

The primary objective of the survey was the characterisation of Ghost bat activity on Mesa H. All aspects of the survey including site access using 4WD, team make-up and experience levels, equipment used, logistics and safety support provided by Rio Tinto were suitable for the task.

No activities were undertaken that could cause harm to the bats present.

Detailed internal dimensions of a cave and its daytime use by bats cannot be reliably determined from the entrance or by the size of the entrance. Entry of candidate caves was therefore necessary to confirm internal characteristics including the bat species present. (Note that distinctive Ghost bat social calls heard from the entrance, or Ghost bats seen departing caves in daylight following the approach of survey parties, serve to confirm the presence of Ghost bats but do not provide information on their numbers or maternity status).

Detailed interior searches of caves were carried out under the guidelines of the Rio Tinto safety procedures. These prohibited entry into any cave that was deemed to have an unstable ceiling as characterised by loose rocks overhead or around the entrance, heavy cracking or the presence of fresh slab like roof material fallen to the floor. These procedures also prohibited entry into any chamber that required sliding on stomach or back or that required climbing or descending 2 m using rock-climbing techniques. The rear areas of some caves could therefore not be searched completely and the possible presence and number of Ghost bats in such caves was therefore not confirmed absolutely.

Due to the porous nature of the Robe Pisolite and the very high number of cracks and sinuous tubes and pipes throughout the strata, the floors of a number of caves had been washed clean of any evidence of Ghost bat occupation by the preceding heavy rain. In addition most caves were inhabited by a species of beetle that is known to act as a scat cleaner thereby removing Ghost bat scats. This combination resulted in fewer caves being identified with scats than expected from the previous surveys.

3.0 Results

A number of observations of Ghost bats middens and scat piles were made during this assessment with Ghost bat presence and foraging activity confirmed generally around the perimeter. In addition two diurnal roost caves with the characteristics of occasional maternity roosts have been located on Mesa H, figure 3.

Assessments of each cave and observations of Ghost bat activity are provided below, table 2, with detailed characteristics of the caves examined including floorplans and dimensions in Attachment A. Most caves were found to be less than 20 m deep and therefore not expected to be impacted by the mining behind the facade. Caves MH16-34 and AC4 were found to be over 30 m deep, depths that are significant when planning the facade to be retained.

Eleven sites were assessed as being suitable for roosting by Ghost bats including two diurnal roost caves and nine nocturnal roost shelters. Note that this total includes shelter AC05 that is in the Buckland Hills BIF strata (Newman land system) adjacent to Mesa H. The two assessed as diurnal roost caves are MH16-34 (50K 415815 7595655), a simple linear chamber 30 m deep with a single high dome at the distal end, and cave AC04 (50K 417586 7594895), a more complex cave with six ceiling domes between 2.5 and 3.9 m high along its length. Both were assessed as being maternity cave candidates although no evidence of significant Ghost bat use of this type was found during the survey. Cave AC04 had a number of scats present.

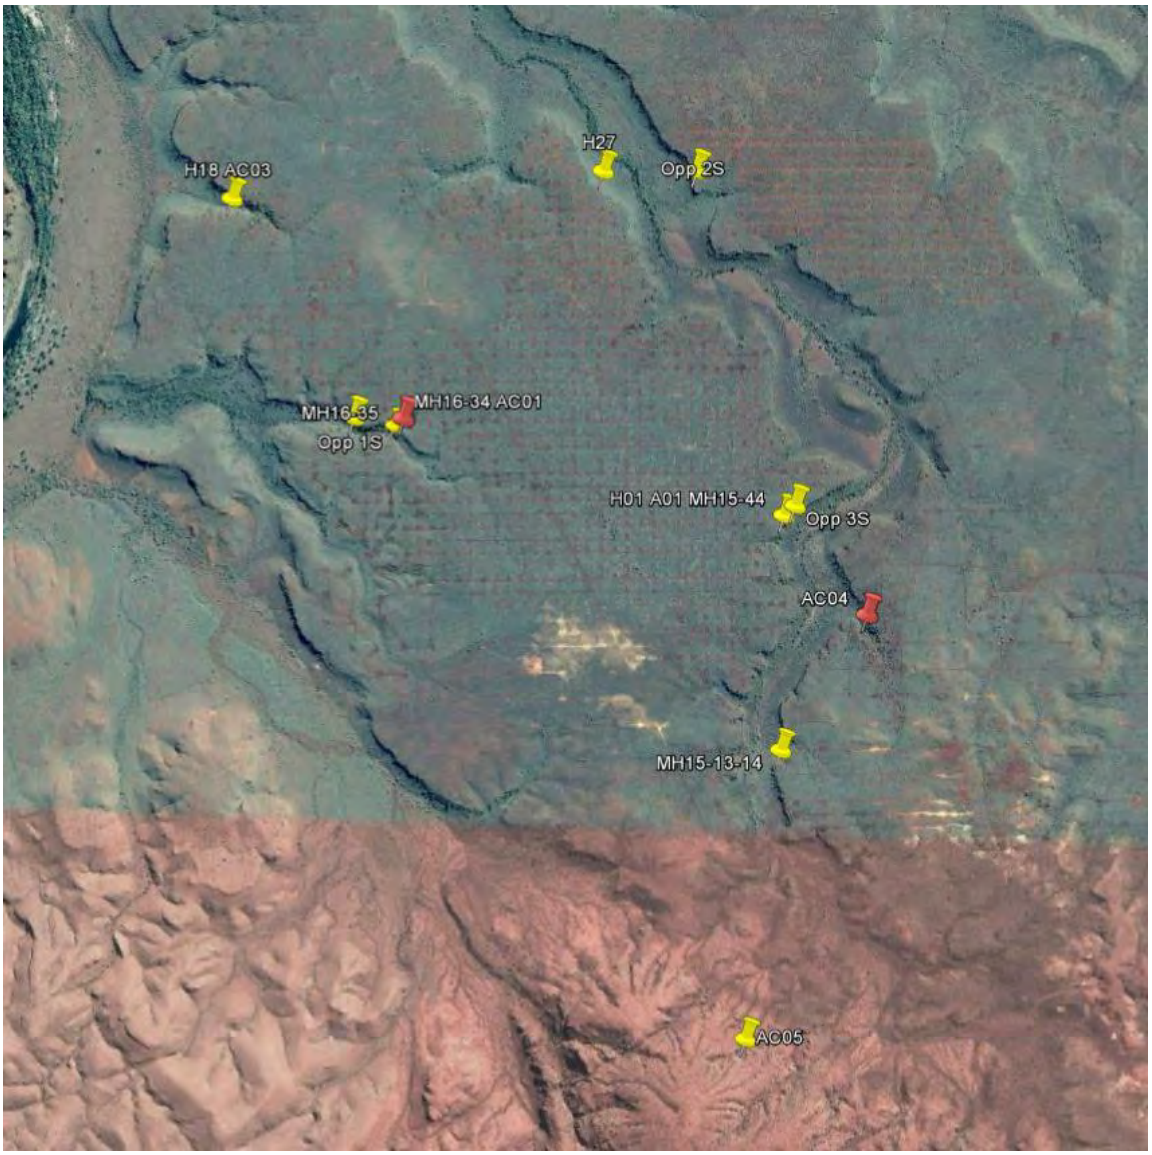

Figure 3. Mesa H caves and shelters where positive Ghost bat assessments were made. The red dots denote the diurnal caves MH16-34 and AC04. Yellow dots denote caves/shelters assessed as nocturnal feeding roosts.

Table 2. Summary of caves visited on Mesa H and assessed for Ghost bat usage.

Cave	Easting	Northing	Observations	Assessed Ghost Bat roost type
H01-A01 MH15- 44	417270	7595276	Shelter with a low internal dome. Several overhangs to the north and south. Ghost bat guano present	Nocturnal feeding roost
H2	414628	7597699	Overhang. No Ghost bat guano present	Overhang only. Not used
H3,H4,H5,H6,H7	414730	7597728	A series of overhangs along cliff face. No Ghost bat guano present	Overhang only. Not used
H16	415266	7596488	Shelter with low roof. No Ghost bat guano present. Additional overhangs nearby and on opposite side of gully with no Ghost bat evidence.	Shelter only. Not used
H18	415164	7596495	Shallow cave with two low domes. No Ghost bat guano present	Nocturnal feeding roost
H19	415126	7596488	Shelter with low roof. No Ghost bat guano present	Shelter only. Not used
H24	416776	7596072	Overhang. No Ghost bat guano present	Overhang only. Not used
H27	416587	7596590	Deep shelter with two low internal domes. Several overhangs to the north and south. No Ghost bat guano present	Nocturnal feeding roost
H34	415315	7595811	Shelter with several overhangs to the east and west. No Ghost bat guano present	Shelter only. Not regularly used
H36	415667	7595692	Unable to approach due to steep cliff. Assessed from opposite side of gully.	Shallow shelter only. Not used
MH15-13 MH15-14	417252	7594383.	Shelter with a high pipe in roof. Ghost bat guano present	Nocturnal feeding roost
MH15-25 H29	416571	7597124	Shelter with overhangs to west and east. No Ghost bat guano present	Shelter only. Not regularly used
MH15-47	417248	7595912	Shelter with low roof. No Ghost bat guano present	Not used
MH15-95	414938	7597150	Shelter with low roof. No Ghost bat guano present. Has additional overhangs nearby and on opposite face with no Ghost bat evidence.	Not regularly used
MH15-96	414925	7597127	Shelter with low roof. No Ghost bat guano present	Not used

Cave	Easting	Northing	Observations	Assessed Ghost Bat roost type
MH15-97	414899	7597103	Shelter with low roof. No Ghost bat guano present	Not used
MH16-34	415815	7595655	Deep cave with a single internal dome. No Ghost bats present	Diurnal roost. Possible maternal roost
MH16-35	415782	7595640	Shelter with overhangs to west and opposite. No Ghost bat guano present	Nocturnal feeding roost
AC04	417586	7594895	Cave with a multiple internal domes. Ghost bat scats present	Diurnal roost. Occasional use as a maternal roost possible but no current evidence of use this year
AC05	417109	7593285	Cave with a single internal dome. Ghost bat scats present	Nocturnal feeding roost
AC06	418068	7592683	Shelter with overhangs at creek level to the east. No Ghost bat guano present	Shelter only. Not regularly used
MH-Opp 1S	415625	7595659	Deep shelter with several overhangs to the east and west. No Ghost bat guano present	Nocturnal feeding roost
MH-Opp 2S	416948	7596585	Deep shelter with several overhangs to the north. No Ghost bat guano present	Nocturnal feeding roost
MH-Opp 3S	417330	7595332	Deep shelter with several overhangs to the south. No Ghost bat guano present	Nocturnal feeding roost

Note: All coordinates are zone 50K.

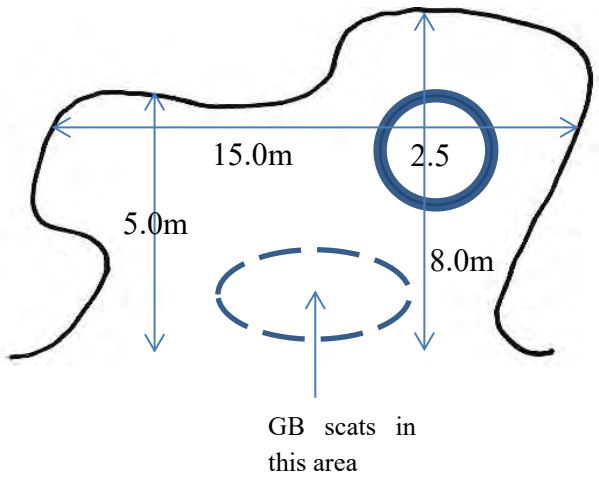
Mesa H Shelter H01-A01 MH15-44:

Assessed Ghost bat usage: Nocturnal shelter with Ghost bat scats.	**Coordinates:** 50K 417270 7595276
Entrance safe or unsafe to approach: Assessed safe	**Basic Geology: Land system at site** Robe Pisolite mesa: Robe
Entrance type and dims – WxH (m): Single wide entrance 9.0 x 1.5 m.	**Entrance Orientation:** South
Cave Grouping: Shelter has additional shallow overhangs along gully wall to the north and south.	**Insulation from surface above:** Middle of local landscape
Cave Type: Shelter is 8 m deep with low roof and one low dome.	**Internal domed chamber:** Yes. 2.5 m high
Rear passages that may have roosts: No.	**Internal temp. and relative humidity:** Ambient
Local foraging opportunities: Excellent, In central Mesa H gully that opens onto the Robe River riparian zone.	**Current distance to disturbance:** Mesa J mine is 2.5 km distant. Resource evaluation drilling nearby on mesa top.

Cave floorplan and entrance photo:



Mesa H Shelter H2:

Assessed Ghost bat usage: Shallow shelter/Overhang only. No Gb guano present. Not used.	**Coordinates:** 50K 414628 7597699
Entrance safe or unsafe to approach: Assessed safe	**Basic Geology: Land system at site** Robe Pisolite mesa: Robe
Entrance type and dims – WxH (m): Wide shallow shelter.	**Entrance Orientation:** North
Cave Grouping: Shelter is a part of a complex of shelters and overhangs overlooking the Robe River.	**Insulation from surface above:** Middle of local landscape
Cave Type: Shallow shelter ~5 m deep.	**Internal domed chamber:** No
Rear passages that may have roosts: No.	**Internal temp. and relative humidity:** Ambient
Local foraging opportunities: Excellent, Mesa H is adjacent to Robe River riparian zone.	**Current distance to disturbance:** Mesa J mine is 6 km distant. Resource evaluation drilling nearby on mesa top.

Executive Summary

Rio Tinto commissioned Bat Call WA (Bat Call) to undertake an assessment of the impact on Ghost bat populations of open cut iron ore mining on the Robe River valley's Deepdale, East Deepdale and Middle Robe deposits, east and west of Pannawonica, in the Pilbara region of Western Australia. This area includes the current and proposed Rio Tinto operations on Mesas A to J/K and the previously mined East Deepdale and Middle Robe areas.

Level one and two fauna surveys have been conducted in the area previously. Early surveys by Biota (Biota 2006, 2009, 2010) and more recently by Biologic in 2014, Astron Environmental Services in 2015/16, Rio Tinto internal ecologists in 2016 and 2017 and Bat Call in 2016 and 2017 have confirmed the ongoing presence of Ghost bats in the Robe River valley.

Data collected indicate that Ghost bats forage generally across the mesas and are roosting in a number of caves along the mesa perimeters. Multiple records including visual observations, cave middens and echolocation recordings, have been detected within and adjacent to the mesas confirming the presence of permanent or semi-permanent roosts supporting a number of maternity colonies.

This survey was designed to provide an assessment of the impact of mining practices since the Middle Robe operations began last century and to confirm whether the current mining practices under Rio Tinto management are effective in retaining the numbers of Ghost bats present in the Robe River valley.

There are twenty mesas of the thirty four (including Pannawonica Hill) on the Robe River system that have recent Ghost bat records. In addition there are five other sites within 10 km of the river where Ghost bat activity has been recently recorded.

There are eighteen mesas which have not been mined. The surveys from 2015 to 2017 show that the perimeters of the mesas that have not been mined including those that have had intense drilling programs on their caps remain as proven Ghost bat habitat and the caves and deep shelters continue to offer diurnal and maternity roost opportunities for the species.

There are two mesas where current large scale open cut resource extraction activities are underway, Mesas A and J. Neither of these currently has a known diurnal presence of Ghost bats although this is speculative due to a lack of survey data on the mesas from recent years. Scats collected in a shelter on Mesa A (Emma Carroll pers. comm.) and under a breakaway on Mesa J (Astron 2016) suggests that the species is using the mesa perimeters for foraging on an

occasional basis. Based on data from other Pilbara iron ore mine sites (e.g. West Angelas and others; author's unpublished data), the lack of diurnal presence is thought to be due to the disturbance from the sound, vibration and airborne dust generated by the blasting, crushing and hauling operations nearby.

There are thirteen mesas where mining of the cap has been completed. Of those, ten have a percentage of the original escarpment retained. The percentage ranges from 16% on Mesa 2402E to 93% on Mesa 2403D. This supplementary assessment of data previously collected (e.g. Astron 2016) demonstrates that the perimeters of the mesas that have been mined and retained in original condition in the Robe River valley remain as viable Ghost bat habitat and the protected caves and deep shelters continue to offer nocturnal and diurnal roosting opportunities for the species. It is also probable that the retained deepest caves and shelters are used as maternity sites although no evidence of this is available at this time.

An estimate of the combined impact of the iron ore mining on the Ghost bat species in the Robe River valley mesas has been made by assessing the lengths of the perimeters that are retained to a width that protects the deepest caves and shelters. The total perimeter length of the mesas between Mesas A and 2405A is approximately 275 km. Of this, approximately 227 km, or 83% has been retained or is in place on mesas not yet mined. Virtually all of these escarpments are in good condition although there have been some localised collapses and cut-outs for access roads. By applying a ratio of 2 deep caves (caves and shelters over 10 m deep) per km of escarpment, assessed from detailed surveys carried out in 2016 and 2017 by Rio Tinto and Bat Call on Mesas B, C, G and H, to the undisturbed remaining perimeter it is possible that there may be as many as 400 deep shelters and caves suitable for Ghost bat usage remaining on the mesas. While the height and definition of the escarpments varies from mesa to mesa, work done to date suggests that the ratio of 2 caves per km may be applied over the length of the Robe valley. The mesas therefore provide, in combination with the Robe River riparian zone, a continuous habitat for Ghost bats.

For the 48 km of perimeter that have been removed or destroyed, up to 100 caves and deep shelters may have been removed. The impact of removing these on the Ghost bats is unclear. In the Robe River valley, the numbers present may be limited by roosting opportunities or may be limited by the availability of prey. Firstly, based on the current understanding that availability of roosts is a limiting factor to Ghost bat presence (Woinarski *et al*. 2014), this removal may have had an impact on the total number of Ghost bats. It is also apparent, based on the evidence from the supplementary sites within 10 km of the river, that the areas surrounding the mesas have

retained all of their Ghost bat population. With a current estimate of 150 Ghost bats (author's unpublished data consistent with the population estimates in TSSC 2016) in the lower and mid Robe River valley, and recognising that the number will vary with the quality of the northern wet seasons, the loss of Ghost bats from mining in the early decades due to the loss of roosting habitat could be less than 20 individuals. However, this impact is offset by the presence of the very productive Robe River riparian and the major tributaries of Jimmawurrada, Bungaroo and Mungarathoona Creeks. In such a productive district, it is possible that the Ghost bat numbers are limited by seasonal and annual variations in prey numbers in the available high quality foraging opportunities in the river riparian and surrounding areas as has been shown to be the case in a number of predator/prey studies. If this is the case, the minimal impact on the Robe River riparian zone by mining would have left the original population levels virtually unchanged.

Currently in accordance with the statement, "The implication from all genetic studies is that losses of maternity sites containing breeding females have the potential to reduce the Area of Occupancy significantly" in Woinarski *et al*. (2014) it must be assumed that the presence of the caves and deep shelters is a limiting factor. Therefore retaining a minimum perimeter width of 20 m so as not to destroy the caves internal characteristics, together with providing specific protection for identified diurnal/maternal roosts and other candidate caves over 20 m deep, is unlikely to result in any significant loss of Ghost bats in the Robe River valley.

1.0 Introduction.

1.1 Project Background

Rio Tinto commissioned Bat Call to undertake an assessment of the impact of mining on the Ghost bat presence and activity along the Robe River valley. There are a series of mesas of Robe tertiary pisolitic limonite deposits (also known as Channel Iron Deposits, CIDs) that are in various stages of mining along approximately 90 km of the valley in the Pilbara region of Western Australia (WA). Pannawonica, in the Robe valley, lies roughly central in this district, figure 1. Mesa naming convention in this study follows the Rio Tinto names from Mesa A to Mesa N. Mesas further to the east mined by predecessors have been labelled Mesas 2400A to 2405A, figure 2.

Rio Tinto and its predecessors have been mining the mesa deposits for iron ore for five decades beginning at the eastern end of the line of mesas and progressively moving west. The mining operations involve the following main components and activities:

- Initial resource definition surveying involving track building and skeletal drilling patterns.
- Detailed resource evaluation drilling at various scales down to 50 m grids.
- Progressive open pit mining of ore and overburden from mesa deposits using open-cut pit mining techniques. These operations have generally removed the inner core of the mesa while leaving lengths of the rocky face of the perimeter intact to a width of at least 20 m at the mesa surface except where cuts are required for access. During the early years of mining, the larger mesas at the eastern end of the valley, Mesas L to 2405A, had their perimeters either removed entirely or the majority removed, and had overburden dumped over the side on top of the original talus. In recent decades facades facing the Robe River have been retained to varying widths to preserve caves and shelters that have been identified as significant to indigenous cultural heritage and/or the presence of conservation significant fauna-flora, e.g. Mesas A and J.
- Placement of overburden in out-of-pit waste dumps either adjacent to the mesas or on top of the original low mesa perimeters, and
- Construction and use of haul and access roads to the mine areas within the mesas.

Recent surveys have identified that two species of cave roosting bat of conservation significance are present in the area, the Ghost bat (*Macroderma gigas*) and the Pilbara leaf-nosed bat (*Rhinonicteris aurantia*) (PLNb). PLNb have been assessed as using the mesas for foraging while originating from a yet to be discovered roost further to the south or east (Bat Call 2016b, 2016d, 2017a). Multiple Ghost bat records including visual observations, echolocation recordings and cave middens have been detected within and adjacent to the study area (Biota 2006, 2009, 2010; Astron 2016, 2017; Bat Call 2015, 2016a, 2017a, 2017b, 2017c, 2017d).

The purpose of this survey was to assess the impact of open cut iron ore mining on the presence and activity of Ghost bats in the Robe valley, including bat colonies and/or nocturnal foraging. The study area is shown in figure 2. It includes all of the mesas between Mesa A and Mesa 2405A plus the areas immediately adjacent to the Robe River between these sites. In total, Ghost bats observations covering 33 mesas adjacent to the Robe River plus results from five sites within 10 km of the River are included in this assessment, figure 2.

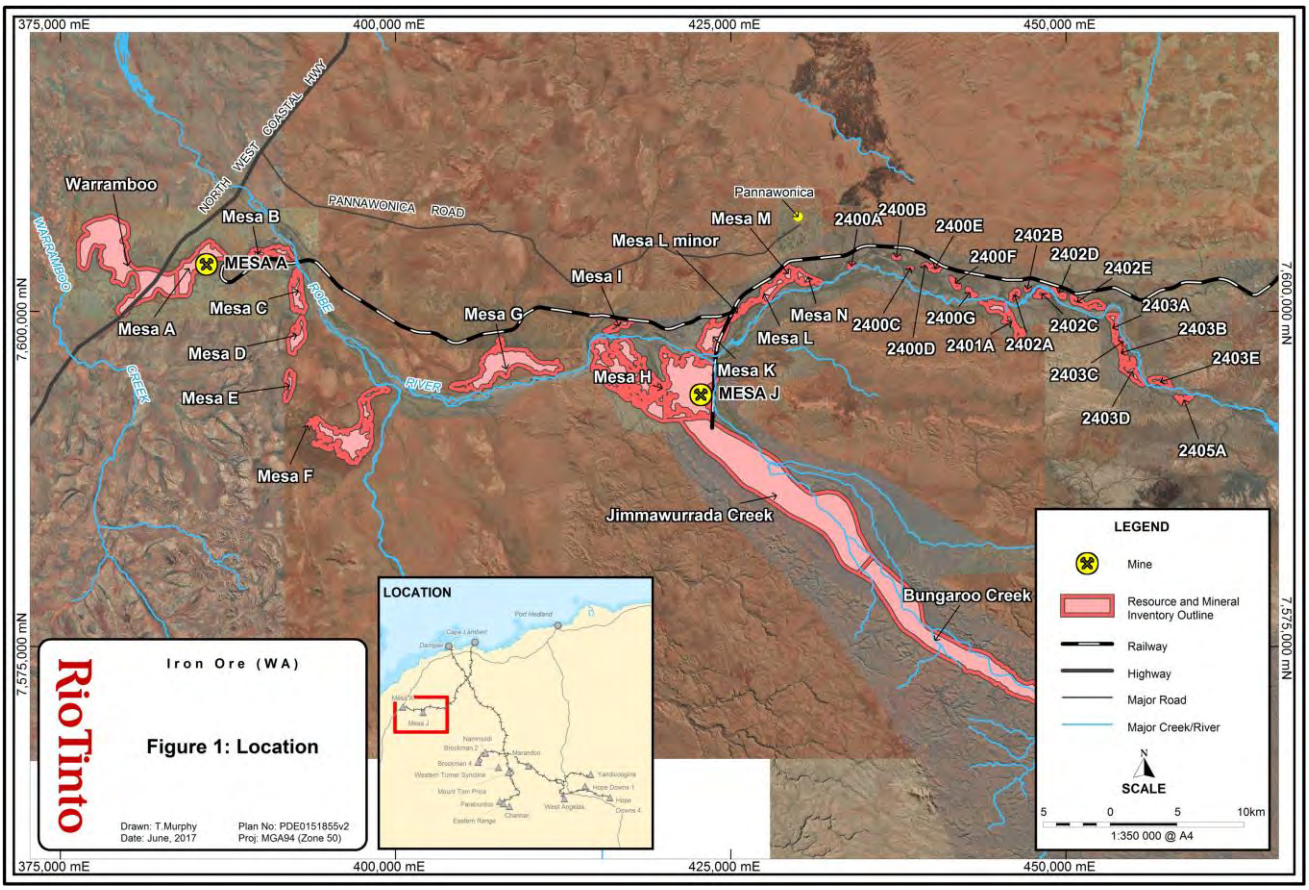

Figure 1. General Arrangement of Robe River valley mining area.

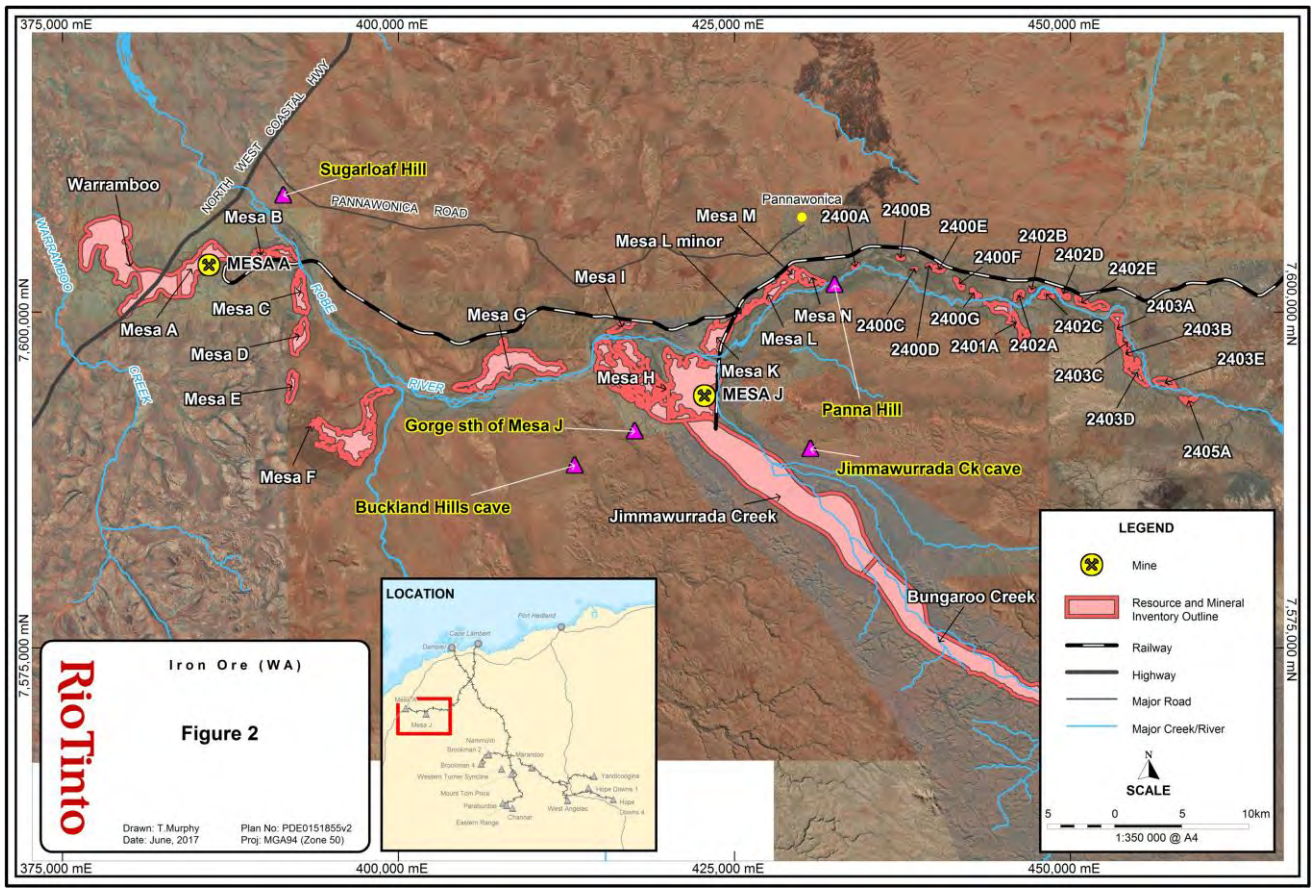

Figure 2. Mesas and supplementary sites (triangles) included in the assessment.

1.2 Existing Environment at Robe River valley Mesas and Surrounds

Topography

The Robe valley mesas cover an extensive area beginning at Mesa A in the west and running approximately 90 km eastward roughly paralleling the current orientation of the Robe River. They stand approximately 50 m higher than the flat plains that are crossed by the Robe River. Most of the mesas lie immediately adjacent to the river riparian zone with Mesas A, E and the majority of F being the most distant at 5 km. They vary in size from small unnamed pinnacles to very large mesas. The small unnamed pinnacles are not included further in this assessment. Pannawonica Hill is the smallest mesa with a cap of approximately 800 m^2 and perimeter of 0.11 km. Mesa F, with a cap of over 17 km^2 and a perimeter length over 39 km, is the largest. To the north and south the area is dominated by ironstone and basaltic uplands of the Hamersley Range, e.g. plate 1

Geology

In the Robe valley, the Robe Pisolite forms flat-topped mesa landforms (known as Channel Iron Deposits, CIDs) that are the remnants of the ancestral drainage channels of the Robe River formed during the Tertiary period. Erosion of the surrounding landscape has exposed the Pisolite formations creating an 'inverted topography' and subsequent erosion has created isolated mesa landforms. The larger mesas are incised with deep gullies around their perimeter. Pre mining, all mesas originally had overhangs, shelters and caves along extensive lengths of their perimeters and within major and minor gullies, e.g. plate 2.

Plate 1. Example of the three major land systems in the study area. This view is of the northern end of Yeera Bluff (Newman l.s., upper left), the Robe River riparian centre (River l.s., centre) and the north west rim of Mesa H (Robe l.s., right) showing the talus slope topped by the mesa cap.

Overhangs, shelters and caves are defined herein as:

- Overhangs are shallow hollows in a rock wall with a distinct roof structure. Their shape is such that they are fully lit by sunlight to their back wall. Their depth is typically 2 to 5 m.
- Shelters are deeper hollows or shallow caves in the rock wall that have ceiling structures from 1.0 to 5 m and higher and offer significant protection from predators and the weather. These are typically 5 to 15 m deep and have dark twilight conditions at their rear

extremities. Some have domed areas in their ceilings offering roosting and feeding opportunities to Ghost bats.

- Caves are defined as deep structures of various heights, widths and depths that are very dark in their deeper recesses. They often have one or more rear chambers separated from the entrance by constriction points. Those chambers that have ceiling heights of over 2.5m and an entrance constriction larger than 0.6 m square. They offer excellent roosting opportunities for Ghost bats.

- All three can have cracks or voids that continue back from their rear walls that may lead to additional internal cavities within the rock strata behind or above. Such cavities that are almost fully enclosed and can retain high levels of humidity are roosting opportunities for PLNb and Ghost bats if the entrance cracks are large enough.

Overhang and shelter density is high along the majority of the mesa perimeters with the rock strata forming numerous shallow shelters in mid and higher levels of the walls. There are a number of deeper caves formed in the Pisolite at mid and higher levels of the mesa walls but these rarely extend beyond 15 m in depth. Most shelters and caves were found on the mesa walls at or just above the top of the talus slope junction with the cliff wall.

Plate 2. Example of the presence of overhangs and shelters along the perimeters and within the incised gullies of mesas. This view is of a cave, shelter and overhang complex on Mesa H.

Land Systems (after Van Vreeswyk *et al.* 2004)

The mesas and their gullies and the surrounding talus slopes are elements of the Robe land system. They are low limonite mesas that support spinifex grasslands and thin Eucalypt (Snappy Gum) woodlands. The lower slopes and adjacent gravelly plains support spinifex grasslands and very scattered to moderately close Acacia and Eucalypt shrublands and woodlands, plate 2.

The adjacent Robe River flows westward from the distant Hamersley Range uplands. It is a very complex and productive linear river channel and flood plain with a Eucalyptus and Melaleuca woodland over tall Acacia and Petalostylis shrubland. It is an element of the Pilbara's River land system.

Yeera Bluff and the Buckland Hills to the south and west of Mesas H and J are rugged jaspilite ridges and hills of the Newman land system supporting Grevillia and Eucalypt shrublands and woodlands over hummock grasses.

The majority of the upland areas both north and south of the Robe to the east of Pannawonica are rounded and gently inclined basalt hills and plateau of the Rocklea land system. These support hummock grasslands with scattered Acacia and Senna shrublands.

The majority of the area to the north and south of the lower Robe mesas are stony plains of various land systems and low sedimentary hills of the Nanutarra land system. These support hummock grasslands with scattered Acacia and Senna shrublands.

Climate

The climate in the district is semi-desert tropical. Mean monthly minimum and maximum temperatures in the lower Robe valley range from 12 to 41 degrees Celsius (^{o}C). Annual rainfall is extremely variable and averages 400 mm, usually in cyclonic or thunderstorm events during the northern wet season. The northern dry season lasts from May to November and winter rainfall is uncommon.

Water Sources

Drainage systems in the district are associated with ephemeral gullies on the perimeters of the mesas that run into the Robe River drainage system. The Robe River riparian zone has a number of permanent and ephemeral pools along its length such as Gnieraoora Pool at the base of Yeera Bluff. Major tributary creeks include Jimmawurrada and Bungaroo Creeks to the south and east of Mesa J and Mungarathoona Creek to the south of Mesa F.

1.3 Bats of Conservation Significance

The Pilbara region contains 17 species of microbat, and of these, 13 have the potential to be found in the Robe valley (Van Dyke and Strahan 2008, McKenzie and Bullen 2009). A number of fauna surveys including targeted bat surveys have been previously conducted in the area, most recently by Astron in 2015 and 2016 and Bat Call in conjunction with internal Rio Tinto ecologists in 2016 and 2017, see table 1. Two Pilbara bat species of conservation significance have been recorded in the area, the Ghost bat (*Macroderma gigas*) and the PLNb (*Rhinonicteris aurantia*).

The Ghost bat is a large (130 g) carnivorous predator and the PLNb is a small (10 g) insectivore. Both are endemic to northern Australia and are obligate cave roosting species requiring specific cave environments for permanent roosting especially for supporting a successful maternity colony. The Ghost bat's foraging strategy and high trophic niche, as a top night-time carnivorous predator, is unique in Australian microbats. Both Ghost bat and PLNb populations are isolated from the main tropical populations that are extant across the mesic tropics by the uninhabitable arid zone of the Great Sandy Desert to the north and east. Both species are "conservation significant" as they are semi-desert adapted populations that have specific roosting requirements. The Ghost bat has suffered significant range loss in historical times. The reasons for the range contraction are open to speculation but it is known that the species is subject to disturbance (Richards *et al*. 2008, Woinarski *et al.* 2014). The Ghost bat has been detected within the study area and one or more caves are suspected as being maternity roost candidates.

The PLNb has been detected foraging across the mesas in the Robe valley. The PLNb is not discussed further in this report as a separate study is underway to determine the location of a PLNb roost thought to occur in the lower Robe valley.

Ghost bat (*Macroderma gigas*)

The Ghost bat has a conservation status of Vulnerable under the Commonwealth *Environment Protection and Biodiversity Act 1999* (EPBC Act), Vulnerable under the Western Australian *Wildlife Conservation Act* (1950) and Vulnerable C1 (a vulnerable species numbering less than 10,000 and in decline) under the IUCN Redlist (IUCN 2017). These listings are on the basis of the impact of loss of suitable roost opportunities. The Pilbara Ghost bat population is estimated at 1500-2000 based on recently published estimates (approximately 600, N.L. McKenzie pers. comm. in IUCN 2017; approximately 1200, Armstrong and Anstee 2000; "more common than previously supposed", McKenzie and Bullen 2009) and author's unpublished database

summarising data from a range of surveys carried out in recent years by Pilbara mining companies, including Rio Tinto and other organisations, supplemented by author's own data (summarised in Threatened Species Scientific Committee (TSSC) (2016)). These recent data (estimates less than 15 years old) cover the entire Pilbara bioregion. Current population estimates in the Hamersley and Chichester subregions are approximately 350 and 1500 respectively (author's unpublished database summarised in TSSC (2016)).

There is no information available regarding the population size upper limits in an undisturbed environment. For a mammal such as a Ghost bat with a restricted roosting habitat niche, there are two possibilities limiting species density. The numbers may be limited by the availability and size of roost caves offering suitable habitat or the number may be limited by the availability of prey, especially during the post breeding season when lactating mothers and juveniles are in an energetic bottleneck. If the former is the dominant limit, then the number of bats in a district would be proportional to the availability of the roosts. If the latter is the primary determinant, as is the case in a number of classical predator-prey studies (e.g. Peterson and Page, 1988; discussion on predator-victim ratios in Rosenzweig, 1995; but see Peterson *et al*., 1998) then the population of Ghost bats would rise, fall and be limited by the availability of prey of the favoured size on a seasonal or annual basis. We therefore cannot directly attribute a loss of population to a measured loss of roost sites. Current knowledge based on populations in the Northern Territory and Queensland summarised in Woinarski *et al.* (2014) and TSSC (2016) supports the statement, "The implication from all genetic studies is that losses of maternity sites containing breeding females have the potential to reduce the Area of Occupancy significantly". Future research may resolve this for the Pilbara Ghost bat. Currently we must assume that the loss of roosting opportunities will have a negative and permanent impact on numbers.

Ghost bats hunt their prey in two primary ways. They hunt birds and bats at cave entrances and elsewhere "air-to-air" by swooping from above or from a perch. They also hunt ground level prey in their target food size range by dropping onto the prey from a perch, either tree branch or rock outcrop. Their diet includes small mammals (including other bats), birds, reptiles, frogs and large insects. The proportion of food items in the diet varies with availability and reported foraging areas vary from a few to 10 km from the roost cave. In May 2016, a Ghost bat carcass was found entangled in a barbed wire fence (DPaW 2016) over 12 km from the nearest cave forming rocky strata suitable for roosting.

Ghost bat breeding populations are known from a small number of maternity roosts in the Pilbara and reproduce during the northern wet season. The largest of these colonies are in abandoned

mines in the Chichester subregion and number up to several hundred (Armstrong and Anstee 2000, author's unpublished observations)). Hamersley Range populations are typically between five and twenty five individuals in local groups (author's unpublished data). There is one known large, permanent maternity roost numbering over 70 bats in the lower Robe River valley on Mesa F (see Results below). For these groups to persist the bats need an "apartment block" of roosting opportunities, at least one deep cave with characteristics of a maternity roost, multiple caves/shelters and overhangs in close proximity offering nocturnal feeding and refuge opportunities, a local productive set of gullies and gorges, a productive foraging area within 5-10 km radius, usually including a good quality riparian line or ephemeral fresh water lake bed and appropriate protection from human interference (author's unpublished data). These groups are known to reproduce in good years using suitable natural roost caves. Examples are a group numbering 5 to 10 including reproducing females at West Angelas caves in 1980 (Dr Nic Dunlop pers. comm.), a small group including reproducing females at caves at Nammuldi/Silvergrass area (Hamersley Iron 1999), observation of a heavily pregnant female at a cave near Mt Robinson by the author in 2013 and a group numbering 14 including four juveniles at another cave near Mt Robinson in 2015 (Mr. Morgan O'Connell pers. comm.). The Ghost bat is also known to spread great distances on an annual cycle from these locations depending upon seasonal weather conditions and availability of suitable day roosts. Sporadic records of Pilbara Ghost bats have been identified in the Gascoyne (author's unpublished data) and the Little Sandy Desert (sightings by W.H. Butler at Durba Springs in 1971 and others since). Genetic work by Worthington Wilmer and Armstrong (summarised in Woinarski *et al.* 2014) suggests that the females remain or return to their birthplace and that the males can move between districts.

Ghost bats use three types of roost regularly, these being nocturnal roosts or feeding sites, diurnal or day roosts that may be permanent or semi-permanent sites and maternity roosts that are diurnal roosts with the range of characteristics allowing regular or permanent occupancy.

Nocturnal roosts or feeding sites are only used at night, either habitually or for transitory visits. They are typically shallow caves and shelters that are well lit during the day. They are often high in the strata and may be well or poorly insulated from the elements. They often contain guano scatters and/or midden(s) of various sizes containing guano and food scraps but these remains are sometimes removed by rainfall, disturbed by various larger mammals and marsupials such as macropods and goats and/or removed by varieties of "dung beetle" that are known to forage on the scats (author's unpublished observations).

Diurnal roosts are caves and mine adits that are deeper and more complex. They typically have one or more large chambers at or beyond the twilight area with additional fissures or chambers at the rear in the fully dark regions. They have a minimum roof height in the chambers of 2 to 3 m providing protection from attack by terrestrial predators. They are often at mid-levels or lower in the strata and are well insulated overhead providing a stable temperature environment. They typically contain multiple scat piles and middens of guano and food remains that include feathers and skeletal material.

Maternity roosts are diurnal roosts that provide additional features listed above that are able to support a reproducing population. These features usually include an interior chamber that is rising toward the rear thereby trapping warmer and more humid air at the top allowing suitably benign conditions to form during the period when reproductive females and pups are present.

Being carnivorous predators, during a nights foraging they may also hang for short periods in any deep overhang, shelter or cave with a high enough ceiling or tree branch overhead a cleared patch of ground for feeding or resting on an opportunistic basis. These sites are not routinely visited and show no evidence of Ghost bat presence.

1.4 Summary of Previous Bat Surveys

Prior to 2017 there have been a number of fauna surveys commissioned by Rio Tinto and predecessors in the lower Robe valley that have included bat species listings. These indicated the presence of both significant species foraging across the area. More recent surveys carried out in 2015 and 2016, summarised in table 1 below and including caves on Mesas F and G whose assessments are included in attachment B herein, indicated that the Ghost bats are roosting locally and include maternity colonies on Mesas B and F, plus other diurnal roost candidates at various other mesas.

Table 1. Summary of Fauna Surveys that Include Ghost Bat records in the Robe valley.

Date	Reference	Ghost bat activity detected.
2006	Biota (2006)	• Ghost bat sighted at cave on Mesa A prior to commencement of mining.
2009	Biota (2009)	• Ghost bats harp trapped at Mesa G
2010	Biota (2010)	• Group of Ghost bats sighted at Mesa F cave MF-01
2014	Biologic (2014)	• Visual sightings of Ghost bats at several caves within 10 km of the lower Robe River in the Yarraloola district.
2015	Astron (2015)	• Mid Robe survey where Ghost bats were detected at several locations between Mesas L and 2405A. Diurnal roost candidates identified at Mesas 2400E, 2402B and nearby 2403E
2015	Astron (2016)	• Ghost bat echolocation calls detected at Mesa H and surrounding area. A number of shelters/caves with scats recorded. Diurnal roost candidates identified on Mesas G and H and in hills south of Mesa H.
2015, 16 and 17	RTIO internal heritage staff	• Surveys of caves and shelters on various mesas. Several candidate diurnal roosts identified on Mesas B, C, G and H.
2016	Bat Call (2016a, b, d)	• Ghost bat visual sightings, cave assessments and echolocation calls detected at mesas between B and F. Maternity roost cave identified at Mesa B. Candidate diurnal roost identified on Mesa C.
2016	Astron (2017)	• Ghost bat echolocation calls detected at various mesas in East Deepdale and Middle Robe and a number of shelters/caves with scats recorded.
2017	RTIO internal ecologists	• Ghost bat seen at Mesa H at cave H27. Presence detected at Mesa F cave MF-01. Maternity roost candidate identified near Jimmawurrada Creek (Bat Call 2017b)

Date	Reference	Ghost bat activity detected.
2017	Bat Call (2017a, b, c, d)	• Visual sightings including bats, middens and scats and echolocation call detections at Mesas A, B, C, D, F, G, H. Maternity roost identified at Mesa F. Diurnal roosts identified at Mesas G and H.

2.0 Survey and Assessment Methods

2.1 Categorisation of status of mesas.

Mesas were measured for area and perimeter using aerial photography available on GOOGLE EARTH PRO. The complete perimeter of the upper cap of each mesa was outlined with a polygon and the area and perimeter length recorded. The length of the retained undamaged perimeter was then measured, e.g. figure 3.

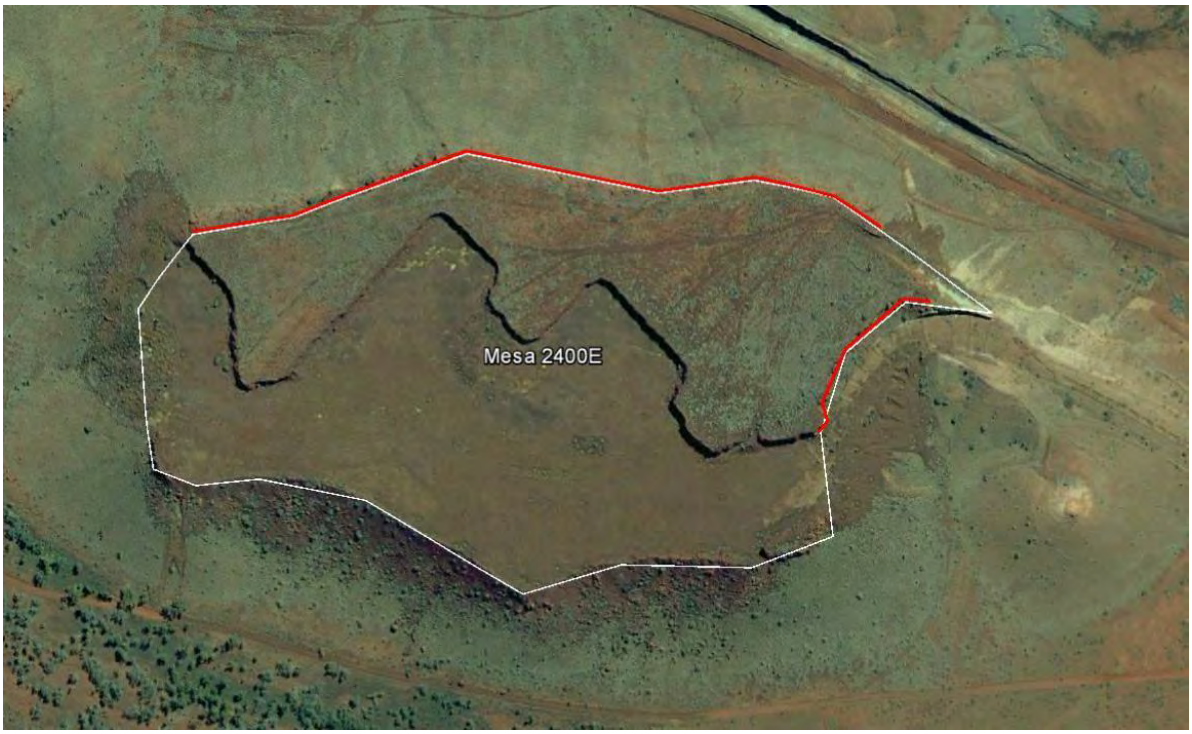

Figure 3. An example of the assessment of the size, perimeter length and state of preservation of the original mesa escarpment; Mesa 2400E in the Mid Robe valley. The white polygon surrounds the original mesa top cap. The red lines indicate the extent of the retained original perimeter containing caves, shelters and overhangs. The extent of the perimeter removed by mining is indicated by the visible overburden dumped along its length (dark brown scree outside polygon). The retained perimeter with original talus or abandoned haul track below is the light colour areas immediately outside the polygon.

Each mesa was then categorised for the extent of mining operations carried out. These operations covered:

- Mesa in original state.
- Initial resource evaluation including track building and skeletal drilling.
- Resource evaluation drilling on close grid patterns down to 50 m spacing.

- Overburden removal and resource mining operations including the building of access haul tracks through the perimeter.

- Post mining rehabilitation.

2.2 Density of caves and deep shelters on mesa rims

The locations of the deep caves and shelters around the complete perimeters were available from surveys completed on Mesas B, C, G and H (Rio Tinto data base). The number of sites was counted and the lengths of the facades including these were measured. Sites that included complexes or groups of caves/shelters/deep overhangs in close proximity, typically separated by less than 25 m, were counted as a single site.

2.3 Observation of current Ghost bat presence and usage.

Results from surveys included in this study were collected over a number of years using a variety of techniques. The majority of observations are recent dating from 2014 to 2017 and result from visual assessments of caves and shelters made on foot. These were supplemented by harp trap, mist net and echolocation detector records from the years since 2006.

The most recent fieldwork focussed on the assessment of habitat of Ghost bats at all mesas between A and 2403E by Astron, Bat Call and RTIO internal ecologists. In 2015 and 2016, Astron completed assessments of the mesas from the East Deepdale and Middle Robe areas. In July 2016 and April 2017 Bat Call and RTIO completed detailed assessments of all identified caves and shelters on Mesas B, C, F, G and H. Characterisation of significant caves on Mesas F and G are included in attachment A herein. In April 2017 a visual assessment was made of the state of preservation the mesas east of Mesa J to allow correlation with the Ghost bat presence records from the earlier surveys and to ground truth the aerial photography assessments.

2.4 Survey Team

The July 2016 and April 2017 survey teams consisted of two experienced ecologists on each survey. In 2016 and 2017, Ms Emma Carroll (Rio Tinto) and Ms Tenielle Brown (Rio Tinto) were team leaders respectively. Mr Robert Bullen (Bat Call) acted as principal ecologist for both surveys. In April 2017, Ms Melinda Brand (Rio Tinto) accompanied the assessments of Mesa H and those further to the east.

2.5 Inclusion of sites nearby Robe River in study

Ghost bat presence records from five sites within 10 km of the river but not on the named CID mesas were included in the study for context. These sites are all locations were Ghost bats have been sighted during daytime survey activities and are therefore possible diurnal roost candidates.

2.6 Survey Limitations

Detailed interior searches of caves were carried out under the guidelines of the Rio Tinto safety procedures. Prior to July 2016 entry by fauna surveyors into caves and shelters was prohibited. Post July 2016, entry into any cave that was deemed to have an unstable ceiling as characterised by loose rocks overhead or around the entrance, heavy cracking or the presence of fresh slab like roof material fallen to the floor continued to be prohibited. These procedures also prohibited entry into any chamber that required sliding on stomach or back or that required climbing or descending 2 m using rock-climbing techniques. The rear areas of some caves could therefore not be searched completely and the possible presence and number of Ghost bats in such caves was therefore not confirmed absolutely.

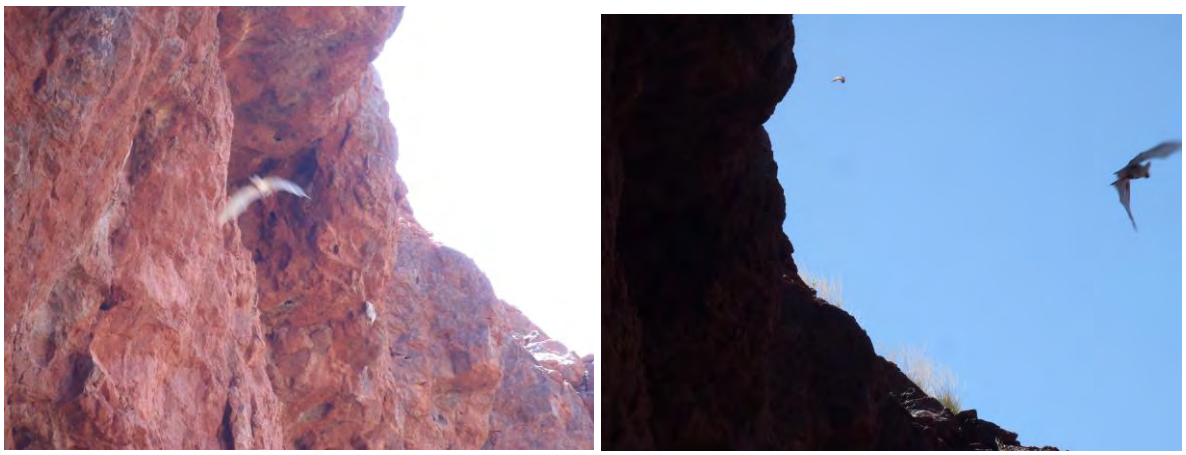
Complete perimeter searches for caves and deep shelters greater than 10 m depth have only been completed on mesas A, B, C, G and H. Incomplete searches that identified only the most visible caves and shelters have been completed on the rest of the mesas.

3.0 Results

3.1 Cave Characterisations at Mesas F and G

Mesa F

During this study an ongoing Ghost bat presence at cave MF-01 on Mesa F was confirmed. Ghost bats had been reported at this site by a number of earlier visits (e.g. Biota 2010 and Rio Tinto internal ecologists 2017). On entering the first chamber of the cave, audible social calls were heard originating at the rear of the cave. Almost immediately over 70 Ghost bats emerged at high speed along the rear tunnel, flew past the author and observer, and departed the main entrance, plates 3 and 4. A number roosted under overhangs beside the cave, plates 5 and 6, and then re-entered once the observers had departed. Additionally, as the main group was exiting the cave the observer at the entrance saw a number flying above the entrance that appeared to be originating from a secondary entrance higher up the cliff directly above. Following the departure of the main group, the rear tunnel was found to have a very large and high second chamber where the bats had been roosting, attachment A. During the assessment, the floor of the cave was found to have Ghost bats scats along its full length. The characteristics of this cave supported by the multiple observations of roosting bats, the extensive scat carpet and the presence of a large number of "dung beetles" are consistent with its use as a permanent diurnal/maternity cave.



Plates 3 and 4. Ghost bats departing cave MF-01.

Plates 5 and 6. Ghost bats roosting temporarily under overhangs outside the entrance of cave MF-01.

Due to the speed of their departure from the cave, no observations regarding their gender or apparent age could be made.

Mesa G

During this study a group of caves on the southern face of Mesa G was assessed. In conjunction with the earlier data, a Ghost bat presence at Mesa G was confirmed, figure 4.

Figure 4. Mesa G caves and shelters where Ghost bat observations were made. The red dot denotes the diurnal cave G02 at the eastern end of the mesa. The yellow dot denotes a nocturnal feeding shelter at G03. The white dot denotes one location where Ghost bats have been reported (Biota 2009) but no other indication of a roost cave or activity was observed during this survey.

Two sites in one deeply incised gully were assessed as being in possible current use by Ghost bats including one diurnal roost cave and one nocturnal roost shelter. Assessments of each cave and observations of Ghost bat activity are provided below, attachment A, with detailed characteristics of the caves including floorplans and dimensions. Cave G02 was found to be over 20 m deep and to have the characteristics of a diurnal roost although no evidence of current habitation was found.

The eastern gully on the south face containing caves G02 and G03 was assessed as the most significant areas on Mesa G. Cave G02 (50K 411740 7595774) being a part of a complex of caves, shelters and overhangs, and the gully containing it, has all of the characteristics required by Ghost bats for this to be considered a possible maternity roost. These characteristics include an internal shape adequately deep and dark along with a high domed chamber at the rear shaped to trap warm humid air, multiple nocturnal roost opportunities, multiple daytime refuge opportunities, multiple early evening observation sites and a major productive riparian zone within 5 km. No evidence of Ghost bat presence was found within this complex during this survey although a small midden containing scats and *Taphozous* sp. wing bones, the age which could not be determined, was found in cave G03 (50K 411727 7595625) nearby.

3.2 Unmined mesas, density of caves and shelters.

There are nine mesas with no mining activity evident, attachment B. These are Mesas D, E, I, L2, 2400A, 2400B, 2400C, 2400D and 2402B. A view representative of the rim of an unmined mesa is presented in plate 7.

The density of caves and shelters greater than 10 m deep on unmined mesas was assessed from the data available from Mesas B, C, G and H that have 100% of their original perimeters intact, are presented in table 2. A density of up to 2 caves/shelters per km of unmined facade was found to be typical of the mesas west of Pannawonica. The visual review of the mesas east of Pannawonica undertaken suggests that this figure is also applicable in the East Deepdale and Middle Robe areas. Ghost bats have been found to be present on Mesas B, C, G and H for both roosting and foraging. The current Ghost bats presence records for Mesas B, C and H are presented in detail in Bat Call (2016a, 2017c, 2017d). These data are supplemented with Mesa G data herein. Diurnal roosts classified as maternal have been identified at caves on Mesas B (MBC-05) and F (MF-01). Five diurnal roosts candidates have been identified on Mesas C, G, H and 2402B. A summary of the results and the available data from the other unmined mesas is

given in attachment B. A summary of the available data from the unmined supplementary sites within 10 km of the river is in attachment C.

Plate 7. A view of the unmined central gully and eastern face of Mesa H showing the upper rim, the cliff face with caves and shelters present and the lower talus slope. This view is representative of the condition of the unmined mesas along the valley.

Table 2. Density of caves and deep shelters on unmined Robe River mesas.

Mesa	Number of sites with caves and/or deep shelters	Perimeter of mesa facade containing the sites	Density of caves and shelters deeper than 10m
B	16	9.6	~1.7 / km
C	21	10.5	~2 / km
G	12	6.0	~2 / km
H	46	25	~1.9 / km

3.3 Mesas with initial resource evaluation activities or resource evaluation drilling.

An assessment of the impact of resource evaluation drilling on the caves and shelters potentially in use by Ghost bats has shown that skeletal resource assessment drilling programs do not impact the mesa facades and therefore do not impact the caves and shelters, figure 5. A minor length of facade is lost when access tracks are cut through the face but these lengths are typically very short, i.e. 25 to 50 m. An example is given in figure 6. There are three mesas that have an initial, drilling (or equivalent) program with only skeletal tracks and pads present, Mesas F, L1 and 2405A.

Figure 5. View of the top of an unnamed mesa west of the Buckland Hills showing a recent skeletal drilling pattern retaining an unaffected perimeter at least 50 m wide.

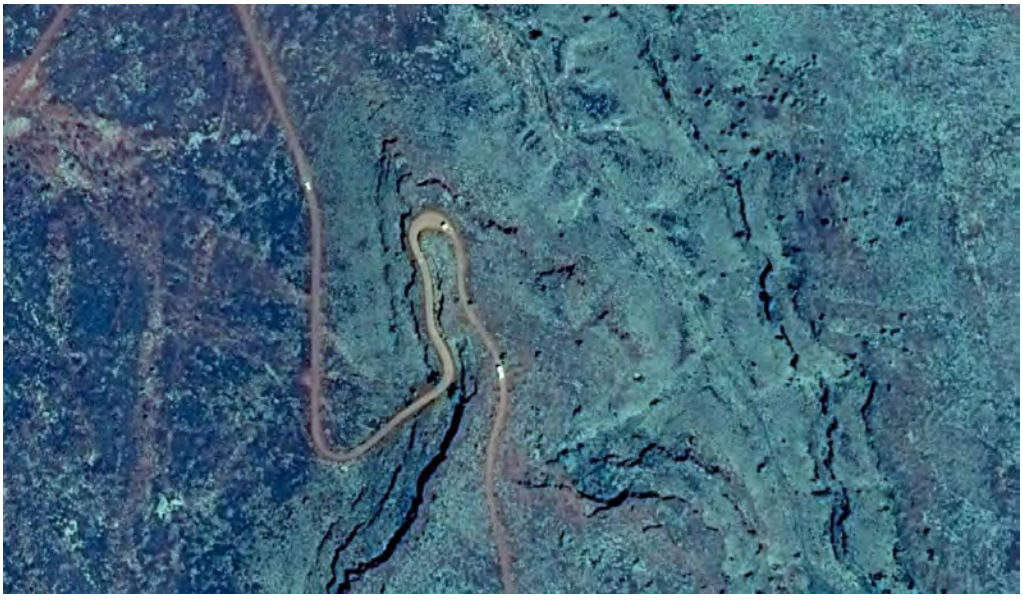


Figure 6. View of the top of the northern end of Mesa C access track to the top of the mesa that has removed approximately 25 m of the lower cliff and 20 m of the upper cliff.

In early decades facade retention was not prioritised and the pattern of resource evaluation disturbance continued to within 10m of the rim edge, figure 7. This is evident on Mesa 2403E. This suggests that some limited loss of habitat due to localised rim collapse was possible on these mesas prior to mining operations beginning. More detailed resource evaluation drilling patterns in recent years have maintained an approximately 50 m standoff from the rim of the mesa cap, figure 8. There are four mesas with this type of pattern, Mesas B, C, G and H. This has ensured that all but the very deepest caves have remained unaffected by drilling programs on mesas between B and H.

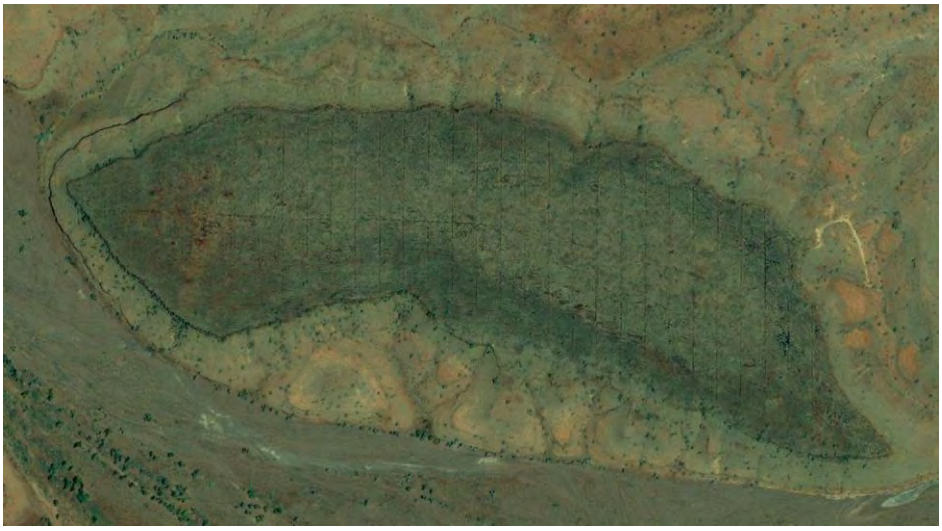

Figure 7. View of the top of Mesa 2403E showing a resource evaluation work pattern dating from several decades ago that extends to the mesa perimeter (facade) potentially impacting sites on the cliff below.

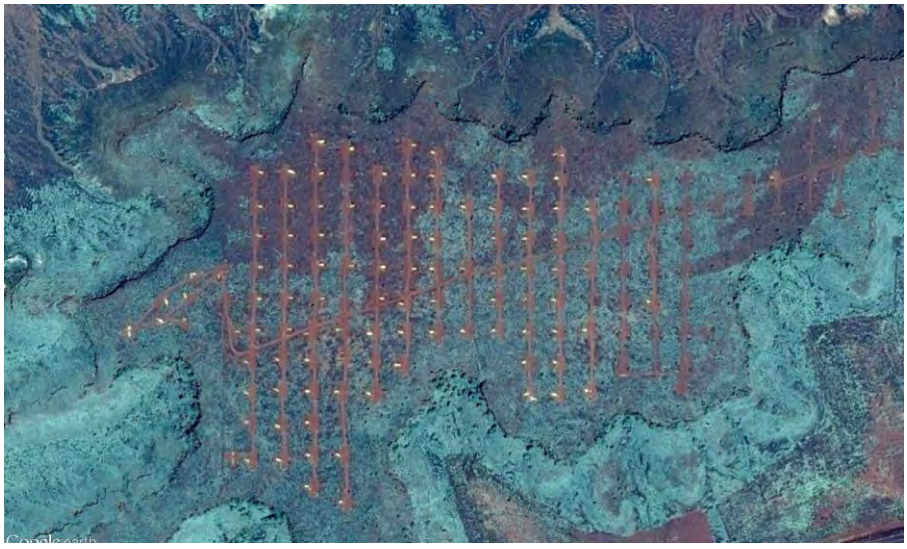

Figure 8. View of the top of the western end of Mesa B showing a recent drilling pattern retaining an unaffected facade at least 50 m wide.

3.4 Mesas with current overburden and/or open-cut resource extraction operations.

There are two mesas with current mining operations. These are A and J, attachment B. Mining at Mesa A has been in progress since 2010 and the operations now cover the majority of the original mesa. Mesa A does not have an escarpment on its southwestern side. Almost 100% of the original escarpment of the northern half of the mesa has been retained to a width of 50 to over 100 m, figure 9. This retained length includes an area in the north-eastern corner that surrounds a deeply incised gully to a width of 150 m. Cave MAI06-SH17 was assessed in September 2016 as a nocturnal roost and a single scat was found by an internal Rio Tinto ecologist (Emma Carroll pers. comm.). Cave A5 was assessed in April 2017 to be a nocturnal roost candidate with no current evidence of Ghost bat presence. No other current evidence indicating Ghost bat presence has been recorded on the mesa in recent years however minimal surveying has been completed in this period.

Figure 9. View of the top of Mesa A showing the extent of the mining operations and the retained perimeter. Caves MA-05 and MA-06 are shown in the retained north-eastern gully.

Mining at Mesa J began in 1994 and the operations also cover the majority of the original mesa. The majority, 88%, of the original perimeter that was an escarpment, i.e. the northern half of the mesa, (see attachment B) has been retained to a width of 50 to over 100 m, figure 10. Similar to Mesa A, minimal surveying has been completed in recent years at this mesa, the only current Ghost bat record at Mesa J is a single site with scats on the north-western bluff opposite the Robe River. This site is behind a retained facade of over 500 m width locally.

Figure 10. View of the top of Mesa J showing the mining operations and the retained perimeter (red line). Ghost bat scats have been recorded at the bluff on the retained north-western corner (circled).

While limited, the available evidence suggests that while there are caves and shelters available on the retained perimeter of a mesa with active mining, Ghost bats are generally not roosting in numbers where blasting, crushing and hauling operations are underway behind a facade of 20 to 50 m. This is likely to be the result of disturbance by sound, vibration and/or airborne dust. The evidence also suggests that with perimeters of such width, Ghost bats are foraging occasionally on the facades.

3.5 Mesas with historical mining operations.

There are thirteen mesas with historical mining operations. These are Mesas K, L, M, N, 2400E, 2400F, 2400G, 2401A, 2402A, 2402C, 2402E, 2403ABC and 2403D, attachment B, all of which were mined in the early decades of the Robe valley operations. The extent of the retained perimeters is 0% on N, 2402A and 2402C and is generally less than 50% on the others. Only Mesa 2403D has retained the majority of its original facade at 93%. Examples of the extent of perimeter removal are given in figures 3 and 11. Figure 3 shows Mesa 2400E that has 50% of its perimeter retained. The disturbance to the other 50% where overburden has been dumped is evident. Figure 11 shows Mesa 2402C which has no original perimeter retained. A side view of a mesa with its perimeter destroyed by dumped overburden is given in plate 8. There is no retention of any of the original cliff line or its cave/shelter features. On mesas where parts of the original perimeter have been retained, the original caves and shelters are in general in good

condition, plate 9. The available evidence detailed in attachment A, and summarised below, shows that Ghost bats have recolonised these undamaged perimeters following the completion of mining and are roosting in appropriate caves.

Figure 11. Aerial view of Mesa 2402C that was mined in the early decades and has had all of its original facade removed. The extent of dumping overburden over the side and covering the talus is clearly visible as darker brown scree flowing over the lighter original material.

Plate 8. Image of the side of a mesa that has had overburden dumped on the original façade. This is typical of the condition of the current state of the majority of the perimeters of the mesas mined in the 1970s.

Plate 9. Image of the side of a mesa that has had a portion of its original façade retained. This indicates that caves and shelters on those portions of facade remain as viable Ghost bat habitat.

3.6 Summary of Ghost bat records on the Robe River mesas.

There are twenty mesas of the thirty four, including Pannawonica Hill, on the Robe River system that have recent Ghost bat records. In addition there are five other sites within 10 km of the river where Ghost bat activity has been recently recorded. These are detailed in attachments B and C.

There are eighteen mesas that have not been mined. Of these, three have had skeletal drilling on their caps (Mesas F, L1 and 2405A) and four (Mesas B, C, G and H) have had extensive resource evaluation drilling programs, all of which have a retained facade of 50 m. Of the unmined eighteen, twelve mesas that have been surveyed for Ghost bat activity in recent years have evidence of activity. Of these, there are maternity roosts identified on Mesas B and F plus diurnal roosts, some of which may be utilised as maternity sites, on Mesas C, G, H and 2402B, plus three of the supplementary sites, attachments B and C. Of the supplementary sites, three have current evidence in the form of sites with scats or with recorded calls. Of the six unmined mesas without current evidence (Mesas E, L1, 2400B, 2400C, 2403E and 2405A) insufficient survey activity has been carried out and evidence of Ghost bat usage may be present.

This result shows unequivocally that the escarpments of the mesas that have not been mined including those that have had intense drilling programs on their caps remain as confirmed Ghost

bat habitat and the caves and deep shelters continue to offer diurnal and maternity roost opportunities for the species.

There are two mesas where current large scale open cut resource extraction activities are underway, A and J. Neither of these currently has a known diurnal presence of Ghost bats although this is speculative due to a lack of survey data on the mesas from recent years. The available data suggests that it is possible that the species does use the perimeters for foraging on an occasional basis as a single scat has been identified on Mesa A (cave MA06) and scats have been recorded on the facade of Mesa J (cave Opp02). Based on data from other Pilbara iron ore mine sites (e.g. West Angelas and others; author's unpublished data), the lack of diurnal presence is thought to be due to the disturbance from the sound, vibration and airborne dust generated by the blasting, crushing and hauling operations nearby.

There are thirteen mesas where mining has been completed. Of these, three have had their caps completely removed and none of their perimeters retained. There is no current evidence of Ghost bat usage on these three although it is possible that occasional foraging visits are made. Of the remaining ten, the percentage of retained perimeter varies from 16% on Mesa 2402E to 93% on 2403D. The six that have been recently surveyed all have current evidence of Ghost bat usage, one of which, Mesa 2400E, has a site that has been identified as a possible diurnal roost, attachment A. This result shows unequivocally that the perimeters that have been retained on the mesas that have been mined remain as Ghost bat habitat and the protected caves and deep shelters continue to offer nocturnal and diurnal roost opportunities for the species. It is also possible that the retained deepest caves and shelters are used as maternity sites although no evidence of this is available at this time.

An assessment of impact of iron ore mining on the Ghost bat species in the Robe valley mesas therefore was made by reviewing the lengths of the perimeters that are retained to a width that protects the deepest caves and shelters that are available for nocturnal and diurnal roosting. The total original escarpment length of the mesas between Mesa A and Mesa 2405A is approximately 275 km. Of this, approximately 227 km, or 83% has been retained or is in place on mesas not yet mined. Virtually all is in good condition although there have been some localised collapses such as one noted at Mesa A adjacent to cave MAI06-SH17 (note that this collapse occurred prior to 2001 before mining began nearby). By applying the 2 caves/km ratio from above to the undisturbed perimeter it is possible that there are up to 400 deep shelters and caves suitable for Ghost bat usage remaining on the mesas.

For the 48 km of perimeter that have been removed or destroyed, potentially up to 100 caves and shelters may have been removed. This quantity may have had an impact on the total number of Ghost bats present although this is speculative as the numbers may be limited by availability of prey, see section 1.3 above. Based on the observations since 2014 of Ghost bats and/or their scats and middens at the supplementary sites that are in the upland areas nearby the Robe River and its mesas stretching from Sugarloaf Hill in the west to the bluff opposite Mesa 2403D in the east, Attachment C, it is also apparent that the areas surrounding the mesas have retained all of their Ghost bat population. With a current estimate of 150 Ghost bats in the Robe valley, from above, and recognising that the number will vary with the quality of the seasons, the loss of bats due to the loss of roosting habitat that has already occurred is estimated to be less than 20 individuals. For current and future mining operations, retaining a facade of greater than 20 m around the mesa perimeters and providing particular protection to significant diurnal/maternal roost caves will result in no further loss of Ghost bats in the valley due to roost destruction.

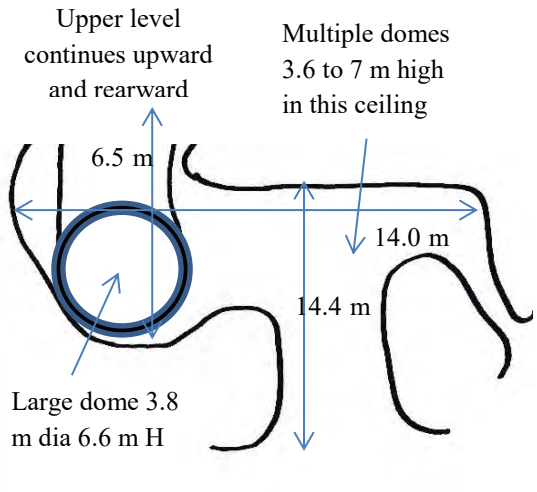
Unboxed dimensions indicate cave/shelter width and depth and boxed or "dome height" (solid circles) dimensions indicate ceiling heights.

Mesa F Cave MF01:

Assessed Ghost bat usage: Permanent maternity roost. 70 present.	**Coordinates:** 50K 398218 7591036
Entrance safe or unsafe to approach: Assessed safe	**Basic Geology: Land system at site** Robe Pisolite mesa: Robe
Entrance type and dims – WxH (m): Cave has two entrances opening into a mid-size chamber. Left 6 x 7 m. Right 0.8 x 0.5 m.	**Entrance Orientation:** East
Cave Grouping: Other overhangs along gully sides outside entrance.	**Insulation from surface above:** Middle of local landscape
Cave Type: First chamber 15 m deep with four high domes. Second chamber is 5.0 x 6.5 m with a 6.6 m high dome and a higher level.	**Internal domed chamber:** Yes. Multiple between 2.5 and 7.0 m high.
Rear passages that may have roosts: Second chamber has an upper level going back an unknown distance.	**Internal temp. and relative humidity:** Ambient to second chamber then hot and humid behind.
Local foraging opportunities: Excellent, Mesa F is adjacent to Robe River riparian zone.	**Current distance to disturbance:** Mesa A mine is >17 km distant. Resource evaluation drilling nearby on mesa top.



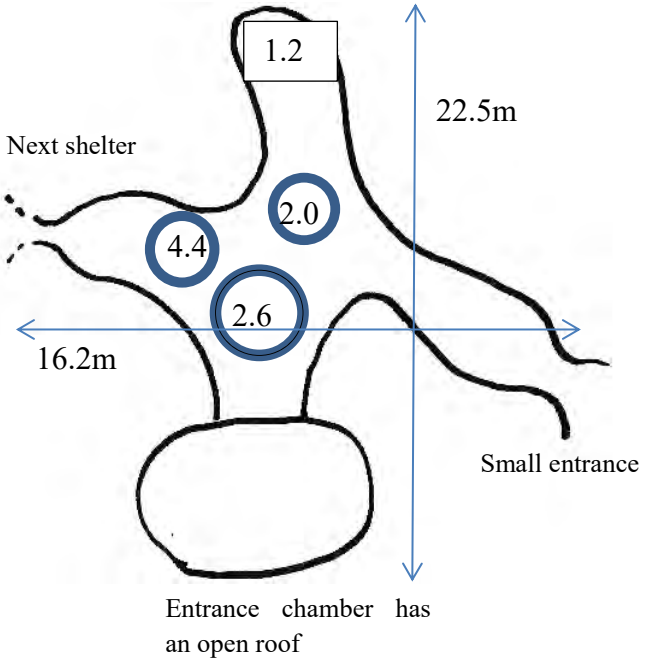
Mesa G Site G01:

Assessed Ghost bat usage: Shallow overhangs and semipermanent pool nearby coordinates. Ghost bats trapped in 2009. No deep cave found in April 2017. Probable foraging site.	**Coordinates:** 50K 410531 7595661
Entrance safe or unsafe to approach: Assessed safe	**Basic Geology: Land system at site** Robe Pisolite mesa: Robe
Entrance type and dims – WxH (m): N/A	**Entrance Orientation:** N/A
Cave Grouping: Group of overhangs and shallow shelters along a gully.	**Insulation from surface above:** Middle to Top of local landscape
Cave Type: N/A.	**Internal domed chamber:** N/A
Rear passages that may have roosts: N/A.	**Internal temp. and relative humidity:** Ambient
Local foraging opportunities: Excellent, Mesa G is adjacent to Robe River riparian zone.	**Current distance to disturbance:** Mesa J mine is >10 km distant. Resource evaluation drilling nearby on mesa top.
Cave floorplan and entrance photo:	

Mesa G Cave G02:

Assessed Ghost bat usage: Diurnal Roost although no Ghost bats present in April 2017	**Coordinates:** 50K 411740 7595774
Entrance safe or unsafe to approach: Assessed safe	**Basic Geology: Land system at site** Robe Pisolite mesa: Robe
Entrance type and dims – WxH (m): Entrance chamber has a large open roof.	**Entrance Orientation:** South
Cave Grouping: Cave is a part of a complex of shelters and overhangs with some internal connection.	**Insulation from surface above:** Middle of local landscape
Cave Type: Cave 22.5 m deep with low roof and three domes.	**Internal domed chamber:** Yes. 2.0 m to 4.4 m high
Rear passages that may have roosts: Side chambers interconnect to other shelters along the gully.	**Internal temp. and relative humidity:** Ambient
Local foraging opportunities: Excellent, Mesa G is adjacent to Robe River riparian zone.	**Current distance to disturbance:** Mesa J mine is >10 km distant. Resource evaluation drilling nearby on mesa top.

Cave floorplan and entrance photo:



Mesa G Shelter G03:

Assessed Ghost bat usage: Nocturnal shelter with a Ghost bat midden.	**Coordinates:** 50K 411727 7595625
Entrance safe or unsafe to approach: Assessed safe	**Basic Geology: Land system at site** Robe Pisolite mesa: Robe
Entrance type and dims – WxH (m): Cave has two entrances opening into a mid-size shelter. Left 1.2 x 2.5m. Right 2.8 x 2.6m.	**Entrance Orientation:** West
Cave Grouping: Other overhangs along gully side to the north.	**Insulation from surface above:** Middle of local landscape
Cave Type: Cave 7.0 m deep with low roof, a dome and a tight rear tunnel.	**Internal domed chamber:** Yes. 5.0 m high
Rear passages that may have roosts: One rear sinuous tunnel continues on the left side. It has as small Ghost bat midden under its entrance.	**Internal temp. and relative humidity:** Ambient
Local foraging opportunities: Excellent, Mesa G is adjacent to Robe River riparian zone.	**Current distance to disturbance:** Mesa J mine is >10 km distant. Resource evaluation drilling nearby on mesa top.

Attachment A. Characteristics of caves examined during this survey

Executive Summary

Rio Tinto commissioned Bat Call WA (Bat Call) to undertake a targeted assessment of bat conservation values of caves at Mesa H. This resource is located in the Robe River valley 17 km south west of Pannawonica, in the Pilbara region of Western Australia. This assessment was completed in parallel with a broader assessment of bat conservation values across the entire Robe River that is the subject of a separate report.

Level one and two fauna surveys have been conducted in the area previously, most recently by Astron Environmental Services in 2015/16. Two bat species of conservation significance have been recorded within the area, namely Pilbara leaf-nosed bat (*Rhinonicteris aurantia*) (Pilbara form of the Orange leaf-nosed bat) (PLNb) and Ghost bat (*Macroderma gigas*), both listed as Vulnerable under Federal and State legislation. PLNb have been assessed as using Mesa H for foraging while originating from a yet to be discovered roost further to the south or east (e.g. Bat Call 2016, 2017). Multiple Ghost bat records including echolocation recordings, visual observations and cave middens have been detected within and adjacent to the study area (e.g. Biota 2009; Astron 2016; Astron 2017).

This survey was designed to provide an assessment of the conservation value of caves associated with the presence of Ghost bats at Mesa H. A visual assessment of cave environments and an extensive search for Ghost bat presence, including roosting bats, was carried out. Ghost bat presence on Mesa H was determined to be irregular with the mesa being used for nocturnal foraging and occasional diurnal roosting. Ghost bat presence, in the form of guano and middens, was recorded across all of the different areas inspected. Eleven of twenty four sites were found to be used or suitable for use by the species. No colonies of diurnally roosting Ghost bats were found. Two caves on Mesa H (MH16-34 and AC04) were found to have the characteristics of diurnal roosts for the species with the possibility of occasional use as maternity roosts. Eight sites on Mesa H were assessed to be nocturnal feeding sites. One site south of Mesa H in the nearby Buckland Hills was also assessed to be a nocturnal feeding site. Thirteen sites on Mesa H were determined to be not currently used by Ghost bats and not suitable for regular occupancy. A number of additional overhangs nearby the caves and shelters were also assessed for signs of Ghost bat use but none were found.

The caves and surrounding environments at Mesa H were found to be supporting foraging Ghost bats originating from either the Buckland Hills to the south, Yeera Bluff between mesas G and H or the Three Peak Hills to the north-west. Two diurnal roost caves with maternity cave potential

have been confirmed. These are located in productive gullies and are associated with a number of near-by caves and shelters providing a series of escape and nocturnal foraging opportunities, including the presence of the Robe River riparian zone, required by the species for successful reproduction.

1.0 Introduction.

1.1 Project Background

Rio Tinto commissioned Bat Call to undertake a targeted assessment of bat conservation values at the Mesa H deposit located approximately 17 kilometres (km) south-west of Pannawonica in the Robe River valley, in the Pilbara region of Western Australia (WA), figure 1. Rio Tinto is considering sustaining its Robe Valley operations by including additional deposits to replace ore supply from the Mesa J operations as it nears the end of its mine life. In summary, the planned mining operation would involve the following main components and activities in addition to the existing approved operations:

- progressive open pit mining of ore and overburden from Mesa H using similar open pit mining techniques to those currently used at Mesa J. These operations are planned to remove the inner core of the mesa while leaving the rocky face of the perimeter intact to a width of at least 20m at the mesa surface,
- placement of overburden in out-of-pit waste dumps adjacent to the mesa, and
- construction and use of haul and access roads to the mine areas within the mesa.

Recent surveys have identified that two species of cave roosting bat of conservation significance are present in the area, the Ghost bat (*Macroderma gigas*) and the Pilbara leaf-nosed bat (*Rhinonicteris aurantia*) (PLNb). PLNb have been assessed as using the Mesas for foraging while originating from a yet to be discovered roost further to the south or east (Bat Call 2016, 2017). Multiple Ghost bat records including echolocation recordings, visual observations and cave middens have been detected within and adjacent to the study area (Biota 2009; Astron 2016; Astron 2017).

The purpose of this survey was to assess the conservation values of caves potentially associated with Ghost bats at Mesa H that had been previously identified by both external and internal resources. This involved a visual assessment of cave geometry and environments and an extensive search for Ghost bat presence, including bat colonies and/or middens. The study area is shown in figure 1. It includes the perimeter of Mesa H including its major central gully.

1.2 Existing Environment at Robe Valley Mesas and Surrounds

Topography

The Robe River Valley mesas cover an extensive area beginning at Mesa A and running approximately 100 km upstream. Mesa H lies immediately adjacent to that river riparian zone. It is roughly circular and is 3.5 km in diameter and stands approximately 50 m higher than a flat plain that is crossed by the river. It is bisected by a major gully running south to north toward the Robe River riparian zone.

Geology

Mesa H is a tertiary Robe Pisolite iron ore deposit, also known as a Channel Iron Deposit (CID), incised with deep gullies around the perimeter. It has overhangs, shelters and caves along extensive lengths of the perimeter and the central gully, e.g. plate 1.

Overhangs, shelters and caves are defined herein as:

- Overhangs are shallow hollows in a rock wall with a distinct roof structure. Their shape is such that they are fully lit by sunlight to their back wall. Their depth is typically 2 to 5 m.
- Shelters are deeper hollows or shallow caves in the rock wall that have ceiling structures from 1.0 to >5 m. They offer significant protection from predators and the weather, are typically 5 to 15 m deep and have dark twilight conditions at their rear extremities. Some have domed areas in their ceilings offering nocturnal roosting and feeding opportunities to Ghost bats. Some are occasionally used diurnally.
- Caves are defined as deep structures of various heights, widths and depths that are very dark in their deeper recesses. They often have additional rear chamber(s) separated from the entrance by a constriction point(s). Those chambers that have ceiling heights of over 2.5m offer excellent roosting opportunities for Ghost bats.
- All three can have cracks or voids that continue back from their rear walls that may lead to additional internal cavities within the rock strata behind or above. If these cavities are almost fully enclosed, have entrance cracks large enough, and can retain high levels of humidity, they provide roosting opportunities for PLNb and Ghost bats.

Overhang and shelter density is high along the majority of the mesa perimeters with the rock strata forming numerous shallow shelters in mid and higher levels of the walls. There are a

number of deeper caves formed in the Pisolite at mid and higher levels of the mesa walls but these rarely extend beyond 15 m in depth. Most shelters and caves were found on the mesa's cliff walls at or just above the top of the talus slope.

Land Systems (after Van Vreeswyk *et al.* 2004)

Mesas H including the gullies and the surrounding gravelly plains are elements of the Robe Land System. It is a low limonite mesa that support spinifex grasslands and scattered Snappy Gums. The lower slopes and adjacent gravelly plains support spinifex grasslands with sparse Acacia and Eucalypt shrubs with low trees that sometimes form thickets.

The adjacent Robe River is a very complex and productive linear river channel and flood plain with a Eucalyptus and Melaleuca woodland over tall Acacia and Petalostylis shrubland. It is an element of the Pilbara's River Land System

The Buckland Hills to the south of Mesa H and Yeera Bluff to the west are rugged jaspilite ridges and mountains of the Newman Land System supporting open shrublands and open low woodlands of Grevillia and Eucalypt over hummock grasses.

Climate

The climate in the district is semi-desert tropical. Mean monthly minimum and maximum temperatures in the lower Robe Valley range from 12 to 41 degrees Celsius (^{o}C). Annual rainfall is extremely variable and averages 400 mm, usually in cyclonic or thunderstorm events during the northern wet season. The northern dry season lasts from May to November and winter rainfall is uncommon.

Water Sources

Drainage systems in the immediate area are associated with ephemeral gullies on the perimeters of the mesas that run into the Robe River drainage system. That riparian zone has a number of permanent and ephemeral pools along its length such as Gnieraoora Pool at the base of Yeera Bluff.

Plate 1. Example of the presence of overhangs and shelters along the perimeters and within the incised gullies on Mesa H. This view is of the Cave H18, H19 complex.

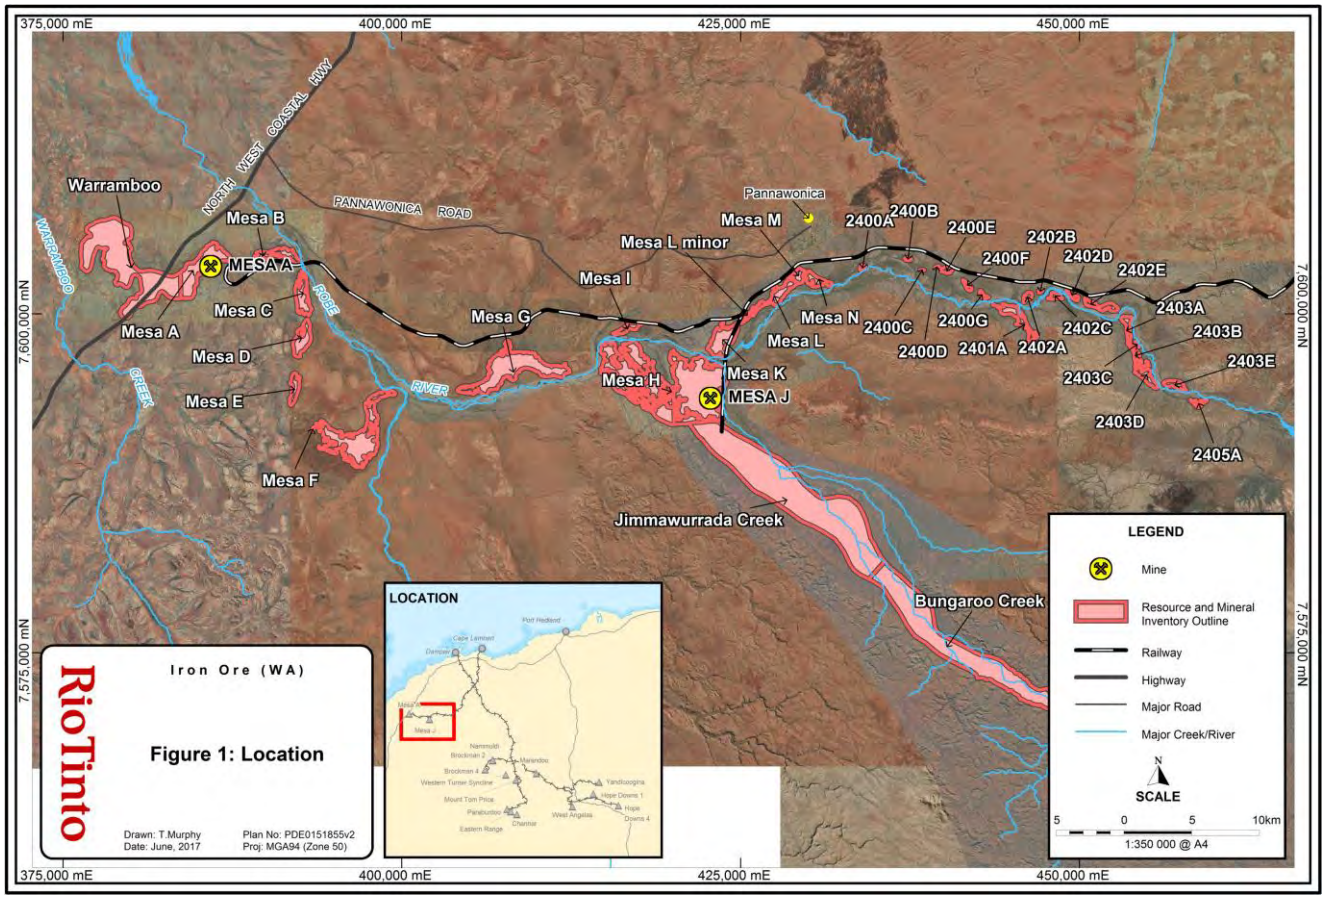

Figure 1. General Arrangement of Robe River valley mining area.

1.3 Bats of Conservation Significance

The Pilbara region contains 17 species of microbat, and of these, 13 have the potential to be found in the Mesa G-H vicinity (Van Dyke and Strahan 2008, McKenzie and Bullen 2009). A number of fauna surveys including targeted bat surveys have been previously conducted in the area, most recently by Astron in 2015 and 2016 and internal Rio Tinto ecologists in 2016-17, see table 1. Two Pilbara bat species of conservation significance have been recorded in the area, the Ghost bat (*Macroderma gigas*) and the PLNb (*Rhinonicteris aurantia*).

The Ghost bat is a large (130 g) carnivorous predator and the PLNb is a small (10 g) insectivore. Both are endemic to northern Australia and are obligate cave roosting species requiring specific cave environments for permanent roosting especially for their maternity colonies. The Ghost bat's foraging strategy and high trophic niche, as a top night-time carnivorous predator, is unique in Australian microbats. The Pilbara's Ghost bat and PLNb populations are isolated from Australia's other populations that are extant across the mesic tropics by the uninhabitable arid zone of the Great Sandy Desert to the north and east. Both species are "conservation significant" as they are semi-desert adapted populations that have specific roosting requirements. The Ghost bat has suffered significant range loss in historical times. The reasons for the range contraction are open to speculation but it is known that the species is sensitive to disturbance (e.g. Richards *et al*. 2008, Woinarski *et al.* 2014)).

The PLNb has been detected foraging across the mesas in the Middle Robe valley. A roost has not been identified on Mesa H and echolocation records indicate that it lies to the south or east of Mesa H or J.

The Ghost bat has also been detected within the study area.

1.3.1 Ghost bat (*Macroderma gigas*)

The Ghost bat is listed as Vulnerable under the commonwealth *Environment Protection and Biodiversity Act 1999* (EPBC Act), Vulnerable under the Western Australian *Wildlife Conservation Act* (1950) and Vulnerable C1 (a vulnerable species numbering less than 10,000 and in decline) under the IUCN Redlist (IUCN 2017). The listing is on the basis of the impact of loss of suitable roost opportunities. The Pilbara Ghost bat population is estimated at 1500-2000 based on recently published estimates (approximately 600, N.L. McKenzie pers. comm. in IUCN 2016; approximately 1200, Armstrong and Anstee 2000; "more common than previously supposed", McKenzie and Bullen 2009) and author's unpublished database summarising data from a range of surveys carried out in recent years by Pilbara mining companies, including Rio

Tinto and other organisations, supplemented by author's own data (summarised in Threatened Species Scientific Committee (TSSC 2016). These recent data (estimates less than 15 years old) cover the entire Pilbara bioregion. Current population estimates in the Hamersley and Chichester subregions are approximately 350 and 1500 respectively (author's unpublished database summarised in TSSC (2016)).

Ghost bats hunt their prey in two primary ways. They hunt birds and bats "air-to-air" at cave entrances and elsewhere by swooping from above or from a perch. They also hunt ground level prey in their target food size range by dropping onto the prey from a perch, either tree branch or rock outcrop. Their diet includes small mammals including other bats, birds, reptiles, frogs and large insects. The proportion of food items in the diet varies with availability and reported foraging areas vary from a few to 10 km from the roost cave. One Ghost bat carcass was found recently entangled in a barbed wire fence in the Fortescue Marsh over 12 km from the nearest cave forming rocky strata suitable for roosting (Stephen Van Leeuwen pers. comm.).

Along the lower Robe River valley multiple Ghost bat records including visual observations and the presence of cave middens have been detected on the various mesas within and adjacent to the study area (table 1).

Ghost bat breeding colonies are known from a small number of maternity roosts in the Pilbara and reproduce during the northern wet season. The largest of these colonies are in abandoned mines in the Chichester subregion and number up to several hundred (Armstrong and Anstee 2000). Hamersley Range populations are typically between 5 and 25 individuals in local groups (author's unpublished database). There is one known large, permanent maternity roost (unpublished assessment by the author) numbering over 70 bats in the lower Robe River valley of the Hamersley subregion. For these groups to persist the bats need an "apartment block" of roosting opportunities, at least one deep cave with characteristics of a maternity roost, multiple caves/shelters and overhangs in close proximity offering nocturnal feeding and refuge opportunities, a productive set of gullies and gorges locally, a productive foraging area within 5 to 10 km radius, usually including a good quality riparian corridor or ephemeral fresh water lake bed and appropriate protection from human interference (author's unpublished data base). These groups are known to reproduce in good years using suitable natural roost caves. Examples are a group numbering 5 to 10 including reproducing females at West Angeles caves in 1980 (Dr Nic Dunlop pers. comm.), a small group including reproducing females at caves at Nammuldi/Silvergrass area (Hamersley Iron 1999), observation of a heavily pregnant female at a cave near Mt Robinson by the author in 2013 and a group numbering 14 including four juveniles

at another cave near Mt Robinson in 2015 (Mr. Morgan O'Connell pers. comm.). The Ghost bat is also known to spread great distances on an annual cycle from these locations depending upon seasonal weather conditions and availability of suitable day roosts. Sporadic records of Pilbara Ghost bats have been identified in the Gascoyne (author's unpublished data) and the Little Sandy Desert (sightings by W.H. Butler at Durba Spring in 1971 and others since). Genetic work by Worthington Wilmer and Armstrong (summarised in Woinarski *et al.* 2014) suggests that the females remain or return to their birthplace and that the males can move between districts.

Ghost bats use three types of roost regularly, these being nocturnal roosts or feeding sites, diurnal or day roosts that may be permanent or semi-permanent sites and maternity roosts that are diurnal roosts with the range of characteristics allowing regular or permanent occupancy.

Nocturnal roosts or feeding sites are only used at night, either habitually or for transitory visits. They are typically shallow caves and shelters that are well lit during the day. They are often high in the strata and may be well or poorly insulated from the elements. They often contain guano scatters and/or midden(s) of various sizes containing guano and food scraps but these remains are sometimes removed by rainfall and/or varieties of "dung beetle" that are known to forage on the scats (author's unpublished observations).

Diurnal roosts are caves and mine adits that are deeper and more complex. They typically have one or more large chambers at or beyond the twilight area with additional fissures or chambers at the rear in the fully dark regions. They have a minimum roof height in the chambers of 2 to 3 m providing protection from attack by terrestrial predators. They are often at mid-levels or lower in the strata and are well insulated overhead providing a stable temperature environment. They typically contain multiple scat piles and middens of guano and food remains that include feathers and skeletal material.

Maternity roosts are diurnal roosts that provide additional features to those listed above that are able to support a reproducing population. These features usually include an interior chamber that is rising toward the rear thereby trapping warmer and more humid air at the top allowing suitable conditions to form during the period when reproductive females and pups are present.

Being predators, during a night's foraging they may also hang for short periods in any deep overhang, shelter or cave with a high enough ceiling or tree branch above a cleared patch of ground for feeding or resting on an opportunistic basis. These sites are not routinely visited and usually show no evidence of Ghost bat presence.

1.3.2 Pilbara leaf-nosed bat (*Rhinonicteris aurantia*)

The PLNb is listed as 'Vulnerable' under the federal *Environment Protection and Biodiversity Act 1999* (EPBC Act) and by the Western Australian *Wildlife Conservation Act* (1950). This listing is on the basis of the impact on its population of the loss of suitable roosts with the correct microclimate.

The PLNb requires roosts with very specific requirements of high temperature and humidity for survival in the Pilbara. These are warm deep and humid caves and historical underground mines. The humidity required is higher than the Ghost bat, approaching 100%. The species is subject to rapid dehydration and death within a day if removed from its roost. It is known to have a usual foraging range up to 20 km from its primary roost caves (Bullen 2013). It also appears to spread from these roosts to satellite roosts when wet season conditions allow and to consolidate back to permanent sites during dry periods.

1.4 Summary of Previous Bat Surveys

Prior to 2017, a number of the fauna surveys commissioned by Rio Tinto in the lower Robe River valley have included microbat species listings. These indicated the presence of both significant species foraging across the area (e.g. Bat Call 2010). More recent surveys carried out since 2015, summarised in table 1 below, indicated that the Ghost bat may be roosting locally and may include a maternity colony at Mesa H and that the PLNb was foraging generally across all Robe valley mesas but not roosting on Mesa H.

Table 1. Summary of Fauna Surveys that Include Ghost Bat records in the Mesa H District

Date	Reference	Ghost bat activity detected.
2009	Biota (2009)	• Ghost bats harp trapped at Mesa G
2015	Astron (2016)	• Ghost bat echolocation calls detected at Mesa H and a number of shelters/caves with scats recorded
2016	Astron (2017)	• Ghost bat echolocation calls detected at Mesa G and a number of shelters/caves with scats recorded
2017	RTIO internal ecologists	• Ghost bat seen at cave H27on Mesa H.

2.0 Survey and Assessment Methods

A survey consisting of three days field work was completed in April 2017 (9th to 11th April) on Mesa H. Twenty four sites were assessed plus nearby overhangs and shallow shelters.

The fieldwork focussed on the assessment of potential roosting habitat of Ghost bat that previous surveys had indicated were important for this species. Eight sites listed as Ghost bat habitat were assessed. In addition, 13 caves/shelters on Mesa H that the Rio Tinto heritage surveys had recorded with depths greater than 10m were also included in the survey. Three previously unrecorded deep shelters suitable for Ghost bat use were also found and assessed.

On an opportunistic basis, a secondary set of overhangs and shelters recorded by the heritage surveys (often within 100m of the primary caves) were also searched.

2.1 Survey Team, Timing and Weather

The survey team consisted of two experienced ecologists. Ms Tenielle Brown (Rio Tinto) was team leader and Mr Robert Bullen (Bat Call) acted as principal ecologist.

The northern wet season of 2016-17 was wetter than average in the Pilbara region. Heavy rain fell in the district in the three months prior to the survey with 535 mm being recorded at the Bureau of Meteorology station at Pannawonica (Bureau of Meteorology station No 5069) between January and March. This rain continued until a week prior to the survey. The weather during the assessment was typical late wet season conditions being hot and dry with temperatures between 20 and 40^{O}C.

Sunset and sunrise were at 18:09 and 06:26 during the survey while dusk and dawn civil twilight were at 18:31 and 06:04 respectively. The moon phase was full.

2.2 Survey Techniques

The survey was designed to assess all Ghost bat (and any PLNb) roost cave candidates, to review cave morphology, geology and cave conditions, and to narrow down the list of potential Ghost bat maternity and/or PLNb roost caves. These visits were completed during daylight hours. Caves and shelters were entered after a rigorous safety inspection that assessed potential hazardous rock structures. Each was then measured for height, width and depth using a hand held laser (Bosch model PLR-50). Some caves and gorges had been surveyed earlier by Astron, for evidence of Ghost bat activity including the presence of middens and scats. Along the perimeter of Mesa H, twenty four sites were visited and were assessed by their attributes as probable night

feeding locations, seasonal day roost candidates or permanent day/maternity roost candidates. Numerous overhangs and shallow shelters identified by the Rio Tinto heritage surveyors near these sites were also assessed. These combined totals constituted all potential Ghost bat roost caves and shelters previously known or identified during the survey on the two mesas.

The presence of Ghost bat was confirmed by either of the following observations:

- Visual observation of a large pale bat entering or departing the cave. Note that the Ghost bat is distinctive in being much larger than any other cave dwelling bat in the region; or
- Detection of Ghost bat scats or middens on the floor of the caves or shelters entered, plate 2.

Plate 2. Typical Ghost bat midden containing scats and feathers on the floor of a cave

Caves and Shelters were then classified as maternal, diurnal, nocturnal or "not used" based on the cave characteristics and evidence found. The "not used" classification was applied when there is unsuitable characteristics such as low ceilings (typically <1.5m) and/or shallow depth (typically < 5m) with no physical evidence or other record such as a sighting or echolocation recording.

Observations of bat species other than the two conservation significant species were not recorded during this assessment.

2.3 Survey Effort

Sites previously identified were approached from either the top rim or from the plain below and scanned visually for the presence of caves. Caves were assessed for safe entry and sections of the perimeter that showed cave forming strata were then walked at the height of the top of the talus slope where the caves were most common. Twenty four caves and shelters were visited, see figure 2, and assessed for Ghost bat presence. One ecologist entered each cave following agreed Rio Tinto health and safety guidelines covering personal protective equipment (PPE), access limitations and communication strategies. The cave interior was searched for evidence of Ghost bat roosting including the presence of middens and adult Ghost bats. The team's second member remained at the entrance to observe any Ghost bat that might depart the cave behind the observer inside, a common behaviour of this species. Any Ghost bats that departed and/or entered the caves or were seen flying close to the entrance were thereby recorded visually. Any that departed could be tracked visually to record the alternative cave or shelter that they re-entered.

Figure 2 Mesa H with locations of caves and shelters assessed during the survey.

2.4 Survey Limitations

The primary objective of the survey was the characterisation of Ghost bat activity on Mesa H. All aspects of the survey including site access using 4WD, team make-up and experience levels, equipment used, logistics and safety support provided by Rio Tinto were suitable for the task.

No activities were undertaken that could cause harm to the bats present.

Detailed internal dimensions of a cave and its daytime use by bats cannot be reliably determined from the entrance or by the size of the entrance. Entry of candidate caves was therefore necessary to confirm internal characteristics including the bat species present. (Note that distinctive Ghost bat social calls heard from the entrance, or Ghost bats seen departing caves in daylight following the approach of survey parties, serve to confirm the presence of Ghost bats but do not provide information on their numbers or maternity status).

Detailed interior searches of caves were carried out under the guidelines of the Rio Tinto safety procedures. These prohibited entry into any cave that was deemed to have an unstable ceiling as characterised by loose rocks overhead or around the entrance, heavy cracking or the presence of fresh slab like roof material fallen to the floor. These procedures also prohibited entry into any chamber that required sliding on stomach or back or that required climbing or descending 2 m using rock-climbing techniques. The rear areas of some caves could therefore not be searched completely and the possible presence and number of Ghost bats in such caves was therefore not confirmed absolutely.

Due to the porous nature of the Robe Pisolite and the very high number of cracks and sinuous tubes and pipes throughout the strata, the floors of a number of caves had been washed clean of any evidence of Ghost bat occupation by the preceding heavy rain. In addition most caves were inhabited by a species of beetle that is known to act as a scat cleaner thereby removing Ghost bat scats. This combination resulted in fewer caves being identified with scats than expected from the previous surveys.

3.0 Results

A number of observations of Ghost bats middens and scat piles were made during this assessment with Ghost bat presence and foraging activity confirmed generally around the perimeter. In addition two diurnal roost caves with the characteristics of occasional maternity roosts have been located on Mesa H, figure 3.

Assessments of each cave and observations of Ghost bat activity are provided below, table 2, with detailed characteristics of the caves examined including floorplans and dimensions in Attachment A. Most caves were found to be less than 20 m deep and therefore not expected to be impacted by the mining behind the facade. Caves MH16-34 and AC4 were found to be over 30 m deep, depths that are significant when planning the facade to be retained.

Eleven sites were assessed as being suitable for roosting by Ghost bats including two diurnal roost caves and nine nocturnal roost shelters. Note that this total includes shelter AC05 that is in the Buckland Hills BIF strata (Newman land system) adjacent to Mesa H. The two assessed as diurnal roost caves are MH16-34 (50K 415815 7595655), a simple linear chamber 30 m deep with a single high dome at the distal end, and cave AC04 (50K 417586 7594895), a more complex cave with six ceiling domes between 2.5 and 3.9 m high along its length. Both were assessed as being maternity cave candidates although no evidence of significant Ghost bat use of this type was found during the survey. Cave AC04 had a number of scats present.

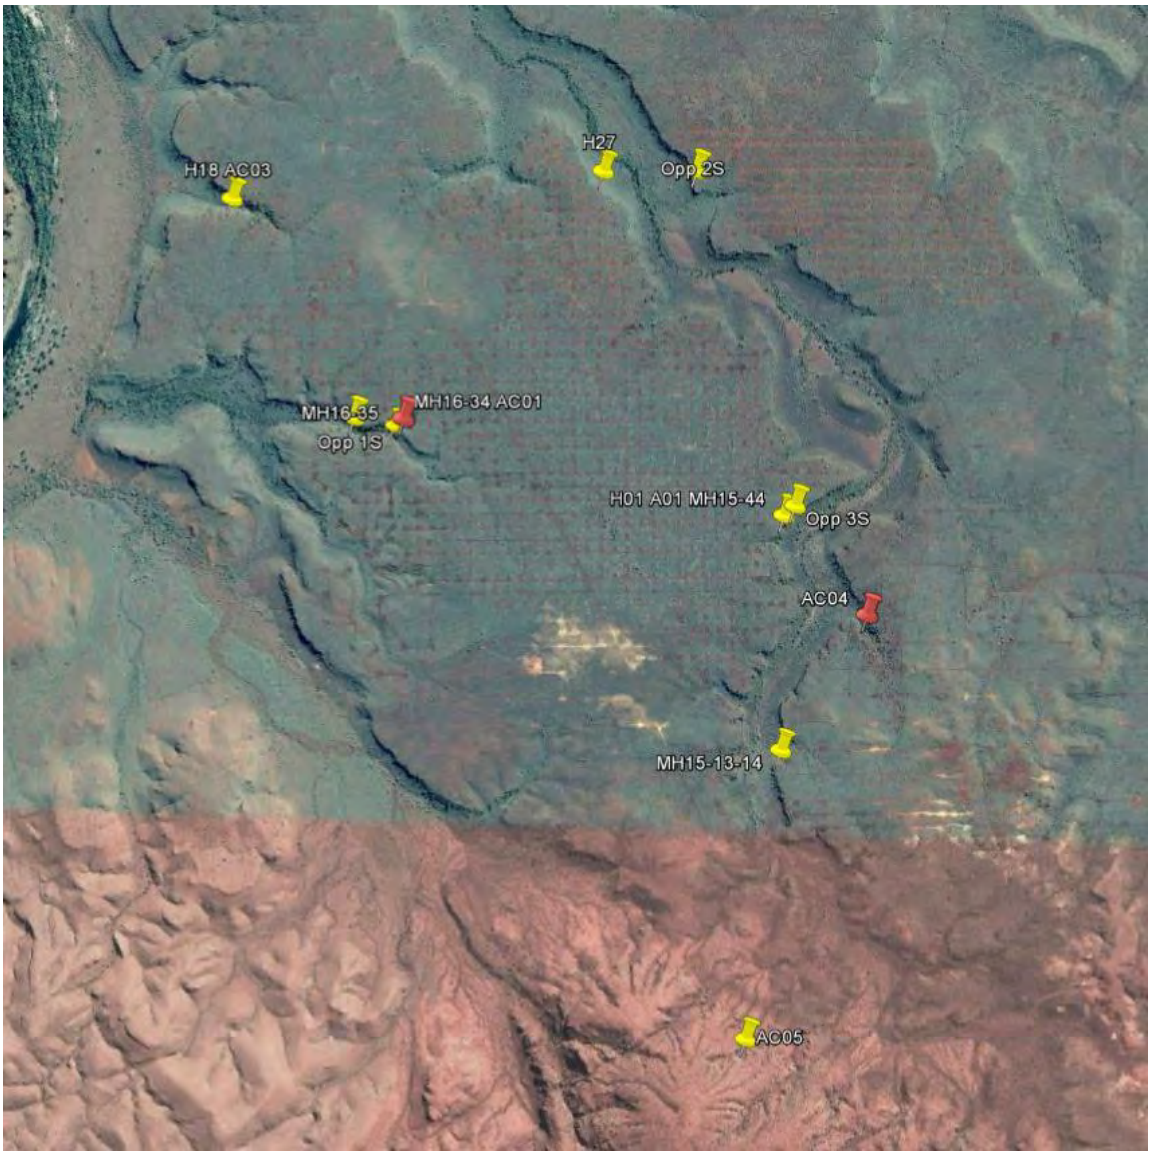

Figure 3. Mesa H caves and shelters where positive Ghost bat assessments were made. The red dots denote the diurnal caves MH16-34 and AC04. Yellow dots denote caves/shelters assessed as nocturnal feeding roosts.

Table 2. Summary of caves visited on Mesa H and assessed for Ghost bat usage.

Cave	Easting	Northing	Observations	Assessed Ghost Bat roost type
H01-A01 MH15- 44	417270	7595276	Shelter with a low internal dome. Several overhangs to the north and south. Ghost bat guano present	Nocturnal feeding roost
H2	414628	7597699	Overhang. No Ghost bat guano present	Overhang only. Not used
H3,H4,H5,H6,H7	414730	7597728	A series of overhangs along cliff face. No Ghost bat guano present	Overhang only. Not used
H16	415266	7596488	Shelter with low roof. No Ghost bat guano present. Additional overhangs nearby and on opposite side of gully with no Ghost bat evidence.	Shelter only. Not used
H18	415164	7596495	Shallow cave with two low domes. No Ghost bat guano present	Nocturnal feeding roost
H19	415126	7596488	Shelter with low roof. No Ghost bat guano present	Shelter only. Not used
H24	416776	7596072	Overhang. No Ghost bat guano present	Overhang only. Not used
H27	416587	7596590	Deep shelter with two low internal domes. Several overhangs to the north and south. No Ghost bat guano present	Nocturnal feeding roost
H34	415315	7595811	Shelter with several overhangs to the east and west. No Ghost bat guano present	Shelter only. Not regularly used
H36	415667	7595692	Unable to approach due to steep cliff. Assessed from opposite side of gully.	Shallow shelter only. Not used
MH15-13 MH15-14	417252	7594383.	Shelter with a high pipe in roof. Ghost bat guano present	Nocturnal feeding roost
MH15-25 H29	416571	7597124	Shelter with overhangs to west and east. No Ghost bat guano present	Shelter only. Not regularly used
MH15-47	417248	7595912	Shelter with low roof. No Ghost bat guano present	Not used
MH15-95	414938	7597150	Shelter with low roof. No Ghost bat guano present. Has additional overhangs nearby and on opposite face with no Ghost bat evidence.	Not regularly used
MH15-96	414925	7597127	Shelter with low roof. No Ghost bat guano present	Not used

Cave	Easting	Northing	Observations	Assessed Ghost Bat roost type
MH15-97	414899	7597103	Shelter with low roof. No Ghost bat guano present	Not used
MH16-34	415815	7595655	Deep cave with a single internal dome. No Ghost bats present	Diurnal roost. Possible maternal roost
MH16-35	415782	7595640	Shelter with overhangs to west and opposite. No Ghost bat guano present	Nocturnal feeding roost
AC04	417586	7594895	Cave with a multiple internal domes. Ghost bat scats present	Diurnal roost. Occasional use as a maternal roost possible but no current evidence of use this year
AC05	417109	7593285	Cave with a single internal dome. Ghost bat scats present	Nocturnal feeding roost
AC06	418068	7592683	Shelter with overhangs at creek level to the east. No Ghost bat guano present	Shelter only. Not regularly used
MH-Opp 1S	415625	7595659	Deep shelter with several overhangs to the east and west. No Ghost bat guano present	Nocturnal feeding roost
MH-Opp 2S	416948	7596585	Deep shelter with several overhangs to the north. No Ghost bat guano present	Nocturnal feeding roost
MH-Opp 3S	417330	7595332	Deep shelter with several overhangs to the south. No Ghost bat guano present	Nocturnal feeding roost

Note: All coordinates are zone 50K.

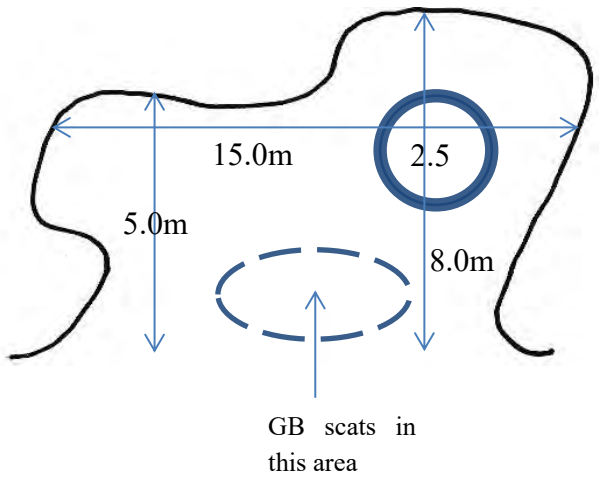
Mesa H Shelter H01-A01 MH15-44:

Assessed Ghost bat usage: Nocturnal shelter with Ghost bat scats.	**Coordinates:** 50K 417270 7595276
Entrance safe or unsafe to approach: Assessed safe	**Basic Geology: Land system at site** Robe Pisolite mesa: Robe
Entrance type and dims – WxH (m): Single wide entrance 9.0 x 1.5 m.	**Entrance Orientation:** South
Cave Grouping: Shelter has additional shallow overhangs along gully wall to the north and south.	**Insulation from surface above:** Middle of local landscape
Cave Type: Shelter is 8 m deep with low roof and one low dome.	**Internal domed chamber:** Yes. 2.5 m high
Rear passages that may have roosts: No.	**Internal temp. and relative humidity:** Ambient
Local foraging opportunities: Excellent, In central Mesa H gully that opens onto the Robe River riparian zone.	**Current distance to disturbance:** Mesa J mine is 2.5 km distant. Resource evaluation drilling nearby on mesa top.

Cave floorplan and entrance photo:



Mesa H Shelter H2:

Assessed Ghost bat usage: Shallow shelter/Overhang only. No Gb guano present. Not used.	**Coordinates:** 50K 414628 7597699
Entrance safe or unsafe to approach: Assessed safe	**Basic Geology: Land system at site** Robe Pisolite mesa: Robe
Entrance type and dims – WxH (m): Wide shallow shelter.	**Entrance Orientation:** North
Cave Grouping: Shelter is a part of a complex of shelters and overhangs overlooking the Robe River.	**Insulation from surface above:** Middle of local landscape
Cave Type: Shallow shelter ~5 m deep.	**Internal domed chamber:** No
Rear passages that may have roosts: No.	**Internal temp. and relative humidity:** Ambient
Local foraging opportunities: Excellent, Mesa H is adjacent to Robe River riparian zone.	**Current distance to disturbance:** Mesa J mine is 6 km distant. Resource evaluation drilling nearby on mesa top.

Geotechnical assessments – Potential diurnal Ghost Bat roost complexes at Robe Valley

1 Summary

The D3 Assurance and Systems team was requested to geotechnically assess the potential diurnal Ghost Bat roost complexes located at Robe Valley (Mesa H). The purpose of the assessments is to determine the level of blast control needed to be put in place to mitigate large scale damaged induced by mining, and to highlight any other possible geotechnical hazards within the sites that may present a risk for future access.

The geotechnical sensitivity (robustness) of the site was assessed in conjunction with the assessed environmental significance to determine the tolerable blast vibration range required to protect the integrity of the structure. Blast vibration thresholds were based on guidance that were developed for protection of heritage sites, specifically caves and shelters, based on discussions with the Explosive and Dangerous Goods team and referring to the Australian Standard AS2187.2 – Ground Vibration and Air blast Overexposure (Reference 1) as a guideline. The objective is to define vibration levels where routine mining activities (excavation and blasting) do not negatively impact on the integrity of the identified cave. However, natural weathering processes will continue to physically act on the cave and might eventually affect the integrity of the cave.

The tolerable vibration level for the sites has been assessed and are summarised in Figure 6. All the sites that were reviewed have recommended threshold Peak Particle Velocity (PPV) values of 50mm/s. The scaled distance method, as outlined in the AS2187.2:2006, should be used to determine the expected vibration levels at the sites. If the predicted PPV levels exceed the thresholds, more detailed blast management plans must be developed for the relevant sites.

2 Introduction

A list of sites to be assessed was provided by the Rio Tinto Environmental team. Some of the sites listed were previously also assessed for heritage purposes. The Geotechnical assessment of stability from a heritage perspective considers the possibility of any disturbance to the site, from a relative small rockfall to total collapse of the site. For the environmental assessment, smaller rockfalls were not evaluated. The main consideration is the permanent, large scale collapse of the site, preventing future Ghost Bat useof the site.

Development of a blast vibration threshold is based on a combination of the geotechnical sensitivity and the heritage / environmental value. All of the bat roost sites that are reported in this document are considered to have a high sensitivity. Where the environmental thresholds differed from the heritage thresholds, the more conservative threshold, i.e. the lower PPV number, was applied.

The sites that are reported in this document are listed in Table 1.

Astron Cave 4	417586	7594895

Table 1 List of sites that were assessed and reported in this document

3 Methodology

The level of required blast control depends on a combination of environmental significance and geotechnical sensitivity. These assessments are recorded on a matrix and the vibration thresholds, and other possible controls, determined depending on where it plots on the risk matrix (Figure 17). The Peak Particle Velocity (PPV) thresholds are based the Australian Standard AS2187.2 – Ground Vibration and Air blast Overexposure and discussions with the Explosive and Dangerous Goods team.

Some of the terminology used to describe the different areas of the caves or overhangs are explained in Figure 1.

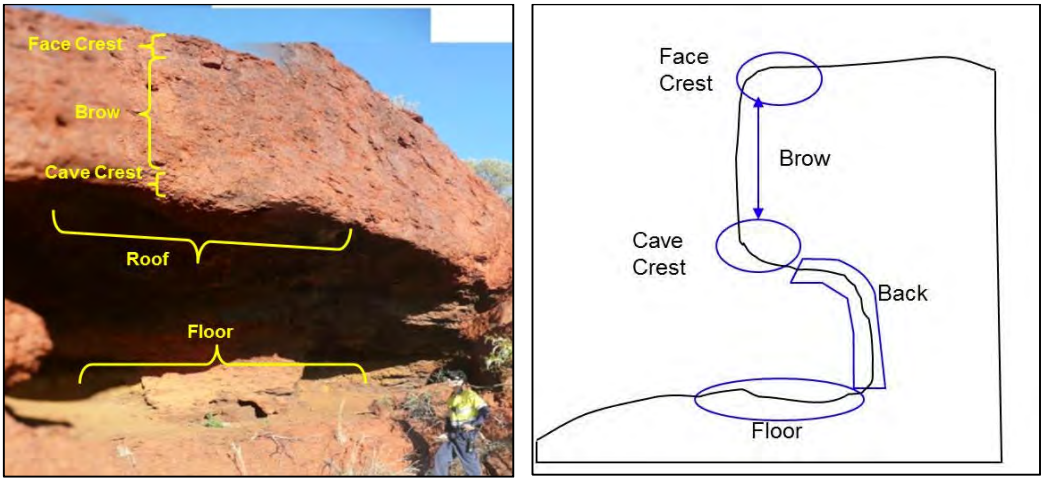

Figure 1 Explanation of terminology used in this report.

The size descriptions for the caves are based on the hydraulic radius measured in the field. In general cave sizes that are:

- Small caves – 1-50 m^2
- Medium caves – 51-100 m^2
- Large caves – 101 – 150 m^2
- Very Large caves >150 m^2

The size descriptions of historical rock-falls are based on size of particles in the rock-fall. In general the sizes are as follows:

- Very small rock-fall – very small size gravels and cobbles/slabs (< 0.1m)
- Small rock-fall – small size boulders/slabs (0.1 - 0.3m)
- Medium rock-fall – medium size boulders/slabs (0.3 – 0.6m)
- Large rock-fall – large size boulders/slabs (0.6 – 1.0m)
- Very large rock-fall – very large size boulders/slabs (> 1.0m)

4 Mesa H Assessments

The sites that were assessed for Mesa H are shown in Figure 2.

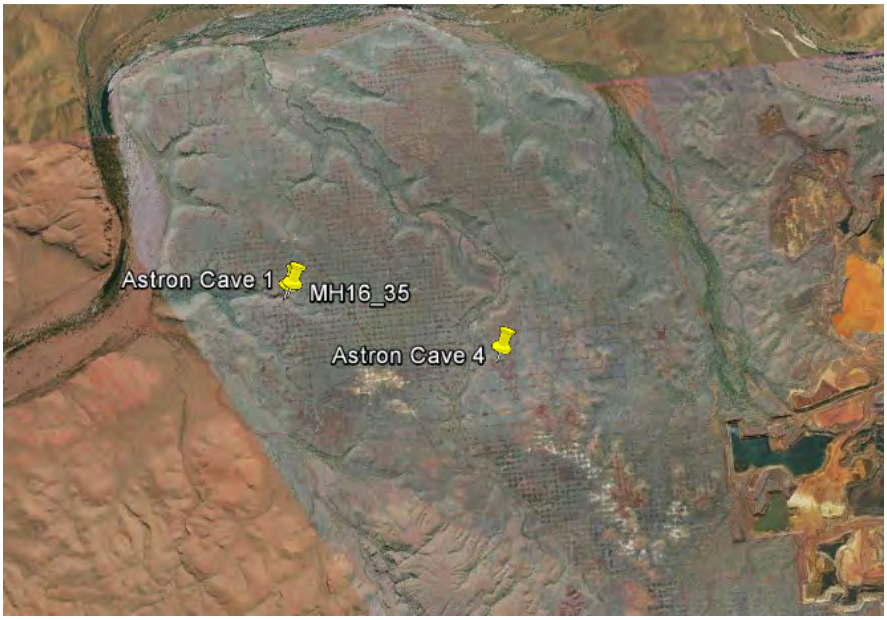

Figure 2 Location of environmental sites in Mesa H.

4.1 Astron Cave 1

Astron Cave 1 is a large (20 W x 3.5 H x 12 m D) cave developed in hydrated hardcap. There are three different entrances and two pillars. The roof is dome shaped. The floor is sloped towards the entrances and is covered in sediment and some historical rock falls. There is relic bedding which is tight, short, undulating and rough. There are no major joint sets in the cave. There are smaller random discontinuities throughout which are short and tight. Some roof slabs have developed along bedding planes and there are signs of spalling on the roof and walls of the cave. The pillar to the north appears sound with no defects. The south pillar has bedding and some random defects throughout with cracks opening up. The brow appears stable, with some minor spalling. There is a moderate rock fall potential at this site. The likelihood of a structural instability of the cave is rated as low.

Based on the absence of large continuous structures that could lead to collapse of the cave the geotechnical sensitivity of this site is rated as low.

The recommended PPV threshold is 50mm/s.

Figure 3: General view of Astron Cave 1

4.2 MH16_35

The site is a large (8 W x 4 H x 8 m D), wide cave developed in hydrated hardcap pisolite. It has a dome shaped roof, with a floor that inclines towards the rear with a large hump in the middle from historical rock falls, varying in size from medium to very large. These historical rock falls also partially obstruct the cave entrance. There is a secondary cavern at the western side of the cave and widely spaced relic bedding that disappears towards the rear of the cave where the structure becomes more massive. There is minor discontinuities near the entrance, however these are short and are not visible towards the rear of the cave. There is minor spalling around the centre pillar of the entrance, with potential for some smaller slabs to fail. These failures would not block the cave entrance. The roof and walls are stable inside the cave. The brow is stable with no signs of spalling or loose rocks above the brow. However the roof is a long unsupported span which increases the risk of failure. There is a moderate potential of rock fall in this cave but the likelihood of overall instability is rated as low.

The absence of large scale structures and low likelihood of overall instability results in a low geotechnical sensitivity rating of overall instability. The geotechnical sensitivity to rockfalls is also rated as low..

The recommended PPV threshold is 50mm/s.

Figure 4: General view (MH16_31) Blue arrow indicates central pillar; red oval is historical rock falls.

4.3 Astron Cave 4

Astron 4 is a large (7 W x 3.5 H x 25 m D), deep cave developed in hydrated hardcap pisolite. The cave is square shaped, with a flat roof controlled by relic bedding. There are large historical rock falls on the floor. The main structures in the cave are relic bedding planes spaced ±1 m, tight, cemented and persistent through the whole cave. The floor rises towards the rear of the cave where the internal height is around 1.5 m. There are a number of additional random joint sets all widely spaced which are vertical to sub-vertical dipping which define side walls of the cave. The main structural concerns are the well-defined large blocks in the roof, similar to the historical rock falls on the floor of the cave. There is a moderate potential for rockfall in this cave. Due to the tabular shape and size of these rocks, it is not expected to impact on cave entrance, in the event of a rock fall. No large scale instabilities are expected.

The sensitivity for overall structural collapse is rated as low. Due to the large blocks in the roof which have potential to fall as well as historical rock fall evidence, the geotechnical rock fall sensitivity of the site is rated as medium.

The environmental PPV threshold of 50mm/s.should apply to this location.

Figure 5 Entrance to Astron Cave 4.

5 Recommendations

The recommended blast vibration thresholds are based on a combination of the environmental significance and the geotechnical sensitivity. The results are summarised in Table 2 and Figure 6. All the sites assessed have a recommended PPV threshold of 50mm/s.

The scaled distance method as outlined in the Australian Standard AS2187.2:2006 should be used to determine the expected vibration levels at the sites. In the absence of site specific data, use of proxy constants K = 1140 and b = -1.6 can be used as a starting point. Should the calculated vibration levels exceed the recommended thresholds, the Drill and Blast team can:

- develop site specific K and b values, or
- modify the blast design to reduce the maximum charge weight.

Cave/shelter ID	Environmental Rating	Geotechnical Rating	Recommended PPV
Mesa H			
Astron Cave 1	High	Low	50
MH16_35	High	Low	50
Astron Cave 4	High	Low	50

Table 2 Summary of recommended blast vibration thresholds

Should the predicted estimated thresholds levels still be exceeded following these modifications, a more detailed blast management plan should be developed.

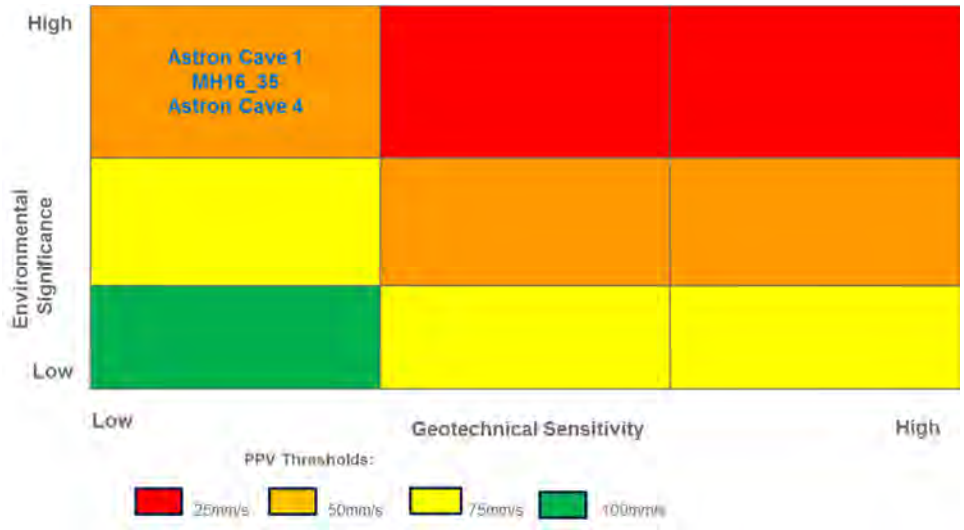

Figure 6 PPV recommendations based on environmental geotechnical assessments. All the environmental thresholds are 50mm/s.

1. Introduction

Explosives are charged into drilled holes and fired to break and loosen intact rock, so that ore and other material can be excavated and delivered to the processing plant, a stockpile, or a waste dump. Rio Tinto Iron Ore utilises around 200,000 tonnes of explosives each year in blasting across its Pilbara mines.

Uncontrolled ground vibrations from blasting can lead to damage or adverse effects to sensitive sites, so the blast planning process includes risks assessment and, where required, implementation of specific management plans to control blast vibrations.

This document highlights some recent examples of programs implemented by Rio Tinto's Pilbara mines to control blast vibrations and achieve a required risk level.

2. Blast vibration overview

Ground vibrations are generated from blasting buried explosives, and these travel through the ground in much the same way that sound travels through air. There are several types of waves generated (e.g. compressive, shear and surface waves), and the sum of these waves can be detected and measured using geophones, accelerometers or other sensors with appropriate data acquisition equipment.

A geophone glued to rock mass, ready to capture blast vibration data

Blast vibration is often expressed as a 'peak particle velocity', measured in millimetres per second. The vibration may be expressed in terms of the three orthogonal components (e.g. longitudinal, transverse and vertical), or the vector sum of these components. Key measures are defined in Appendix J of AS2187.2–2006.

The magnitude of measured blast vibrations depends on the size of the explosives charge fired, the blast timing (i.e. the layout and delays between firing successive holes), the distance from the blast to the monitoring location, the topography and the geological properties of the ground.

Table 1 shows the typical vibration levels associated with potential negative impacts to sensitive sites, and limits typically applied by Rio Tinto to prevent vibration-induced damage.

Table 1. Potential adverse effects from blast vibration

	Typical vibration levels (PCPV) associated with adverse effects	**Typical vibration control levels applied by Rio Tinto in Pilbara mines**
Human discomfort (residential areas)	> 5 mm/s	N/A (no residential areas directly impacted)
Human discomfort (industrial areas)	> 25 mm/s	< 25 mm/s
Minor damage to sensitive heritage sites (e.g. rock shelters with recognised heritage importance)	> 50 mm/s	< 25 mm/s (95% confidence)
Damage to buried gas pipeline	> 50 to 100 mm/s	< 10 mm/s (95% confidence)
Cosmetic damage to reinforced or framed structures (Industrial and heavy commercial buildings)	> 50 mm/s (as per Table J4.4.2.1 of AS2187.2)	< 25 mm/s (95% confidence)
Structural damage to buildings of reinforced concrete or steel construction	> 100 mm/s (as per Table J4.5(b) of AS2187.2)	< 50 mm/s (95% confidence)
Damage to communications or other key infrastructure	> 50 to 100 mm/s	< 25 to 50 mm/s (95% confidence)
Fracturing of intact rock	Typ. 250 - 1000 mm/s	

Notes: These values are examples only; in practice the vibration limits will be based on specific risk assessment, with due consideration of structural design, potential mechanical resonance and other factors. PCPV is the peak component particle velocity, defined in Appendix J of AS2187.2–2006.

2.1 Blast vibration modelling

Models can be developed to predict vibration, and refined over time as new data comes to hand and as pit conditions change. Figure 1 shows an example of a ‘scaled distance’ plot from a recent Rio Tinto vibration control project.

3. Recent examples of blast control in Pilbara operations

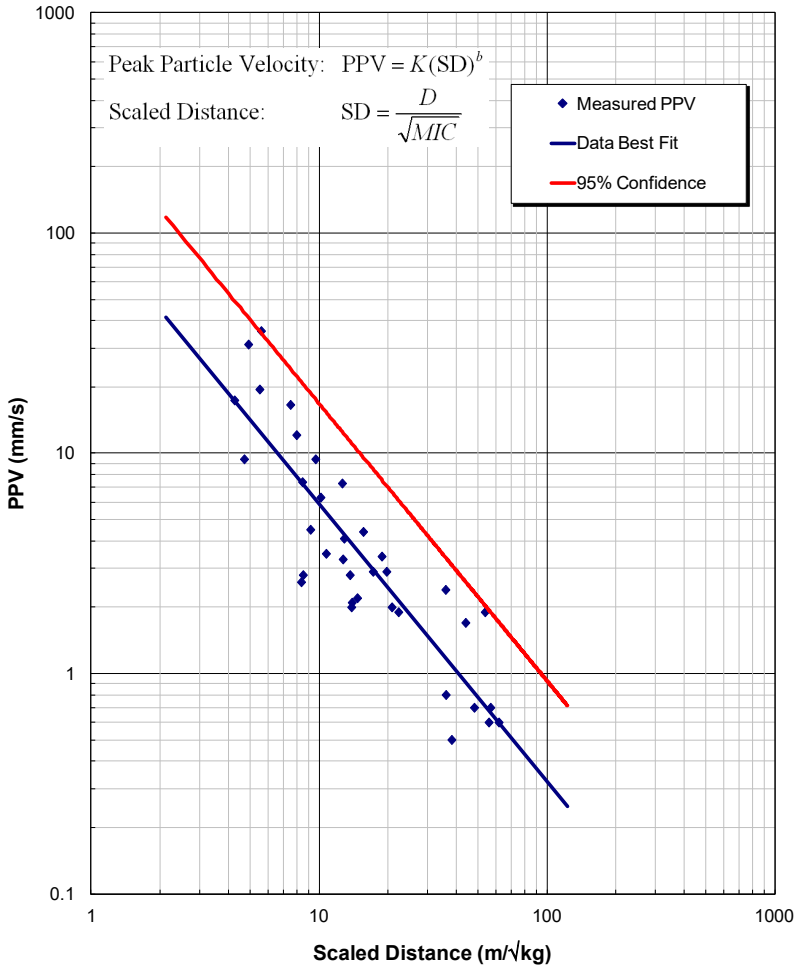
Vibration control and management projects are regularly established to protect sensitive sites. The projects may apply to a small number of blasts, or through a large mining area and last a number of years. The level of rigour applied is commensurate with the risk.

In a number of specific cases, Blast Vibration Management Plans have been put into effect to ensure that accountabilities and responsibilities are clear, appropriate test work is conducted, blast vibration is monitored and controlled through the blast design and execution phases, and review and reporting is completed to share insights.

3.1 Culturally sensitive sites

A number of rock shelters in the Pilbara are designated as having high cultural significance to the traditional owners. The proximity of some of these sites to mine pit limits means that tight vibration control is required to ensure the integrity of the sites. Current examples include sites on the Hope Downs 1, West Angelas and Tom Price mining leases.

Figure 1. Example of a Scaled Distance plot for monitoring & predicting blast vibration



Best Fit: PPV = 107 (SD)$^{-1.26}$ 95% Confidence: PPV = 305 (SD)$^{-1.26}$

$R^2 = 0.78$

105	158.4	2.6	8.3		469	68.9	0.7	56.5

A recent example is a rock shelter at West Angelas Deposit E. A management plan has been developed that defines limits on explosives charge per hole and per delay interval; quality assurance and control requirements; site access control; and monitoring and reporting expectations. The drill and blast engineers, blast crew and other personnel involved are all trained in the vibration control process.

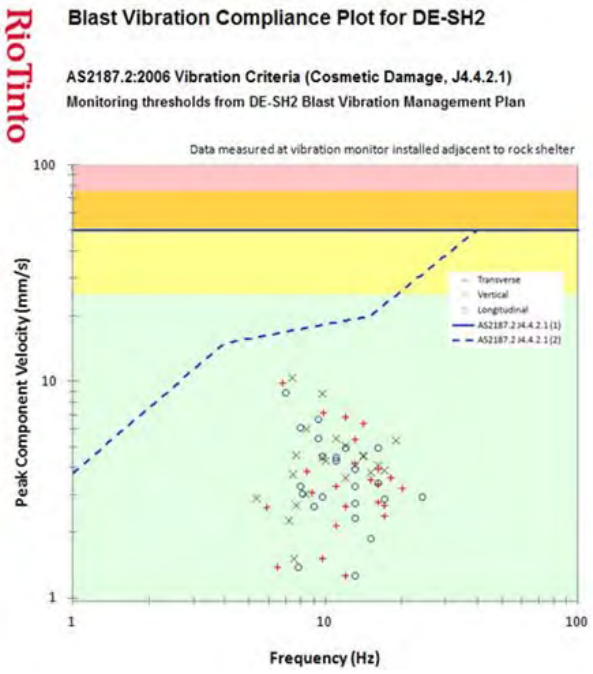
To establish the vibration criteria, a geotechnical survey was conducted to assess stability of the rock shelter and specific structures. In line with current best practice, a set of trial blast holes were individually fired to set a baseline for a vibration model.

To the end of October 2013, almost forty blasts have been conducted under the management plan, with no vibration readings outside of the target range. Figure 2 shows peak vibration through many blasts as measured adjacent to the rock shelter (blasts less than 1 mm/s are not visible).

The blast vibration model is regularly reviewed and adjusted to account for changing pit topography (e.g. the vibration response varies depending on the direction from a blast to the monitoring location).

Following the management plan will enable mining to within 60 metres of the rock shelter.

Figure 2. Example of Blast vibration data from West Angelas Deposit E rock shelter



3.2 High pressure gas pipeline at Eastern Range

A 10 MPa gas pipeline runs close to the Eastern Range mining area near Paraburdoo. Damage to the pipeline could lead to a rupture of the pipeline resulting in a loss of gas and the potential for an explosion.

A vibration control program was established in 2010 following test work in 2009. The test work involved development of a scaled distance vibration model, plus use of advanced vibration analysis tools to assess the 'worst case' vibration potential. The blast vibration management plan placed a vibration limit of 10 mm/s at the surface above the buried

pipeline. With blasts as close as 120 metres from the pipeline, a number of controls had to be established, including strict limits on the explosives charge per hole and per delay, reduced blast sizes, a custom quality assurance program and a strict reporting regime.

3.3 Protecting Troglobitic fauna at Mesa A

'Troglofauna' species and populations have been identified at the Mesa A mine. Blasting activities during mining have the potential to cause collapses of strata and other features such as mesocaverns in the retained portion of the mesa formation. There is also the possibility of direct impacts on fauna close to blasting activity through direct physical effects.

A blast management program was established at Mesa A to ensure that blast vibrations are controlled and potential for damage beyond the defined 'mining exclusion zone' is limited. This program is ongoing to ensure that the troglofauna are protected.

3.4 Communications tower at Yandicoogina

At the Yandicoogina central pit, a key communications tower is located less than 30 metres from the pit crest. Due to the resonant nature of the tall structure, a blast vibration control program was put in place whilst blasting within 100 metres of the tower, to ensure that blasts were engineered to avoid undesirable vibration frequencies that could induce significant mechanical stress.

Small scale test blasts were conducted to identify the dispersion and attenuation characteristics of the rock mass, and to characterise the frequency response of the tower. Blasts were simulated to assess the dominant frequencies that the blast would produce, and the blast timing adjusted until requirements were met.

The subsequent production blasts were conducted without any damage to the tower.

3.5 Cape Lambert Port B Construction Blasting

The construction of Cape Lambert Port B necessitated blasting within close proximity of critical port and infrastructure and ongoing construction works. These included blasting:

- within 10m of live rail;
- within 2m of concrete;
- immediately under live water mains;
- within 30m of a gas pipeline;
- within 30m of a diesel line;
- within 50m of office buildings;
- for shallow trenches whilst managing fly rock; and
- for presplit rock faces to minimise construction footprint.

A variety of techniques including varying drill hole diameters, drill angles, uncharged holes, deck loading and air decking were combined with careful initiation sequencing to ensure all blasting met required rock fragmentation without exceeding blast vibration limits, fly rock occurrences, whilst controlling shear force acting on the existing infrastructure from blast muckpile displacement.

Blast design parameters to predict PPV limits were calibrated through a heavily observed blasting monitoring program. The monitoring included video surveillance and ground vibration monitors for every blast on site.

A stringent blast management plan was also put in place to ensure all personnel involved in the blast were safely evacuated behind blast radiuses. Blast wardens were elected and trained for every contractor and RTIO department affected by the blasting.

3.6 Pit walls

The underlying intent of blasting is to break rock for subsequent excavation; this is in direct opposition to the need to maintain structural integrity of pit walls for safe and economic mining. Vibration monitoring programs have been setup at a number of mines to establish criteria for safe and effective blasting that minimises unwanted damage to pit walls. In these cases, the use of vibration measurement equipment forms a key part of the monitoring and review elements of the continuous improvement cycle.

4. Conclusion

Rio Tinto follows best practice methodology in managing blast vibration risks to people, cultural heritage, threatened species and other environmental concerns. AS2187.2–2006 provides guidance on vibration control and management, and this represents the baseline (minimum requirement) for vibration management in Rio Tinto's Pilbara operations. Advanced vibration analysis techniques are used where required.

Rio Tinto has developed strong internal vibration control capability and knowledge across the mining teams. The examples provided in this report are a selection of projects across Rio Tinto's Pilbara iron ore mines where blast vibration control allows safe, effective and sustainable mining.

1. SUMMARY

An annual biophysical/ ecological survey of the Robe River (the Pilbara region of north-western Australia) was conducted in April 2017, as on-going commitment to assess environmental impacts of mine development at Mesa J on the adjacent and downstream aquatic ecosystem of the river (largely the permanent, 'refugial' pools). The aquatic monitoring program was undertaken by *Streamtec Pty Ltd* and commissioned by Rio Tinto (RTIO). This assessment has been conducted annually since 1991 (*i.e.* before mining at Mesa J). This sampling addresses specific commitments made under the (then) Western Australian Minister for the Environment (see Conditions, 7.2.3, 7.2.4, 7.2.5 and 7.2.7) and later under *Ministerial Statement MS208* (see Conditions 3, 4 and 5).

The long-term biophysical/ ecological surveys of the Robe River are an integrated , long-term assessment of environmental parameters including aquatic fauna (*i.e.* aquatic macroinvertebrates and fish), channel/pool morphology, riparian/bank condition, weeds, water flows and water quality.

The significant value of this program is in its long-term commitment to assess impacts, if any, of mining and evaluate these in the context of extreme natural events which typically have a long-term return frequency (*e.g.* prolonged dry-spells, tropical cyclones). The study is an upstream-downstream design, where upstream sites (those from Mesa J) serve as controls for 'impact' sites occurring in the pools downstream from Mesa J. This study has been nominated as a Global Long Term Ecological Research (LTER) site[1] where sampling design/methodology have been consistent over the near-thirty year duration of the program.

The current survey conducted April 2017 is consistent with the framework outlined by previous findings that changes in ecological conditions of the pools, are primarily the result of seasonal and annual variation in rainfall and subsequent river flows with extreme natural events (and dry spells) providing the overarching ecological 'framing' context. The April 2017 sampling was conducted following the 'wet season'. In this survey, although water levels were elevated and 13 pools were located. Additional pools were located with assistance of two local Indigenous Elders accompanying the sampling trip.

In April 2017, the pools sampled were: Martangkuna ('Permanent Pool'), Pulari Nyunangka ('Duck Pool'), Japanese Pool, Medawandy Waters, Pannawonica Hill Pool, Thintuoona[2], 'Cams Pool', Pirathalu, Gungaree[2], Ngalooin ('Mussel Pool'), Yarramudda, Gnieraoora ('Yeera Bluff') and Robe Pool[2]. Although pool water levels were low, there were measurable flows at Pannawonica Hill, Pulari Nyunangka, Yarramudda, Gungaree, Martangkuna, Cams Pool and Medawandy Waters. However, the rate of these flows was low generally at between 0.25m^3/s and 1m^3/s.

Fixed station underwater cameras were trialed for the fish surveys and found to be largely unsuitable due to the inherent high turbidity of the water. Acoustic cameras will be further tested as a technique suitable for highly turbid water (note, these camera can record at night). Additional techniques to be trialed include assessing the value of environmental DNA (e-DNA) and the required genetic 'fingerprinting' of fish. If this technique proves suitable, it will only require a pool-water sample to determine the fish present.

Detailed statistical (*e.g.* aquatic fauna) and qualitative analyses (*e.g.* of riparian condition) of April 2017 data showed there have been no statistically significant or qualitatively detectable changes to the aquatic ecology/ environmental conditions of the Robe River pools adjacent and downstream to Mesa J that could be attributable to mining and its attendant operations alone. This annual assessment is consistent with previous analyses (1991-2017) where extreme natural events (*e.g.* tropical cyclones and extended dry spells) determine the structure of pool morphology, riparian condition and consequently the pool ecological assemblages.

1. The Long Term Ecological Research (LTER) Network was created by the US National Science Foundation in 1980.
2. Signifies a newly-sampled pool in 2017. Robe Pool was visited, but not sampled due to cultural sensitivities.

Field sampling the focal Robe River pools emphasised the prior influence of wet periods on pool biodiversity; with most of the fish observed being juvenile presumably as the pools were re-colonised following hydrological re-connection. The number of aquatic macroinvertebrate species collected during April 2016 (67 taxa= 'species') was low when compared across the long-term data record. At the individual pool level, macroinvertebrate species diversity ranged from 33 species at Pannawonica Hill Pool to 40 species at Pirathalu. A total of seven species of fish were observed (Spangled Perch, Barred Grunter, Bony Bream, Fortescue Grunter, Rainbowfish, Eel-tailed Catfish and Freshwater Mullet). The dominant species observed were Bony Bream (*Nematalosa erebi*), Rainbowfish (*Melanotaenia splendida australis*) and a highly-regional endemic, the Fortescue Grunter (*Leiopotherapon aheneus*).

The water chemistry of the pools was of high biological quality with the exceedances of ANZECC (2002) Trigger Levels limited to turbidity and a small elevation of total phosphorus (0.02mg/L *vs.* ANZECC/ARMCANZ Trigger Value 0.01mg/L) at Pirathalu. This small increase over the trigger values for nutrients is considered a consequence of unrestricted livestock access to the pool. Dissolved oxygen levels were low; a consequence of high water temperatures (29-31^{O}C). Salinity/conductivity showed a gradient of increasing concentration downstream (*e.g.* 571µs/cm at Ngalooin to 996µs/cm at Thintuoona; near the railway crossing). This gradient is considered a function of the underlying geology. Pool turbidity was highly variable ranging from 2.7NTU at Martangkuna to approaching 30NTU at Gnieraoora.

Vegetation condition of the riparian zones was good and the riparian weed Mexican Poppy which, in the past, has been common was recorded at low levels of infestation in 2017, both upstream and downstream of Mesa J. The emergent aquatic weed (Indian Fern) was observed at some sites (*e.g.* Yarramudda where it occupied a small area of ~2.5m^2). Both weeds can be spread directly by human activities. The bulrush *Typha* was common at many sites and dominated the shorelines at Yarramudda.

The re-sampling of the pools in April 2017 followed significant rainfall and river flows during December 2016/ January 2017. Consequently, the ecological condition of the pools has shown a level of recovery reflecting the ability of fauna, particularly fish, to re-colonise the previously dry reaches of the river. Therefore, any artificial barriers to migration (*e.g.* badly-placed culverts) have the potential to limit upstream fish movement; however during high flows most culverts are generally 'drowned-out' (*e.g.* the low level crossing at Mesa J) and not considered to represent a significant obstacle to migration.

2. STUDY CONTEXT

This study addresses important Ministerial Requirements and environmental commitments related to management of mining and associated activities of RTIO largely at Mesa J.

The initial Mesa J- Environmental Management Program outlined in a Consultative Environmental Review (CER) (Robe River Iron Assoc. 1992). Section 5.1 outlined a requirement for a monitoring program of key permanent river pools adjacent to Mesa J (see Streamtec 1991) both upstream and downstream of operations at Mesa J. In this design, the upstream sites serve as controls. The parameters measured in these pools by Streamtec (1992), (turbidity, salinity/ conductivity, depth, pH, dissolved oxygen, nutrients, water temperature and aquatic fauna) formed the basis of all subsequent monitoring and environmental assessments. The sampling from 1992 (Streamtec 1991-2016) addressed the following Environmental Commitments of the CER:

7.1.1 Develop and implement environmental monitoring and management programs for the mining operation and associated activities in the course of the project implementation.

7.1.4 Minimise as far as practicable, recognising the requirements of the mining and ore transfer, direct and indirect alteration of the physical environment for the duration of the project.

7.1.7 Monitor and manage dewatering of the mining area, and discharge of excess water to adjacent watercourses.

7.1.8 Take appropriate steps to protect and manage hydrology and vegetation within the adjacent riverine environment.

7.1.9 Monitor and manage any scour or siltation in the Robe River and Jimmawurrada Creek adjacent to the project.

Following the acceptance of the CER (Robe River Iron Assoc. 1992), the conditions set by the (then) Minister for the Environment were addressed by the monitoring program (Streamtec 1991-2016) where:

7.2.3 Environmentally Significant Areas: "The Robe River- Jimmawurrada Creek environment, its vegetation, water levels and water quality, and particularly the permanent pools of the Robe River, are to be protected from unacceptable direct and indirect impacts of this project during the life of the project, recognising the requirements of mining and ore transport."

7.2.4 Drainage Management: "The Robe River- Jimmawurrada Creek system needs to be protected from pollution and unacceptable sedimentation, recognising the requirements of mining and ore transport".

7.2.5 Dewatering Management: "The permanent pools and vegetation of the Robe River- Jimmawurrada Creek system are to be protected from unacceptable environmental impacts, recognising the requirements of mining and ore transport".

7.2.7 Environmental Management Programme: "A comprehensive management programme should be prepared to integrate the various components in conditions" (e.g. 7.2.3, 7.2.4, 7.2.5).

Key Project Approvals addressed by this monitoring program are under Part IV of the Environmental Protection Act 1986: Mesa J- Ministerial Statement 208.

Rio Tinto produced an Operations Environmental Management Plan (RTIO-HSE 0162720:2012). Sections 4.1 and 4.2 relate to water abstraction and discharge. Appendix 1 of that document outlines the comprehensive monitoring program developed for the Robe River.

The Rio Tinto "*Robe Valley Mesa J&K Surface Water Management Plan*" (RTIO-PDE-0068650, see http://iodms/iodms/wdk/theme/documentum/images/space.gif) outlines a framework for effective water management. The potential environmental impacts of climate change in the Pilbara were also identified as a potential risk. The long-term Streamtec study, by providing an extensive time-series (1991-2017), is clearly well-placed to assess impacts to surface water ecosystems, from both mining, natural and larger-scale anthropogenic influences (*e.g.* climate change). In addition, by including control sites (*i.e.* upstream of Mesa J in the program), any changes to ecological baselines, in the absence of mining, can be determined and consequently better-managed.

3. INTRODUCTION

The current program outlined in this report (conducted during April 2017) was commissioned by Rio Tinto (RTIO) to assess impacts, if any, from their mining activities on Robe River pools as per relevant Western Australian Ministerial Statements (see previous). This on-ground program incorporates an annual aquatic ecosystem survey of Robe River pools as part of an on-going commitment to assess any environmental impacts of mine development on the adjacent and downstream aquatic ecosystem (see ecologia/Streamtec 1992, Streamtec 1992 –2017).

The Robe River is situated in the Pilbara bioregion of Western Australia. Rivers and streams in this region are typically episodic with flow occurring following significant rainfall events. The Pilbara has an extreme and highly variable climate changing due to both natural and more recently, through global anthropogenic influences.

In the Pilbara, rainfall has recently been steadily increasing from the northeast and evaporation rates exceed rainfall by a factor of more than 10x. Following rainfall, generally there is only limited run-off and an even smaller fraction recharges groundwater. Despite this, groundwater recharge is required to maintain pool water levels during extensive dry periods. In the Pilbara, it is estimated that about 200GL of (high quality) de-watering is discharged into rivers each year (McFarlane 2015).

During the dry season, rivers are usually restricted to a series of permanent pools; providing an important refuge for both terrestrial and aquatic fauna. The faunal assemblages essentially 'contract' to these pools during dry periods, to re-invade other regions of the riverine system following significant river flow.

Research on the freshwater fauna of Australia's dryland river systems has been largely ad hoc. These systems are typically less disturbed than their counterparts in more populous regions, yet despite recognition of the importance of water-bodies in the Pilbara; there has been only short-term, generally limited scope ecological research.

The current sampling regime was initiated in 1991 offering an important set of data on an arid system within the Pilbara region. The annual assessment is important in providing knowledge of temporal and spatial variability in biological parameters. In addition to providing a better understanding of impacts, if any, associated with mining operations, long-term ecological monitoring improves our understanding of the natural variability (e.g. extended dry spells, tropical cyclones) within the Robe River catchment. This long-term assessment of the aquatic environment of the Robe River has shown natural events have an overriding influence.

To date there have been no detectable changes to aquatic fauna, water levels, water quality and riparian vegetation that could be attributed to direct mining operations at Mesa J. In addition, there have been no detectable impacts to the Robe River/Jimmawurrada Creek system from pollution, unacceptable sedimentation and unacceptable environmental impacts that could be attributed to direct mining operations at Mesa J.

Differences in ecological parameters of pools, is primarily influenced by seasonal climatic influences, with a major determinant factor of variability in both aquatic fauna biodiversity and water quality being pool morphology and permanence (*e.g.* Streamtec 1992-2015). This existing baseline data, combined with continued monitoring of the Robe River, will allow informed solutions to be made on current and future environmental issues and catchment-scale activities.

PROJECT OBJECTIVES

- The completion of an aquatic biomonitoring program (*e.g.* macroinvertebrates, fish, water quality, flows, pool morphology and riparian condition) of significant pools located on the Robe River. Sample sites included thirteen permanent pools (see Appendix 1).

- In order to gain a better understanding of broad-scale ecosystem resilience of the pools, a survey of the Robe River was conducted to identify additional permanent pools (both upstream and downstream from Mesa J).

- Document and interpret the ecological significance of patterns or differences in pools both upstream and downstream of Mesa J.

- Compare biological data collected in 2017 with the previous record and assess any observed changes to natural events in or mining activities.

4. METHODS

Since the commencement of this sampling program (1991), sampling design and methodology have been standardised (with the same operators) and consistent among surveys. This enables valid comparisons to be made across the long-term monitoring period. Consequently the strength of this sampling program is its long- term nature. A summary and general description of the standard sampling protocol is given below. Detailed information on sampling in Appendix 2 and outlined in previous reports (see Streamtec 1991- 2015).

4.1 SAMPLING PERIOD

The present survey taken in April 2017 represents an "early wet" sampling; a period of reduced environmental 'stress' for resident aquatic biota. During this period, aquatic fauna is restricted to refugial pools after flows in December 2016. Previous monitoring has also been conducted following the 'dry season and other high rainfall events, providing a database across a wide range of flow and weather conditions.

4.2 STUDY AREA

The Robe River lies in the Pilbara biogeographic region of Western Australia. For the majority of its course, the Robe River is ephemeral in flow with wide, shallow floodplains. Localised flows and pools are maintained where highly permeable underground aquifers intersect surface river channels; forming isolated ecological 'refugia' (see Figure 1).

The climate of this region is typified by high temperatures, low rainfall (~ 400mm p/a), evaporation rates about 10x rainfall and largely unpredictable cyclonic activity. Rainfall occurs largely between December and June with maximum monthly falls typically recorded between December and April. Mining is near to the rivers course, at the Mesa J deposit, in the Eastern Deepdale region to the south-west of Pannawonica.

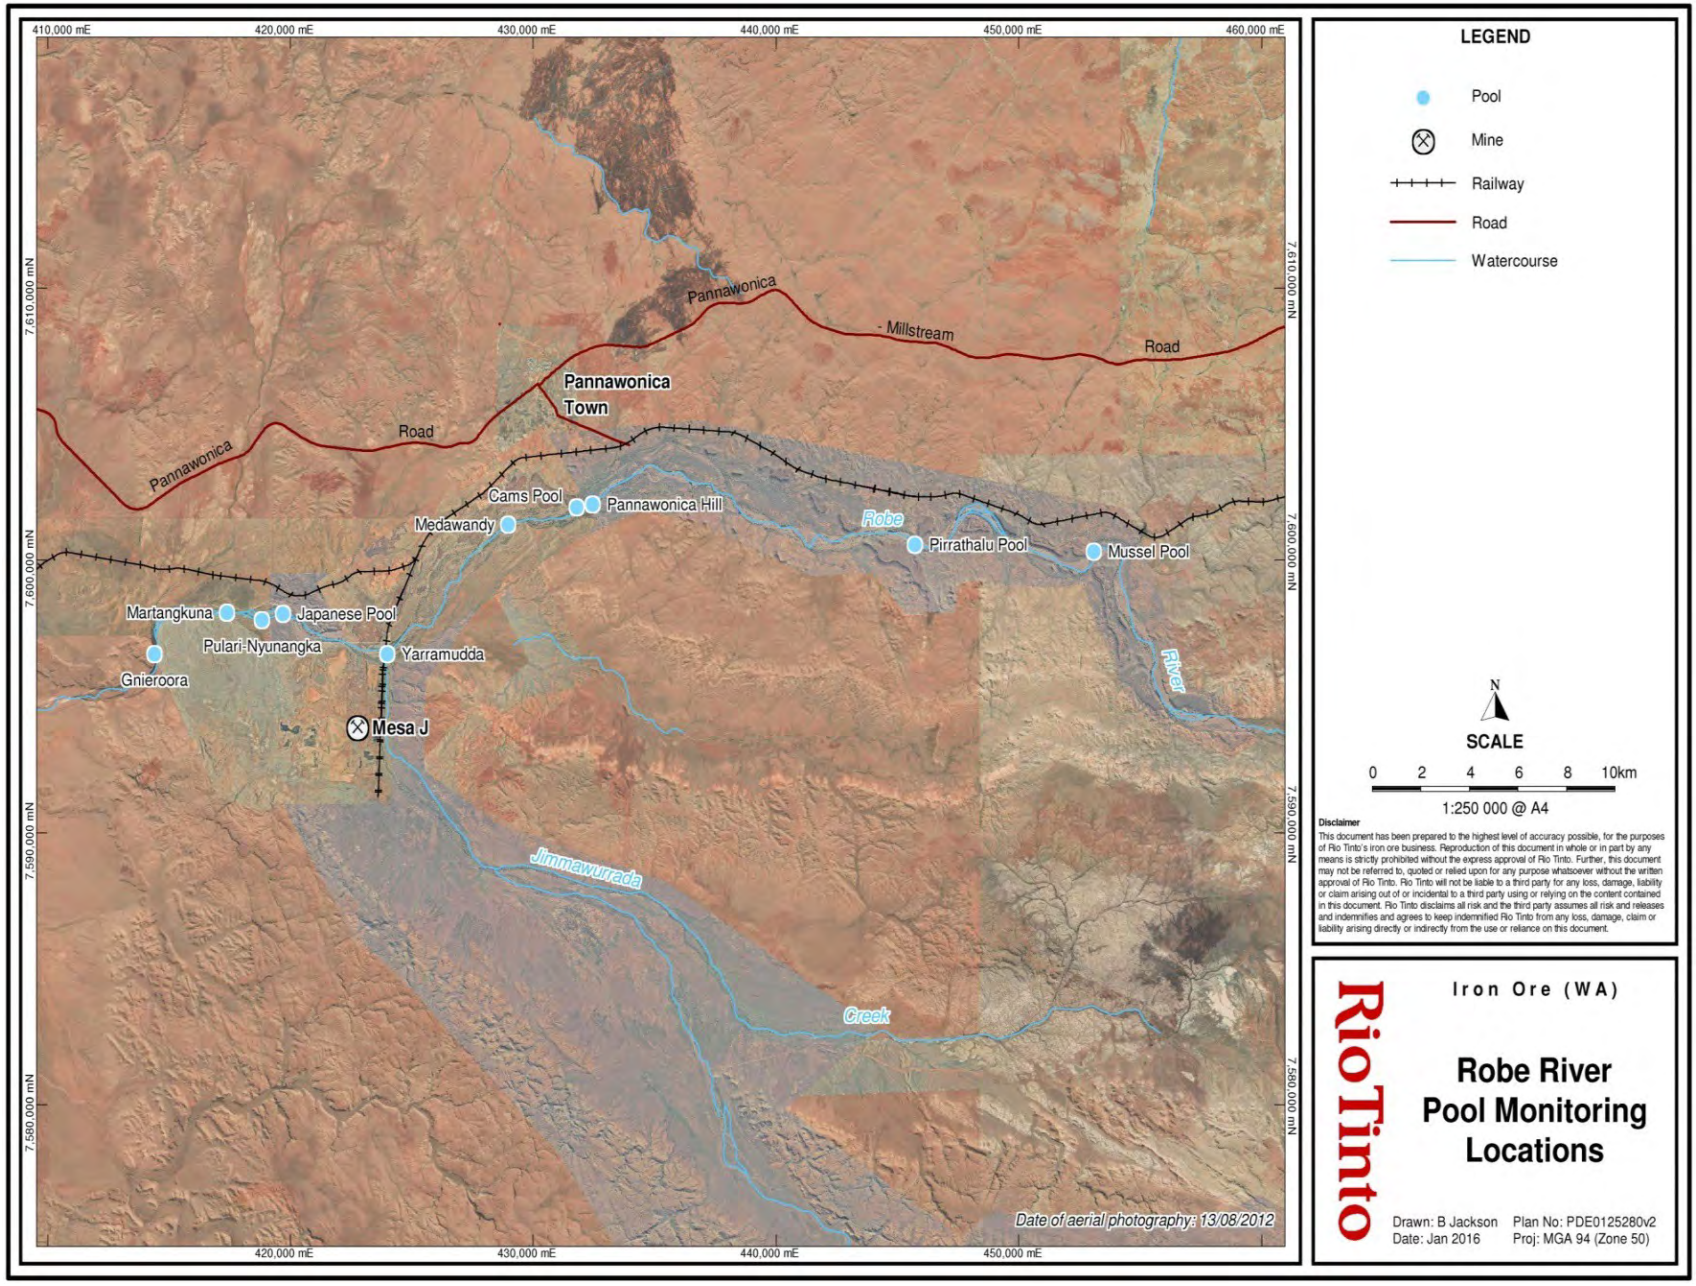

Figure 1. Position of the survey pools in the Robe River (note alternative spellings for Yeera Bluff Pool; Gnieraoora and Gnieroora). Note, Robe Pool, Thintuoona and Gungaree are off the scale of this map being further downstream (west) of these sites (see Appendix 1 for site details and coordinates).

4.3 STUDY SITES

The location of current study sites and their position relative to the Mesa J mine are shown in Figure 1. A total of thirteen focal pools were surveyed in 2017; Martangkuna ('Permanent Pool'), Pulari Nyunangka ('Duck Pool'), Japanese Pool, Medawandy Waters, Pannawonica Hill Pool, Thintuoona*, 'Cams Pool', Pirathalu, Gungaree*, Ngalooin ('Mussel Pool'), Yarramudda, Gnieraoora ('Yeera Bluff'), Robe Pool*. Although pool water levels were low, there were measurable flows at Pannawonica Hill, Pulari Nyunangka, Yarramudda, Gungaree, Martangkuna, Cams Pool and Medawandy Waters. (See Appendix 1, * represents a previously un-sampled pool).

The program's design is based on a BACI model (Before and After Control Impact) where sites upstream of Mesa J serve as control sites for downstream (potential impact) pools. The "before" sampling is represented by baseline surveys conducted in 1991, prior to significant mining operations at Mesa J.

Neither 'before' nor 'control' sites however, should be considered completely representative of pre-mine conditions as mining was initially conducted at Middle Robe between 1972 and 1982 and from Deepdale between 1972-1985.

4.4 HYDROLOGY - RAINFALL AND RIVER DISCHARGE

Patterns in rainfall river discharge were analysed to determine the relationship between hydrological indices and associated changes to pool morphology and permanence. Long-term rainfall data for Pannawonica (Station 5069) was provided by Climate Services, Bureau of Meteorology (Perth). Rainfall and temperature records for the Pannawonica were provided by RTIO.

4.5 PHYSICO-CHEMISTRY - MORPHOLOGY AND WATER QUALITY

Measurements of pool morphology and selected water quality parameters were made in conjunction with the aquatic fauna sampling at each focal pool. Water temperature, dissolved oxygen, salinity/ conductivity, turbidity, redox and pH were measured in situ (0.5 depth) using a YEO-KAL (YK-611) water quality analyser. Water samples were also taken for analysis of nutrients as both total nitrogen (TN) and total phosphorus (TP).

River pool morphology was determined with depth measurements (graduated pole) and pool width and length were qualitative measurements. Levels of fine inorganic sediment and areas of deeper water in each pool were qualitatively assessed and coded by rank (0-4), this was conducted during the fish surveys. The sediment category was assessed as the extent of deposited sediment cover over the natural shale-base of pools on an ordinal rank of 0-4; where 0=no sediment evident, 1=25% coverage, 2=50% coverage, 3=75% and 4=total streambed coverage.

4.6 MACROINVERTEBRATE FAUNA

The pool macroinvertebrate fauna was sampled at all sites (aside from Robe Pool where, due to cultural sensitivities, all sampling was conducted from the bank). Methodologies for collecting fauna were designed to sample the major aquatic habitats and maximise the number of species recorded at each site (see Appendix 2 for details). Quantitative sampling was conducted using a heel-kick (*sensu* Davies 1998) or sweep method (depending on habitat), compatible with the methodology of NRHP (National River Health Program) sampling protocols. Samples, containing sediment, detritus and aquatic macroinvertebrate fauna, were preserved on site.

In the laboratory, macroinvertebrates were removed from the samples under a binocular microscope and identified to the lowest taxon possible either by use of keys or by matching specimens to an existing voucher collection developed exclusively for the Robe River. The existence of rare, restricted or endemic species was determined by cross-referencing taxa lists for each site/habitat with a long-established database. Conclusions on the rarity of any macroinvertebrate species cannot be made with complete surety due to the inherent taxonomic uncertainties associated with this region.

4.7 FISH FAUNA

Fish were recorded by direct observation using a mask and snorkel (a two-assessment transect across 100m reach). A list of presence/absence for each species was constructed for each of the pools. Details of field methods are detailed in Appendix 2. Fish were identified to species based on taxonomy described in Allen (1989) and later in Allen *et al.* (2002). During the previous sampling trip, GoPro underwater cameras were trialed to 'de-risk' the sampling methodology. However, due to naturally high turbidity, the cameras were of limited value and in April 2017, the sampling reverted to direct observation. In the future, acoustic cameras will be trialed; these can operate in highly turbid water (including able to be operated at night).

4.8 RIPARIAN VEGETATION AND WEEDS

An assessment of local riparian vegetation condition was made on the basis of dominant plant species and relative degree of disturbance assessed as weed invasion, livestock damage and fire. Assessments were broadly based on the rapid assessment methodology outlined in Pen and Scott (1995) and WRC (1999). At each site, two 50m transects from the waters' edge upslope were made and the following parameters recorded: slope (in degrees), % leaf litter covering the soil, weeds (in area), livestock disturbance (low, medium, high), and over-story condition: 1= dead, 2= much leaf loss, many dead branches, 3= some dead branches, 4= pristine). Methods are presented in Appendix 2. Opportunistic, qualitative surveys were also made of the noxious aquatic weed Indian Water Fern, *Ceratopteris thalictroides* and the riparian weed Mexican Poppy.

4.9 STATISTICAL ANALYSES

Statistical analyses using ANOVA (analysis of variance) were used to compare spatial and temporal variations in water quality data. PRIMER (Plymouth Routines in Multivariate Ecological Research) computer package was used to describe multivariate (spatial and temporal) patterns in macroinvertebrate community structure and relate these patterns to changes in measured environmental parameters (*e.g.* water chemistry, pool morphology, riparian condition). Analyses were conducted on both species-level presence/ absence and macroinvertebrate abundance data. The relationship between community structure and the pools was analysed using a sub-set of the physico-chemical parameters measured. In summary, similarity matrices (between pools) were calculated based on macroinvertebrate assemblages. These similarity values were then represented graphically using hierarchical clustering (CLUSTER) and multidimensional scaling (MDS) to determine how similar pools were to each other in terms of aquatic fauna. Principal Components Analysis (PCA) was also used to summarise underlying patterns in environmental data.

5. RESULTS AND DISCUSSION

The sampling was conducted in the immediate post-wet period (April 2017). Previous sampling has typically been conducted during the late dry; a period of elevated environmental 'stress' to the resident aquatic fauna of the permanent pools.

5.1 HYDROLOGY - RAINFALL AND RIVER DISCHARGE

The Pilbara biogeographical region of Western Australia is characterised by low and unreliable annual rainfall and, when coupled with high annual evapo-transpiration rates (*e.g.* >10x annual rainfall), results in spatially-restricted aquatic ecosystems (pools). Rainfall is highly unpredictable with significant variation in annual rainfall. The coefficient of variation (CV) for rainfall for the Pilbara ranges 0.4 to 0.7 ('high') in comparison for south-west Western Australia CV is 0.2 ('low') and the Kimberley CV is 0.3 (see Figure 2).

Pannawonica receives the majority of its rainfall over summer in association with cyclonic events. Peaks in rainfall typically occur during January-March with months of lowest rainfall occurring in September and October (Figure 2). Natural flows in the Robe River, both upstream and downstream of Mesa J are tightly linked to annual rainfall patterns. Following trends in rainfall data, maximum flows are typically recorded following peak rainfall (Figure 2). Pool water levels during the dry period are maintained by groundwater (*i.e.* they are groundwater-dependent-ecosystems).

The Pilbara region has >3m evaporation per annum and as most permanent pools are considerably less than this depth, they are maintained by groundwater. Annual rainfall recharges levels and flows are linked to rainfall events. For analysis, these two seasons are referred to as "wet" and "dry". Long term analysis also identified two transitional seasons, the "ramp down" period where rainfall and hence flow declines following the wet and the "the ramp up period" when increasing rainfall and flow following the dry season (Figure 2).

5.2 CLIMATE

The climatic condition in the (approx.) 12 months period prior to the sampling is shown in Figures 3-4. The pattern of temperature and rainfall are considered typical for the region (10-45^{O}C). As previously discussed, heavy rainfall events and peak discharges are generally associated with tropical cyclones or monsoons. In the past, the highest category cyclones that have impacted the Pilbara coastline are listed by the Bureau of Meteorology and include TC Orson in April 1989, TC John in December 1999, TC Monty in March 2004, TC Clare in Jan 2006, and TC Glenda in March 2006.

These cyclones resulted in peak discharges and a number of significant flow events have been recorded in years following above average rainfall in consecutive months (*i.e.* January 1997). The large Robe River floods of September 1993 and January 2000 were also associated with monsoon lows. Flooding is often enhanced if flows follow rainfall that has already saturated the profile leading to elevated water levels.

These data suggest that significant flow events in the Robe River pools are either 'pulse' events that occur through peaks in monthly rainfall or when the extensive duration of rainfall is sufficient to maintain high water levels in the river.

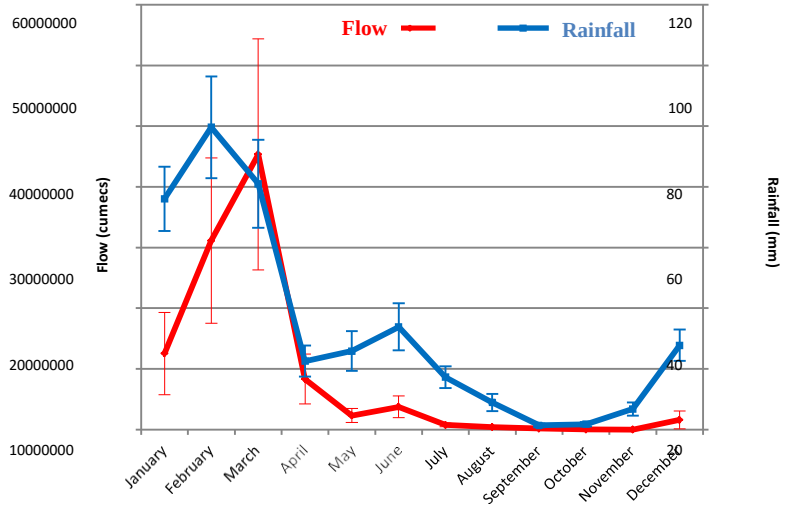

Figure 2. Average monthly flow and rainfall (± SE).
Rainfall measured at Pannawonica and flows at Yarraloola.

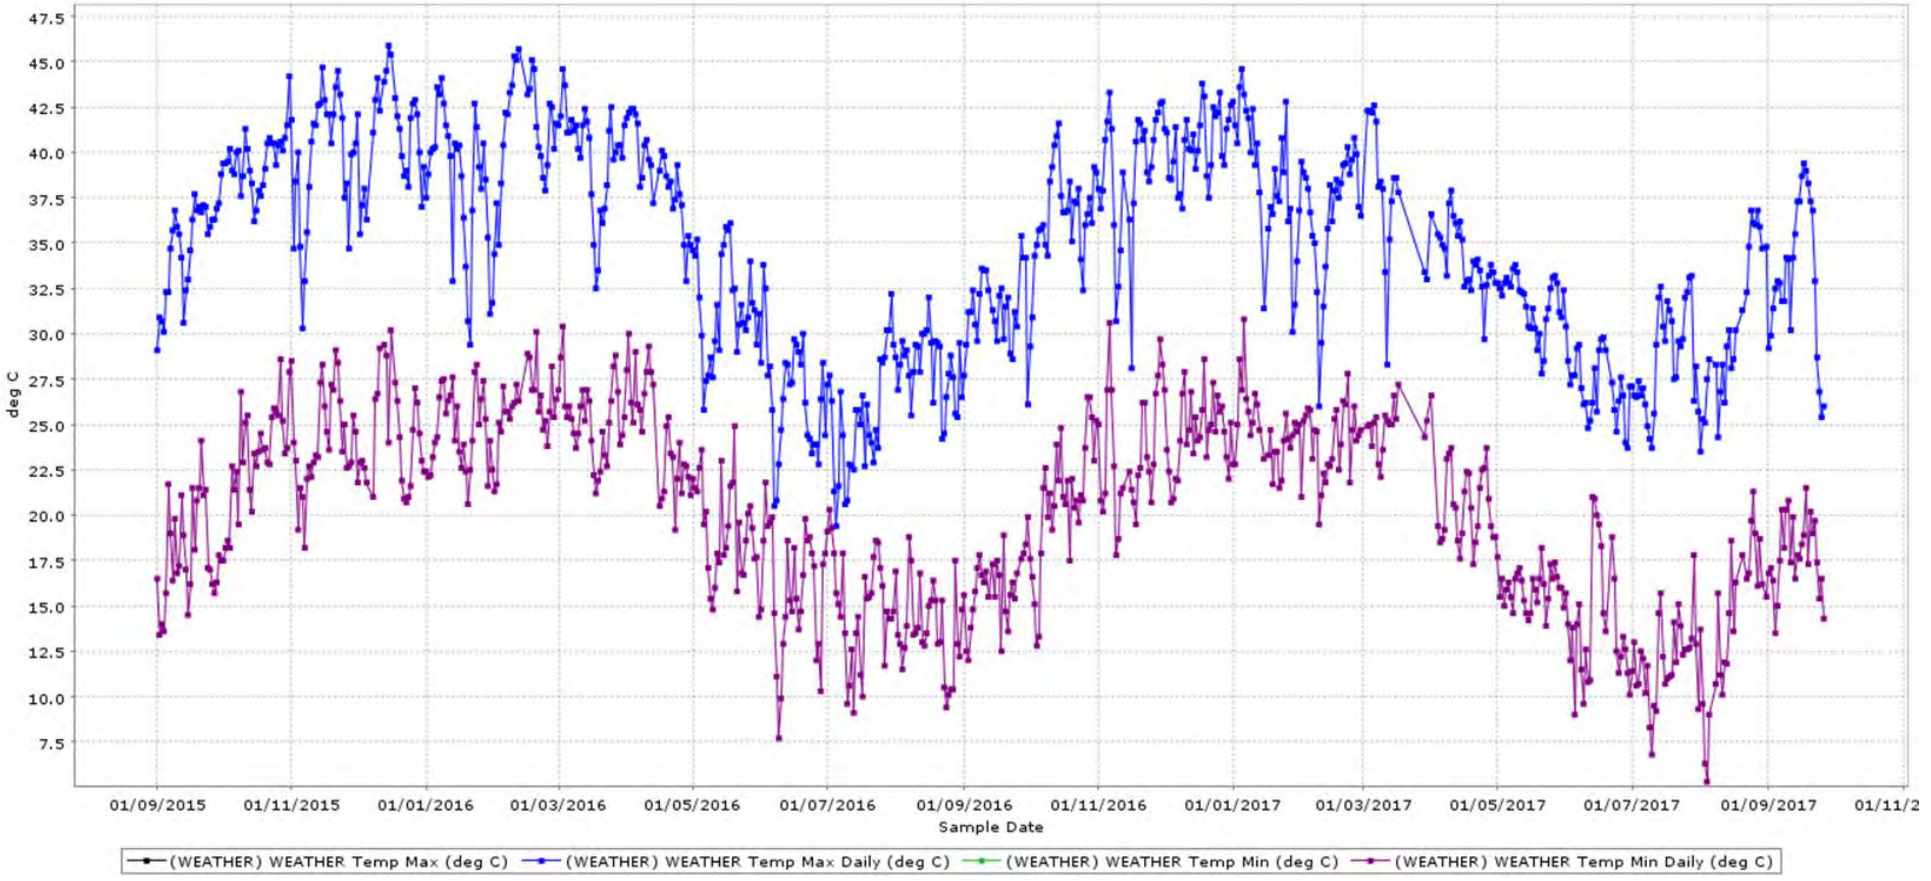

Figure 3. Maximum and minimum daily temperatures (°C) at Pannawonica townsite September 2015 to September 2017.

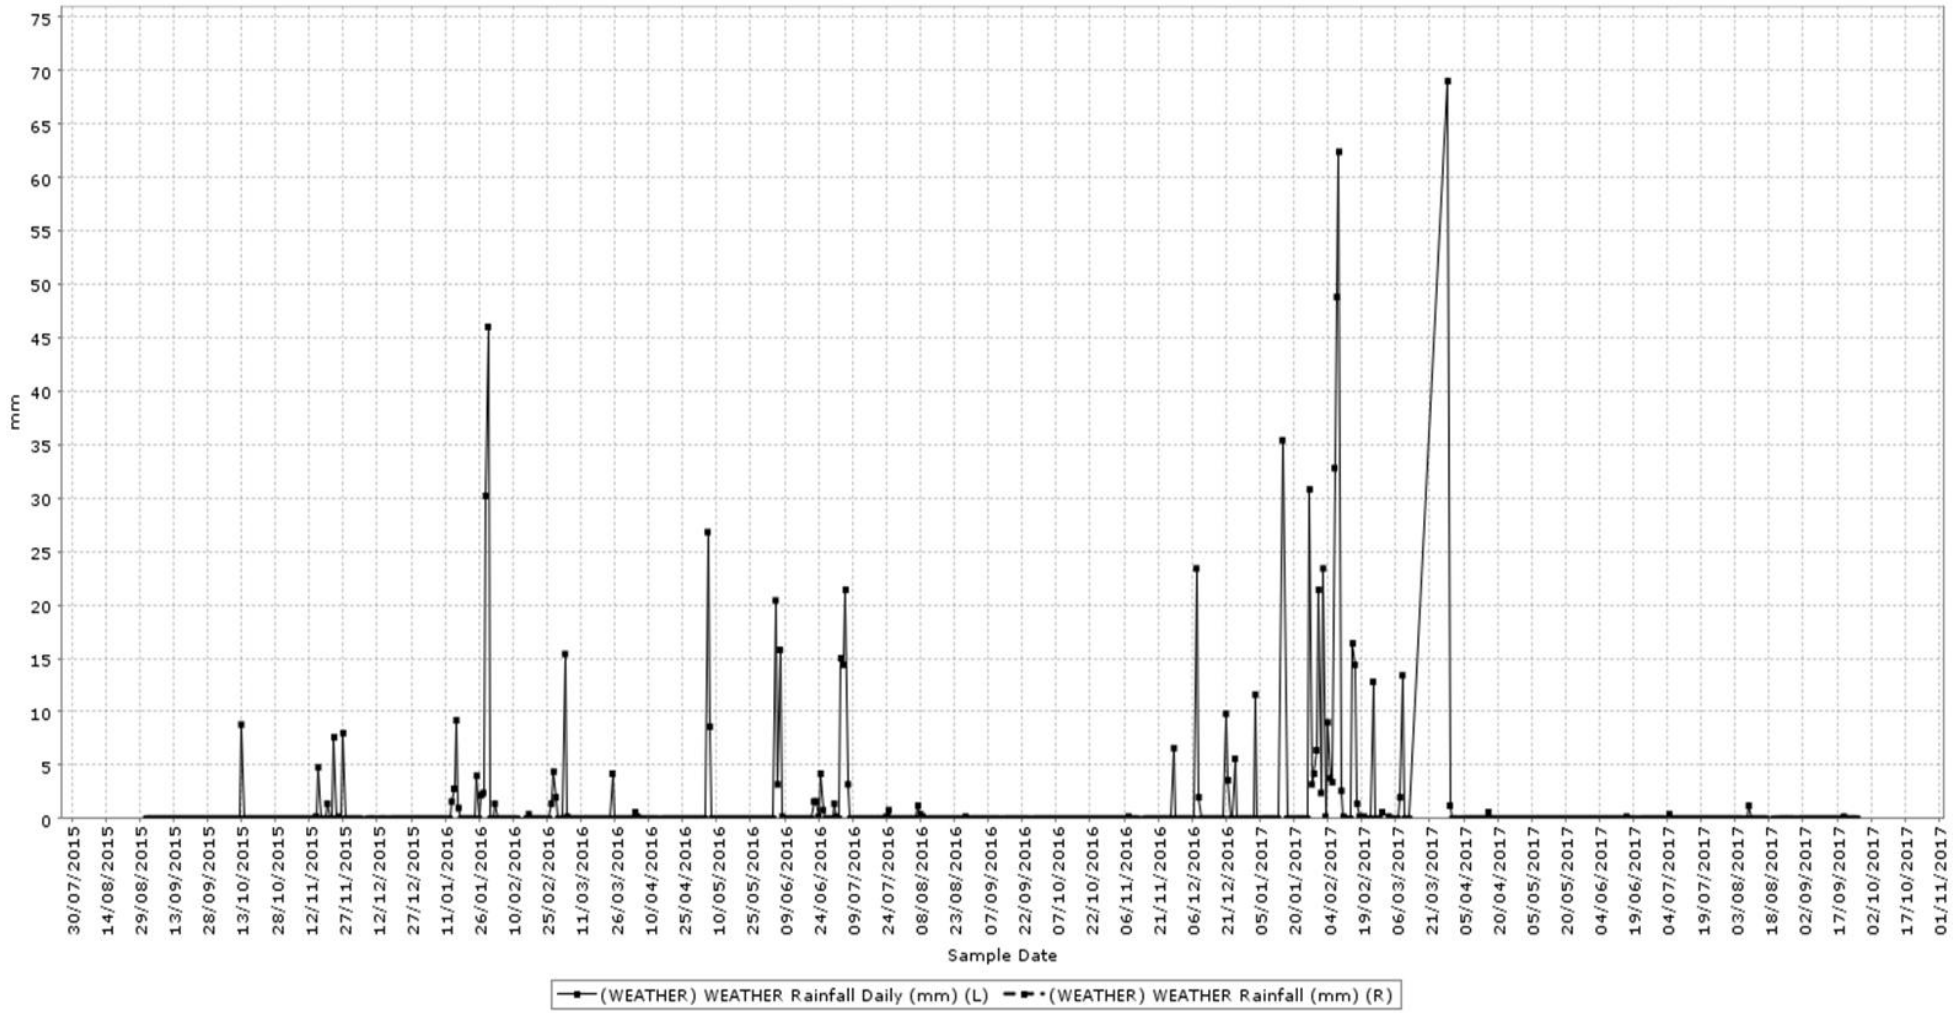

Figure 4. Daily rainfall (in mm) at Pannawonica townsite July 2015 to April 2017.

5.3 SUMMARY OF FLOW CONDITIONS

Since the establishment of the initial biomonitoring in 1991, considerable variance in rainfall and associated flow conditions have been observed within the Robe River. The timing of Robe River aquatic sampling in April 2017 followed significant rainfall in December 2016 and follow-up in 23rd March 2017 (~68mm; see Figure 4). The pool levels were high and presumably pools had been connected following the previous high- rainfall conditions.

Initial surveys in 1991 were conducted following a series of low-flow years. In September 1993, rainfall resulted in a flow event which at the time was the highest peak discharge on record. In subsequent years, relatively high water levels were maintained in pools by a number of high rainfall events. Then, from January 2001, three consecutive years' of lower than average rainfall (January 2001 to May 2003) resulted in significantly lower total annual streamflow being recorded at Yarraloola. In contrast, during March 2004, rainfall contributed from TC Monty to an above- average rainfall for the wet season (September and March). The delivery of this rain was constant over consecutive days and although significant flow was recorded at Yarraloola, there was no extensive flooding associated with this cyclone. At this time, the Yarraloola gauging station recorded the highest monthly discharge since 1972 (596611 ML), and total annual flows for 2004 were the highest on record. High flows were also observed during the sampling in 2014.

Significant rainfall events from tropical cyclones (*e.g.* Glenda and Clare) during 'summer' 2006 resulted in significant total monthly flows being recorded. Three consecutive months of higher than average rainfall resulted in high levels of discharge being maintained during January to March 2006. Following the October 2006, monthly rainfall was below average an in 2007 zero-flow was again recorded at Yarraloola. On the west coast of Western Australia a TC occurred each month from November 2007 to April 2008, resulting in higher than average rainfall recorded. The April 2017 sampling followed significant rainfall in the preceding months (*e.g.* 24mm 6th December 2016, 36mm in 20th January 2017, 63mm in February 2017 and 68mm in March 2017. Long term annual rainfall for Pannawonica is 427mm (Figure 5). There has been a trend, across the >40 year rainfall record, for increasing annual rainfall. This is consistent with some of the predictions for climate change in the Pilbara and Kimberley regions of Western Australia.

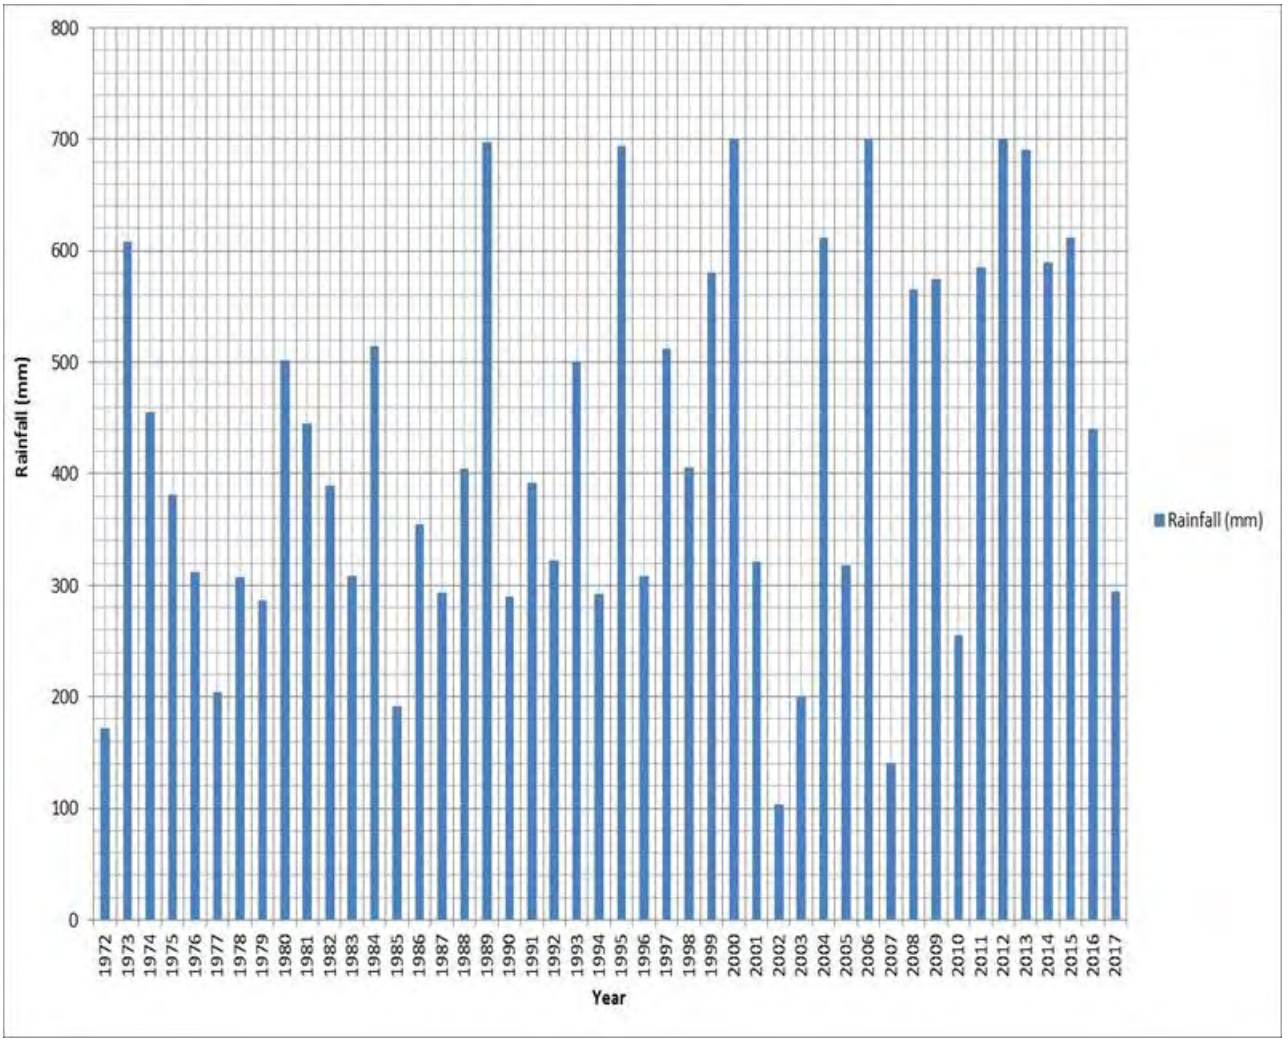

Figure 5. Total annual rainfall for Pannawonica (Station 5069). Note, the 2017 rainfall data are up to the sampling period (April). The long-term annual average is 427mm.

Total annual rainfall was above average for the three years prior to the 2017 sampling (see Figure 5). Monthly records revealed that the majority of rainfall occurred in the month of December-April (Figure 4). Peak rainfall coincided with a weak low that approached the far west Pilbara coast which then combined with a mid- latitude upper trough. Previously this low has resulted in heavy rainfall and substantial flooding in both the Robe and adjacent Fortescue rivers (BOM, 2008).

5.4 PHYSICO-CHEMISTRY

The physico-chemistry of the river system is largely dependent on local geology and riparian conditions. Large flow events can lead to increased turbidity which is transported downstream.

Pool water quality in the Robe River pools was fresh, slightly alkaline, with moderate levels of turbidity. Generally, the water chemistry of the pools was of high biological quality with the exceedances of ANZECC (2002) Trigger Levels limited to turbidity and a small elevation of total phosphorus (0.02mg/L *vs.* ANZECC/ARMCANZ Trigger Value of 0.01 mg/L) at Pirathalu. This small increase over the trigger values for nutrients is considered a consequence of unrestricted livestock access to pools. Dissolved oxygen (DO) levels were low; a consequence of high water temperatures (29-31^{O}C). Salinity/conductivity showed a slight gradient of increasing concentration downstream (*e.g.* 571µs/cm at Ngalooin to 996µs/cm at Thintuoona). This gradient is considered a function of the underlying geology rather than any anthropogenic influences; although dewatering may connect pools (see Table 1). Pool turbidity was highly variable ranging from 2.7NTU at Martangkuna to almost 30NTU at Gnieraoora (Yeera Bluff). Low levels were recorded at Pannawonica Hill Pool (Figure 6).

Long-term monitoring has revealed that water chemistry of pools show predictable levels largely associated with the sampling season (Dobbs and Davies, 2009). To date, there have been no statistically significant changes in the water quality of the Robe River that could be directly attributable to mining operations. Rainfall and river flows have been identified as having the greatest influence on pool morphology and water chemistry (Streamtec 2001-2016). A summary of the April 2017 physico-chemical parameters measured in conjunction with the aquatic survey is presented in Table 2.

5.5 MINE DEWATERING

A series of pools in Jimmawurrada Creek and in the Robe River downstream from discharge points were previously sampled for pH, DO, temperature, salinity/ conductivity, turbidity, total nitrogen and total phosphorus. Previously, the values showed considerable similarities with water in the Robe River; due to the permeability of the Robe pisolite and water being essentially 'recycled' from the mine to and from the river. The de-watering volumes into Jimmawurrada were low at point B (200kL) in March and ranged from 66-191ML in June 2017 (Table 1, Figure 7).

Table 1. Monthly discharge into Jimmawurrada Creek (points 5, 6) and the Robe River (point B) (volumes in kL).

5.6 POOL MORPHOLOGY AND SEDIMENTATION

Turbidity and sedimentation levels are generally a function of the interaction of river hydrology and underlying geomorphology. Water levels in the permanent pools have showed a trend upstream and downstream of Mesa J*; i.e.* dropping slightly over the winter dry season and rising again following summer rainfall events. At some sites turbidity exceeded ANZECC guidelines (mean values ~20NTU). These high values were measured both upstream and downstream from Mesa J (Table 1) and were considered a consequence of local pool geology.

Table 2. Physico-chemical parameters measured in conjunction with aquatic fauna surveys of the Robe River, April 2017. Shading indicates exceedance of ANZECC/ARMCANZ guidelines (2000). Blue-shaded; new pool sampled only in 2017.

* Areas of deeper water in each pool were coded by rank where: 1 = no areas > 2.5 m in depth, 2 = some areas > 2.5 m in depth, 3 = many areas > 2.5 m in depth, 4 = substantial areas > 2.5 m in depth. Cont=continuous.

Figure 8. Pirathalu upstream of Mesa J on the Robe River (left). Medawandy Waters (right).

5.7 WATER TURBIDITY

Natural turbidity and sedimentation are dependent on the hydrology, geomorphology and the suspended load from upstream. Turbidity levels in the Robe River have fluctuated both annually and seasonally, with elevated turbidity (70NTU; see Dobbs and Davies 2009) typically recorded immediately following flood events. Previous surveys of Robe pools have shown consistently low levels of turbidity in the dry season. Several pools, notably Yarramudda, have consistently shown elevated levels of turbidity.

5.8 SALINITY

In 2017, salinity levels within all pools were categorised as fresh[3]. The low salinity of water in the north-west of Western Australia has been attributed to long-term geochemical processes and geological history (Williams & Buckney 1976). A salinity gradient was evident in April 2017 and considered a consequence of local geomorphology. This gradient was evident prior to commencement of mining at Mesa J and not considered the direct result of mining activities.

5.9 DISSOLVED OXYGEN

Dissolved oxygen (DO) in survey pools showed significant spatial and temporal variation (Dobbs and Davies 2009). Previous spot measurements of DO, coupled with information from data- loggers have revealed concentrations ranging from overnight lows close to zero to supersaturated levels after midday. Dissolved oxygen levels of 70 – 120% (*i.e.* typically >2 mg/L) are generally considered suitable for resident aquatic fauna.

DO levels less than 2.0mg/L are considered the critical threshold at which respiration becomes difficult for many fish (ANZECC/ARMCANZ 2000). Daytime dissolved oxygen (DO) levels well-above threshold values both upstream and downstream of the mine (see Table 1). The DO of the pools reflects time of day with low levels in the morning (following night-time respiration of both plants and animals) to rise during the day due to photosynthesis by both macrophytes and algae.

[3] Fresh defined as <2,700 µS/cm; brackish/moderately saline 2,700 – 9,000 µS/cm; saline 9,000 – 55,000 µS/cm. Dept. of Agriculture, Government of Western Australia, 2002.

5.10 WATER TEMPERATURE

Long-term monitoring has highlighted the correlation between pool temperatures and ambient air temperatures both upstream and downstream from Mesa J (Figure 3). Temperature levels in 2017 were consistent with the long term averages for the month of April and generally varied between 29 and 32^{0}C.

5.11 NUTRIENTS

In long-term monitoring of the Robe River (Dobbs and Davies 2009), nutrient levels have sometimes exceeded Trigger Value guidelines. Previous high levels (see Streamtec 2001, 2015) of nitrogen and phosphorous have thought to be influenced by livestock access to the pools.

It should be noted that ANZECC guideline limits were developed primarily for water bodies other than those in the arid and semi-arid tropics of the Pilbara. The acceptable or 'normal' nutrient concentrations common to water bodies of this region remains poorly-understood and long-term monitoring of the Robe River suggest that guidelines are not directly transferable.

5.12 MACROINVERTEBRATE FAUNA

A total of 67 macroinvertebrate taxa[4] ('species') were collected and identified from the study sites in April 2017. Biodiversity of individual sites is shown in Table 2. The macroinvertebrate biodiversity recorded in 2017 approximated the 'average' when compared to the longer-term dataset (Dobbs and Davies 2009).

In 2017, the macroinvertebrate fauna was characterised by several regional endemic with no species considered rare or locally restricted. As with previous sampling, macroinvertebrate assemblages were dominated by larval stages of non-biting and biting midges (chironomids and ceratopogonids), freshwater prawns (Caridines), polychaetes (oligochaetes) and snails (gastropods). In the long-term data set 'low- occurrence' taxa (*i.e.* taxa recorded at <20% of sites) accounted for approximately 65% of all species recorded in 2017. This was similar to macroinvertebrate distributions in 2010 and 2014. Kay *et al.* (1999) conducted the first comprehensive study of aquatic macroinvertebrate distribution patterns in northern Western Australian and also found that ~25% of species occurred at most sites, while the remainder had widespread, but with a very heterogeneous spatial distribution.

The distribution of species in pools suggests that major differences are de-coupled from mining operations. Biodiversity of individual pools in 2017 ranged from 33 species at Pannawonica Hill Pool to 40 species at Pirathalu (Table 2, Figure 8). When comparing individual species, about 21% of species were exclusive to upstream sites compared to 24% of species found only in downstream sites. There was no statistically significant difference in species richness between upstream and downstream sites (one-way ANOVA, $p>0.05$; all cases). The multi-dimensional spatial patterns in macroinvertebrate community structure were investigated using multivariate classification and ordination techniques. Interpretation of the ordination (MDS) is reasonably straightforward, with sites clustering closer together representing samples that are similar in species composition and sites further apart having more different community structures.

Multi-dimensional ordination and multivariate analysis using ANOSIM revealed that there was no statistically significant difference in community structure/ clustering between sites upstream and downstream of Mesa J (Table 2).

Analysis of the long-term dataset revealed a broad separation of pools largely based on a simple measurement of pool morphology (depth and habitat) (see Figure 9, Figure 11). Highly episodic events such cyclones are important determinants of pool structure and habitat and consequently aquatic community structure (Streamtec 1991- 2017). Initially, there was a strong predictive model between simple measurements of pool size and macroinvertebrate community structure (Streamtec 1992). This indicated a structured, deterministic relationship. Following significant cyclones and extended dry periods, this model has shown less predictive success as recolonisation of species can be opportunistic and largely unpredictable. The biodiversity of pools is highly linked to pool morphology both upstream and downstream of Mesa J.

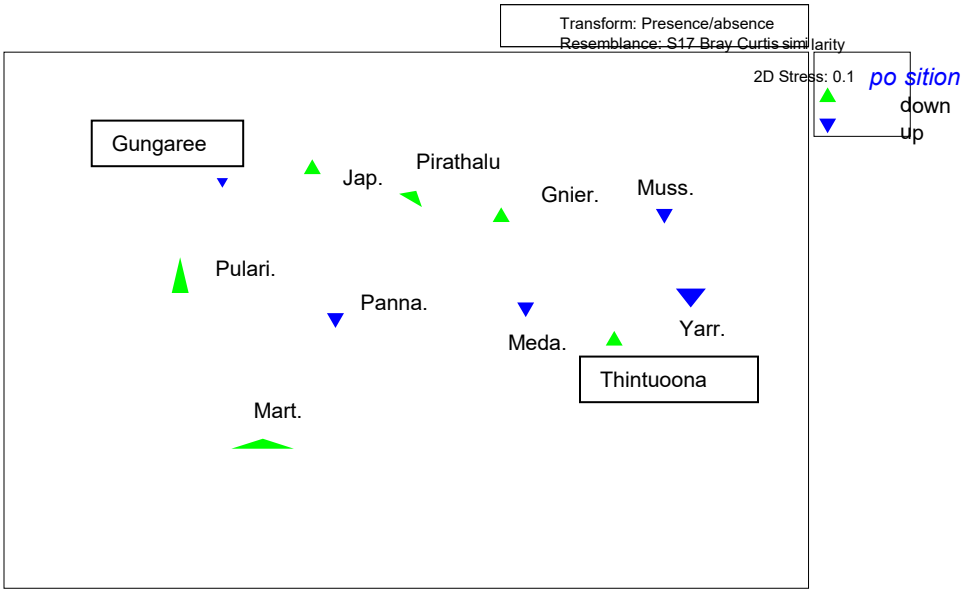

Figure 9. MDS ordination of 2017 macroinvertebrate presence/absence data set showing separation of sites (NB position of pools in relation to Mesa J has been overlaid showing no pattern in community structure based on this parameter).

5.13 TEMPORAL VARIATION

In the Pilbara bioregion, highly episodic and events with an extended return-period (*i.e.* cyclones) are important determinants of freshwater habitat and consequently aquatic community structure. A comparison of community structure across the long-term dataset shows significant rainfall and flow events the overriding determinants of ecological patterns. However, following high flow events, changes to macroinvertebrate community structure does not occur in a predictable manner with stochastic differences/shifts in species, recovery time and response (see Figure 9, Figure 11).

Changes to the macroinvertebrate community structure in April 2017 include an increase in juvenile species when compared to the previous sampling occasions. The macroinvertebrate community assemblages have shown significant resilience across the data record.

Figure 10. Measuring flow using cross sectional measurement methodologies.

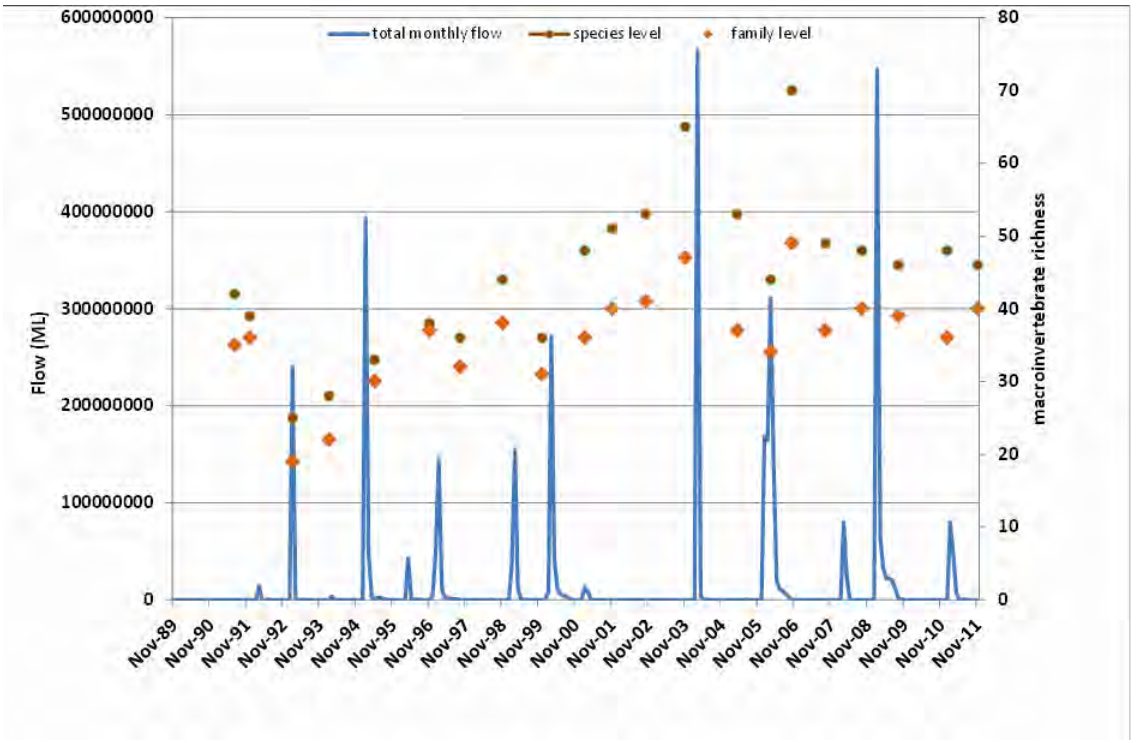

Figure 11. Species richness of macroinvertebrates as a function of flow (note, using previous data).

5.16 FISH FAUNA

A history of isolation of river systems of the north-west results in a low biodiversity of freshwater fish with few fish being recorded from the Pilbara (12 species) (Allen *et al,* 2002). A total of ten species have been recorded in the Robe River during aquatic surveys since 1991. Six of these species are classified by Allen *et al* (2002) as freshwater and the remaining four as freshwater/estuarine species (Table 3). To date, no introduced species have been recorded.

Seven species of fish were recorded in April 2017. Previously, patterns in fish biodiversity and distribution were consistent with the importance of habitat as per the long-term monitoring of pools, showing that biodiversity was linked to pool water levels, habitat and previous hydrological connectivity. All the seven fish species were recorded in both upstream and downstream sites. Mangrove jack, the striped butterfish and other estuarine species, previously observed in small downstream pools were absent in 2017 Patterns of fish species diversity and distribution were not related to the position of sites in relation to Mesa J.

In April 2017, fish were again numerically dominated by freshwater species from the Tetrapontidae (Grunters) group particularly species of Rainbowfish (*Melanotaenia splendida australis*) (Table 2). The patterns of fish species distribution were unrelated to the position of sites in relation to Mesa J (*e.g.* similar patterns upstream and downstream). The distribution of fish species along the length of the river showed that all seven species were recorded both upstream and downstream of Mesa J. Previously, variations in fish diversity and distribution between upstream and downstream sites were correlated to pool depth and volume (see Figure 12). These patterns in species distribution are consistent with long-term trends and consistent with current knowledge of tropical fish (see Warfe *et al.* 2011). Freshwater/estuarine species, have exhibited the greatest variations temporally across surveys. Mangrove Jack, absent in early 2011, were sampled during September 2015 and again absent in 2017. The April 2017 sampling was characterised by high numbers of juvenile species of fish, presumably recently recolonising pools after the recent flows of December 2016 to March 2017. There has been anecdotal information about freshwater mullet being present in some pools (*e.g.* Cams Pool); however this is yet to be verified.

Table 3. Fish species recorded in the Robe River pools in all surveys.

	FRESHWATER SPECIES	
CLUPEIDAE - HERRINGS	*Nematalosa erebi* GUNTHER	Bony Bream
PLOTOSIDAE - EEL-TAILED CATFISH	*Neosilurus hyrtlii* STEINDACHNER	Eel-tailed Catfish

5.17 RIPARIAN VEGETATION

The Robe River riparian zone is dominated by moderately-dense to dense mixed woodland of Cadjeput *Melaleuca leucadendra*, River Gum *Eucalyptus camaldulensis* and Coolibah *E. microtheca*. In all cases, the riparian vegetation was in excellent condition.

The open understory of tall shrubs is dominated by *Petalostylis labicheoides*, with scattered *Sesbania formosa* and *Gossypium robinsonii* over sedges and mixed herbs. Filamentous green algae are common in the waterways, together with emergent macrophytes, such as *Potamogeton* and *Vallisneria* species, and fringing rushes, such as *Eleocharis* sp. The bulrush *Typha* was dominant on the shorelines of some pools, particularly Yarramudda.

The introduced Indian Fern (*Ceratopteris thalictroides*), common in previous surveys, was extremely restricted in 2017. The riparian weed, Mexican Poppy, was largely absent in April 2017. Vegetation condition was similar upstream and downstream of Mesa J (*e.g.* over story tree health was good with no significant difference upstream to downstream; ANOVA $p>0.05$; all cases).

5.18 REGIONAL ASSESSMENT

Broader scale and longer-term multivariate analyses of the structure of freshwater fauna in a range of sites in the Pilbara (including Turner Creek, Yule Brook, Fortescue River, Ashburton River) showed the Robe River sites, both upstream and downstream of Mesa J, "grouped" on a gradient of sites largely based on pool size, habitat and water permanence (see Vorosmarty *et al.* 2010). The larger permanent pools in the Fortescue River were the most diverse of the sites (due to presence of v- tailed catfish and freshwater turtles; absent in the Robe River) and the least diverse were the smaller, more ephemeral pools in the Turner River and Yule Brook. Sites in the Robe were transitory between these extremes and grouped with similar sized pools in the Ashburton River.

6. CONCLUSIONS

In April 2017, there were no statistically significant changes to the ecology of river pools from the long-term envelope. The long term database that exists from these Robe surveys allows informed analysis and interpretation of these changes. The current survey supports previous findings that difference in environmental characteristics of pools are primarily a result of overriding climatic influences determining pool permanence and local morphology (see Davies 2010, Catford *et al.* 2013).

These findings support previous analysis showing that rainfall and river flows have had influence on pool morphology, water chemistry and the resulting aquatic fauna (Streamtec 2001-2016). Highly episodic and extreme events such as cyclones appear to be an important determinant of aquatic biodiversity and fundamental ecological processes.

To date, there have been no detectable changes in the aquatic ecology of the Robe River that could be attributed to mining operations alone. Long Term Ecological Research (LTER) is an important global initiative providing extensive data bases of temporal and spatial variability in biological parameters. The current sampling regime was initiated in 1991 and offers a unique dataset on an arid system in the Pilbara region (see Pettit *et al.* 2011, Jardine *et al.* 2012). In addition to providing a better understanding of impacts, if any, associated with mining operations, long-term ecological monitoring improves our understanding of the natural variability within the Robe River catchment. The support of RTIO for this LTER is gratefully acknowledged.

The continued investigation of new pools greatly increases the knowledge of the larger scale distribution of refugial habitat. A 2-D model of the hydrology of the Robe River *(e.g.* map when flows connect pools and the required antecedent conditions (rainfall) leading to pool connectivity will assist modelling dewatering movement and pool condition.

The use of Indigenous locals in the sampling program has been valuable (particularly for developing 'stories' about the pools, historic names and traditional ecological knowledge). This emphasises the important link between ecological condition and community 'health' (see Speldewinde *et al.* 2009).

8. APPENDICES

APPENDIX 1. POSITION OF STUDY SITES SAMPLED IN THE ROBE RIVER (also see Figure 1).

A pool name in inverted commas indicates a provisional naming. Grid references in MGA94. Highlighted= sampled in 2017.

Pool	Easting	Northing
Cameron's Pool	431800	7602021
Pannawonica Hill	432444	7602133
Medawandy	428965	7601388
Yarramudda	424044	7596692
Japanese Pool	419714	7598110
Duck Pool	418837	7597875
Martangkuna	417396	7598134
Pirathalu	445718	7600650
Yeera Bluff	414408	7596619
Mussel Pool	453089	7600382
Ooranah Pool	392656	7603524
Gungaree	400726	7594557
Thintuoona	399920	7594475

Description	Position relative to Mesa 'J'	Northing Zone 50	Easting Zone 50
Most upstream site surveyed. Upstream from A1.	upstream	7600396.71	453906.68
Upstream, adjacent to Water Corporation gauging station (flying fox)	upstream	7600650.05	445718.12
Adjacent to Pannawonica Hill.	upstream	7602138.34	433354.72
3km downstream of Pannawonica Hill.	upstream	7600894.25	430026.59
2km downstream of Pannawonica Hill.	upstream	7601451.43	430886.25
Downstream of confluence with Jimmawurrada Creek.	adjacent	7596946.50	420850.66
Adjacent to Mesa J.	downstream	7597951.51	418920.71
Adjacent to Mesa J & upstream of Japanese Pool.	downstream	7597650.40	420186.37
2km upstream of Deepdale.	downstream	7597949.17	418461.02
Adjacent to Yeera Bluff; downstream of Deepdale homestead.	downstream	7595961.06	414592.93

'Mesa C'	Furthest downstream site, new large pool sampled in 2011	downstream	7593929.71	414230.39
Additional Sites				
Site 10	Left Turnoff just before Rocky Creek	upstream	7600836.501	550573.993
Site 11	Turnoff at Hollow Log, and straight towards Mesa	upstream	7601641.977	551562.173
Site 12	Turnoff at Mesa near the white drum	upstream	7600428.612	554026.502
Site 13 Mesa C	Near Railway Bridge (on left)	downstream	7603493.646	607325.702
Site 14 Mesa C	Turnoff right into river bed towards Railway Bridge	downstream	7603859.150	607388.508
Thintuoona Pool	Adjacent (to the north) of Robe Pool	downstream	7594475.522	399920.422
Gungaree Pool	Adjacent (to the north) of Robe Pool	downstream	7594556.710	400726.350

APPENDIX 2. SAMPLING METHODS (BASED ON ANZECC 2000 GUIDELINES AND THE NATIONAL RIVER HEALTH MONITORING PROGRAM (SEE DAVIES 1998).

WATER QUALITY

Water samples were collected using clean 250ml polyethylene bottle; one per site. Bottles washed thoroughly three times with site water (with lid attached).

Undisturbed water collected at 0.5 depth for laboratory analyses of total nitrogen and total phosphorus (analysed by Natural Resources Chemistry Laboratory, Chemistry Centre (WA)). Both the bottle and lid labelled.

Sample kept cool in esky on ice or stored at 4^0C where possible. Measured dissolved oxygen, temperature, salinity, electrical conductivity and pH *in situ*.

MACROINVERTEBRATES – Qualitative – D-net sampling

Sampled all habitats with 250µm D-net (heel-kick with opening of net facing into flow). Standardised protocol (see below). Fixed composite sample in ethanol in plastic bag with label.

Qualitative sampling was conducted using a 'heel-kick' or sweep method (depending on habitat) compatible with the methodology of NRHP/MRHI (National River Health Program and Monitoring River Health Initiative) protocols. 'Heel-kick' and sweep sampling was conducted with a dip net with 250µm mesh, a 350 x 250mm opening, 50-75cm depth and a 1-1.5m handle. The net was washed thoroughly after sampling each site to remove any adhering animals left from previous sampling. For channel and riffle habitats, the substratum was vigorously disturbed whilst holding the net downstream with its mouth facing the disturbed area and into the stream-flow.

Cobbles were picked-up, turned over and rubbed by hand to dislodge attached organisms into the net. This process continued upstream over a total distance of about 50m, covering both the fastest and slowest flowing sections of the specific habitat. Macrophytes were sampled by vigorously sweeping the net within the aquatic vegetation over a length of about 10m. All sweep samples, containing sediment, detritus and macroinvertebrate fauna, were preserved in 80% ethanol in sealed plastic bags. In the laboratory, samples were washed in a flume-hood to remove formalin.

Organic sediments, including macroinvertebrates, were then separated from the inorganic material by water elutriation. The organic sediments were then washed through 3mm, 500µm and 250µm mesh sieves to partition the sample into 'large' and 'small' fractions. The small fractions were sorted under a binocular microscope and collected macroinvertebrates transferred to 100% ethanol. For each sample, the entire 3mm and 500µm fractions were sorted, while 250µm fractions were sub-sampled by one fifth. All animals were identified to the lowest practicable taxonomic level.

FISH

Standardised the time/effort (see Methods). Fish identified to species by direct observation. For most sites, direct observation proved the most efficient method for surveying species presence.

CHANNEL MORPHOLOGY

The channel morphology was measured as pool length, width and depth. This was measured using a range-finder.

To estimate water discharge, a narrow segment of stream of uniform shape was selected and velocity measured, at 0.1m intervals across the segment. Bank-full widths were interpreted from debris zones and high-water marks on banks and riparian trees. River bed materials were qualitatively assessed (e.g. sand, gravels, cobbles, organics *etc*). Measured velocity (Marsh-McBirney Model 201M meter) across channel at 0.6 maximum depth (*sensu* Newbury & Gaboury 1993). Depth measured average depth (graduated pole or metal tape measure).

Sedimentation, as pool aggradation, was assessed as the relative amount of fine inorganic material covering the typical bed substrate. This was completed as a visual assessment by a single operator using mask/snorkel across a 50m transect, where 0= no sediment, 1 = present (0-25%) covering of the pool bed by sediment, 2= common (25-50%), 3= dominant (50-75%) of the pool bed covered by sediment, 4= total covering (100%) of pool bed by sediment.

Areas of deeper water are considered a strong surrogate of habitat complexity. Typically in Robe River pools, areas of deeper water formed around tree roots and large woody debris (LWD). Qualitative measurements of deeper water were made by a single operator using a mask/snorkel across a 50m ('zig-zag') transect, where = 0 areas of water deeper than 2.5m, 1= areas of deeper water (>2.5m) between 0 and 25% of the total pool bed area, 3= areas of deeper water (>2.5m) between 25 and 50% of the total pool bed area, 4= areas of deeper water (>2.5m) greater than 50% of the total pool bed area.

RIPARIAN VEGETATION CONDITION

This is a qualitative assessment of riparian condition with a note of dominant species. At each site, two 50m transects from the waters' edge upslope were made and the following parameters recorded: slope (in degrees), % leaf litter covering the soil, weeds (in area), livestock disturbance (low, medium, high), and over-story condition: 1= dead, 2= much leaf loss, many dead branches, 3= some dead branches, 4= pristine). Opportunistic, qualitative surveys were also made of the noxious aquatic weed Indian Water Fern, *Ceratopteris thalictroides* and the weed Mexican Poppy.

Assessments were broadly based on the rapid assessment methodology outlined in Pen and Scott (1995) and WRC (1999). At each site, two 100m transects from the waters' edge upslope were made and the following parameters recorded: slope (in degrees), % leaf litter covering the soil, weeds (in area), and livestock disturbance (*e.g.* low, medium, and high).

Pen, L. & Scott M. (1995). Stream Foreshore Assessment in Farming Areas. Blackwood Catchment Co-coordinating Group. National Landcare Program. Department of Agriculture WA. June 1995.

WRC (1999). Planning and Management: Foreshore Condition Assessment in Urban and Semi-rural Areas of South-west Western Australia. Water and Rivers Commission River Restoration Report No. RR2. ISBN 0-7309-7443-X. October 1999.

VEHICLE DISTURBANCE

Multi-year sampling of the Robe River pools has been associated increasing levels of recreational 4WD vehicle use (particularly around some important pools, Pannawonica Hill and Gnieraoora). Consequently a qualitative coding was developed based on a visual assessment of the level of car tracks across two 100m vertical transect from the waterline, where 0= no tracks, 1= 1-5 tracks ('tracks' were coded as one per vehicle, so two tracks is one 4WD), 2= 5-10 tracks, 3= 10-20 tracks and 4= > 20 tracks.

STATISTICAL ANALYSES: PRIMER

To identify spatial (between sites) and temporal (between-sampling occasions) differences in water quality and macroinvertebrate community structure, data was classified and ordinated using PRIMER (Plymouth Routines in Multivariate Ecological Research) software (Clarke and Gorley, 2001). PRIMER performs multivariate analyses on data sets commonly recorded in biological monitoring of environmental impacts and is widely used for interpretation of community patterns.

Analyses of macroinvertebrates were conducted on presence/absence and abundance data. Similarity matrices were calculated using the Bray Curtis association measure which is appropriate for ecological data in freshwater systems. Sites were classified using hierarchical clustering (CLUSTER) which produces a dendrogram in which samples are grouped according to the similarity of their water quality or macroinvertebrate community composition. Hierarchical clustering is designed to provide ecological information on the occurrence of an assemblage of species from a number of sites - members of each division or group in the dendrogram have a more similar community structure and therefore more similar ecology.

Analysis of Variance (ANOVA)-type tests were then performed to determine if there was a significant separation between groups. This was done by ANOSIM, which compares the mean within-group similarity to the mean between-group similarity. Data were then ordinated using non-metric multi-dimensional scaling MDS. The ordination represents the samples as points in low-dimensional space where sites closest together have more in common than those further apart. Groups identified in the CLUSTER analysis are then overlaid onto the ordination. Species contribution to similarity of groups was calculated using the SIMPER routine. By looking at the overall percentage of contribution each species makes to the average dissimilarity between groups, species can be listed in decreasing order of their importance in discriminating the two groups.

In order to link environmental variables with patterns seen in community structure, physico- chemical data was analysed separately and then its multivariate pattern was compared to that of species data. Ordination of environmental data utilised Principal Components Analysis (PCA). The BIOENV routine was then used to examine whether a particular environmental variable or groups of variables distinguished sites in the as that of community structure.

APPENDIX 3. ANZECC/ARMCANZ (2002) WATER GUIDELINES

Default trigger values for nutrients, dissolved oxygen and pH for protection of aquatic ecosystems for tropical Australia for slightly disturbed ecosystems (from ANZECC/ARMCANZ 2002).

Trigger values are used to assess risk of adverse effects due to nutrients, biodegradable organic matter and pH in various ecosystem types. Data derived from trigger values supplied by Australian states and territories, for the Northern Territory and regions north of Carnarvon in the west and Rockhampton in the east.

TP = total phosphorus, FRP = filterable reactive phosphate, TN = total nitrogen, NOx = oxides of nitrogen, NH4+ = ammonium, DO = dissolved oxygen.

Ecosystem type	TP (mg/L)	FRP (mg/L)	TN (mg/L)	NOx (mg/L)	NH4+ (mg/L)	DO[2] (%)	pH
Upland River[1]	0.01	0.005	0.15	0.03	0.06	90-120	6.0-7.5
Lowland River[1]	0.01	0.004	0.2-0.3[4]	0.01[b]	0.01	85-120	6.0-8.0
Freshwater lakes & reservoirs	0.01	0.005	0.35	0.01	0.01	90-120	6.0-8.0
Wetlands	0.01-0.05[3]	0.005-0.025[3]	0.35-1.2[3]	0.01	0.01	90-120	6.0-8.0

1 = no data available for tropical WA estuaries or rivers. A precautionary approach should be adopted when applying default trigger values to these systems;
2 = percent saturation dissolved oxygen values were derived from daytime measurements. Dissolved oxygen concentrations may vary diurnally and with depth. Monitoring programs should assess this potential variability;
3 = higher values are indicative of tropical WA river pools;
4 = lower values from rivers draining rainforest catchments.

Acknowledgements

WRM thank Mathew Love for overall management of the project on behalf of Astron Environmental Services Pty Ltd (Astron). Dr Stuart Pearse and John Trainer (Astron) are thanked for comments on the draft report. Laboratory analyses of surface water quality samples collected by WRM were performed by ChemCentre, Bentley WA. Groundwater data were provided courtesy of the Proponent. Adrian Pinder (Parks and Wildlife) is thanked for providing raw data from the Pilbara Biological Survey (PBS), and Streamtec Pty Ltd/UWA are thanked for sharing their unpublished reports on the aquatic fauna of the Robe River. The authors acknowledge, and are very grateful to the Kuruma-Marthudunera Traditional Owners and in particular Brendan Bobby, for sharing their stories, welcoming us to the land and allowing the sampling of the river pools.

EXECUTIVE SUMMARY

This report summarises the results of a baseline sampling program for aquatic ecosystems of the Robe River system, both upstream and downstream of the proposed Mesa H iron ore development ("the Project"), managed by Rio Tinto on behalf of the Proponent (Robe River Mining Co. Pty Ltd) in the West Pilbara region of Western Australia. The aim of the sampling program was to document the current ecological condition of the Robe River prior to the implementation of the Mesa H development, which will require dewatering and surplus water discharge, which will result in a surface discharge footprint along the Robe River. The baseline survey included a number of named permanent pools in the Project area known to have ecological and cultural value, such as Gnieraoora (or Dthulurat) at Yeera Bluff. This report also includes a review of previous aquatic fauna surveys of the Robe River, and other nearby systems (*e.g.* Bungaroo Creek, Jimmawurrada Creek and Mungarathoona Creek), including conservation significant species known to occur in the vicinity of the Project area, which provides regional context for the sampling program.

The sampling design included six sites downgradient of the confluence of Jimmawurrada Creek and the Robe River (immediately upstream of the existing Mesa J operation) (RRD1 - 6), which are likely to fall within the zone of dewatering discharge (*i.e*. 'potentially exposed' sites), and six sites (RRU1 - 6) located upstream of the confluence (*i.e.* 'reference' sites). Sites were surveyed during the late wet season (April/May) 2016. The permanency and consistency of flow in the Robe River is already influenced by groundwater abstraction and dewatering discharge from the existing Mesa J mine operation, and so the current sampling program documents "current" ecological condition, more so than "natural" condition. Water quality, microinvertebrates (zooplankton), hyporheic fauna, macroinvertebrates and fish were successfully sampled at each of the 12 sites.

The main findings of the baseline survey were:

- Water quality was highly variable amongst sites, with salinity levels ranging from fresh (592 µS/cm) to brackish (1,700 µS/cm), pH from circum-neutral (6.9) to slightly alkaline (7.9) and dissolved oxygen from hypoxic (14.5%) to supersaturated (134.9%). There were no obvious longitudinal gradients in water quality parameters upstream or downstream. Site RRU6 (~1 km upstream of the Jimmawurrada-Robe confluence) and the downstream sites tended to have higher salinity (as electrical conductivity and total dissolved solids), alkalinity, hardness and concentrations of associated ions, than sites upstream. Some of this variability was attributed to differences in volume of the remnant pools sampled and evapoconcentration effects under recessional flows, however, higher concentrations of some ions downstream of the Jimmawurrada-Robe confluence (most notably magnesium and sulfate) was considered a possible artefact of current mining operations.
- Exceedances of ANZECC/ARMCANZ (2000) default trigger values for the protection of 95% of species in slightly-moderately disturbed tropical northern Australian systems were recorded for nitrogen nutrients (N-total, N-NO_x and N-NH_3) at most sites upstream and downstream of the Jimmawurrada-Robe confluence. Elevated background levels of N-NO_3 and N-NH_3 within the Project area are unsurprising, given that the Robe River catchment is already effected by current and historic pastoral practices, with groundwaters also appearing to be enriched. Elevated N-total and N-NO_x downstream of the Jimmawurrada-Robe confluence may also reflect discharge of nitrogen-enriched groundwater from existing mine operations, though the relative contribution of anthropogenic and natural sources to nitrogen enrichment in surface and groundwater of the Project area is unknown. The majority of heavy metal analytes, with the exception of dissolved zinc at RRU5 and RRD3, did not exceed ANZECC/ARMCANZ (2000) default 95% trigger values in the Project area.
- A total of 81 microinvertebrate taxa were recorded from the Project area, of which 46 were present at potentially exposed sites downstream of the Jimmawurrada-Robe confluence, and 69

were recorded at upstream reference sites. The microinvertebrate fauna was generally typical of that commonly recorded from tropical/sub-tropical freshwater systems, comprising Protista, Rotifera, Copepoda, Cladocera (water fleas) and Ostracoda (seed shrimp), with species from the family Lecanidae dominating within the Rotifera. There were no significant differences in total mean microinvertebrate taxa richness between reference and potentially exposed sites, nor was there any significant difference in richness of any of the major microinvertebrate groups (protists, rotifers, micro-crustaceans) between these sites. One microinvertebrate species listed for conservation significance, the copepod *Eodiaptomus lumholtzi* (IUCN Vulnerable), was recorded at potentially exposed site RRD6. The conservation listing of this species is considered in need of revision because it is known to occur at numerous locations across the Pilbara region, including sites along the Fortescue River, Coondiner Creek, Kalgan Creek, Weeli Wolli Creek, Mindy Mindy Creek, Koodaideri Springs, Caves Creek, Duck Creek and the Cane River, as well as Papua New Guinea.

- A total of 59 taxa were recorded from hyporheic samples, the majority of which were species not specially adapted to groundwater environments (stygoxene). Of these 59 taxa, 8% were considered stygobitic (obligate groundwater inhabitants), 31% occasional hyporheic stygophiles (species that use the hyporheic zone seasonally or during early life history stages), and 2% possible hyporheic taxa. There were no obvious longitudinal gradients or patterns in hyporheic taxa richness between reference and potentially exposed sites, though hyporheic taxa richness was relatively high at RRD1, RRU6, RRD2 and RRU4, suggesting strong connectivity between ground- and surface waters at these sites. Stygobitic taxa collected included the amphipod *Nedsia* sp., the thermosbaenacean *Halosbaena tulki,* and the ostracods *Candonopsis* cf. *tenuis* and *Vestalenula marmonieri.* Of these, *Nedsia* sp. is considered a potential short range endemic (SRE) species. *Nedsia* sp. was collected from sites potentially exposed to dewatering discharge (RRD1 – 4), as well as upstream reference sites (RRU3, RRU4 and RRU6).
- A total of 148 macroinvertebrate taxa were recorded from surface waters (117 from upstream reference sites, and 116 from downstream potentially exposed sites), with composition typical of freshwater systems throughout the world, being dominated by Insecta, in particular Diptera (true flies) and Coleoptera (aquatic beetles). There were no clear upstream/downstream gradients in macroinvertebrate richness within the Project area, with no significant difference in mean total taxa richness, or mean richness of most major macroinvertebrate groups, between reference and potentially exposed sites. Similarly, multivariate analysis detected no distinguishable separation of reference or potentially exposed sites based on macroinvertebrate species assemblage structure. One macroinvertebrate species listed for conservation significance, the Pilbara pin damselfly *Eurysticta coolawanyah* (IUCN Near Threatened), was recorded at potentially exposed downstream sites RRD3 and RRD4.
- A total of 3,515 individual fish, representing 11 species, were recorded in the Project area. True freshwater species included western rainbowfish, spangled perch, Pilbara tandan (eel-tailed catfish), Fortescue grunter, barred grunter, Terapontidae (grunter) hybrids and bony bream. Estuarine/marine vagrant fish species included milkfish, tarpon/ox-eye herring, mullet and banded scat/striped butterfish, the majority of which were recorded at the downstream reach. The conservation listed Fortescue grunter (*Leipotherapon aheneus*; IUCN Lower Risk/Near Threatened; Parks and Wildlife Priority 4) was the second most abundant fish species of the Project area, recorded at all upstream and downstream sites. Similar to other fauna indices, there was no significant difference in mean total abundance of fish between upstream and downstream sites, nor was there any significant difference in mean abundance of each individual species within the Project area. Healthy (breeding) populations of western rainbowfish, the most abundant fish species of the Project area, were recorded from upstream and downstream reaches; however, spangled perch and Pilbara tandan recruitment appeared to be low throughout the Project area.

1 INTRODUCTION

1.1 Background

Robe River Mining Co. Pty Ltd (the Proponent) is evaluating the potential development of the Mesa H iron ore deposit, located 16 km south-west of Pannawonica, in the West Pilbara region of Western Australia (Figure 1). The development envelope for Mesa H traverses the Robe River and lies adjacent to the existing Mesa J mine operation.

As part of the Mesa H development, dewatering of underlying groundwater will be required to allow mining of sections of ore (~20%) which occur below the water table (BWT). Options for disposal of excess dewatering water from the Mesa H development include discharge to an unnamed ephemeral tributary of the Robe River, between Mesa H and Mesa J, and/or discharge into Jimmawurrada Creek, east of Mesa J (Figure 1, or potentially an additional location north of Mesa H). The former two discharge points are currently used by the Mesa J operation.

The permanency and consistency of flow in the Robe River is already influenced by groundwater abstraction and dewatering discharge from existing mine operations (Aquaterra 2004). Groundwater drawdown and discharge from Mesa H may also affect aquatic ecosystems in the local vicinity. This includes a number of named permanent pools known to have ecological and cultural value, such as Gnieraoora (or Dthulurat) at Yeera Bluff (Figure 1).

Astron Environmental Service Pty Ltd (Astron) commissioned *Wetland Research & Management* (WRM) to design and conduct a baseline sampling program encompassing aquatic ecosystems of the Robe River both upstream and downstream of the Mesa H development (the "Project area"). The aim of the sampling program is to document current ecological condition of the system, and procure benchmark aquatic fauna and water quality data against which any future changes may be assessed post-commencement of the Mesa H development, including cumulative effects from dewatering drawdown ('drying') and discharge (quality and quantity). The permanency and consistency of flow in the Robe River is already influenced by groundwater abstraction and dewatering discharge from the Mesa J mine, and so the current sampling program will document "current" ecological condition moreso than "natural" condition. Where possible, monitoring sites established by Streamtec Pty Ltd (Streamtec) and The University of Western Australia (UWA) on the Robe River (Figure 1) have been included in the program. Since 1991, annual sampling for fish and benthic macroinvertebrates has been conducted by Streamtec/UWA as part of long-term monitoring for the Mesa J Project (Streamtec 1996, 1999, 2003, 2007, 2009, 2010, 2012 and 2014, Dobbs and Davies 2009).

1.1.1 Legislative framework

At a State level, native aquatic fauna are protected under the *Wildlife Conservation Act 1950* (WC Act) and their environment is protected under the *Environmental Protection Act 1986* (EP Act). This includes freshwater turtles, frogs, fish and invertebrates (including hyporheic and stygal invertebrates). Hyporheic invertebrates inhabit subsurface interstitial spaces in coarse creek bed sediments. Stygal invertebrates are aquatic, obligate groundwater-dwelling species known to be present in a variety of rock types and are often also present in the hyporheos.

The EP Act provides for environmental impact assessment (EIA) of proposals (and schemes) likely to have a significant effect on the environment. As part of the EIA process, the Act requires the Environmental Protection Authority of Western Australia (EPA) to report on key environmental factors to the Minister for Environment. Environmental factors and associated objectives are the EPA's basis for assessing whether a proposal (or scheme's) impact on the environment is acceptable. Two key environmental factors relate to water resources:

i) Hydrological Processes - with the objective "To maintain the hydrological regimes of groundwater and surface water so that environmental values are protected".

ii) Inland Waters Environmental Quality - with the objective "To maintain the quality of groundwater and surface water so that environmental values are protected".

Proponents are required to provide baseline information on these two factors (and others) in order to inform the EIA process.

The WC Act provides for species and ecological communities to be specially protected and listed as either 'threatened' because they are under identifiable threat of extinction, or 'priority' because they are rare, or otherwise in need of special protection. This encompasses species with small distributions (occupying an area of less than 10, 000 km^2) defined as short range endemics, or SREs (Harvey 2002, EPA 2009). The EPA's Guidance Statement 20 (EPA 2009) requires that impacts on SRE invertebrates be considered during the EIA process.

It can be difficult to determine whether or not a species belonging to a SRE Group is actually a species with a range <10,000 km^2. The Western Australian Museum (WAM) uses a three-tier classification scheme for SRE species which we have applied to hyporheic fauna in this report:

- **Confirmed SREs** are species with a known distribution range <10,000 km^2. The taxonomy is well known and the group is well represented in collections and/or via comprehensive sampling.

- **Potential SREs** are species that belong to a group where there are gaps in our knowledge of the taxon, either because the group is not well represented in collections, taxonomic knowledge is incomplete, or the distribution is imperfectly understood because sampling has been patchy.

- **Widespread (not SRE) species** have a known distribution range >10,000 km^2. The taxonomy is well known and the species is well represented in collections and/or via comprehensive sampling.

WAM further uses five sub-categories if a species is determined to be a "Potential SRE". These sub-categories are:

1. Data deficient: There are insufficient data available to determine SRE status, either because there is a lack of geographic and taxonomic information, or because the individuals sampled cannot be identified to species level (*e.g.* wrong sex, juvenile, damaged);

2. Habitat Indicators: The status of a species can be elucidated through its association with a particular habitat and vice versa;

3. Morphological Indicators: The status of a species can be determined through its morphological characteristics;

4. Molecular Evidence: DNA sequence data reveal patterns congruent or incongruent with SRE status for a species; and

5. Research & Expertise: Available research data and/or WAM expertise provide the basis for a decision about the species' status.

The Department of Parks and Wildlife (Parks and Wildlife) also maintains a list of priority fauna species that are of conservation importance but, for various reasons, do not meet the criteria for listing as threatened. Parks and Wildlife uses the International Union for Conservation of Nature (IUCN) Red List

criteria for assigning species and communities to threat categories. Not all Western Australian species listed by the IUCN are also listed by Parks and Wildlife.

Objectives for the management of potential impacts on water-dependent ecosystems are also outlined in the Western Australian Department of Water (DoW) Western Australian Water in Mining Guideline (DoW 2013) and include:

- Minimise the adverse effects of the abstraction and release of water on environmental, social and cultural values;
- Ensure the cumulative effects of mining operations are considered and managed;
- Use a monitoring and evaluation process, to adaptively manage the effects of abstractions and releases on the water resources;
- Maximise cooperation in water management activities between nearby water users, to reduce impacts on the environment;
- Plan for, and manage, the effects of climate variability and change.

At a Federal level, the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) provides for native fauna and their habitats to be specially protected and listed as nationally or internationally important. Relatively few aquatic species in Western Australia are listed as threatened or endangered under the WC Act or EPBC Act. Lack of knowledge of their distributions often precludes aquatic invertebrates for listing as threatened or endangered. The EPA has stated that listing under legislation should therefore not be the only conservation consideration in EIA (EPA 2004).

The current baseline sampling constituted a Level 1 survey for EIA, as described under the EPA's Environmental Assessment Guideline (EAG) No. 12 (EPA 2013), and in accordance with EAG No. 8 (EPA 2015), with the focus on hydrological processes and ecosystem maintenance. At the time of the survey (April/May 2016), the aforementioned EAGs were the most up-to-date EAGs availaible.

1.1.2 Other relevant policy - ANZECC/ARMCANZ (2000) Guidelines

The Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC/ARMCANZ 2000) "… provide an authoritative guide for setting water quality objectives required to sustain current, or likely future, environmental values (users) for natural and semi-natural water resources in Australia and New Zealand". These guidelines form part of the National Water Quality Management Strategy (NWQMS), a joint national approach to improving water quality in Australian and New Zealand waterways. The NWQMS was originally endorsed by two Ministerial Councils - the former Agriculture and Resources Management Council of Australia and New Zealand (ARMCANZ) and the former Australian and New Zealand Environment and Conservation Council (ANZECC).

State regulators have been known to apply the trigger values detailed in the ANZECC/ARMCANZ (2000) guidelines as compliance values for mining companies in the Pilbara, where developments may impact creeklines through dewatering and discharge operations. Yet, in some systems water quality data recorded during baseline surveys, conducted prior to any disturbance, do not actually meet the default ANZECC/ARMCANZ (2000) trigger values. Therefore, it is important to obtain adequate baseline water quality data and develop system-specific guidelines, as recommended in the ANZECC/ARMCANZ (2000) guidelines, to avoid issues with non-compliance as a result of inappropriate trigger values being used by regulators.

The ANZECC/ARMCANZ (2000) guidelines are currently under review and updates are provided by the Joint Steering Committee for the Revision on the Federal Department of the Environment and Energy website (www.environment.gov.au/water/quality/national; downloaded on 30 May 2016).

1.2 Scope of Works for Current Study

The scope of works for the current study was to establish riverine baseline monitoring sites, and to develop a robust dataset to allow statistical testing for potential change over time. Specifically, the scope of work included:

- Identification of baseline and future riverine monitoring sites, and where possible, include long-term monitoring sites established previously by Streamtec/UWA;
- Semi-qualitative sampling for aquatic fauna (microinvertebrates, hyporheic invertebrates, benthic macroinvertebrates, fish) and water quality to allow statistical comparison of any changes overtime;
- Qualitative visual assessment of general habitat conditions at all sites;
- Record opportunistic visual sightings of any turtle and frog species present;
- Identification of all specimens to the lowest taxonomic level practicable;
- An assessment of the conservation status of aquatic fauna recorded;
- Report water quality data against ANZECC/ARMCANZ (2000) guidelines for freshwater ecosystems;
- Preparation of a detailed technical report of all findings.

1.3 Rationale for Sampling Components of Aquatic Fauna

Microinvertebrates

Aquatic microinvertebrate fauna consists of microscopic fauna including micro-crustacea (ostracods, copepods and cladocera), protists and rotifers (nominally <53 μm in size). Aquatic microinvertebrates are used as bioindicators throughout the world for many reasons. The microinvertebrate community holds a strategic position in food webs (Bunn and Boon 1993, Zrum and Hann 1997, Jenkins and Boulton 2003). They provide a food source for higher trophic levels, such as macroinvertebrates (Bunn and Boon 1993, Jenkins and Boulton 2003), fish (King 2004, Vilizzi and Meredith 2009), and waterbirds (Crome 1985). Most fish species depend on microinvertebrates for their first feed after hatching (Geddes and Puckridge 1989). Therefore, any change in the microinvertebrate community will ultimately result in changes to the entire aquatic ecosystem. Microinvertebrates also have intimate contact with the surrounding environment, being planktonic, and continually exposed to the ambient water quality. Hence, they are vulnerable to environmental pollutants and can be a useful biomonitoring tool (Kaur and Ansal 1996).

Hyporheic fauna

The hyporheic zone, comprising subsurface interstitial spaces in coarse creek bed sediments, is recognised as a critical component of many streams and rivers (Edwards 1998). The hyporheic zone creates habitat and connectivity between surface and sub-surface (groundwater) zones, provides a rearing habitat and important refuge for aquatic invertebrates, and importantly in the context of the Pilbara region, buffering from floods (Palmer *et al.* 1992, Dole-Olivier and Marmonier 1992), disturbance in food supply (Edwards 1998) and drought (Cooling & Boulton 1993, Coe 2001, Hose *et al*. 2005). The aquatic fauna of hyporheic zones is collectively referred to as hyporheos. Typically, hyporheos have poor dispersal capabilities, are confined to discontinuous habitats, are highly seasonal (usually more active in the wet season following significant flows) and have low levels of fecundity, and are therefore commonly classified as SRE as defined by Harvey (2002)[1]. A number of taxa frequently encountered in hyporheic zones, including stygal amphipods, isopods and syncarids (crustaceans) are classified as SRE, and are therefore of high conservation value. The subterranean fauna of the Pilbara is characterised by high levels of diversity and short range endemism (Eberhard *et al*. 2005, Halse *et al*. 2014), with increasing aridity and cessation of surface flows over the last 60 – 70 million years causing once epigean

[1] Short range endemic as defined by Harvey (2002): a species occupying an area of less than 10, 000 km^2.

(surface dwelling) fauna to disperse and become isolated in groundwater environments (Finston *et al*. 2011).

Macroinvertebrates

Aquatic macroinvertebrates (nominally 53 - 250 µm in size) typically constitute the largest and most conspicuous component of aquatic invertebrate fauna in both lentic (still) and lotic (flowing) waters. Macroinvertebrates are used as a key indicator group in the bioassessment of the health of Australia's streams and rivers under the National River Health Program (Schofield and Davies 1996), and have inherent value for biological monitoring of water quality (ANZECC/ARMCANZ 2000). Macroinvertebrates are considered to be temporary residents if their life-cycle contains a winged-adult form (*e.g.* dragonflies, damselflies, mayflies, aquatic beetles, caddisflies, *etc.*), therefore being proficient in aerial dispersal between waterbodies (Gray and Fisher 1981). Permanent residents include those which can persist as larvae during periods of drought by aestivating or encysting in sediments (*e.g.* Baetidae, Simuliidae, Ceratopogonidae, Chironomidae), or produce desiccation-resistant propagules or eggs which hatch upon inundation (*e.g*. ciliates, rotifers, flatworms, nematodes, segmented worms and crustaceans) (Radzikowski 2013).

Fish

Historically, fish diversity has been used worldwide as an indicator of ecosystem health (*e.g.* Hugueny e*t al*. 1996, Oberdoff *et al.* 2002, Pont *et al.* 2006). Because fish continually inhabit the receiving water, they integrate the chemical, physical and biological 'histories' of the watercourse. Most fish species have a long life span and therefore reflect both long-term and current water quality. Sampling fish assemblages can be used to assess a range of environmental disturbances, such as changes in habitat, water quality and land use (Hugueny *et al.* 1996). Fish also tend to be the most conspicuous biota in freshwater systems, have significant social amenity and are relatively easy to sample and identify.

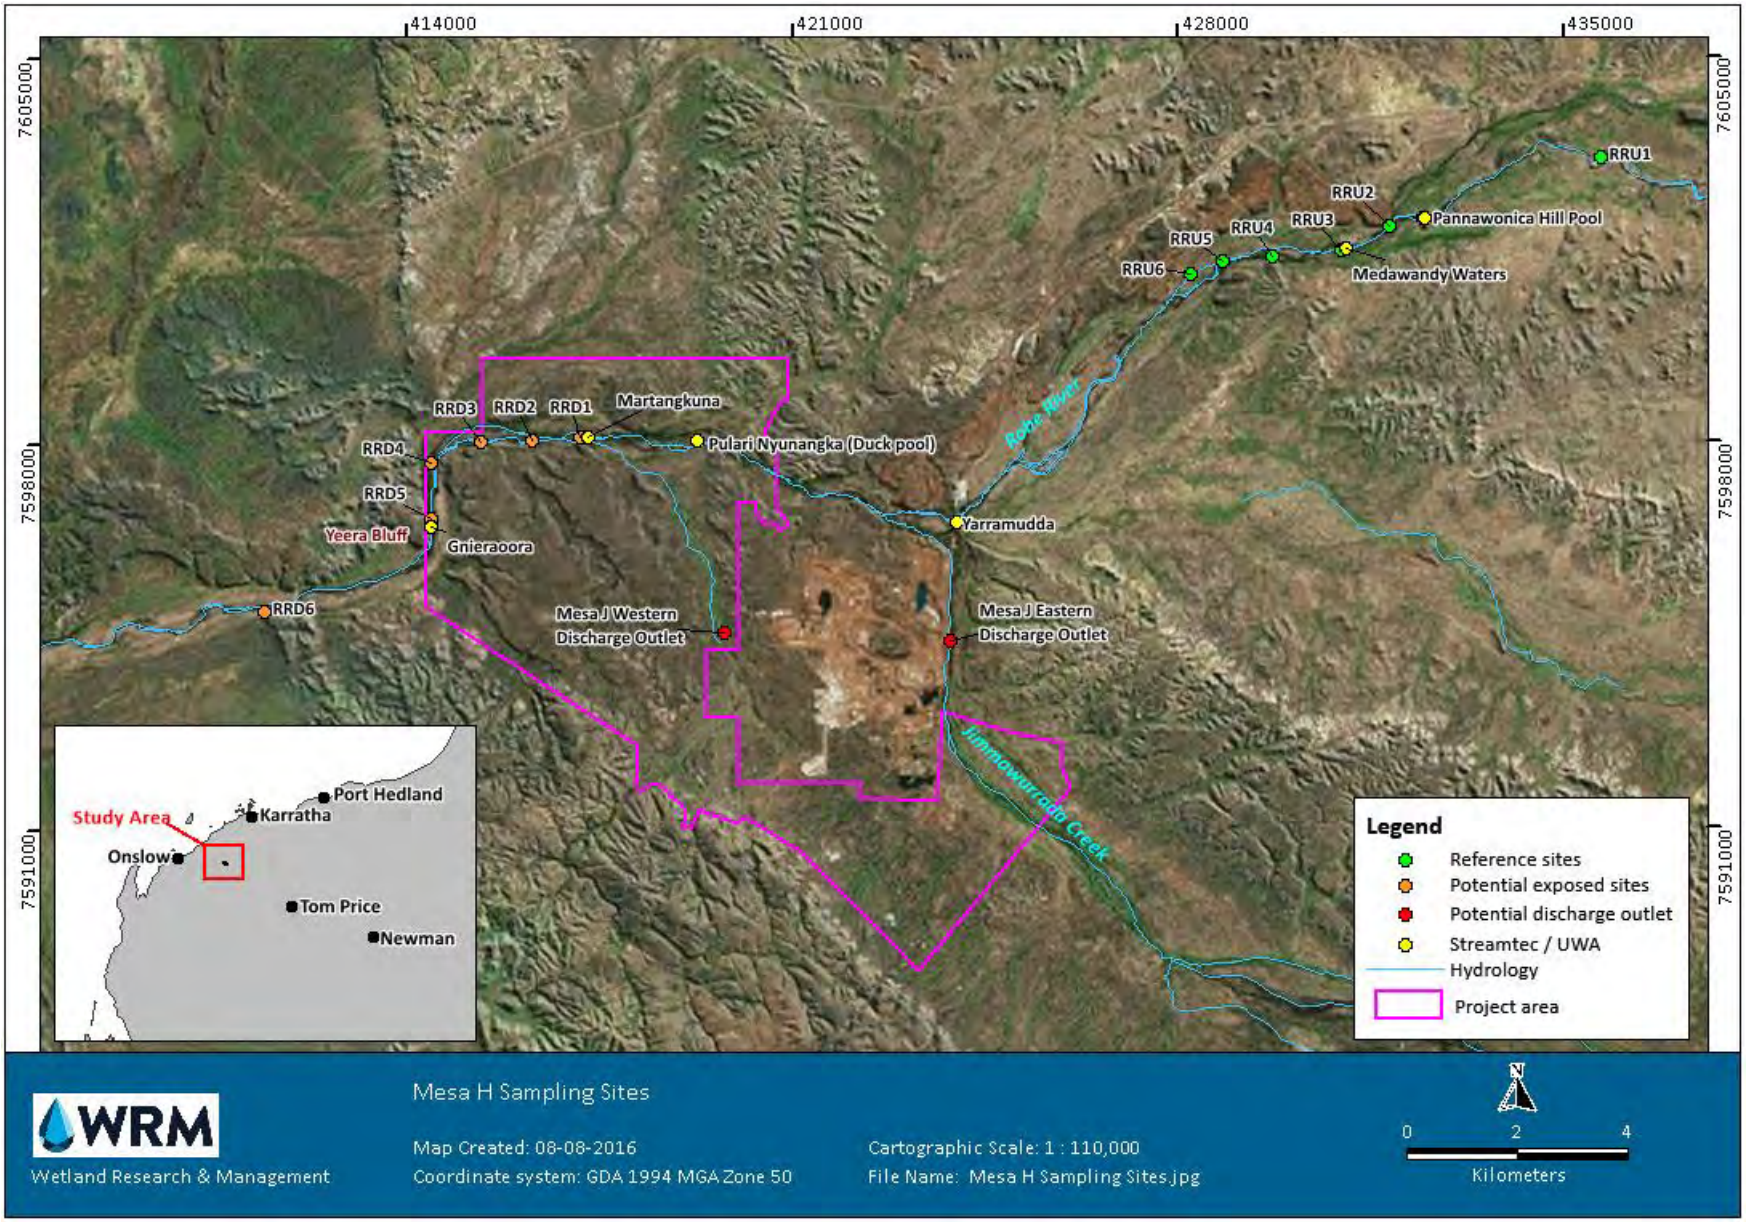

Figure 1. Location of Mesa H Project area and baseline aquatic ecosystem sampling sites (reference, potential exposed) and historic Streamtec/UWA sites ( ).

2 STUDY AREA

2.1 Climate

The Project area is located on the western edge of the Hamersley Ranges, approximately 100 km south-west of Karratha and south-west of Pannawonica. Climate of the region is semi-arid, with relatively dry winters and hot summers. The nearest long-term Bureau of Meteorology (BOM) gauging station is Pannawonica (no. 005069; 1971 - 2016), where total annual rainfall ranges from 113 to 700 mm, and monthly rainfall from 0 to 444 mm. Most rainfall occurs during the summer months (November to March) and is predominantly associated with cyclonic events; when flooding frequently occurs along creeks and rivers. Due to the nature of cyclonic events and thunderstorms, total annual rainfall in the region is highly unpredictable and individual storms can contribute several hundred millimetres of rain at one time.

Prior to sampling in April/May 2016, slightly above-average monthly rainfall was recorded in the latter part of 2015 (October & November) (Figure 2). However, total monthly rainfall was well below the 45-year average in the mid to late wet season of 2016, particularly during February, March and April (Figure 2). As such, there was no surface flow connecting pools along the Robe River at the time of sampling between 1st and 8th May. However, toward the end of the sampling period, a major storm event on the 5th - 6th May caused widespread flooding across the Robe River catchment, resulting in above average total rainfall for May (Figure 2). Pannawonica also recorded above average rainfall in June and July (Figure 2).

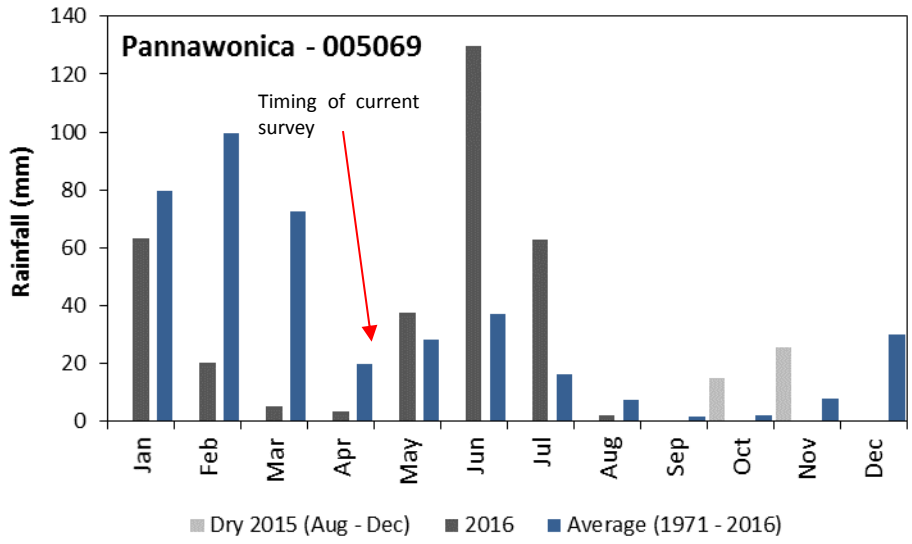

Figure 2. Average monthly rainfall (1971 – 2016) and total monthly rainfall (2016) for Bureau of Meteorology (BOM) Pannawonica Gauging Station (005069).

2.2 Hydrogeology

The Project area lies within the Robe River catchment, a significant river system in the region, with a catchment area of 7,571 km^2 and numerous braided tributaries (DoW 2012). The Robe River channel covers a linear distance of 190 km, 63% of which lies upstream of the Project area (EPA 1991). The immediate valley is 300 - 500 m wide. Jimmawurrada Creek is the only major tributary in the vicinity of the Project area, flowing northward along the eastern flank of Mesa J.

Jimmawurrada Creek joins the Robe River upstream of Mesa J (Figure 1). The Jimmawurrada Creek sub-catchment has an area of approximately 400 km^2 and constitutes the lower section of Bungaroo Creek

catchment, with a combined area of around 1,261 km^2 (DoW 2012). Both the Jimmawurrada and Bungaroo Creek catchments are included in the Bungaroo Creek Water Reserve that protects the water resources in these catchments and underlying aquifer that supply the West Pilbara Water Supply Scheme (WPWSS) (RDA 2013). The WPWSS delivers public drinking water to the towns of Karratha, Dampier, Roebourne, Cape Lambert and Point Samson (DoW 2012).

Surface flow in the Robe and tributary rivers is naturally ephemeral, typically only occurring in response to significant rainfall events and continuing for one to two months. There is one DoW streamflow gauging station on Robe River; Yarraloola (no. 707 002; 1972 - 2016), at the North West Coastal Highway crossing, 36 km west of the Project area. The maximum total monthly river discharge for the period of record at Yarraloola is 773.9 GL (February 2009) and the maximum instantaneous discharge is 12,203 m^3/sec (February 2009). Low or no flow typically occurs from July to December, when the river is reduced to a series of isolated pools. The number and permanence of these pools is dependent on antecedent rainfall and groundwater levels (Antao & Braimbridge 2010). Since streamflow records began at Yarraloola in 1972, 14 zero-flow years have been recorded, including seven in the last two decades (2002, 2003, 2007, 2010, 2012, 2013 & 2014).

The major aquifer underlying the Robe River is the gravelly alluvium which has a saturated thickness of up to 15 m adjacent the main channel and extends laterally up to 5 km across the Robe River Valley (Antao & Braimbridge 2010). Groundwater flow through the gravels maintains permanent pools in the Robe River. The gravelly aquifer is underlain by fractured, permeable Trealla Limestone and highly transmissive Robe Pisolite. Robe Pisolite is an iron-enriched pisolitic alluvial sedimentary rock that fills the broad valley between ridges of the Brockman Iron Formation, originally as ancestral drainage channels (palaeochannels) of the Robe River (commonly known as a Channel Iron Deposits (CID), and forms the target ore deposit at Mesa H (and Mesa J).

Groundwater flow in the Pisolite is towards the Robe River and where the Pisolite is deepest, probably contributes to baseflow within the Robe River (Aquaterra 2005). The gravel and Pisolite aquifers are recharged primarily *via* river discharge. Modelling by DoW indicates the aquifers have the potential to absorb a significant percentage of river flow; however, due to the unpredictable flow regime, recharge is very low in two out of every five years (Antao & Braimbridge 2010). Near the Jimmawurrada-Robe confluence, the Pisolite is very shallow and unsaturated. Stream-aquifer interaction upstream in the Bungaroo and Jimmawurrada valleys contributes to recharge along with direct rainfall infiltration.

2.3 Water Quality

2.3.1 Surface water

Water quality monitoring has been conducted quarterly at five pools in the Robe River and at the existing dewatering discharge point on Jimmawurrada Creek. The Robe River pools are located upstream (Medawandy Waters), adjacent to (Yarramudda) and downstream (Japanese, Martangkuna, Gnieraoora) of the existing mine operation (refer Figure 1 & Section 3). Pools have been monitored for pH, conductivity (EC), total dissolved solids (TDS), nitrogen and phosphorus, turbidity, total suspended solids (TSS) and biological and chemical oxygen demand. Dewatering discharge has been monitored for pH, TDS, TSS and concentration of dissolved metals (Al, As, Cd, Cr, Cu, Fe, Mn, Ni, Pb, Zn). Unfortunately, the limit of reporting for most metals was not sufficiently low to allow comparison against ANZECC/ARMCANZ (2000) default trigger values (TVs) for the protection of freshwater ecosystems. In general, dewatering discharge to Jimmawurrada Creek appeared to be of low salinity (< 800 mg/L TDS), low TSS (< 5 NTU) and with a pH range of 6.2 - 8.5. The water is a predominantly sodium bicarbonate and calcium bicarbonate type, indicative of recharge water (Aquaterra 2004).

Available long-term quarterly monitoring data for the Robe River pools (1992 - 2004) indicates surface waters to be fresh (453 - 1,400 µS/cm EC; 300 - 904 mg/L TDS), with pH values typically in the range 7.0 - 9.0, and relatively low turbidity (< 10 NTU) under baseflow conditions. Maximum salinity levels recorded during quarterly monitoring were in 2003 following two years of low rainfall. Salinity generally tends to be lower in upstream pools than in pools adjacent to, and downstream of Mesa J. Background levels of total nitrogen (N-total) and nitrate-nitrogen ($N\text{-}NO_3$) often exceed default ANZECC/ARMCANZ (2000) TVs for protection against eutrophication (0.15 mg/L N-total; 0.03 mg/L $N\text{-}NO_X$), with levels of up 3.45 mg/L N-total and 3.1 mg/L $N\text{-}NO_3$ recorded at Medawandy waters, upstream of Mesa J. In general $N\text{-}NO_3$ appears to constitute most of the N-total present in surface waters in the pools. There are no data on dissolved metal concentrations in the pools.

Long-term annual monitoring of Robe River pools by Streamtec/UWA indicated similar physicochemical water quality characteristics to those identified from quarterly monitoring by the Proponent; fresh (EC < 1,200 µS/cm), slightly acidic to alkaline (pH 6.6 - 8.3) waters with relatively low turbidity during the dry season (< 8 NTU), becoming markedly more turbid following wet season flood events (often exceeding 70 NTU) (Dobbs & Davies 2009, Streamtec 2014). There was significant spatial and temporal variation in dissolved oxygen (DO) levels (< 2 mg/L to > 12 mg/L), depending on time of day sampled and permanency of pools. N-total and total phosphorus (P-total) often exceeded ANZECC/ARMCANZ (2000) default TVs (Dobbs & Davies 2009, Streamtec 2014).

2.3.1 Groundwater

At the time of reporting, groundwater quality sampling in the Project area had been conducted on three occasions, in December 2015 and twice during 2016. A comprehensive suite of parameters was sampled in 10 bores; MB15MEH001 to 4, 6 to 9, and 13 to 14. This sampling will be followed by more comprehensive groundwater assessment during 2016. The December 2015 sampling suggests groundwater quality in the majority of the bores to be similar to surface waters, *i.e.* fresh (489 - 1,110 µS/cm, 452 - 822 mg/L TDS), circum-neutral to slightly alkaline (pH 7.3 - 7.7) and with relatively high DO levels (7.2 - 9.1 mg/L). Two bores had brackish water; MB15MEH013 (3,040 µS/cm, 2,770 mg/L) and MB15MEH014 (1,920 µS/cm, 1,450 mg/L). Groundwaters in most bores (except MB15MEH001) were enriched in $N\text{-}NO_3$ relative to ANZECC/ARMCANZ (2000) default TVs for surface waters for protection against eutrophication. Maximum concentration was 23.9 mg/L $N\text{-}NO_3$ in MB15MEH014. Default TVs have yet to be developed for groundwaters. In their absence, ANZECC/ARMACANZ (2000) recommend that default TVs for surface waters be applied with caution, acknowledging that they may not be representative of natural background concentrations in groundwater.

In three bores, dissolved concentrations of chromium (Cr), manganese (Mn) and/or zinc (Zn) were also in exceedance of ANZECC/ARMCANZ (2000) default 95% species protection level TVs[2] for surface waters. This included MB15MEH001 (Mn, Zn), MB15MEH004 (Zn), MB15MEH013 (Cr, Zn) and MB15MEH004 (Cr).

2.4 Cultural and Ecological Values

The Project area is located within the Hamersley sub-region of the Pilbara Biogeographic Region as categorised under the national Interim Biogeographic Regionalisation for Australia (IBRA). Existing tenure in the area is a mixture of unallocated and leased Crown land. The Mesa H development would be implemented under Mining Lease ML248SA, which covers the Project area and other deposits

[2] Note, default TV for Ni should be modified for water hardness (as $CaCO_3$) at the time of sampling using algorithms provided in Table 3.4.3 of ANZECC/ARMCANZ (2000).

throughout the Robe River valley. In addition to ML248SA, the Project area lies substantially within Yarraloola Station pastoral lease (PL 3114-1127). The lease is held by Robe River Iron Associates joint venture through the Yarraloola Pastoral Company, and managed by Rio Tinto. The Station was established in 1916 as a sheep station, but currently runs cattle.

Numerous Aboriginal sites of significance have been identified within the Robe River valley. The Native Title Claim of the Kuruma Marthudunera Native Title Claimant Group covers 15,717 km^2 south of Karratha, incorporating the Project area and Yarraloola Station (YMAC 2011). The entire Robe River, also known as Jajiwarra, is of significant cultural value to the Kuruma and Marthudunera people, in particular permanent pools such as Yarramudda and Weedai immediately upstream of the Project area, Dthulurat (Gnieraoora) at Yeera Bluff, Joordi (or Jongardi) 14 km downstream of Yeera Bluff, and Chalyarn Pool on Mungarathoona Creek, a tributary of the Robe River.

As the Pilbara has an arid and variable climate with irregular episodic rainfall events, sources of water are of high ecological value. The permanent pools of the Robe River are an important component of the river ecosystem, supporting a diverse range of aquatic fauna and specialised flora such as yellow bladderwort (*Utricularia australis*) and water chestnut (*Eleocharis dulcis*). The pools act as refuges for fauna during periods of drought (EPA 1991). The riparian zone in the vicinity of the Project area also supports woodlands of silver cadjeput (*Melaleuca argentea*) and eucalypt (*Eucalyptus camaldulensis*, *E. victrix*). Lower tree and shrub layers in these woodlands are atypical of the Fortescue Botanical District, and as such, warrant conservation (EPA 1991). Cyclonic events and associated rainfall can severely affect the riparian vegetation, re-arrange braided channels and alter the size and position of permanent pools through scouring and aggradation (Dobbs & Davies 2009). In March 2004 for example, a rain depression in the wake of tropical cyclone Monty resulted in record rainfalls (376.6 mm) that caused widespread flooding throughout the Robe River valley and its surrounding catchments (Aquaterra 2004). High flows and flash flooding associated with cyclone Monty uprooted much of the Cadjeput woodland along the river channel in the vicinity of the Jimmawurrada-Robe confluence.

A number of potential short range endemic (SRE) aquatic invertebrates are known from the vicinity of the Project area and potentially occur within drawdown and dewatering impact zones. These species include stygal amphipods, isopods and syncarids, which are also known to occur in the hyporheic zones of the Robe River and/or tributary rivers. Further discussion of these species is provided in Section 3.

3 REVIEW OF PREVIOUS AQUATIC FAUNA AND STYGOFAUNA SURVEYS

The most comprehensive surveys of aquatic fauna within the Project area are those of Streamtec/UWA, who have conducted annual sampling of Robe River pools since 1992 (Dobbs & Davies 2009, Streamtec 1996 - 2014). Other recent studies include the Parks and Wildlife Pilbara Biological Survey (PBS); a region-wide survey of aquatic invertebrates conducted between 2003 and 2006, as part of a broader biodiversity survey (see Pinder *et al.* 2010). The PBS featured a number of ephemeral, long-term and permanent waterbodies within the vicinity of the Project area, including Mungarathoona Creek to the west, Myannore Creek and Yarraloola Station Claypan to the north-west, Nyeetbury Spring on upper Bungaroo Creek to the south-east, Kumina Creek in the upper Robe, and two pools on the Cane River to the south-west (Pinder *et al*. 2010). Morgan and Gill (2004) studied the distribution of fishes in inland waters of Pilbara, sampling 171 sites across 21 river systems between 2000 and 2002. Nearby sites included two pools on the Robe River close to the Project area; two on the lower Robe west of Mesa A/Warramboo, two on the lower Fortescue River to the north-west, and one on the Cane River. WRM previously sampled aquatic invertebrates and fish at Nyeetbury Spring (2009 - 2015) and Yalleen Pool (2010 - 2011) on Bungaroo Creek under the Proponent's Regional Aquatic Fauna Program (see WRM 2016). In 2008 and 2009, baseline surveys for the Australian Premium Iron (API) West Pilbara Iron Ore Project (WPIOP) were conducted, including sites on Mungarathoona Creek, Red Hill Creek and the Cane River (WRM 2009).

Additionally, stygofauna[3] have been sampled by Biota Environmental Sciences in the Mesa A/Warramboo Yarraloola Borefield to the west (Biota 2006a), and within the Ken's Bore and Cardo Bore areas along Red Hill Creek to the south-west (Biota 2010). Bennelongia Environmental Consultants surveyed stygofauna within the Bungaroo Creek catchment in the Buckland Hills area (Bennelongia 2013). Stygofauna were also surveyed by Parks and Wildlife as part of the PBS, including 36 bores within the Robe River catchment, sampled between 2002 and 2005 (see Eberhard *et al*. 2009, Halse *et al.* 2014).

A review of previous aquatic fauna surveys conducted within 100 km of the Project area, including sites sampled, methods used, and notable fauna found, is presented in the following sub-sections. A summary of the studies is provided in Table 1 and the sampling locations are shown in Figure 3. Studies referenced in this review were either conducted by WRM for the Proponent, or were publicly available, or records sourced from the Parks and Wildlife database NatureMap (http://naturemap.dpaw.wa.gov.au). In addition, direct requests were therefore made to Parks and Wildlife in order to obtain additional information on distribution of threatened, priority and vulnerable aquatic fauna.

For each species, conservation significance was assessed by reference to the IUCN Red List of Threatened Species, Parks and Wildlife Threatened and Priority Fauna Lists, as well as The Australian Faunal Directory, The Australian National Insect Collection Database and WRM's in-house database for distribution and occurrence information. Collectively, the previous studies have identified a number of species of conservation significance and/or scientific interest, which have the potential to reside, either seasonally or permanently, within the Project area and its expected drawdown zone and/or dewatering discharge footprint (acknowledging hydrological modelling for drawdown and dewatering discharge was not completed at the time of the survey or reporting).

A summary of aquatic species (including hyporheic species) of conservation and/or scientific value known to occur, or likely to occur within the Project area, is provided in Table 2, at the end of Section 3.

[3] Obligate inhabitants of groundwater environments, *e.g.* aquifers, caves and hyporheic (interstitial) spaces. Morphological adaptations to such environments include reduced body size, lack of pigmentation, reduced or absent eyes, and elongated appendages (*e.g.* antennae).

Table 1. Summary of previous recent aquatic fauna studies (invertebrates and fish) conducted within a 100 km radius of the Mesa H Project area, together with methodologies. Studies are listed in chronological order. Stygofauna assessments appropriate to the Project area are also included. Codes for 'Fauna sampled': Macro = macroinvertebrate; Micro = microinvertebrate; Hypo = hyporheos; Stygo = stygofauna).

Program	Sampled by	Locations sampled	Fauna sampled	Methods used	Taxonomic level	Sampling dates	Reference
Aquatic Fauna (Surface Water and Hyporheos)							
Proponent Mesa J Project Aquatic Ecosystem Study (long-term)	Streamtec / UWA	Robe River pools: • Gnieraoora, Martangkuna, Pulari-Nyunangka, Japanese pool, Yarramudda, Medawandy Waters, Pannawonica Hill pool, Chundy Pool, Ngalooin, Mussel Pool.	Macro Fish	• Macro – kick sampling (250 µm net) all habitats, • Fish – seine net and visual observation (mask and snorkel).	Species	Annually between Nov - Mar, 1991 - 2013.	Streamtec (1996, 1998, 2002, 2007-2009, 2011, 2014); Dobbs and Davies (2009)
Fish Fauna of Pilbara inland waters	Murdoch Uni	• Robe River near Mesa H and J, • Lower Robe River, west of Mesa A/Warramboo, • Lower Fortescue River (40 km NE), • Cane River (75 km SW).	Fish	• Fish – seine nets, gill nets, cast nets, rod and line, and visual observation (mask and snorkel).	Species	Once between Dec 2000 - Nov 2002.	Morgan and Gill (2004)
Hyporheos of five Pilbara springs	Parks and Wildlife	• Nyeetbury Spring on Bungaroo Creek, Robe River catchment (33 km SE).	Hypo	• Stirring up sediments and sweeping with a 250 µm mesh dip net, • Digging up sediments to a depth of 30 cm and collecting fauna caught with 50 µm and 250 µm mesh nets (Karaman-Chappuis method).	Species	Sep 2001.	Halse *et al*. (2002)
Pilbara Biological Study (PBS)	Parks and Wildlife	• Chalyarn Pool, Mungarathoona Creek, Robe River catchment (20 km W), • Red Hill Creek Pool, Robe River catchment (30 km SW), • Nyeetbury Spring on Bungaroo Creek (33 km SE), • Duck Creek Pool on Duck Creek, Ashburton River catchment (46 km SE), • Myannore Creek (49 km NNW), • Yarraloola Station Claypan (65 km NNW), • 2 sites on Cane River; House Pool and Creek Pool (70-75 km SW), • Kumina Creek (74 km SW).	Macro Micro	• Macro - kick sampling (250 µm net) all habitats, • Micro – sweep netting (50 µm mesh).	Species	Aug/Sep 2003, Aug/Sep 2004, May 2005, May 2006.	Pinder *et al*. (2010)

Program	Sampled by	Locations sampled	Fauna sampled	Methods used	Taxonomic level	Sampling dates	Reference
Aquatic Fauna (Surface Water and Hyporheos)							
API WPIOP Baseline Aquatic Fauna Survey	WRM	• 2 sites on Mungarathoona Creek (20 km W), • 6 sites on Red Hill Creek, (40 km SW).	Macro Micro Hypo Fish	• Macro – kick sampling (250 µm net) all habitats, • Micro – sweep netting (53 µm net) water column, • Hypo – Karaman-Chappuis method (53 µm net), • Fish – seine nets and gill nets.	Species	Dec 2008, Apr 2009.	WRM (2009)
Proponent Regional Aquatic Program (long-term)	WRM	• Yalleen Pool on Bungaroo Creek (23 km SE), • Nyeetbury Spring on Bungaroo Creek (33 km SE).	Macro Micro Hypo Fish	• Macro – kick sampling (250 µm net) all habitats, • Micro – sweep netting (53 µm net) water column, • Hypo – Karaman-Chappuis method (53 µm net), • Fish – seine nets and gill nets.	Species	Ongoing, wet and dry seasons since 2009.	WRM (2013, 2016)
Stygofauna							
Pilbara Biological Study (PBS)	Parks and Wildlife	• 36 bores across the Robe River catchment	Stygo	• Replicate hauls with weighted plankton nets (50 µm and 150 µm mesh).	Species	3 wet and 3 dry season occasions 2002 - 2005.	Eberhard *et al.* (2005, 2009); Halse *et al.* (2014)
Robe River Mining Co. Mesa A/Warramboo Baseline Stygofauna Assessment	Biota	• 21 bores within the Warramboo area, Robe River catchment (45 km W) • 20 bores within the Yarraloola area, Robe River catchment (40 km W)	Stygo	• Hauls with weighted plankton nets (150 µm mesh).	Species	Oct 2005.	Biota (2006a)
API WPIOP Baseline Stygofauna Assessment	Biota	• 58 bores within the WPIOP tenement areas, Red Hill Creek catchment (40 km SW)	Stygo	• Hauls with weighted plankton nets (70 µm mesh).	Species	Jun 2008, Sep 2009.	Biota (2010)
Iron Ore Holdings Bungaroo South Subterranean Fauna Assessment	Bennelongia	• 61 bores within Bungaroo South tenement, immediately south of the Project area.	Stygo	• Replicate hauls with weighted plankton nets (50 µm and 150 µm mesh).	Species	Jul 2012, Oct 2012.	Bennelongia (2013)

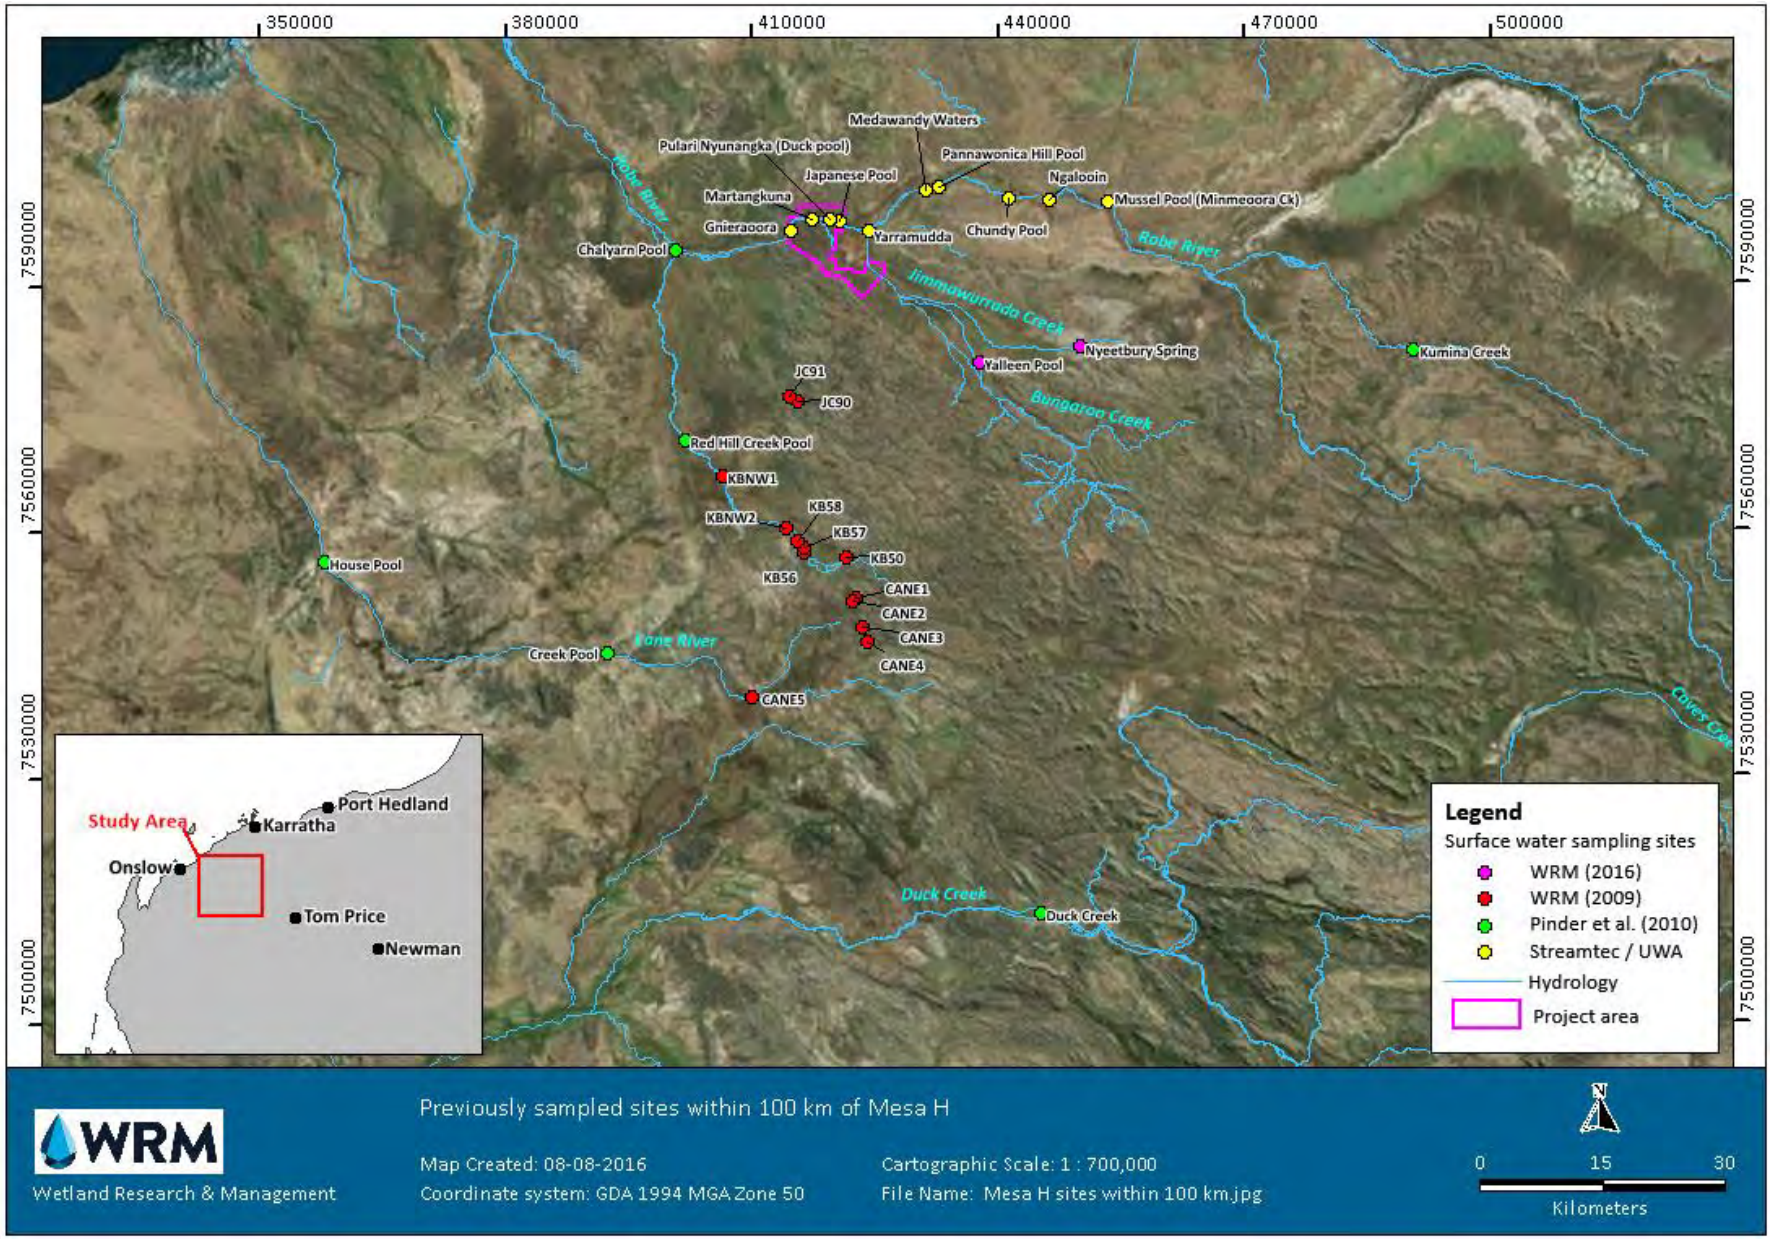

Figure 3. Locations previously sampled for aquatic invertebrates (Streamtec/UWA 1991 - 2014, WRM 2009 - 2016, Pinder *et al.* 2010) and fish (Streamtec 1991 – 2014) within 100 km of the Mesa H project area. Note, individual groundwater bores sampled for stygofauna (Biota 2006a, 2010, Eberhard 2009, Bennelongia 2013, Halse *et al.* 2014) are not detailed. Morgan and Gill (2004) did not provide GPS co-ordinates for their study of Robe River fish fauna.

3.1 Microinvertebrates (zooplankton)

The microinvertebrate fauna within the vicinity of the Project area is poorly known. Eight sites within 100 km of the Project area were sampled for microinvertebrates as part of the Parks and Wildlife PBS (Table 1). Pools sampled within the Robe River catchment included Chalyarn Pool (Mungarathoona Creek) and pools along Red Hill Creek, Myannore Creek, Kumina Creek, Nyeetbury Spring, Yalleen Pool and an ephemeral claypan on Yarraloola Station (Figure 3). Locations sampled outside the Robe River catchment included two pools on the Cane River to the south-west, and one on Duck Creek in the Ashburton River catchment (Figure 3). A combined total of 216 microinvertebrate taxa were recorded from these sites both within and outside of the Robe River catchment, sampled in August and September 2003/2004 (dry season) and May 2005/2006 (wet season). Wet season sampling appeared to favour microinvertebrate richness, with some of the most specious samples taken in May 2005 at House Pool on the Cane River (45 taxa), Red Hill Creek (42 taxa) and Chalyarn Pool (35 taxa).

WRM (2009) surveyed microinvertebrates in Mungarathoona Creek (two sites adjacent to the Jewel Cochrane development, to the south-east) and Red Hill Creek (six sites adjacent to Ken's Bore development) to the south east, as part of baseline aquatic surveys for API's WPIOP (Figure 3). A total 135 microinvertebrate taxa were recorded across two sampling events, conducted in December 2008 and April 2009 (WRM 2009).

WRM also conducts an ongoing aquatic fauna surveys under the Rio Tinto Pilbara Regional Program, which has previously included the microinvertebrate fauna of Yalleen Pool and Nyeetbury Spring on Bungaroo Creek (Figure 3). Biannual surveys collected a total 45 microinvertebrate taxa from Yalleen Pool, sampled between 2010 and 2011 (WRM 2013), and 160 taxa from Nyeetbury Spring, sampled between 2009 and 2016 (WRM 2016).

In each study, the microinvertebrate fauna was generally found to be typical of systems in the arid tropics (*e.g.* Koste and Shiel 1983, Tait *et al.* 1984, Smirnov and De Meester 1996, Segers *et al*. 2004). For example, in the nine featured PBS sites within the Robe River catchment (Table 1), species from the family Brachionidae (Rotifera) were poorly represented (14 taxa). This family tends to dominate temperate rotifer plankton, but is largely replaced by Lecanidae in tropic zones, as appears to be the case in the Pilbara (27 taxa; Pinder *et al.* 2010).

Microinvertebrate fauna of note (*i.e*. of conservation or scientific value) recorded from these studies included the stygal ostracod *Vestalenula matildae*, the rotifers *Colurella oblonga* and *Lecane noobijupi* and the cyclopoid copepod *Paracyclops* sp. 6. All these species have been recorded from within the Robe River catchment.

Vestalenula matildae was recorded at Mungarathoona Creek (Chalyarn Pool) during the PBS (Pinder *et al*. 2010). *V. matildae* is a recently described stygal species of ostracod known from groundwater (bores and wells) in the Ashburton River catchment (Government Well, Divide Well), DeGrey River catchment (Kylena Well, Home Well), and Sherlock River (Muorena Well). It has been recorded from hyporheic zones in the Ashburton (Yindabiddy Pool) and Fortescue River catchments (Weeli Wolli Spring), as well as surface waters in the Ashburton (Horrigans Pool), Fortescue (Gregory Gorge) and DeGrey (Coppin Gap, Chinaman Spring, Running Waters) (Martens and Rosetti 2002, Halse *et al*. 2002, Pinder *et al.* 2010, Schön *et al*. 2010). It appears to be endemic to the Pilbara, with no record to date of occurrence outside the region.

Colurella oblonga was collected at Nyeetbury Spring by WRM in 2012. This constituted the first record of *Colurella oblonga* from the Australian continent. This species is previously known from the southwest islands of Japan and from Europe (Dr Russel Shiel, University of Adelaide, pers. comm.).

Lecane noobijupi was collected from Nyeetbury Spring by WRM in 2011 and 2012, and from Red Hill Creek in 2009. This species is endemic to Western Australia, and appears to have a highly disjunct distribution. It was described from specimens collected from a wetland in the Muir-Unicup catchment in the south-west of the state (Lake Noobijup), and it had been thought to be restricted to that catchment (Segers and Shiel 2003). WRM has since recorded *Lecane noobijupi* from a number of locations throughout the Pilbara region, including Weeli Wolli Creek, Marillana Creek, Coondiner Creek, Mindy Mindy Creek and Kalgan Creek and (WRM 2016). Pinder *et al*. (2010) also recorded it from the DeGrey River. It would now appear that the Pilbara may be the normal locality of this species, and the Muir location in the south-west was an isolated occurrence.

Closer to the Project area, *Paracyclops* sp. 6 was collected from Chalyarn Pool, as well as Nyeetbury Spring and Kumina Creek (Pinder *et al*. 2010). This species is endemic to the Pilbara and is known from only 20 locations across the region, including the Ashburton River (Bobswim Pool, Fork Spring, Whiskey Pool, Cheela Spring, Paperbark Spring, Innawally Pool), Fortescue River (Palm Pool, Gregory Gorge, Palm Spring near Millstream, Joffre Creek), DeGrey River (Pelican Pool, Glen Herring Pool, Chinaman Spring, Minigarra Creek pools, Skull Springs and Bonnie Pool), Harding River (Springs Creek, Harding River Pool) and Sherlock River (Erawallana Spring and Pool Spring) (Pinder et al. 2010, WRM unpub. data).

Of the above-mentioned species, *Lecane noobijupi, Vestalenula matildae* and *Paracyclops* sp. 6 potentially occur within the Project area and its immediate vicinity but have a widespread distribution across the Pilbara.

3.2 Hyporheos

The hyporheos was not sampled by Streamtec/UWA during their long-term study of Robe River pools upstream, nor during the PBS (Pinder *et al.* 2010, Halse *et al.* 2014). However, biannual surveys of the hyporheos of upper Bungaroo Creek by WRM recorded a total of 22 hyporheic taxa from Yalleen Pool (WRM 2013) and 103 from Nyeetbury Spring (WRM 2016). Halse *et al.* (2002) recorded 62 hyporheic taxa from Nyeetbury Spring during one-off sampling in 2001. WRM (2009) also sampled the hyporheos of upper-Mungarathoona Creek and Red Hill Creek in 2008/2009, recording a combined total of 45 taxa.

Fauna of note collected during these studies included stygal amphipods and isopods that are likely SREs. Amphipods from the family Paramelitidae were collected from Yalleen Pool (WRM 2013), one site on Mungarathoona Creek, and three sites on Red Hill Creek (WRM 2009). These specimens were not able to be identified further than family level due to immaturity of life stage; however, they were considered likely to be SREs, given that most stygal Paramelitidae species are restricted to a small number of river systems within close geographical proximity to one-another (Finston *et al.* 2011).

At least three large isopod species are known from the subsurface zone of the Robe River catchment; *Pygolabis* sp. (Tainisopidae), *Tainisopus* sp. (Tainisopidae) and *Pilbarophreatoicus platyarthricus* (Amphisopodidae). Keable and Wilson (2006) documented *Pygolabis* sp. as occurring in the Robe River catchment but did not disclose the specific locality. Bennelongia (2013) also recorded P*ygolabis* sp. from two groundwater bores in the Bungaroo South area. All species of *Pygolabis* appear to be restricted to groundwaters and/or hyporheic zones of one or several creek drainages of the Pilbara region (Fortescue, Ashburton or Robe River catchments) (Keable and Wilson 2003) and at least some appear to be restricted to single sub-basins (Finston *et al.* 2009). Another undescribed, but closely related species, *Tainisopus* sp., is known to occur in the hyporheos of Nyeetbury Spring (Halse *et al.* 2002), as is *Pilbarophreatoicus platyarthricus* (WRM 2016). *P. platyarthricus* was first identified by Knott and Halse (1999) from Robe River specimens (including Chalyarn Pool), which were exclusively collected during the wet season "under cobbles in slow-flowing riffles … maintained by groundwater discharge." This species was also collected in surface water samples at Chalyarn Pool during the PBS (Pinder *at al.* 2010).

Although not specifically targeting hyporheic fauna, there have been a number of surveys of stygal communities in the vicinity of the Project area. These communities have taxa frequently encountered in hyporheic zones including SRE amphipods and isopods. These species may potentially occur in hyporheic zones within dewatering and drawdown zones in the Project area and the immediate vicinity.

The PBS sampled a total of 507 wells and drill holes across the Pilbara between 2002 and 2005, including 36 within the Robe River catchment area (Eberhard *et al.* 2005, 2009, Halse *et al.* 2014). A total of 110 stygal invertebrate taxa were recorded from bores in the Robe River catchment, including taxa belonging to the groups Oligochaeta (segmented worms), Polychaeta (bristle worms), Nematoda (round worms), Turbellaria (flat worms), Gastropoda (snails), Acarina (mites), Rotifera (wheel animals), Copepoda (copepods), Ostracoda (seed shrimps), Isopoda (aquatic slaters), Amphipoda (amphipods/side swimmers), Syncarida (syncarids) and Themosbaenacea (thermosbaenaceans). These taxa are also likey to occur within hyporheic zones of the Robe River. Out of the 110 taxa captured in the Robe River area, 83 were recorded from three or less bores (*i.e*. present at < 10% of bores), while just eight taxa were recorded from more than eight bores (*i.e.* present at > 20% of bores). It is possible that many of the uncommonly recorded stygofauna in this study are SREs.

Biota (2006a) sampled stygofauna from 21 bores within the Mesa A/Warramboo Project area and 20 bores in the Yarraloola area during 2005. In this study, a number of species which are occasionally encountered in hyporheic zones, such as stygal amphipods, copepods, and the themosbaenacean *Halosbaena tulki* were recorded, though it was noted that "there appears to be little in the way of a stygal community present at Warramboo". DNA sequencing delineated four new stygal amphipod species (Melitidae spp.), including two from the bores within the Mesa A/Warramboo Project area (Melitidae sp. A and sp. F), which currently are known only from the Mesa A/Warramboo Project area (Biota 2006a).

Biota (2010) sampled 58 bores in the Cardo East and Ken's Bore areas of the Red Hill Creek catchment. A number of potential SREs were recorded, including Paramelitidae (*Pilbarus* nr *millsi*, Paramelitidae sp. 2 and sp. 6), Melitidae (*Nedsia* spp., nr *Norcapensis* sp.), isopods (*Haptolana yarraloola*, *Kagalana tonde*, *Pygolabis* sp., *Pilbarophreatoicus platyarthricus*) and syncarids (*Bathynella* spp., Billibathynella sp. *Hexabathynella* sp. *Notobathynella sp.*).

Bennelongia (2013) sampled stygofauna in 61 bores within the Bungaroo South area in July and October 2012. Potential SREs recorded included Paramelitidae (Genus 2 sp. B12), Melitidae (*Nedsia* spp.), Neoniphargidae (nr *Wesniphargus*), the isopod *Pygolabis* sp. and syncarids (*Bathynella* spp., *Billibathynella* sp.).

3.3 Macroinvertebrates

Since 1991, Streamtec/UWA have conducted annual surveys for macroinvertebrates at seven long-term pools on the Robe River (Streamtec 1996 - 2014, Dobbs and Davies 2009). Pools include Medawandy Waters, Yarramudda, Japanese Pool, Martangkuna, Pannawonica Hill Pool, Pulari-Nyunangka, Gnieraoora (Figures 1 and 3). Four additional pools were included in the program during the 1990s; Chundy Pool, A1, Ngalooin and Mussel Pool (Figure 3). To date, over 112 macroinvertebrate taxa from 64 families have been recorded by Streamtec/UWA from 16 sampling occasions between February 1991 and December 2013. The most commonly encountered groups were the segmented Oligochaeta, Atyidae (freshwater prawns), Ephemeroptera (mayflies), Chironomidae (non-biting midges) and Dytiscidae (diving beetles). Streamtec/UWA noted that caddisflies (Trichoptera) were susceptible to changes in flow regime and water quality, with a decline in the number of species recorded following 1993, 2005, and 2012 cyclone events (Streamtec 2014).

The macroinvertebrate fauna of Chalyarn Pool (Mungarathoona Creek) was sampled during the PBS (Pinder *et al.* 2010). A total of 70 macroinvertebrate taxa were recorded at Chalyarn Pool in the wet season (May 2005), and 97 taxa were recorded in the dry season (August 2003). Other locations surveyed for macroinvertebrates in the vicinity of the Project area during the PBS included Red Hill Creek pools, Myannore Creek Pool and the Yarraloola Station claypan (Figure 3). A total of 196 macroinvertebrate taxa were recorded across these sites, sampled in August 2003/2004/2005 (dry season) and May 2003/2005/2006 (wet season). The most specious samples among these were collected at Red Hill Creek, with 90 taxa collected in both the wet and dry seasons (Pinder *et al.* 2010).

Macroinvertebrates from Mungarathoona Creek and Red Hill Creek were also sampled as part of baseline aquatic surveys for API's WPIOP area (WRM 2009). A total of 128 macroinvertebrate taxa were recorded across two sampling events; dry season (December) 2008 and wet season (April) 2009 (WRM 2009). The taxonomic list comprised Nematoda (roundworms), Hydrozoa (freshwater hydra), Oligochaeta (segmented worms), Gastropoda (snails and bivalves), Acarina (aquatic mites), Ephemeroptera (mayflies), Odonata (dragonflies and damselflies), Hemiptera (true bugs), Coleoptera (aquatic beetles), Diptera (aquatic fly larvae, including Chironomidae/midges), Trichoptera (caddisflies) and Lepidoptera (aquatic caterpillars).

The macroinvertebrate fauna of Yalleen Pool and Nyeetbury Spring on Bungaroo Creek have been sampled as part of the ongoing Pilbara Regional Aquatic Program for the Proponent (see WRM 2016). A total of 83 macroinvertebrate taxa were collected from Yalleen Pool from a total three sampling occasions; wet (March) and dry season (October) 2010 and wet season (March) 2011 (WRM 2013). A total of 190 macroinvertebrate taxa were recorded from Nyeetbury Spring from a total 13 occasions during biannual sampling (wet and dry seasons) between and October 2009 and May 2016 (WRM 2016).

The composition of macroinvertebrate taxa recorded during all of the above studies was typical of freshwater systems throughout the world (Hynes 1970), being dominated by Insecta (insects), within which Diptera (flies) and Coleoptera (beetles) were particularly well represented.

Of the macroinvertebrate fauna recorded from the Robe River catchment, two species are listed for conservation significance (IUCN Red List), and six are of scientific interest, being Pilbara endemics and/or relatively new to science. All potentially occur within the Project area. Three other Pilbara endemics have the potential to occur within the Project area (having been recorded within 100 km), and based on their known dispersal capabilities (*i.e.* with winged-adult forms with strong capacity for flight). These species are as follows:

- Conservation listed species recorded from the Robe River catchment:

  Eurysticta coolawanyah (Pilbara pin damselfly) (IUCN Near Threatened);
  Hemicordulia koomina (Pilbara emerald dragonfly) (IUCN Near Threatened);

- Pilbara endemic species recorded from the Robe River catchment:

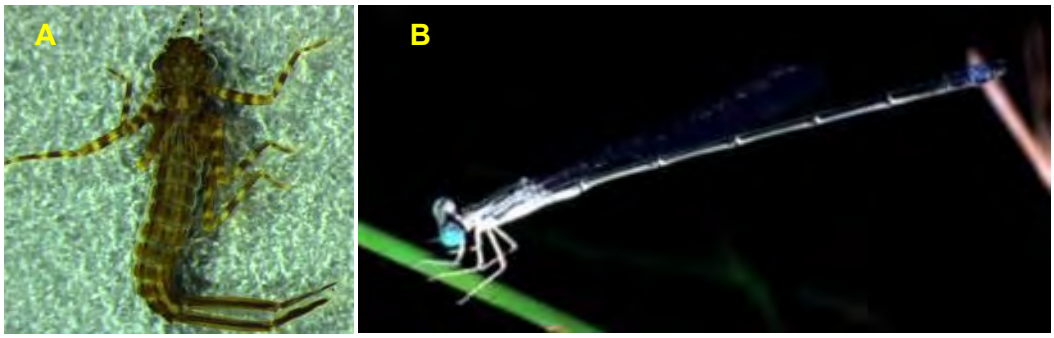
  Agriocnemis kunjina (Pilbara wisp damselfly);
  Ictinogomphus dobsoni (Pilbara tiger dragonfly);
  Nannophlebia injibandi (Pilbara archtail dragonfly);
  Tiporus tambreyi (diving beetle);
  Laccobius billi (water scavenger beetle);
  Haliplus halsei (crawling water beetle);

- Pilbara endemic species recorded from other locations within 100 km of the Project area:
  - *Sternopriscus pilbaraensis* (diving beetle);
  - *Tiporus lachlani* (diving beetle);
  - *Haliplus pilbaraensis* (crawling water beetle).

The Pilbara pin damselfly, *Eurysticta coolawanyah* (Plate 1A-B), is restricted to the Pilbara region, where it prefers riverine pools with an abundance of perching mediums (*e.g.* emergent reeds or overhanging riparian vegetation). *E. coolawanyah* has been collected from Robe River pools by Streamtec/UWA, and from Bungaroo Creek by WRM (2013, 2016). It has also been previously recorded at Chalyarn Pool (Pinder *et al.* 2010). *E. coolawanyah* is listed as Near Threatened[4] on the IUCN Red List of Threatened Species (IUCN 2016), based on its (initially recorded) restricted distribution to an area of less than 500 km^2, and it being thought to occur at less than five locations (Millstream Station, Nanuturra Pools, Palm Pool and the Millstream area); however, it has since been recorded from over 40 locations throughout the Pilbara (Pinder *et al*. 2010). Hawking (2009a) lists no known threats currently, or in the near future, to this species. WRM has encountered *E. coolawanyah* in habitats with a range in frequency of inundation and degree of persistence, including permanent/semi-permanent pools, permanent springs, ephemeral pools and sites permanently inundated and flowing due to dewatering discharge operations, for example at Weeli Wolli Spring.

The Pilbara emerald dragonfly, *Hemicordulia koomina* (Plate 1C-D), has been recorded by Streamtec/UWA from the Robe River, and from Red Hill Creek by Pinder *et al.* (2010). It is known to prefer large, permanent/semi-permanent pools. *H. koomina* is currently listed as Near Threatened on the IUCN Red List (IUCN 2016) but this listing is in need of revision given its more recent collections from numerous localities across several river catchments, including the Fortescue River (Hamersley Gorge, Fortescue Falls, Kalgan Creek), DeGrey River (Bamboo Springs, Minigarra Creek), Ashburton River system (Moreton Pool, Creek Pool near Mt Amy, Henry River pools, Pool at Gorge Junction), Sherlock River (Pool Spring) and Shaw River (Panorama Spring). Despite its widespread occurrence, *H. koomina* is infrequently collected, likely due to its preference for large, permanent pools, which are somewhat uncommon in the Pilbara region and inherently difficult to sample. The major threat to this species is considered to be loss of habitat (*i.e.* drying of permanent pools/waterways) through groundwater abstraction (Hawking 2009b).

Both of these species, particularly the large dragonfly *H. koomina*, are likely to have excellent dispersal capabilities in their winged-adult form (see Plate 1). Dispersal (the movement of individuals from one site to another) is an integral factor in determining the composition of biological communities (Palmer et *al*. 1996, Leibold *et al*. 2004). Aerial dispersal by winged-adult invertebrate fauna (*e.g.* Odonata, Coleoptera, Hemiptera, Ephemeroptera, Diptera and Trichoptera, *etc*.) has been recognised as the most important pathway for colonisation in arid and semi-arid wetlands (Gray and Fisher 1981). Heavy rainfall during the wet season also serves as a cue for many aquatic invertebrate taxa to migrate from perennial wetlands to colonise more ephemeral bodies of water (Lytle and Poff 2004). Given their proficient dispersal capabilities, and the record of these species at multiple locations within close proximity to the Project area, it is considered likely that macroinvertebrate sampling could reveal the presence of one or both of *E. coolawanyah* or *H. koomina* within the Project area.



[4] A species is listed under the IUCN Red List as Near Threatened when it has been evaluated against the criteria but does not qualify for Critically Endangered, Endangered or Vulnerable now, but is close to qualifying for or is likely to qualify for a threatened category in the near future (IUCN 2016).

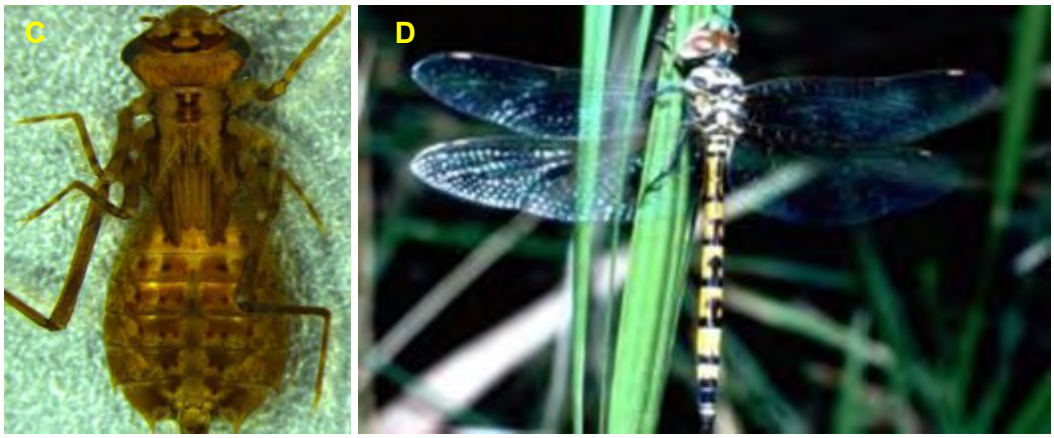


Plate 1. Pilbara pin damselfly, *Eurysticta coolawanyah* (A) nymph and (B) adult, and Pilbara emerald dragonfly *Hemicordulia koomina* (C) nymph and (D) adult (photos A and D courtesy of Jan Taylor ©).

The endemic Pilbara tiger dragonfly, *Ictinogomphus dobsoni*, is recorded infrequently and in low abundances from permanent still or sluggish waters of the Pilbara region (Watson 1991). It is known from a number of sites along the Fortescue, Robe, Ashburton, Yule, DeGrey and Sherlock rivers (DEC 2009, Pinder *et al*. 2010, CSIRO 2015). Near the Project area, *I. dobsoni* has been recorded from pools along the Robe River (Streamtec/UWA), Mungarathoona Creek (Chalyarn Pool) and Red Hill Creek (Pinder *et al*. 2010).

The Pilbara archtail dragonfly, *Nannophlebia injibandi*, is also restricted to the Pilbara region. This species was recorded infrequently during the PBS at Millstream Delta and Gregory Gorge in the Fortescue River catchment (Pinder *et al.* 2010). Within the vicinity of the Project area, *N. injibandi* has been recorded from Robe River pools near Mesa H (Streamtec/UWA) and from Red Hill Creek (WRM 2009).

The Pilbara wisp damselfly *Agriocnemis kunjina,* is a Pilbara endemic rarely encountered. It is previously known from Millstream, Harding River, and Tanberry Creek (ANIC Database); however, it was not recorded during the PBS (Pinder *et al.* 2010). *A. kunjina* is known from both still and flowing waters (Theischinger and Hawking 2006), and has been recorded from Robe River pools in the vicinity of the Project area (Streamtec/UWA) and from Yalleen Pool (WRM 2013).

The aquatic hydrophilid beetle *Laccobius billi* is a Pilbara endemic species that also is rarely collected. *L. billi* was only recorded from one site during the PBS; Cangan Pool on the Yule River (Pinder *et al.* 2010). WRM (2009) recorded *Laccobius billi* at Mungarathoona Creek and from a number of Red Hill Creek sites.

The haliplid beetles *Haliplus halsei* and *H. pilbaraensis* are both endemic to the Pilbara region, and are relatively new to science, having only been recently described (Watts and McRae 2010). Each species appears to occur widely throughout the Pilbara, and have been recorded at localities such as Glen Ross Creek, Coondiner Pool, the Fortescue Marsh, Moreton Pool, Paradise Pool, Munreemya Billabong, Wackilina Creek Pool, West Peawah Creek Pool, Harding River Pool, and an un-named creek in Millstream (Watts and McRae 2010). Closer to the Project area, *Haliplus halsei* has been recorded from Chalyarn Pool and Myannore Creek during the PBS (Pinder *et al*. 2010), while *Haliplus pilbaraensis* has been recorded from Red Hill Creek by WRM (2009).

The dytiscid beetle *Sternopriscus pilbaraensis* is endemic to the Pilbara, is relatively common and known from a range of systems, including Red Hill Creek, the Fortescue River (Gregory Gorge and Kalgan Pool), Ashburton River (Bobswim Pool, Yandabiddy Pool, Whiskey Pool, Ashburton at Gorge Junction, Innawally Pool and Rocky Island Pool), DeGrey River (Pool at Yarrie Homestead, Pelican pool on

Nullagine, Tanguin Rockhole, Paradise Pool, Munereemya Billabong, Carleecarleethong Pool, Minigarra Creek Pools, Bonnie Pool, Cookes Creek Pools, Running Waters and Pool on Tongolock), Rudall River (Watrara Creek Pool), Shaw River (Panorama Spring), Sherlock River (Kangan Pool) and the Harding River (Harding River Pool) (Pinder *et al.* 2010).

The diving beetles *Tiporus tambreyi* and *T. lachlani* are also relatively common and widespread across the region (Pinder *et al.* 2010, WRM unpub. data), though *T. lachlani* is less frequently encountered than its congener (Pinder *et al.* 2010, WRM unpub. data). In the vicinity of the Project area, *T. tambreyi* has been recorded from Robe River pools (Streamtec/UWA), Chalyarn Pool (Pinder *et al.* 2010) and Red Hill Creek (WRM 2009, Pinder *et al.* 2010), while *T. lachlani* has only been previously recorded from Red Hill Creek (Pinder *et al.* 2010).

3.4 Fish

The fish fauna of the Pilbara region is unique, with 13 freshwater species recorded from inland waters to date, including catadromous[5] species (Allen *et al.* 2002, Morgan and Gill 2004). Of the freshwater species, three (or possibly four) are considered endemic to the region. These include the golden gudgeon (*Hypseleotris aurea*), the Murchison River hardyhead (*Craterocephalus cuneiceps*), one undescribed eel-tailed catfish, the Pilbara tandan *Neosilurus* sp.[6], and the conservation listed Fortescue grunter (*Leiopotherapon aheneus*) (Morgan and Gill 2004). *L. aheneus* (Plate 2) is currently listed on the IUCN Red List of Threatened Species as Lower Risk/Near Threatened (IUCN 2016), and as a Priority 4 (P4)[7] species on the Parks and Wildlife Priority Fauna List (Parks and Wildlife 2016). The Fortescue grunter has a restricted distribution within the Pilbara, and is only known from the Fortescue, Robe and Ashburton River systems (Allen *et al*. 2002, Morgan and Gill 2004). This species is considered to be reasonably common within its range.

Plate 2. Fortescue grunter *Leiopotherapon aheneus.* Photo by Chris Hofmeester (WRM) ©.

Other known species from Pilbara inland waters include the spangled perch (*Leiopotherapon unicolor*), barred grunter (*Amniataba percoides*), western rainbowfish (*Melanotaenia australis*), bony bream (*Nematalosa erebi*), flathead goby (*Glossogobius giuris*), empire gudgeon (*Hypseleotris compressa*), Hyrtl's tandan (eel-tailed catfish; *Neosilurus hyrtlii*), blue catfish or lesser salmon catfish (*Arius graeffei*), and the Indian short-finned eel (*Anguilla bicolor*) (Allen *et al.* 2002, Morgan and Gill 2004, Beesley 2006). The most common and widespread species are spangled perch, western rainbowfish and bony bream (Plate 3). The western rainbowfish, for example, has a range extending from the Ashburton River in the Pilbara to the Adelaide River near Darwin, inhabiting rivers, creeks, swamps, lakes and reservoirs

[5] Catadromous fishes live in freshwater as juveniles or sub-adults, but migrate to marine habitats to spawn.

[6] Previously referred to as *Neosilurus hyrtlii*. Recent genetic evidence indicates the Pilbara species is distinct from elsewhere in Australia (Peter Unmack, National Evolutionary Synthesis Centre, North Carolina, pers. comm.).

[7] P4 species are those with limited distributions "in need of monitoring" (Parks and Wildlife 2016).

(Allen *et al.* 2002). Spangled perch and bony bream are considered to be two of Australia's most widespread freshwater fish species, found in drainages throughout the Pilbara, Kimberley, Northern Territory, Queensland, northern New South Wales, as well as in Lake Eyre and the Murray-Darling system (Allen *et al.* 2002).

In addition, the Pilbara Drainage Division contains two endemic cave fishes restricted to the North West Cape region; the blind gudgeon (*Milyeringa veritas*) and the blind cave eel (*Ophisternon candidum*) (Allen *et al.* 2002, Morgan and Gill 2004). Both *M. veritas* and *O. candidum* are listed as Vulnerable under the EPBC Act.

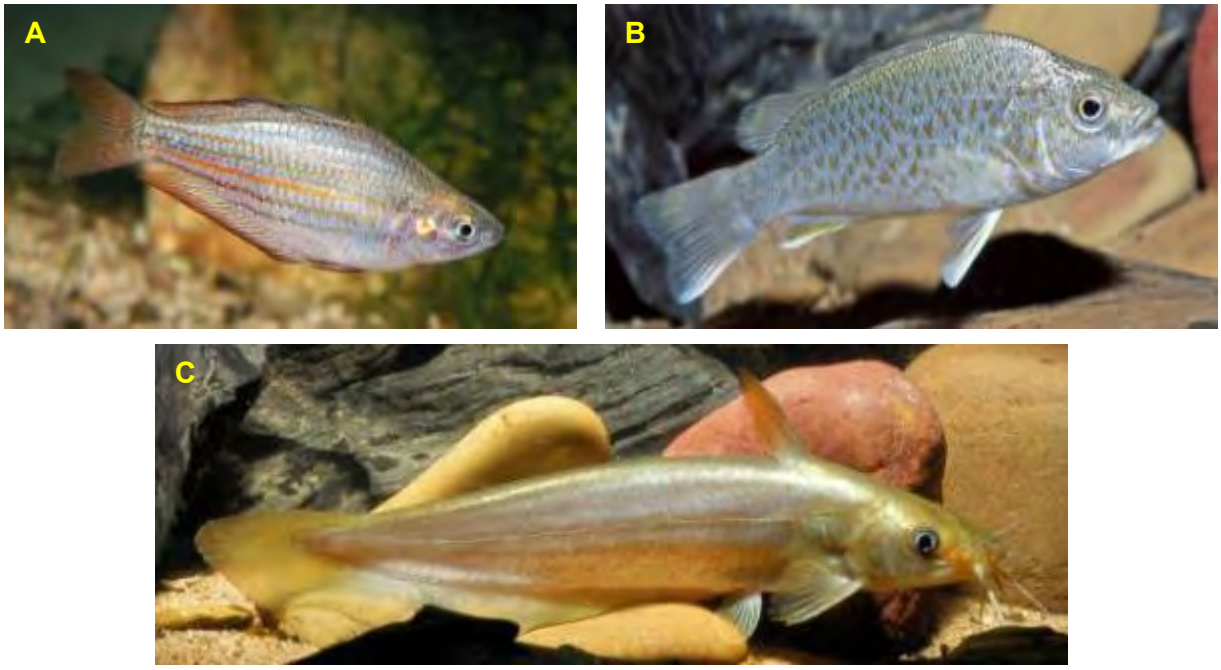

Plate 3. The three most commonly encountered freshwater fish species in the Pilbara; (A) western rainbowfish *Melanotaenia australis*, (B) spangled perch *Leiopotherapon unicolor* and (C) Pilbara tandan *Neosilurus* sp. (photos courtesy of Mark Allen ©).

Freshwater systems of the Pilbara also host a number of species that are considered to be of marine or estuarine origin, most of which have a non-obligatory freshwater juvenile phase. These commonly include barramundi (*Lates calcarifer*), mangrove jack (*Lutjanus argentimaculatus*), sea mullet (*Mugil cephalus*) and tarpon or ox-eye herring (*Megalops cyprinoides*) (Morgan and Gill 2004). The presence of marine/estuarine species in freshwater systems of the Pilbara is likely to be influenced by the frequency, timing and duration of flood events; the species listed above would only enter rivers if flooding coincided with their recruitment phase, while distance moved upstream is governed by the duration of the flood event (Morgan and Gill 2004). As floods recede, it is common for these species to become isolated in permanent upstream pools, forming small remnant populations that are cut-off from marine habitats (Morgan and Gill 2004).

Streamtec/UWA sampled the fish fauna of Robe River pools using seine nets, dip nets, and visual observation. Six freshwater fish species were recorded, including western rainbowfish, spangled perch, Pilbara tandan, barred grunter, bony bream and the conservation listed Fortescue grunter. Additionally, five marine vagrant/estuarine species were recorded, including tarpon, banded scat or striped butterfish (*Selenotoca multifasciata*), threadfin silver-biddy (*Gerres filamentosus*), sea mullet and mangrove jack.

Morgan and Gill (2004) surveyed four Robe River sites for fish using a combination of sampling methods (refer Table 1). Six freshwater species were again recorded (western rainbowfish, spangled perch, Pilbara tandan, barred grunter, bony bream and Fortescue grunter); however, no marine/estuarine

species were reported. Morgan and Gill (2004) also included historic records from the Western Australian Museum (WAM) that list empire gudgeon as occurring in the Robe River in the vicinity of the Project area.

The Department of Water (DoW) conducted a review of the ecological values of the lower Robe River, west of the North West Coastal Highway crossing point and Mesa A/Warramboo deposits, which included a summary of the freshwater and estuarine fish fauna of that reach (Antao and Braimbridge 2010). The review did not document any species from the lower Robe River that were not recorded by Streamtec/UWA or Morgan and Gill (2004).

WRM (2016) has recorded seven species from Nyeetbury Spring on upper Bungaroo Creek; Pilbara tandan, western rainbowfish, flathead goby, spangled perch, Fortescue grunter, barred grunter, and a fish that appears to be a hybrid between two of the three co-occurring terapontids (grunters; spangled perch, barred grunter and Fortescue grunter). At Yalleen Pool on Bungaroo Creek, WRM (2013) recorded only western rainbowfish, spangled perch and Pilbara tandan. WRM (2009) also surveyed the fish fauna of upper-Mungarathoona Creek, recording five species; western rainbowfish, spangled perch, Pilbara tandan, barred grunter and Fortescue grunter.

3.5 Other Fauna

3.5.1 Turtles

Although not typically targeted in aquatic surveys, one species of native turtle is known from the Pilbara region; the flat-shelled *Chelodina steindachneri.* This species has a widespread distribution throughout the Pilbara, having been recorded from most major river systems in the region, from the DeGrey River in the north to the Murchison River in the south (Kuchling 1988, WRM unpub. data). These turtles are adapted to survive drought by burrowing into the dry river beds (Kuchling 1988). Only one clutch of seven to eight relatively small eggs is laid each year; a pattern that appears to be adapted to a relatively long period of aestivation of up to three years (Kuchling 1988).

EPA (1991) note *Chelodina steindachneri* as present at Gnieraoora and Martangkuna, but do not state the source of the records, which was possibly the 1991 survey by Streamtec/UWA. Neither Antao and Braimbridge (2010) nor Pinder *et al.* (2010) document turtles. Similarly, turtles were not recorded or observed at upper-Mungarathoona Creek or Red Hill Creek by WRM (2009); however, given its widespread distribution across the Pilbara region, it is possible that *Chelodina steindachneri* may reside in pools in the vicinity of the Project area.

3.5.2 Frogs

The Pilbara is host to 13 species of frogs, three of which are endemic to the region; *Pseudophryne douglasi* (Gorge toadlet), *Uperoleia glandulosa* (Glandular toadlet) and *U. saxatilis* (Pilbara toadlet) (Tyler and Doughty 2009, Doughty *et al*. 2011). None of these species are currently listed for conservation significance, though *U. saxatilis* has only recently been described (Catullo *et al.* 2011). *U. saxatilis* is broadly distributed throughout the Pilbara, occurring in or near rocky creeks, and appears to be adapted to rocky landscapes (Catullo *et al.* 2011, Doughty *et al*. 2011). *U. glandulosa* has a more restricted distribution in the northern coastal Pilbara but penetrates inland along the Yule River drainage (Catullo *et al.* 2011, Doughty *et al*. 2011). *Pseudophryne douglasi* is a rare species that has an ancient relictual arid distribution separate from other toadlets (Doughty *et al*. 2011, WA Museum).

The Pilbara, Gascoyne and Murchison populations of the desert tree frog, *Litoria rubella*, are separated from Kimberley and Northern Territory populations by the Great Sandy Desert. *L. rubella* is known to

occur in a wide range of habitats across northern Australia, including northern Western Australia, Northern Territory, north-east of South Australia, Queensland, and northern New South Wales (Tyler and Knight 2011). The desert tree frog is commonly found sheltering under stones or bark around creeks and waterholes, and can breed at any time of year if water is present (Tyler and Knight 2011).

Frogs are difficult to survey in the Pilbara region, as captures are typically dependent on rainfall that is spatially and temporally variable (Doughty *et al*. 2011). Many frog species of the Pilbara aestivate over dry periods to avoid desiccation, emerging following rains to opportunistically breed and spawn (Tyler and Doughty 2009). No data were available on targeted frog surveys in the vicinity of the Project area, and although there have been a number of terrestrial vertebrate surveys (*e.g.* Biota 2005, 2006b, 2009, Strategen 2006), few have recorded frogs. Biota (2006a) recorded two species of Hylidae (tree frogs): *L. rubella* and *Cyclorana maini* - and one Myobatrachidae (southern frog) species *Uperoleia russelli* during baseline surveys for the Mesa A/Warramboo project area. In addition to *L. rubella* and *U. russelli*, Biota (2009) recorded the ornate burrowing frog *Platyplectrum ornatus* (formerly *Limnodynastes ornatus)* from the Red Hill Creek catchment.

3.6 Summary of Known Species of Conservation and/or Scientific Interest

Table 2 below provides a summary of known aquatic invertebrates (including hyporheos) and fish of conservation and/or scientific interest.

Table 2. Aquatic species (invertebrates and fish) of conservation and/or scientific value known to occur, or likely to occur, within the Project area.

Species	Common name	Scientific value	Conservation listing	Occurrence within 100 km of Project area	Likelihood of occurrence within the Project area	Occurrence elsewhere
Microinvertebrates						
Lecane noobjupi	Rotifer	WA endemic	N/A	Nyeetbury Spring, Red Hill Creek	High in surface waters	Weeli Wolli Ck, Marillana Ck, Coondiner Ck, Mindy Mindy Ck, Kalgan Ck and Un-named Ck, DeGrey R. Also in SW Western Australia
Paracyclops sp. 6	Copepod (micro-crustacean)	Pilbara endemic	N/A	Chalyarn Pool	High in surface waters	20+ locations Pilbara-wide
Vestalenula matildae	Ostracod (micro-crustacean)	Pilbara endemic	N/A	Chalyarn Pool	High in surface waters	Various systems of the Ashburton R., DeGrey R., Fortescue R. and Sherlock R.
Hyporheos						
Paramelitidae spp.	Stygal amphipods	Potential SRE	N/A	Yalleen Pool, Red Hill Ck, Mungarathoona Ck.	High in ground-waters and hyporheos	Unknown given family level identification.
Melitidae spp.	Stygal amphipods	Potential SRE	N/A	Bores across the Robe River catchment area	High in ground-waters; Low-moderate in hyporheos	Unknown given family level identification
Haptolana yarraloola	Stygal isopod	Potential SRE	N/A	Bores in the lower Robe River catchment area – Mesa A/Warramboo/Yarraloola	Low	Recently described species; known only from Mesa A/ Warramboo/Yarraloola bores
Kagalana tonde	Stygal isopod	Potential SRE	N/A	Bores in the lower Robe River catchment area – MesaA/Warramboo/Yarraloola	Low	Recently described genus and species; elsewhere known from Cane River and Hardey River catchments
Pilbarophreatoicus platyarthricus	Stygal isopod	Potential SRE	N/A	Chalyarn Pool, Nyeetbury Spring, Bores in the Robe River catchment area	High in ground-water and hyporheos	Weeli Wolli Ck, Coondiner Ck, Bobswim Pool (Ashburton R.)
Pygolabis sp.	Stygal isopod	Potential SRE	N/A	One undescribed species known from the Robe River catchment	High in ground-water and hyporheos	Uncertain. Members of this genus restricted to either Fortescue, Ashburton or Robe catchment groundwater and hyporheos
Tainisopus sp.	Stygal isopod	Potential SRE	N/A	Nyeetbury Spring	Low-moderate; only known from Nyeetbury Spring hyporheos	Unknown given genus level identification

Species	Common name	Scientific value	Conservation listing	Occurrence within 100 km of Project area	Likelihood of occurrence within the Project area	Occurrence elsewhere
Parabathynellidae spp.	Stygal syncarids	Potential SRE	N/A	Unknown given genus level identification	High in ground-waters; Low-moderate in hyporheos	Unknown given genus level identification
Macroinvertebrates						
Hemicordulia koomina	Pilbara emerald dragonfly	Pilbara endemic	IUCN, Near Threatened	Robe River pools, Red Hill Ck.	High in surface waters	Fortescue R., Coondiner Ck; now known to be widespread throughout the Pilbara, though infrequently collected
Eurysticta coolawanyah	Pilbara pin damselfly	Pilbara endemic	IUCN, Near Threatened	Chalyarn Pool, Robe River pools, Yalleen Pool	High in surface waters	Ashburton R. (Bobswim Pool); Kalgan Ck; Coondiner Ck; Fortescue R.
Ictinogomphus dobsoni	Pilbara tiger dragonfly	Pilbara endemic	N/A	Chalyarn Pool, Robe River pools, Red Hill Ck.	High in surface waters	Fortescue, Ashburton, Yule, DeGrey and Sherlock rivers
Nannophlebia injibandi	Pilbara archtail dragonfly	Pilbara endemic	N/A	Robe River pools, Red Hill Ck.	Low-Moderate in surface waters	Fortescue R. catchment, but uncommonly collected
Agriocnemis kunjina	Pilbara wisp damselfly	Pilbara endemic	N/A	Robe River Pools, Yalleen Pool	Low-Moderate in surface waters	Millstream, Harding River, Tanberry Ck; rarely collected
Haliplus halsei	Aquatic beetle	Pilbara endemic	N/A	Chalyarn Pool, Myannore Ck.	Low-Moderate in surface waters	Uncommonly collected from ephemeral systems and claypans, *e.g.* the Fortescue Marsh and Coondiner Pool
Haliplus pilbaraensis	Aquatic beetle	Pilbara endemic	N/A	Red Hill Ck.	Low-Moderate in surface waters	Uncommonly collected from ephemeral systems and claypans, *e.g.* the Fortescue Marsh and Coondiner Pool
Sternopriscus pilbaraensis	Diving beetle	Pilbara endemic	N/A	Red Hill Ck.	Moderate in surface waters	A range of systems across the Pilbara, fairly commonly collected
Tiporus tambreyi	Diving beetle	Pilbara endemic	N/A	Chalyarn Pool, Robe River pools, Red Hill Ck.	Moderate-High in surface waters	A range of systems across the Pilbara, very commonly collected
Tiporus lachlani	Diving beetle	Pilbara endemic	N/A	Red Hill Ck.	Low-Moderate in surface waters	A range of systems across the Pilbara, infrequently collected
Laccobius billi	Aquatic beetle	Pilbara endemic	N/A	Mungarathoona Ck, Red Hill Ck.	Low-Moderate in surface waters	Yule R. and Fortescue R.

Species	Common name	Scientific value	Conservation listing	Occurrence within 100 km of Project area	Likelihood of occurrence within the Project area	Occurrence elsewhere
Fish						
Leiopotherapon aheneus	Fortescue grunter	Pilbara endemic	IUCN Near Threatened; Parks and Wildlife P4	Robe River pools, Red Hill Ck., Mungarathoona Ck.	High in surface waters	Fortescue R (below Fortescue Marsh); Ashburton R.

4 METHODS FOR BASELINE SURVEYS

4.1 General

For the current baseline field sampling, WRM employed sampling design, methods and general approaches consistent with the following:

- Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC/ARMCANZ 2000);
- Environment Protection Authority (EPA) Guidance No. 20, Sampling of Short Range Endemic Invertebrate Fauna for Environmental Impact Assessment in Western Australia (EPA 2009);
- EPA Position Statement No. 3, Terrestrial Biological Surveys as an Element of Biodiversity Protection (EPA 2002);
- EPA Guidance No. 56, Terrestrial Fauna Surveys for Environmental Impact Assessment in Western Australia (EPA 2004).

Aquatic fauna sampling methods were also similar to the following:

- Streamtec/UWA surveys of benthic macroinvertebrates of the Robe River (see Dobbs and Davies 2009, Streamtec 2014);
- Parks and Wildlife surveys of benthic macroinvertebrates for the regional Pilbara Biological Survey (PBS) (see Pinder *et al.* 2010).

4.2 Licences

This study was conducted under Department of Fisheries (DoF) Exemption #2706 (Authority to Take Fish for Scientific Purposes), and Parks and Wildlife Licence SF010732 (Licence to Take Fauna for Scientific Purposes).

As a condition of these licences, taxa lists and reports are required to be submitted to the respective government departments, and have been done so.

4.3 Sampling Design and Sites

The sampling design is an mBACI (multiple Controls - Before/After - Control/Impact) type design (Keough and Mapstone 1995). Location and number of sites were selected to provide data for robust statistical analysis and to meet requirements of such a design. An mBACI design is considered ideal for impact assessment, as impacts may be placed in context with natural temporo-spatial catchment changes. An mBACI type design provides both benchmark information as well as a strong basis to detect future changes. Reference sites upstream of the Project area were selected to serve as the "control" for potentially impacted sites. Surveys conducted in April/May 2016 are part of the benchmark or "before" phase against which to assess any potential future changes.

Sampling was conducted during the late wet season, between 28th April and 7th May 2016.

A total of 12 pools were sampled along the main channel of the Robe River (Table 3 and Figure 1). Sites included six potentially exposed sites within the predicted surface extent of dewatering discharge, and six reference sites upstream of the Jimmawurrada Creek-Robe River confluence.

Table 3. Aquatic ecosystem sampling sites on the Robe River. Equivalent sites monitored by Streamtec/UWA are also indicated.

Type	WRM Site	Description	GPS co-ordinates (zone 50 K)		Date sampled	Maximum wetted width, length and depth of pool (m)			Streamtec/ UWA site
			Easting	Northing		Width	Length	Depth	
Reference	RRU1	Approx. 3.7 km upstream of Pannawonica Hill.	435628	7603253	05-05-16	20	100	1.2	
	RRU2	Approx. 600 m downstream of Streamtec/UWA site at Pannawonica Hill Pool; upper end of Medawandy Waters area, adjacent Mesa N.	431811	7602046	28-04-16	9	55	3.0	Pannawonica Hill
	RRU3	Approx. 1.6 km downstream of Pannawonica Hill, near Mesa N; within the Medawandy Waters area.	430912	7601562	28-04-16	5	3	1.0	Medawandy

	RRD6	Approx. 12.5 km downstream of existing Mesa J western discharge point; within projected discharge footprint (at 20 ML/day).	411415	7594924	30-04-16	30	20	1.2	

* Dthulurat = Western Guruma name.

The original intent was that the assessment would utilise, wherever possible, long-term data from sites sampled by Streamtec/UWA; however, only two of these sites are located within the predicted footprint of surface discharge extent; Martangkuna (RRD1) and Gnieraoora/Dthulurat (RRD5). Therefore, four new sites (RRD2, RRD3, RRD4 and RRD6) were added to allow a more robust characterisation of ecological condition within this reach (Table 3 and Figure 1). These sites may also be exposed to any runoff from the Project area.

Of the sites sampled by Streamtec/UWA upstream of the Jimmawurrada-Robe confluence, two were selected as reference sites for the Project area; Medawandy and Pannawonica Hill Pool; however, only Medawandy (RRU3) held surface water at the time of sampling in April-May 2016. Therefore, five new reference sites were established within the Medawandy Waters area; RRU1, RRU2, RRU4, RRU5 and RRU6 (Table 3 and Figure 1). Site photographs are provided in Appendix 1.

The 2016 sampling was timed to correspond with recessional flow conditions at the end of the wet (April-May) season. It was considered that the end of the wet season would be a more ecologically important time of year to sample, as biological diversity would be expected to be at its highest. By comparison, lower biological diversity may be expected at the start of the wet season, as many invertebrate fauna would not yet have emerged/colonised the seasonal creeks.

4.4 Water Quality

At each site, pH, dissolved oxygen and temperature were measured *in situ* using hand-held Wissenschaftlich-Technische-Werkstätten (WTW) field meters. Meters were calibrated immediately prior to field surveys. Water depth was measured using a graduated pole. Undisturbed water samples were collected for laboratory analyses of major ions, alkalinity, dissolved metals, nutrients and total suspended solids (TSS). Water samples for nitrogen and phosphorus nutrient and dissolved metal analyses were filtered in the field through 0.45 µm nitrocellulose filters. To avoid contamination, all sample bottles and filtering equipment used for dissolved metals were acid-washed (0.1% nitric acid) prior to use. Bottles and filters used for nutrients weren't acid washed to avoid nitrogen contamination from nitric acid. Water samples for analysis of dissolved metals and nutrients were collected using nitrile gloves. All samples were double-wrapped in polyethylene zip-lock bags and kept cool on ice-packs in an esky while in the field and during transport. At the end of each field day, samples were either refrigerated (ions and metals) or frozen (nutrients). Samples were stored refrigerated or frozen for a maximum of 10 days prior to transport on ice to analytical laboratories at ChemCentre, Bentley, together with chain-of-custody forms. All water quality variables measured are summarised in Table 4.

4.4.1 Comparison against ANZECC/ARMCANZ Guidelines

Water quality data were compared against default ANZECC/ARMCANZ (2000) guidelines (trigger values) for the protection of freshwater ecosystems (provided in Appendix 2). Default trigger values (TVs) for 95% aquatic species protection were considered more appropriate than default TVs for 99% protection, given that the Robe River catchment in the vicinity of current mining operations is already slightly to moderately disturbed by historic mining and pastoral practices (Strategen 2006). In accordance with ANZECC/ARMCANZ (2000) however, the default 99% TVs were applied to bioaccumulating metals such as selenium. For metals and nutrients, dissolved concentrations (0.45 µm filtered samples) were compared to the default TVs. Filtered concentrations were considered a better reflection of the fraction that may be bioavailable. By contrast, comparison of the default TVs to the total metal or total nutrient concentration may overestimate the risk to the environment (ANZECC/ARMCANZ 2000).

Table 4. Measured and derived water quality and habitat parameters. Metals (Al, As, B, Ba, Cd, Co, Cr, Cu, Fe, Mn, Mo, Ni, Pb, S, Se, U, V, Zn) and nutrients ($N\text{-}NH_3$, $N\text{-}NO_2$, $N\text{-}NO_3$, $N\text{-}NO_X$, N-total, P-total) were measured as dissolved concentration. All units for water quality parameters are mg/L unless stated otherwise.

Water Quality Parameters	Code	Habitat Parameters	Code
Temperature (°C)	Temp	Maximum pool depth (m)	depth
pH (H^+)	pH	Maximum wetted length of pool (m)	length
Dissolved oxygen (%)	DO%	Mean wetted width of pool (m)	width
Dissolved oxygen (mg/L)	DO	Mineral substrates (total % cover within habitat)	min
Conductivity (µS/cm)	EC	Bedrock (% cover)	bedr
Redox (mV)	Redox	Boulders >256 mm (% cover)	boul
Alkalinity (as $CaCO_3$)	Alk	Cobbles 64-256 mm (% cover)	cobb
Ammonia	$N\text{-}NH_3$	Pebbles 16-64 mm (% cover)	pebb
Arsenic	As	Gravel 4-16 mm (% cover)	grav
Barium	Ba	Sand 1-4 mm (% cover)	sand
Boron	B	Silt <1 mm (% cover)	silt
Cadmium	Cd	Mean particle size (from substrate proportions)	phi
Calcium)	Ca	Emergent macrophyte (% cover)	emerg
Carbonate	CO_3	Submerged macrophyte (% cover)	submerg
Chloride (mg/L)	Cl	Floating macrophyte (% cover)	float
Chromium (µg/L)	Cr	Algae (% cover)	algae
Copper (µg/L)	Cu	Detritus (% cover)	detr
Hardness (as $CaCO_3$)	Hard	Riparian vegetation canopy (% canopy cover)	ripvegco
Hydrogen carbonate	HCO_3	Large woody debris (>10 cm diameter) (% cover)	LWD
Iron	Fe	Root mats (% cover)	rootm
Lead	Pb	Trailing riparian vegetation (% cover)	ripveg
Magnesium	Mg	Habitat diversity (total no. of habitat types)	habdiv
Manganese	Mn	Substrate compaction (1 = loose, to 5 = armoured)	compct
Nickel	Ni	Substrate diversity (total no. substrate types)	subdiv
Nitrate-nitrogen	$N\text{-}NO_3$		
Nitrite-nitrogen	$N\text{-}NO_2$		
Nitrogen oxides	$N\text{-}NO_X$		
Nitrogen-total	N-total		
Phosphorus-total	P-total		
Potassium	K		
Selenium	Se		
Sodium	Na		
Sulfate	$S\text{-}SO_4$		
Sulfur	S		
Total dissolved solids	TDS		
Total suspended solids	TSS		
Uranium	U		
Vanadium	V		
Zinc	Zn		

4.5 Habitat Characteristics

Details of habitat characteristics at each site were recorded (Table 4) to assist in explaining any patterns in faunal assemblages, particularly due to existing differences in benthic substrate composition. Habitat parameters were assessed for the approximately 10 m section of river over which each macroinvertebrate sample was collected. Water depth was measured with a graduated pole. Substrate type was visually assessed and recorded as estimated percent cover by bedrock, boulders, cobbles, pebbles, gravel, sand, silt and clay, from which mean particle size was determined using the phi scale. As an indication of habitat heterogeneity, the number of organic and inorganic substrate types

represented at each site was totalled. Habitat characteristics recorded included estimated percent cover by inorganic sediment, submerged macrophyte, floating macrophyte, emergent macrophyte, algae, large woody debris, detritus, roots and trailing vegetation.

WRM has specific worksheets for this task to ensure qualitative habitat recordings between sites are as comparable as possible. To limit variation due to different observers, all estimations were made by the same sampler.

4.6 Microinvertebrates (zooplankton)

Microinvertebrate samples were collected from each site by gentle sweeping over an approximate 15 m distance with a 53 µm mesh plankton net (Plate 4). Care was taken not to disturb the benthos (bottom sediments) during sampling. Samples were preserved in 70% ethanol and sent to Dr Russell Shiel at the University of Adelaide, South Australia, for processing. Dr Shiel is a world authority on microfauna, with extensive experience in fauna survey and impact assessment across Australasia, including the Pilbara.

Plate 4. Microinvertebrate sampling at RRD4.

Microinvertebrate samples were processed by identifying the first 200-300 individuals encountered in an agitated sample decanted into a 125 mm^2 gridded plastic tray, with the tray then scanned for additional missed taxa also taken to species and recorded as 'present'. Specimens were identified to the lowest taxon possible, *i.e*. species or morphotypes. Abundance data were reported as log_{10} scale abundance classes (*i.e.* 1 = individual, 2 = 2-10 individuals, 3 = 11-100 individuals, 4 = 101-1000 individuals, 5 = >1000). Where specific names could not be assigned, vouchers were established. These vouchers are held by Dr Shiel at Adelaide University, Adelaide, Australia.

4.7 Hyporheos

At each site, hyporheic sampling was conducted using the Karaman-Chappuis method (Delamare Deboutteville 1960). This involved digging a hole approximately 20 cm deep and 40 cm diameter in alluvial gravels in dry streambed adjacent to the water's edge, allowing the hole to infiltrate with water, and sweeping the water column with a modified 110 µm mesh plankton net (Plate 5). The water column was swept immediately after the hole had filled, and again after approx. 30 minutes, once other sampling had been conducted.

Plate 5. Hyporheic sampling at RRU3.

Samples were preserved in 70% ethanol and returned to the laboratory for processing. Any aquatic fauna present was removed from samples by sorting under a low power dissecting microscope. In-house expertise was used to identify the majority of hyporheic taxa using available published keys and through reference to the established voucher collections held by WRM. External specialist taxonomic expertise was sub-contracted to assist with Chironomidae (Dr Don Edward, UWA) and micro-crustacea (Dr Russel Shiel, University of Adelaide).

All taxa recorded from hyporheic samples were classified using the categories of Boulton (2001):

- stygobite, *i.e.* obligate groundwater species, with special adaptations to survive such conditions,
- permanent hyporheos stygophile, *i.e.* epigean[8] species that may occur in both surface and groundwaters, but is a permanent inhabitant of the hyporheic zone,
- occasional hyporheos stygophile, *i.e.* species that use the hyporheic zone seasonally or during early life history stages, or
- stygoxene, *i.e.* species that appear rarely and apparently at random in groundwater habitats; there by accident or seeking refuge during spates or drought; not specialised for dwelling permanently underground.

4.8 Macroinvertebrates

Macroinvertebrate sampling was conducted with a 250 μm mesh FBA pond net (Plate 6). All meso-habitats were sampled, including trailing riparian vegetation, woody debris, open water column and benthic sediments with the aim of maximising the number of species recorded. Each sample was washed through a 250 μm sieve to remove fine sediment, while leaf litter and other debris were carefully washed in the sieve and removed by hand. Samples were then preserved in 70% ethanol. In the laboratory, macroinvertebrates were removed from samples by sorting under a low power dissecting microscope.

Plate 6. Macroinvertebrate sampling at RRU5.

Collected specimens were identified to the lowest practicable level (typically genus or species) and enumerated to $\log_{10}$ scale abundance classes (*i.e.* 1 = individual, 2 = 2-10 individuals, 3 = 11-100 individuals, 4 = 101-1000 individuals, 5 = >1000). In-house expertise was used to identify invertebrate taxa using available published keys and through reference to the established voucher collections held by WRM. External specialist taxonomic expertise was sub-contracted to assist with Chironomidae (Dr Don Edward, UWA).

4.9 Fish

A number of fish sampling methods were used at each site in order to collect as many species and individuals as possible. Methods included electrofishing, seine nets and gill nets. Electrofishing was conducted with a Smith-Root Model LR24 battery powered backpack electrofisher (Plate 7A). Electrofishing is an extremely useful and efficient sampling tool in rivers with clear, low salinity, slow flow water. All meso-habitats within a maximum 40 m reach were shocked with the intention of recovering as many species/individuals as possible. Shocking was not continuous, but targeted areas of optimum habitat, whereby the operator would shock, move to a new habitat before shocking again, and so prevent fish being driven along in front of the electrical field.

Duplicate 30 m multi-panel gill nets were set at each site where there was sufficient depth of water (Plate 7B). Each net consisted of 6 x 5 m panels, with panels increasing in size from 1" to 6" stretched mesh size. The nets were set perpendicular to the bank, with the smallest mesh set against the bank, and the large mesh positioned into the channel with a float and weight to keep the nets in place. At

[8] Epigean – living or occurring on or near the surface of the ground.

each sampling location, two nets were set for approximately 2.5 hours. Nets were checked frequently to avoid fish deaths. Catch from the duplicate nets were combined to form one replicate sample from each sampling location.

Smaller species and juveniles were sampled by beach seine (10 m net, with a 2 m drop and 6 mm mesh) deployed in shallow areas where there was little vegetation or large woody debris. Typically, two seine hauls were made at each location to maximise the number of individuals caught.

All fish were identified in the field, measured for standard length (SL)[9], and then released alive. Fish nomenclature followed that of Allen *et al.* (2002). Fish measurements provided information on the size structure, breeding and recruitment of fish populations.

Plate 7. Example of electrofishing (left), and setting gill nets at RRU1 (right).

4.10 Data Analysis

Samples were grouped *a priori* into categories according to exposure; potentially exposed sites downgradient of the Jimmawurrada-Robe confluence (RRD) or reference sites upgradient of the Jimmawurrada-Robe confluence (RRU). Water quality and species richness (number of taxa) data were plotted in order to illustrate spatial differences. For comparison of species richness against previous studies, invertebrate taxonomy was standardised across datasets to account for differences in taxonomic resolution and/or advancements in taxonomic knowledge between studies (*i.e.* some taxa were condensed to family or order level to enable comparison). As such, taxa richness may appear lower than was originally reported in each study. Where sufficient numbers of each fish species were measured, length-frequency histograms of current data were plotted.

Univariate analyses (one-way ANOVA) was used to test for statistically significant (p <0.05) differences in water quality variables and micro- and macroinvertebrate species richness between groups (RRD, RRU). The assumptions of normality and homogeneity of sample variances were checked using Shapiro-Wilk and Levene's tests, respectively. Data were $\log_{10}(x+1)$ transformed where appropriate. All univariate analyses were performed using IBM SPSS Statistics (v21) software package.

Multivariate patterns in micro- and macroinvertebrate species assemblages were analysed using procedures from the PRIMER (v7) software package (Clarke and Gorley 2006). Non-metric Multi-Dimensional Scaling (nMDS) ordination plots (Clarke and Warwick 2001) were constructed to visualise differences between sites. nMDS ordinations were based on Bray-Curtis similarity measures for species abundance ($\log_{10}$ class) data. Ordinations were depicted as two-dimensional plots. The Analysis of

[9] Standard length (SL) - measured from the tip of the snout to the posterior end of the last vertebra or to the posterior end of the mid-lateral portion of the hypural plate (*i.e.* this measurement excludes the length of the caudal fin).

Similarity (ANOSIM) routine within PRIMER was used to test for significant ($p < 0.05$) differences in species assemblages between groups (RRD, RRU), based on both abundance (log_{10} class) and presence/absence data. The SIMPER routine within PRIMER was used to determine those species contributing most to the similarity/dissimilarity between significant site groupings identified by ANOSIM.

Too few taxa were recorded from hyporheic samples to warrant ANOVA or PRIMER analyses of these data.

4.11 Survey Limitations

Inherent physical sampling deficiencies are acknowledged as a barrier to sampling aquatic fauna, and in particular fish. For example, fish catch rates may have been hindered by the abundance of aquatic vegetation (macrophytes and algae) which physically obstructed seine and gill nets at some sites. This was somewhat compensated for by the use of a back-pack electrofisher, which generates a pulsed direct electrical current to draw fish out from under such habitat.

This study provides a snapshot of water quality conditions and faunal communities at a single point in time, and is unlikely to fully capture the range of temporal/seasonal variability within the Project area. Prior to sampling, total monthly rainfall at Pannawonica Gauging Station was well below the 45-year average, particularly during February, March and April. As such, there was no surface flow connecting pools along the Robe River, with pools heavily receded and even some fish mortality evident, possibly due to low overnight dissolved oxygen concentrations. The relative lack of rainfall leading up to the survey may also have caused recordings of some other water quality parameters, such as salinity and nutrients, to be higher than would be expected under “average” wet season baseflow conditions, due to evapo-concrentration effects and lack of flushing within the system. Dry conditions may also have affected aquatic faunal communities, particularly hyporheic fauna, which require saturation of the alluvium and strong connectivity between ground and surface waters, and fish, with many speces known to require higher baseflows and connectivity between pools to enable upstream migration and spawning.

5 RESULTS AND DISCUSSION

5.1 Water Quality

5.1.1 General

Raw data for spot measurements of water quality, made in conjunction with aquatic fauna sampling, are provided in Appendix 3. Water quality was highly variable amongst sites (Figures 4 and 5). Salinity levels ranged from fresh[10] (592 µS/cm, RRD5) to brackish (1,700 µS/cm, RRU6), pH from circum-neutral (6.9, RRU3) to slightly alkaline (7.9, RRU1), hardness from 230 mg/L (RRD2) to 520 mg/L (RRU6), total suspended solids from <1 mg/L (RRD4, RRU3, RRU4) to 34 mg/L (RRD5), and dissolved oxygen from hypoxic[11] (14.5%, RRU5) to supersaturated (134.9%, RRD6).

There were no obvious longitudinal gradients upstream or downstream of the Jimmawurrada-Robe confluence. Site RRU6 (located ~1 km upstream of the confluence), together with the downstream sites, tended to have higher salinity (as EC and TDS), alkalinity, hardness and concentrations of associated ions, than sites upstream (Figure 3). Maximum values for most of these parameters (*i.e.* EC, TDS, hardness, Na^+, Cl^+, Ca^{2+}, $S\text{-}SO_4$, Mg^{2+}) and for nitrogen (as N-total, $N\text{-}NO_X$, $N\text{-}NH_3$) were recorded at RRU6. Average concentration of K^+, $S\text{-}SO_4$ and total dissolved sulfur (S) was significantly higher downstream of the Jimmawurrada-Robe confluence (one-way ANOVA, Table 5).

Table 5. Summary results from one-way ANOVAs testing for significant (p <0.05) differences in mean concentrations of water quality parameters, upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Only significant results are shown. Mean (±SE) vales for untransformed data are also provided.

Water quality parameter	ANOVA (df = 1, 11)			Mean (±SE)	
	MS	F	p	RRD (n = 6)	RRU (n = 6)
Fe	0.005	9.52	0.012	0.05 (0.01)	0.12 (0.005)
K	23.24	21.96	0.001	8.4 (0.52)	5.6 (0.29)
S	352.08	35.62	<0.001	25.3 (0.95)	14.5 (1.54)
$S\text{-}SO_4$	2104.10	15.52	0.003	70.2 (4.67)	43.7 (4.83)

The significantly higher concentrations of some ions, most notably $S\text{-}SO_4$, and to a lesser extent Mg (Figure 4), downstream of the Jimmawurrada-Robe confluence, may reflect the influence of dewatering discharge from current mining operations. Some inter-site variability could also be attributed to differences in volume of the remnant pools sampled, and evapoconcentration effects under recessional flows. For example RRU6, where maximum values for a number of parameters were recorded, was the shallowest of the pools sampled (maximum water depth of 0.6 m), and supported extensive organic deposits and abundant macrophyte growth (*Typha* and *Potamogeton*) (Appendix 4). The relative abundance of macrophytes, algae and accumulated organics would also be expected to have varying effect on DO levels, pH and rates of nutrient recycling within each of the pools. The higher level of TSS recorded at Gnieraoora (RRD5) compared to all other sites (Figure 5) was likely due to recent cattle activity, which caused the physical disturbance and suspension of benthic sediments.

At most sites, Na^+ was the dominant cation, with Ca^{2+} sub-dominant, and HCO_{3-} the dominant anion, with Cl^- sub-dominant. The exception was RRU6, where Cl^- was dominant and HCO_{3-} sub-dominant. This suggests groundwater ingress had less influence on the water chemistry of the remnant pool at RRU6

[10] Fresh defined as < 1,500 µS/cm; brackish = 1,500 – 4,500 µS/cm; saline = 4,500 - 50,000 µS/cm; hypersaline > 50,000 µS/cm (DoE 2003). Classifications were presented as TDS (mg/L) in DoE (2003) so a conversion factor of 0.68 was used to convert to conductivity µS/cm as recommended by ANZECC/ARMCANZ (2000).

[11] Dissolved oxygen (DO) levels of zero percent saturation = anoxic; < 20% = defined as hypoxic; 100% = saturated; >100% = super-saturated; more oxygen is dissolved than would be in a state of equilibrium.

than at other pools, which may help to also explain the relatively higher salinity at RRU6 (*i.e*. less groundwater inflow to offset effects of evapoconcentration).

5.1.2 Exceedance of ANZECC/ARMCANZ default TVs

Exceedance of ANZECC/ARMCANZ default 95% TVs was recorded for EC, DO, dissolved zinc, N-total, N-NO_x and N-NH_3 at a number of sites upstream and downstream of the Jimmawurrada-Robe confluence (refer Appendix 3). No exceedance of ANZECC/ARMCANZ (2000) default TVs was recorded for any other parameter. Exceedances are discussed in the following sub-sections.

Electrical Conductivity (EC)

EC values were in exceedance of the ANZECC/ARMCANZ (2000) TV (250 μS/cm) at all sites sampled, although surface waters could still be classified as "fresh" (<1,500 μS/cm) at most sites (Figure 4). The relatively higher EC at RRU6 (1,700 μS/cm) constitutes "brackish" conditions, and was above EC levels reported during long-term monitoring of Robe River pools by Streamtec/UWA and the Proponent (*i.e.* 453 - 1,400 μS/cm). Elevated EC was again considered due to high levels of evapoconcentration in these isolated pools, a process common to surface waters in arid/semi-arid zones (Jolly *et al.* 2008). Although some dilution may occur following wet season rains, salinity can often remain high in arid-zone surface waters due to the variability of flows and flushing of stored salts (Jolly *et al.* 2008). ANZECC/ARMCANZ (2000) acknowledge that the default TV for EC may not be representative of local background levels in all areas of Australia. In such instances, ANZECC/ARMCANZ (2000) recommend developing site-specific trigger values (SSTVs) relevant to local conditions.

Dissolved Oxygen (DO)

Daytime DO saturation was below the ANZECC/ARMCANZ (2000) lower TV (80%) at the majority of sites, and above the upper TV (120%) at RRD6 (134.9%) (Figure 5 andAppendix 3). In aquatic ecosystems, low DO levels are typically considered of greater concern than high levels; however, super-saturated levels (>100%) during the day are often indicative of anoxic or hypoxic conditions at night. Low DO is commonly associated with standing pools (with little physical aeration) that support heavy organic loads (*e.g.* aquatic vegetation, algae, bacteria, *etc.*) (Caraco and Cole 2002). DO saturation is typically lowest in the early morning, following overnight consumption of oxygen through the respiratory processes of aquatic biota (Caraco and Cole 2002, Connolly *et al.* 2004, Flint *et al.* 2014). Sites which exhibited particularly low DO in the current study (*e.g.* RRU3 16.1%, RRU5 14.5%) were sampled early in the morning (*i.e.* between 0700 hrs and 0830 hrs), and also tended to support relatively high abundances of macrophytes and/or algae (Appendix 4). While the oxygen needs of aquatic biota differ between species and life history stages, values less than 50% saturation are associated with chronic responses in fish and macroinvertebrates (Connolly *et al.* 2004, Flint *et al.* 2014).

Super-saturation can occur when net photosynthesis exceeds total oxygen consumption in waterbodies, and is common in areas of high algal and macrophyte growth, particularly if spot measurements are taken later in the day (Caraco and Cole 2002). The organic habitat at RRD6, (134.9% DO) comprised emergent and submerged macrophyte (covering 50% of the site area; Appendix 4), and the spot measurement of DO was taken at 1230 hrs, when photosynthetic processes were likely near their peak. Waterbodies with super-saturated daytime DO are likely to experience overnight hypoxia or anoxia, as respiration by plants, algae, bacteria and other aquatic fauna deplete DO (Caraco and Cole 2002, Connolly *et al.* 2004, Flint *et al.* 2014).

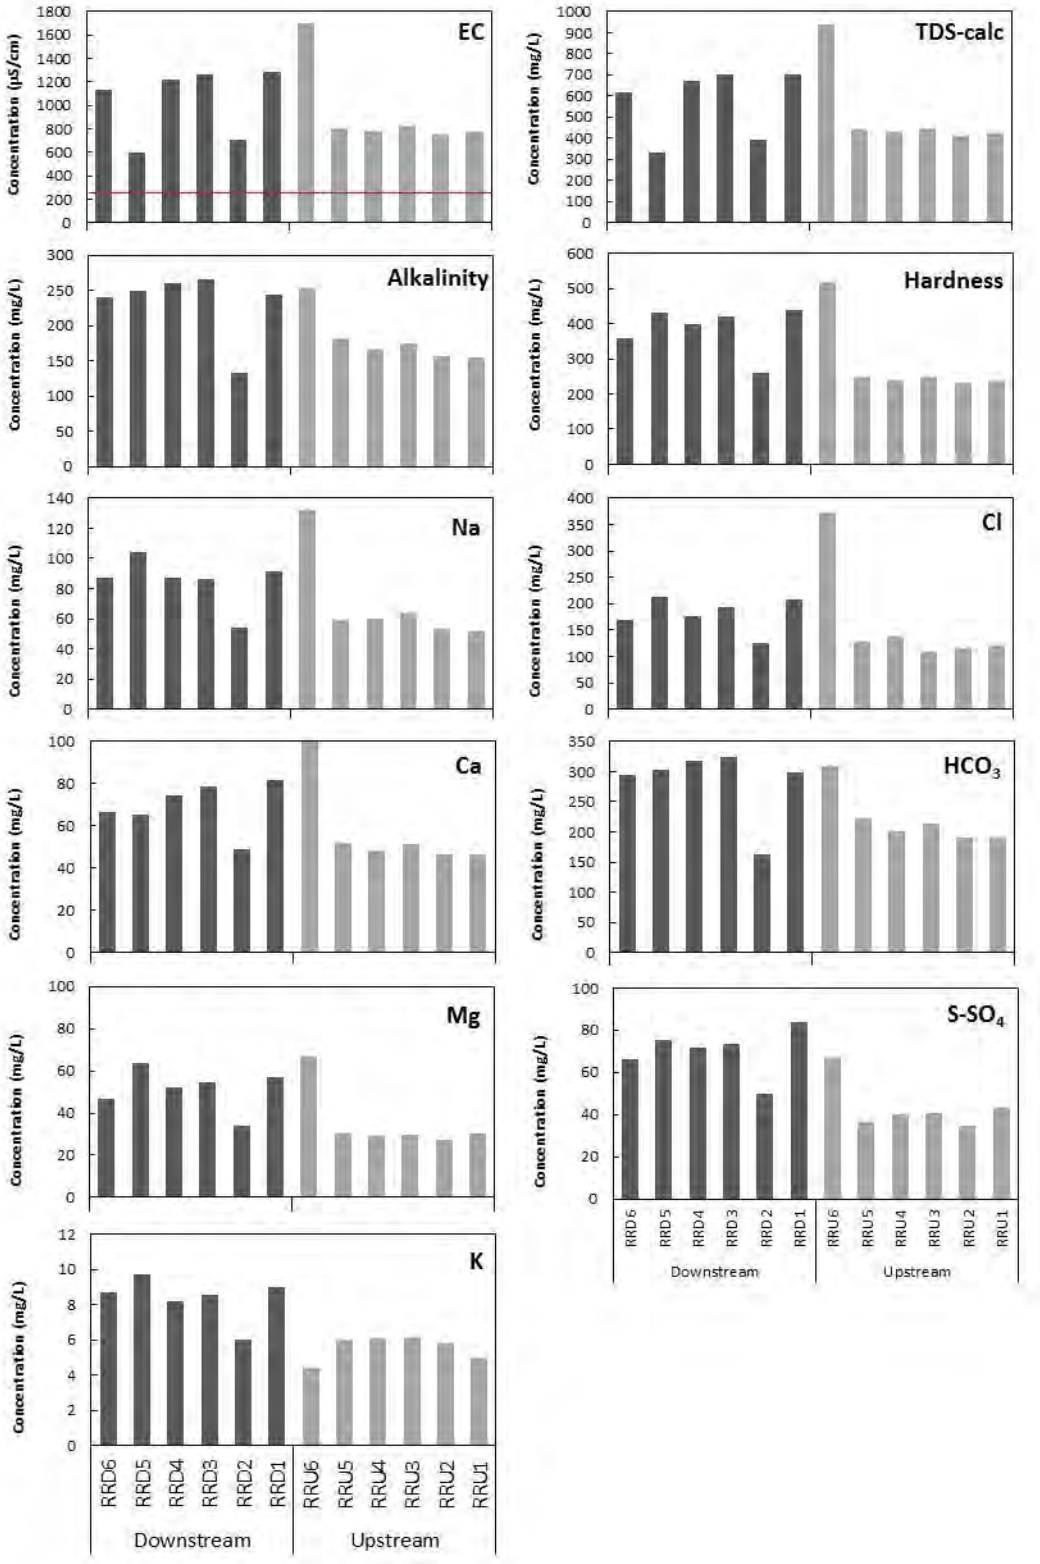

Figure 4. Comparison of EC, alkalinity, hardness and concentration of major ions amongst surface water sampling sites upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence. Refer Table 1 for explanation of site codes and Figure 1 for location of sites. ANZECC/ARMCANZ (2000) default 95% species protection level TV (unbroken red line) is indicated for relevant parameters.

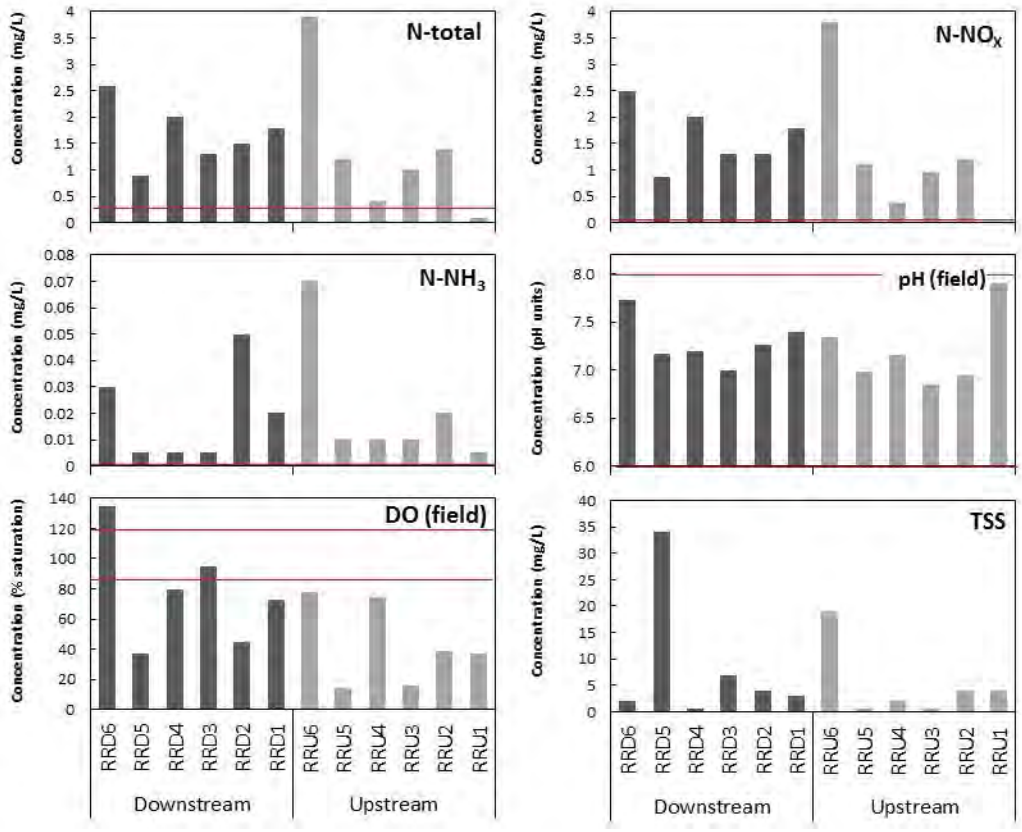

Figure 5. Comparison of N-total, N-NO_X, N-NH_3, pH, DO and TSS amongst surface water sampling sites upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence. Refer Table 1 for explanation of site codes and Figure 1 for location of sites. ANZECC/ARMCANZ (2000) default 95% species protection level TV (unbroken red line) is indicated for relevant parameters; upper and lower TVs are shown for pH and DO.

Dissolved zinc

Dissolved zinc (dZn) concentration was in exceedance of ANZECC/ARMCANZ (2000) TVs (0.008 mg/L) at RRU5 (0.012 mg/L) and RRD3 (0.011 mg/L) (Appendix 3). ANZECC/ARMCANZ (2000) provide algorithms to calculate hardness modified TVs (HMTVs), as hardness has an ameliorating effect on the toxicity of a number of metals including cadmium, lead, nickel and zinc[12]. However, once the algorithm was applied, concentrations of dZn at RRU5 and RRD3 still excceded HMTVs. Although elevated, it is unknown what proportion of dZn was labile (bioavailable) or unavailable through processes such as complexing with dissolved organic carbon. Where dissolved levels are elevated, ANZECC/ARMCANZ (2000) recommends testing for labile concentrations/bioavailability to assess if levels are likely to be toxic to aquatic fauna. Given that exceedances of the ANZECC/ARMCANZ (2000) TV were recorded at sites both upstream (reference) and downstream of the Jimmawurrada-Robe confluence, it is unlikely that current Mesa J discharge operations are influencing dZn levels in the Project area.

Nitrogen (N-total, N-NO_X, N-NH_3)

At most sites (except RRU1), N-total, N-NO_X and N-NH_3 exceeded ANZECC/ARMCANZ (2000) default 95% TVs for protection against eutrophication (0.3 mg/L N-total, 0.01 mg/L N-NO_X, 0.01 mg/L N-NH_4[13])

[12] HMTV algorithm for zinc = Default TV*(Hardness/30)^0.85.
[13] Ammonia was analysed as nitrogen-ammonia (N-NH_3), so a conversion factor of 1 was used to convert to nitrogen as ammonium (N-NH_4) for comparison against ANZECC/ARMCANZ (2000) default TV for protection against eutrophication.

(Figure 5 and Appendix 3). N-NO_X levels were greatly in exceedance, *i.e.,* 10 times the default TV at most sites. N-NO_3 constituted nearly all of the measured N-NO_X and N-total (Appendix 3).

In order to compare against the default 95% TV for nitrate as a toxicant (0.7 mg/L NO_3), N-NO_3 concentrations were converted to NO_3 concentration by multiplying by a factor of 4.4. NO_3 exceeded the default 95% TV for nitrate as a toxicant at most sites (except RRU1); however, the default toxicant TV is currently under review as being too conservative. The new ANZECC/ARMCANZ 95% TV for NO_3 as a toxicant is likely to be around 2 - 2.5 mg/L N-NO_3 (~11 mg/L NO_3) (R. van Dam, *eriss*, pers. comm.), and will incorporate most recent data from acute and chronic toxicity testing in New Zealand. Recently published guidelines for Canada also recommend a higher guideline of 2.9 mg/L N-NO_3 (~13 mg/L NO_3) for freshwaters (CCME 2014). In comparison to the proposed ANZECC/ARMCANZ TV of 2 - 2.5 mg/L N-NO_3, only the concentration at RRU6 (3.8 mg/L) was still in exceedance, though the concentration at RRD6 (2.5 mg/L) was close to exceedance. Similar elevated levels of N-NO_3 have been recorded at Medawandy Waters (3.1 mg/L N-NO_3, 3.45 mg/L N-total) during previous monitoring in the Project area (Rio Tinto unpub. data).

Elevated background levels of N-NO_3 and N-NH_3 within the Project area are unsurprising, given that the Robe River catchment is already effected by current and historic pastoral practices (Strategen 2006). Cattle, or evidence of high cattle use were observed at a number of pools during the survey. Elevated N-NO_3 and N-NH_3 in waterbodies caused by livestock disturbance can reduce acid-neutralising capacities of waterbodies, adversely affect the growth, survival and reproduction of aquatic fauna, and most notably stimulate eutrophication and algal blooms (Camargo and Alonso 2006). Another potential anthropogenic source is ammonium nitrate used in mine explosives, though groundwaters in arid zone areas across Australia are often naturally enriched in nitrate, as is the case in the current Project area (Magee 2009).

Significantly higher concentrations of some ions, most notably S-SO_4, and to a lesser extent Mg, as well as elevated N-total and N-NO_x downstream of the Jimmawurrada-Robe confluence (Figures 4 and 5), may also reflect the influence of current mining operations discharges on the water quality of the downstream reach. The elevated S-SO_4 and Mg may indicate presence of geochemical reactions, resulting in the release of these elements downstream of the existing discharge points. The elevated nitrogen levels may indicate discharge of groundwater elevated in nitrates, with groundwaters in the vicinity of current mining operations appearing to be enriched (*e.g.* up to 23.9 mg/L N-NO_3 in bore MB15MEH014) (Rio Tinto unpub. data). The relative contribution of anthropogenic and natural sources to nitrogen enrichment in surface and groundwater of the Project area is unknown, but discharge of nitrogen-enriched groundwater has resulted in elevated nitrate levels in surface waters downstream of other BWT mining operations in the Pilbara.

5.2 Microinvertebrates

5.2.1 Species richness and abundance

A total of 81 microinvertebrate taxa were recorded from the Project area in May 2016, of which 46 were present at potentially exposed sites downstream of the Jimmawurrada-Robe confluence, and 69 were recorded at upstream reference sites (Table 6 and Appendix 5). The list includes groups which could not be identified to species level due to unresolved taxonomy and/or immature specimens. Therefore, the total microinvertebrate species richness is likely to be greater than that reported. Microinvertebrate composition included Protista (protists), Rotifera (rotifers), Copepoda (copepods), Cladocera (water fleas) and Ostracoda (seed shrimp) (Table 6). Generally, Rotifera dominated microinvertebrate taxa at each site, with comparatively few Copepoda, Ostracoda and Cladocera. The microinvertebrate fauna was generally typical of that commonly recorded from tropical/sub-tropical freshwater systems

(*e.g.* Koste and Shiel 1983, Tait *et al.* 1984, Smirnov and De Meester 1996, Segers *et al*. 2004), with Lecanidae dominating within the Rotifera, with Brachionidae and other families less prominent (Appendix 5).

Table 6. Summary of higher-order microinvertebrate taxa composition in the Robe River, upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Refer Appendix 5 for full species list.

Microinvertebrates		Number of Taxa	
Scientific name	Common name	RRD (*n* = 6)	RRU (*n* = 6)
Protista	Protists	7	12
Rotifer	Rotifers	20	33
Micro-crustacea			
Cladocera	Water fleas	5	11
Copepoda	Copepods	9	6
Ostracoda	Seed shrimps	5	7
Total taxa richness		**46**	**69**

Microinvertebrate taxa richness ranged from 33 taxa at RRD6 and RRU5, to just one taxa at RRD5 (Figure 6). There was no significant difference in mean total taxa richness between downstream potentially exposed sites and upstream reference sites (one-way ANOVA, Table 7). Nor were there any significant upstream-downstream differences in taxa richness of major groups of microinvertebrate (rotifers, protists, micro-crustacea) (Table 7).

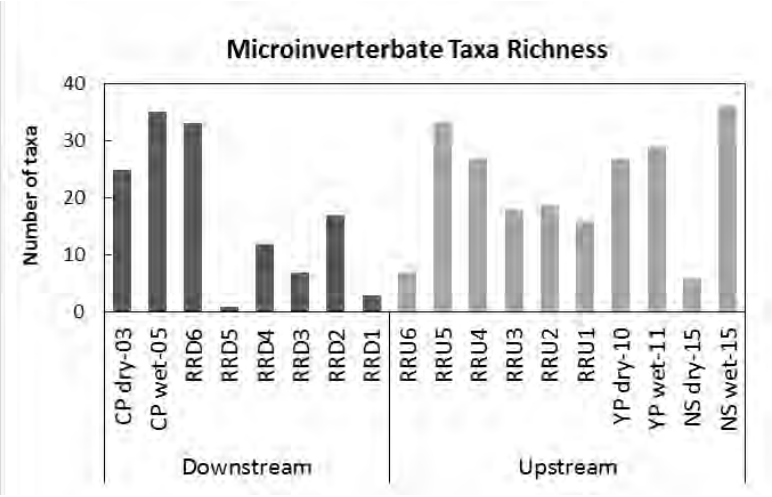

Figure 6. Microinvertebrate taxa richness recorded during the current study, upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence, compared with most recent data for nearby Chalyarn Pool (CP; Pinder *et al.* 2010), Yalleen Pool (YP; WRM 2013) and Nyeetbury Spring (NS; WRM 2016). Refer Figure 1 for location of sites.

Table 7. Summary results from one-way ANOVAs testing for significant (p <0.05) differences in taxa richness of major microinvertebrate groups, upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Mean (±SE) vales for untransformed data are also provided.

Microinvertebrate metric	ANOVA (df = 1, 11)			Mean (±SE)	
	MS	F	*p*	RRD (*n* = 6)	RRU (*n* = 6)
Total taxa richness	184.1	1.672	0.225	12.17 (4.81)	20.00 (3.69)
Protista richness	8.333	1.168	0.305	2.33 (0.92)	4.00 (1.24)
Rotifera richness	80.08	2.313	0.159	3.67 (2.46)	8.83 (2.34)
Micro-crustacea richness	3.000	0.183	0.183	6.17 (2.01)	7.17 (1.20)

5.2.2 Comparison against previous surveys

To provide spatial context for microinvertebrate fauna within the Project area, total taxa richness at each site within the Project area was compared against most recent data for nearby pools upstream and downstream of the Project area, *i.e.* Yalleen Pool and Nyeetbury Spring on upper Bungaroo Creek (WRM 2013, 2016), and Chalyarn Pool on Mungarathoona Creek (Pinder *et al.* 2010) (Figure 6). Each of these previous studies used similar microinvertebrate sampling techniques (sweep netting using 50 - 53 μm mesh FBA pond net) and taxonomic resolution to those approaches for the current study.

Some temporal variation was observed between wet and dry season sampling events, with the wet season favouring microinvertebrate taxa richness at Chalyarn Pool, Yalleen Pool and Nyeetbury Spring (Figure 6). At sites upstream of the Jimmawarruda-Robe confluence, taxa richness was spatially variable, with richness at RRU4 and RRU5 similar to that recorded at Yaleen Pool (both seasons) and Nyeetbury Spring in the wet-15 (Figure 6), and slightly higher than that recorded at RRU1, RRU2 and RRU3. Richness was lowest at Nyeetbury Spring in the dry-15, comparable to that recorded at RRU6 in the current study (Figure 6). Within the potentially exposed downstream reach, taxa richness at sites closest to the confluence (RRD1 to RRD5) was generally lower than that recorded at sites further downstream (RRD6 and Chalyarn Pool in both seasons) (Figure 6).

Large spatial (and temporal) variability in species richness and abundance are commonly reported for freshwater systems world-wide. Variation typically depends on factors such as flow regime (with lotic habitat generally favouring taxa richness), pool size, primary production rates and water quality parameters (Miquelis *et al.* 1998, Schiemer *et al*. 2001, Schöll *et al.* 2012). In Pilbara surface waters, microinvertebrate taxa richness is known to fluctuate markedly between sites and seasons (Pinder *et al.* 2010, WRM unpub. data). It is possible that below-average rainfall in the months prior to the current survey may have contributed to the somewhat lower microinvertebrate taxa richness recorded at sites such as RRD1, RRD3, RRD5 and RRU6. Pinder *et al.* (2010) found the wet season (higher rainfall) to generally favour taxa richness during the PBS, as was the case at Chalyarn, Yalleen and Nyteetbury (Figure 6); however, as these studies only provide a snapshot of the microinvertebrate fauna at pools within the Project area, the specific factors driving taxa richness and composition remain unknown.

5.2.3 Spatial variation in species assemblages

Multivariate analysis (ANOSIM) detected no significant difference in microinvertebrate species assemblage composition between upstream reference and downstream potentially exposed sites (Table 8), suggesting there was a high degree of natural variability and overlap amongst assemblages both upstream and downstream of the Jimmawarruda-Robe confluence. Although SIMPER analysis found only a 21% similarity of species assemblages between the upstream and downstream reaches, nMDS plotting displayed no discernible separation of upstream/downstream sites based on Bray-Curtis similarity (Figure 7). SIMPROF analysis did detect some clustering of sites, though with no clear patterns in relation to upstream/downstream location (Figure 7). For example, the upstream sites RRU1, RRU2 and RRU3 clustered with downstream site RRD2, and upstream sites RRU5 and RRU6 clustered with downstream site RRD6, based on similarity of microinvertebrate species assemblages (Figure 7). RRD1 and RRD3 also clustered with a high degree of similarity (Figure 7).

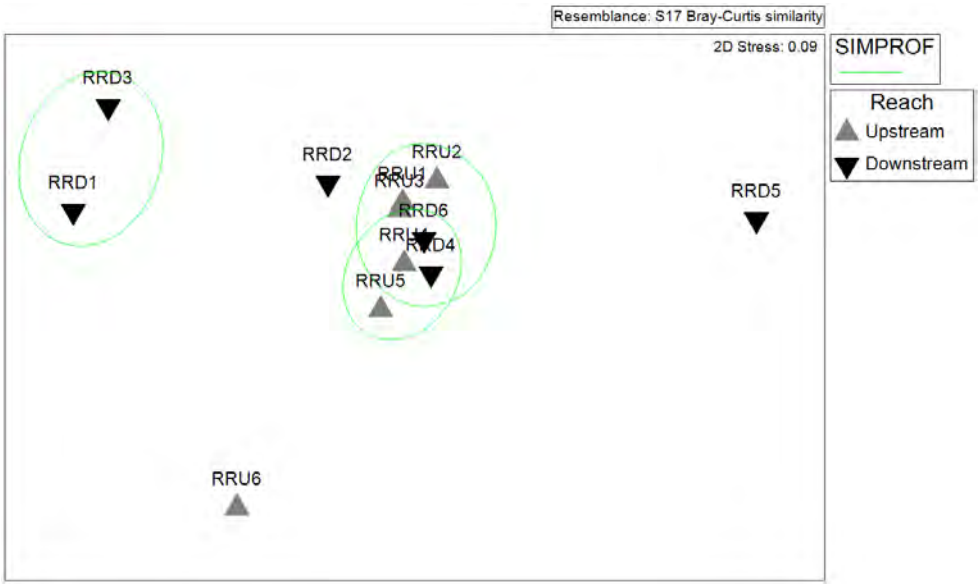

Figure 7. Plot of nMDS ordination on microinvertebrate species assemblages (log_{10} abundance class) upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Ordination based on Bray-Curtis similarity, with SIMPROF analysis as green circles overlain demonstrating significant clustering of sites. Refer Table 1 for explanation of site codes and Figure 1 for location of sites.

Table 8. Summary results from ANOSIM testing for significant (p <0.05) differences in microinvertebrate assemblages (Bray-Curtis similarity) upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence.

Microinvertebrate assemblage similarity (Bray-Curtis)	ANOSIM	
	R-statistic	*p*
Abundance (log_{10} class)	0.115	0.108
Presence/absence	0.137	0.097

The sampling design allows comparison of change in the similarity (Bray-Curtis) of microinvertebrate assemblages over time between reference and potential exposed sites. The premise being that if the degree of similarity between exposed and reference sites differs significantly over time (compared with pre-mine similarity), this would indicate mine-related response rather than stochastic variability due to factors such as climatic change.

5.2.4 Conservation significance of microinvertebrate fauna of the Project area

The majority of microinvertebrate taxa recorded from the Project area were common, ubiquitous species with Australasian or cosmopolitan distributions; however, the calanoid copepod *Eodiaptomus lumholtzi*, currently listed on the IUCN Red List of Threatened Species as Vulnerable (Reid 1996), was recorded at potentially exposed site RRD6. *E. lumholtzi* was assessed as Vulnerable in 1996 (IUCN ver. 2.3), as it was then known only from a few localities; Lake Woods in Northern Territory, Collinson's Lagoon at Ayr and Saltern Lagoon in the Valley of Lagoons, west of Ingham, Queensland. IUCN (2016) states this assessment requires updating because *E. lumholtzi* has since been recorded from many localities across the Australasian region. *E. lumholtzi* has been recorded previously by the authors at locations across the Pilbara region, including sites along Fortescue River, Coondiner Creek, Kalgan Creek, Weeli Wolli Creek, Koodaideri Springs, Caves Creek, Duck Creek and Cane River (WRM unpub. data). *E. lumholtzi* has also been found in Papua New Guinea, and is considered to have a pan-tropical distribution (Vlaardingerbroek 1989, WRM unpub. data).

Of scientific interest was the collection of an undescribed species of Lecanidae rotifer, *Lecane* n. sp., recorded both upstream and downstream of the Jimmawarruda-Robe confluence (RRU5 and RRD6). Morphologically, this species is similar to the described *Lecane quadridentata*, with the two variants synonymized by Segers (1995); however, the smaller Australian variant recorded in the current study is now recognised as a separate species, and forms part of a wider *L. quadridentata* species complex (Dr Russel Shiel, University of Adelaide, pers. comm.).

5.3 Hyporheic Fauna

5.3.1 Species richness and abundance

A total of 59 taxa were recorded from the hyporheic zone of pools in the Project area (Appendix 6). The majority of these taxa were classified as stygoxene (54%), *i.e.* species that appear in groundwater habitats by accident or seeking refuge during drought, and not specially adapted to subterranean inhabitation. Of these, 8% were classified as stygobitic, *i.e.*, obligate groundwater inhabitants with specialised morphological adaptations to survive in such environments (stygofauna). Of the remaining taxa, 31% were considered occasional hyporheic stygophiles (species that use the hyporheic zone seasonally or during early life history stages), 2% were possible hyporheic taxa, and 5% were unable to be classified (Appendix 6). Although classifications followed those of Boulton (2001), this type of analysis should be treated with some caution, as results are likely affected by available information on life history, taxonomic resolution, and interpretation of classification categories.

Hyporheic taxa richness (combined richness of stygobites, occasional hyporheic stygophiles and possible hyporheic fauna) ranged from two taxa at upstream reference site RRU2, to 12 taxa at potentially exposed downstream site RRD1 (Figure 8). Relatively high hyporheic taxa richness was also recorded at RRU6 (nine taxa), RRU4 and RRD2 (eight taxa), and RRU3 and RRD5 (seven taxa) (Figure 8). The high taxa richness encountered in the hyporheos of these sites, and because surface water was present at these sites despite below average rainfall in the months prior, suggests at least some connectivity between ground- and surface waters (*i.e.* they may be groundwater-supported pools).

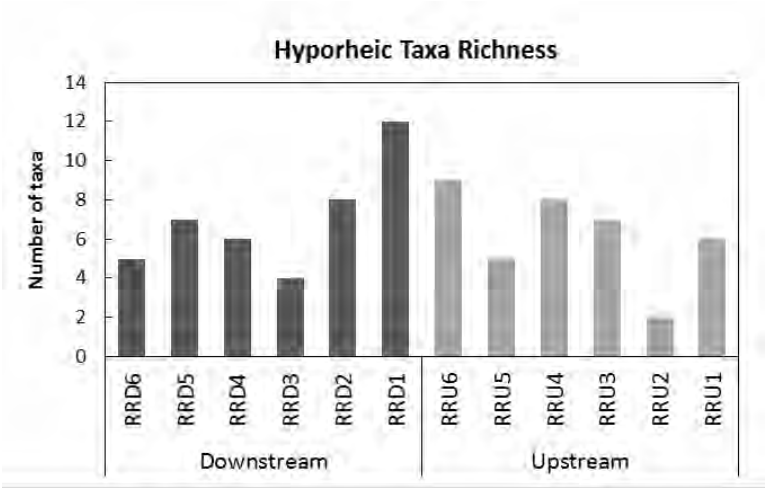

Figure 8. Hyporheic taxa richness (combined richness of stygobites, occasional hyporheic stygophiles and possible hyporheic fauna) of sites upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence.

5.3.2 Conservation significance of hyporheic fauna of the Project area

Of the fauna collected in hyporheic samples of the Project area, only the amphipod, *Nedsia* sp. is considered likely to be a potential SRE species.

Nedsia sp. (family Melitidae) was recorded from the hyporheic zones of RRU3, RRU4 and RRU6 upstream of the Jimmawurrada-Robe confluence, and RRD1, RRD2, RRD3 and RRD4 downstream of the confluence (Appendix 6). *Nedsia* amphipods were also recorded in the surface water macroinvertebrate samples of RRD3 and RRD4 (Appendix 7). These amphipods could not be confidently identified to species level due to a current lack of taxonomic resolution within the Melitidae amphipods and would require DNA sequencing.

Biota (2006a) recorded four genetically-distinct amphipods of the family Melitidae from bores in the Yarraloola area, downstream (west) of the Project area. A fifth distinct Melitidae lineage was recorded from the Bungaroo Creek area to the southeast (Biota 2006a). Interestingly, based on genetic evidence, each of the four Melitidae lineages from the Yarraloola area have been isolated from one-another for between 2.4 and 6.65 million years, highlighting the extreme degree of amphipod short-range endemism that can occur amongst aquifers in the region despite close geographical proximity (Biota 2006a). Biota (2010) and Bennelongia (2013) also recorded a high abundance of Melitidae amphipods from bores to the south of the current Project area. The majority of these specimens belonged to the genus *Nedsia* (*Nedsia* nr. *hulberti* and *Nedsia* spp.). It is currently unknown whether the *Nedsia* recorded in the current study represent one or more of the *Nedsia* species or Melitidae halotypes recorded by Biota (2006a, 2010) and Bennelongia (2013) or a separate species previously unrecorded.

Although not conservation listed or considered SRE species, the following are stygal species, with their presence indicating some connectivity between ground- and surface-waters. As such, they are of some interest.

The Thermosbaenacean *Halosbaena tulki* was recorded both upstream (RRU3) and downstream (RRD2, RRD3 and RRD4) of the Jimmawurrada-Robe confluence. *Halosbaena tulki* is the single species of Thermosbaenacean known from the Southern Hemisphere, where it appears to be restricted to the Pilbara region (Poore and Humphreys 1992). Thermosbaenacea are a rare order of crustacean, with approximately 16 species known worldwide, all of which are restricted to groundwater environments (Poore and Humphreys 1992). In the vicinity of the Project area, this species was previously collected from seven bores in the Yarraloola area by Biota (2006a).

The ostracod *Candonopsis* cf. *tenuis* is known to occur widely across Australia (DeDeckker 1982, Karanovic and Marmonier 2002), including groundwaters of the Pilbara (Halse *et al.* 2002). WRM has recorded *C.* cf. *tenuis* from the hyporheic zone of a number of sites in the Weeli Wolli Creek catchment, Coondiner Creek, Kalgan Creek, Hamersley Gorge and the Ashburton River (WRM unpub. data). During the current study, *C.* cf. *tenuis* was collected from the hyporheic zone of upstream reference site RRU6 (Appendix 6).

Vestalenula marmonieri is a stygal ostracod species known only from Western Australia and New Caledonia (Schön *et al.* 2010). This species is relatively widespread across the Pilbara region (being collected from over 50 locations by Pinder *et al.* (2010) during the PBS), though due to its preference for phreatic[14] environments, is most commonly associated with groundwater-fed systems such as Weeli Wolli Creek (WRM unpub. data). In the current study, *V. marmonieri* was recorded from potentially exposed downstream sites RRD1 and RRD5, and upstream reference site RRU1 (Appendix 6). *V.*

[14] Groundwater environments.

marmonieri was also collected in microinvertebrate samples of RRU1, RRU2, RRU3, RRU6, RRD2, RRD4 and RRD5 (Appendix 5).

5.4 Macroinvertebrates

5.4.1 Species richness and abundance

A total of 148 macroinvertebrate taxa were recorded from the Project area, of which 116 were present at sites downstream of the Jimmawurrada-Robe confluence, and 117 at upstream reference sites (Table 9, Appendix 7). In this context, "taxa" includes groups which could not be identified to species level, due to unresolved taxonomy and/or immaturity of specimens. Therefore, the total macroinvertebrate taxa richness at each site is likely greater than reported herein. The macroinvertebrate fauna comprised Cnidaria (freshwater hydra), Mollusca (freshwater snails and bivalves), Oligochaeta (aquatic segmented worms), Crustacea (amphipods and freshwater shrimp), Acarina (water mites), Collembolla (springtails), Odonata (dragonflies and damselflies), Ephemeroptera (mayflies), Hemiptera (true bugs), Coleoptera (aquatic beetles), Diptera (two-winged or "true" fly larvae), Trichoptera (caddisflies) and Lepidoptera (aquatic moth larvae; Table 9). Macroinvertebrate composition was typical of freshwater systems throughout the world (Hynes 1970), being dominated by Insecta (comprising 89% of all taxa), with Diptera (29%) and Coleoptera (32%) most prominent within this class. There were 46 singleton taxa recorded (*i.e.* those recorded from only one site), and 12 taxa were considered common taxa, *i.e.* they were present at over 80% of sites. These included the snail *Melanoides* spp., segmented worms (Oligochaeata spp.), the freshwater shrimp *Caridina indistincta*, the mayflies Baetidae spp. and *Cloeon* sp. Red Stripe, the pygmy backswimmer *Paraplea* spp., and the midge larvae/pupae Ceratopogonidae spp., Dasyheleinae spp., Chironomidae spp., *Polypedilum* sp. 1, *Larsia albiceps* and *Paramerina* sp. (Appendix 7).

Table 9. Summary of higher-order microinvertebrate taxa composition in the Robe River, upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Refer Appendix 7 for full species list.

Macroinvertebrates		Number of Taxa	
Scientific name	Common name	RRD (*n* = 6)	RRU (*n* = 6)
Cnidaria	Freshwater hydra	1	0
Oligochaeta	Aquatic worms	1+	1+
Gastropoda	Freshwater snails	4	5+
Bivalvia	Freshwater bivalves	0	1
Amphipoda	Stygal amphipods	2	0
Decapoda	Freshwater shrimps	1+	1+
Acarina	Water mites	1+	1+
Ephemeroptera	Mayflies	6	5
Odonata	Dragonflies and damselflies	14	14
Hemiptera	True bugs	18	16
Coleoptera	Aquatic beetles	30	35
Diptera	Two-winged flies	30	31
Trichoptera	Caddisflies	7	4
Lepidoptera	Aquatic moth larvae	2	2
	Total taxa richness	**116**	**117**

+ indicates a taxa could only be identified to genus/family/order level (not species level), and as such more than one species is likely to be present within this taxonomic group.

Macroinvertebrate taxa richness at upstream sites ranged from 34 taxa at RRU3 and RRU5, to 72 taxa at RRU1 (Figure 9). Richness at sites downstream of the Jimmawarruda-Robe confluence ranged from 38 taxa at RRD3 and RRD5, to 56 taxa at RRD2 (Figure 9). There was no significant difference in total

taxa richness between downstream potentially exposed sites and upstream reference sites (one-way ANOVA, Table 10). Nor were there any significant upstream-downstream differences in taxa richness of most major macroinvertebrate groups (Table 10). The exception was Ephemeroptera (mayflies), where mean richness was significantly higher at sites downstream of the confluence (4.3) compared to those upstream (2.5) (Table 10). This was largely due to the lower richness/absence of *Tasmanocoenis* sp. P/*arcuata* (Caenidae) and *Cloeon fluviatile* (Baetidae) at upstream sites, particularly RRU4 to 6 closest to the confluence.

Table 10. Summary results from ANOVAs testing for significant (p <0.05) differences in taxa richness of major macroinvertebrate groups (indicated by *), upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Mean (±SE) vales for untransformed data are also provided.

Macroinvertebrate metric	ANOVA			Mean (±SE)	
	MS	F	p	RRD (n = 6)	RRU (n = 6)
Total taxa richness	0.083	0.001	0.982	46.2 (3.5)	46.3 (6.1)
Diptera richness	0.000	0.000	1.000	14.0 (1.8)	14.0 (4.6)
Coleoptera richness	18.75	0.587	0.461	8.5 (2.4)	11.0 (2.2)
Hemiptera richness	0.333	0.035	0.855	6.3 (1.1)	6.0 (1.4)
Odonata richness	1.333	0.377	0.553	5.33 (0.6)	6.0 (0.9)
Trichoptera richness	1.333	1.429	0.260	1.7 (0.4)	1.0 (0.4)
Ephemeroptera richness	10.08	6.798	0.026*	4.3 (0.5)	2.5 (0.5)
Mollusca richness	0.083	0.068	0.799	2.7 (0.4)	2.8 (0.5)
Crustacea richness	0.750	-0.738	0.411	2.7 (0.5)	2.2 (0.3)

5.4.2 Comparison against previous studies

To provide spatial context for macroinvertebrate fauna within the Project area, total taxa richness at each site was compared against most recent data for nearby pools upstream and downstream, *i.e.* Yalleen Pool and Nyeetbury Pool on upper Bungaroo Creek (WRM 2013, 2016), and Chalyarn Pool on Mungarathoona Creek (Pinder *et al.* 2010) (Figure 9). Each of these previous studies used similar macroinvertebrate sampling techniques (kick-sweep netting using 250 µm mesh FBA pond net) and taxonomic resolution to those of the current study.

Taxa richness within the Project area (34 – 72 taxa) was generally comparable to that previously recorded for Yalleen Pool (39 – 45), Nyeetbury Spring (51 – 52) and Chalyarn Pool (49 – 77) (Figure 9). The lack of spatial variability in macroinvertebrate taxa richness between studies probably reflects the similar hydrological nature and size of these pools (*i.e.* all are either permanent/semi-permanent riverine pools, flowing only after heavy rainfall) because they are all within relatively close geographical proximity to one-another (*i.e.* within 20 – 30 km, and all part of the Robe River catchment). Pinder *et al.* (2010) noted riverine pools of the Pilbara (particularly those of the same catchment) generally display a high degree of homogeneity, in terms of macroinvertebrate species richness and composition, in comparison to similarly sized turbid wetlands and claypans.

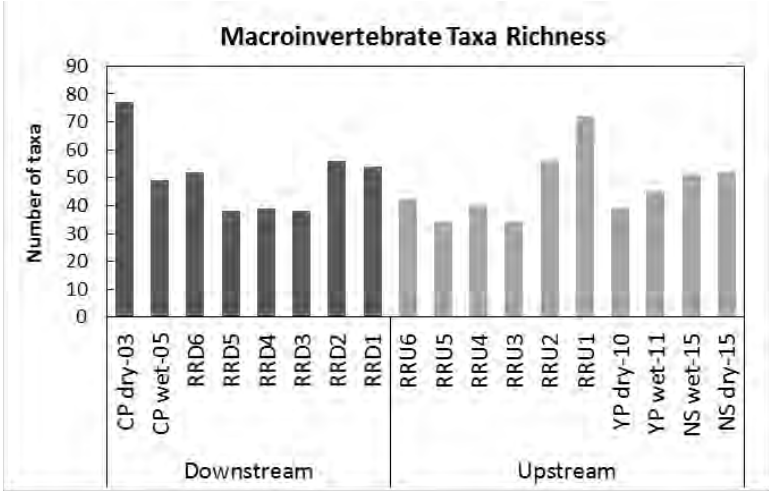

Figure 9. Macroinvertebrate taxa richness recorded during the current study, upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence, together with most recent data for nearby Chalyarn Pool (CP; Pinder *et al.* 2010), Yalleen Pool (YP; WRM 2013) and Nyeetbury Spring (NS; WRM 2016). Refer Figure 1 for location of sites.

To provide temporal/seasonal context for macroinvertebrate taxa richness in the current Project area, April/May (wet season) 2016 figures were compared against historic mean dry season taxa richness recorded at Robe River pools by Streamtec/UWA between 2002 and 2011[15]. Again, both studies utilised the same macroinvertebrate sampling technique (sweep netting using a 250 µm mesh FBA pond net), and taxonomy was standardised across datasets to account for inherent variation/advancements in taxonomic knowledge between studies (*i.e.* some taxa were condensed to family or order level to enable comparison). As such, taxa richness may appear lower than was originally reported in each study.

At the reach upstream of the Jimmawarruda-Robe confluence, mean dry season richness at Medawandy Waters (22) and Pannawonica Hill (23) were generally comparable to wet season taxa richness recorded at RRU3 (22), RRU4 (30), RRU5 (20) and RRU6 (26), but slightly lower than taxa richness recorded at RRU1 (54) and RRU2 (38) (Figure 10). Downstream of the confluence, mean dry season richness recorded at Gnieroora, Martangkuna, Pulari, Japanese Pool and Yarramudda (20 – 27 taxa) was also similar to wet season richness recorded at RRD1, RRD3, RRD4 and RRD5 (21 – 33 taxa), and only slightly lower than that recorded at RRD6 (41 taxa) and RRD2 (38 taxa). The apparent lack of seasonal variability in taxa richness likely reflects the capacity for pools of the Project area to hold water year-round (*i.e.* they are either permanent/semi-permanent), acting as refuge pools for migratory macroinvertebrates during the dry season, and generally favouring both temporary and permanent resident macroinvertebrate species over more ephemeral waterbodies (Sponseller *et al.* 2001, Pinder *et al.* 2010). Furthermore, Pinder *et al.* (2010) found there to be little seasonal variation in macroinvertebrate assemblages at permanent/semi-permanent riverine pools of the Pilbara region in comparison to more ephemeral waterbodies, particularly when flooding had not occurred prior to wet season sampling (as was the case in the current study). It must be noted that the current study provides only a snapshot of the macroinvertebrate fauna of the Project area and taxa richness could still vary considerably between time periods.

[15] The most recent round of macroinvertebrate data (2013) was not included in analysis, as Streamtec (2014) did not feature a raw species list. Earlier species lists (1996 & 1998) were not included in the analysis due to the vast improvements in taxonomic knowledge and microscope technology since those studies.

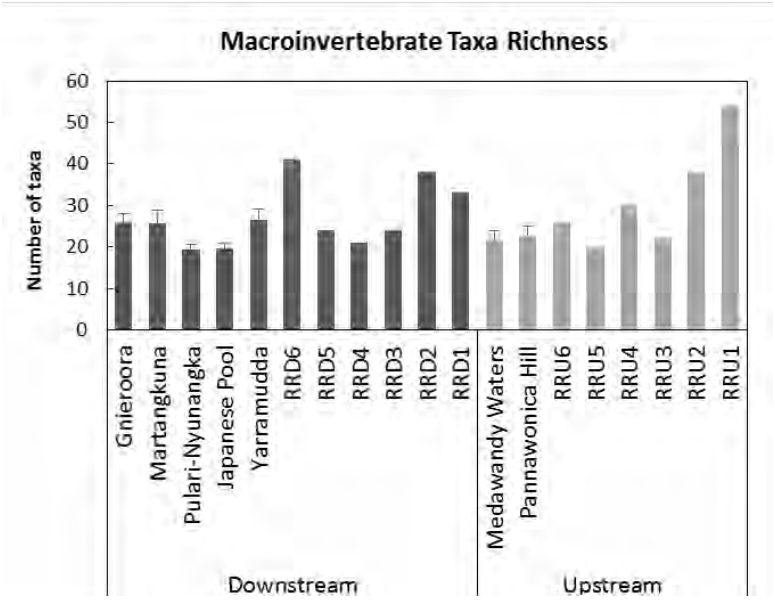

Figure 10. Comparison of standardised macroinvertebrate taxa richness recorded during the current study, with that recorded by Streamtec/UWA during long-term monitoring of Robe River pools. Refer Figure 1 for location of sites.

5.4.3 Spatial variation in species assemblages

Multivariate analysis (ANOSIM) detected no significant difference in macroinvertebrate species assemblage composition between upstream reference and downstream potentially exposed sites (Table 11), suggesting there was a high degree of natural variability and overlap amongst upstream/downstream sites. Although SIMPER analysis found only a 45% similarity of species assemblages between upstream and downstream sites, nMDS plotting displayed no distinguishable separation of upstream/downstream sites based on Bray-Curtis similarity (Figure 11), with SIMPROF analysis (not shown) detecting no clustering of these groups. One site (RRU3) was separate from all other sites, which is attributed to the low overall taxa richness (34) recorded at this site compared to others. As with taxa richness, the lack of variability in upstream/downstream macroinvertebrate assemblages likely reflects the relatively similar hydrological nature (permanent/semi-permanent) of pools in the Project area.

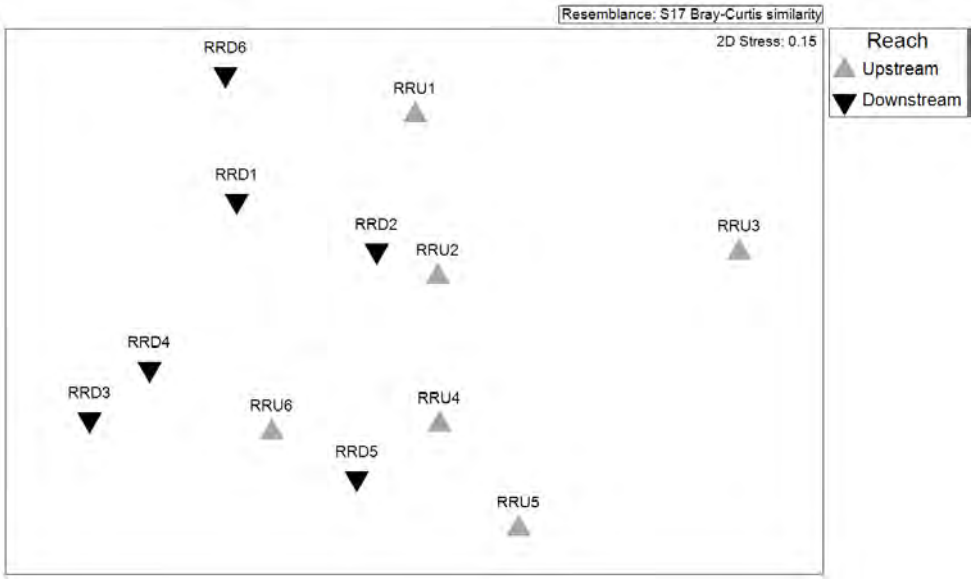

Figure 11. Plot of nMDS ordination on macroinvertebrate species assemblages (log_{10} abundance class) upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence. Ordination based on Bray-Curtis similarity. Refer Table 1 for explanation of site codes and Figure 1 for location of sites.

Table 11. Summary results from ANOSIM testing for significant (p <0.05) differences in macroinvertebrate assemblages (Bray-Curtis similarity) upstream (RRU) and downstream (RRD) of the Jimmawurrada-Robe confluence.

Macroinvertebrate assemblage similarity (Bray-Curtis)	ANOSIM	
	R-statistic	*p*
Abundance (log_{10} class)	0.154	0.106
Presence/absence	0.111	0.186

5.4.4 Conservation significance of macroinvertebrate fauna of the Project area

The Pilbara pin damselfly, *Eurysticta coolawanyah* (family Isostictidae), is endemic to the Pilbara region, and is currently listed as Near Threatened on the IUCN Red List of Threatened Species (IUCN 2016). *Eurysticta coolawnyah* was recorded from two sites in the current study; RRD3 and RRD4, both downstream of the Jimmawarruda-Robe confluence (Appendix 7). *E. coolawanyah* is known from over 40 locations across the Pilbara (Pinder *et al.* 2010), and has been recorded by WRM from a number of riverine pools and springs along the Fortescue River, DeGrey River, Coondiner Creek, Kalgan Creek and Weeli Wolli Creek (WRM unpub. data). Along the Robe River, this species has been recorded consistently by Streamtec/UWA, as well as from Bungaroo Creek (WRM 2013) and Mugarathoona Creek (Pinder *et al.* 2010).

It is likely that both RRD3 and RRD4 are important refuge pools for *E. coolawanyah* in the area, as both are persistent waterbodies which support relatively high densities of emergent macrophyte (see Appendix 4). Damselflies (such as *E. coolawanyah*) are known to actively select sites with greater concentrations of emergent macrophyte, which are used for perching, mating and oviposition (egg-laying) (D'Amico *et al.* 2004, Rouquette and Thomson 2004, Ward and Mill 2005, Remsburg and Turner 2009).

Although the following species are not listed for conservation significance, they are endemic to the Pilbara region and therefore of some scientific interest. The Pilbara tiger dragonfly, *Ictinogomphus dobsoni* (family Lindeniidae), was collected at reference site RRU3, and potentially exposed sites RRD1, RRD4 and RRD6 (Appendix 7). This species appears to be relatively common across the Robe River

catchment, having been recorded from Chalyarn Pool, Red Hill Creek (Pinder *et al*. 2010) and a number of permanent/semi-permanent Robe River pools (Streamtec/UWA). Elsewhere, *I. dobsoni* has been recorded from many of the other major river systems of the Pilbara, including the Fortescue, Ashburton, Yule, DeGrey and Sherlock rivers (DEC 2009, Pinder *et al*. 2010, CSIRO 2015). Large pools within the Project area epitomise ideal refuge habitats for *I. dobsoni*, which is known to prefer still or sluggish permanent riverine waterbodies (Watson 1991).

The Pilbara endemic dytiscid beetle *Tiporus tambreyi* was recorded at reference sites RRU3, RRU4 and RRU6, and potentially exposed site RRD1 (Appendix 7). This species is common and ubiquitous across the region, and in the vicinity of the Project area, has been recorded from Robe River pools (Streamtec/UWA), Chalyarn Pool (Pinder *et al.* 2010) and Red Hill Creek (WRM 2009, Pinder *et al.* 2010).

The haliplid beetle *Haliplus pilbaraensis,* recorded from reference site RRU1 (Appendix 7), is endemic to the Pilbara region and relatively new to science (Watts and McRae 2010). This species appears to occur fairly widely throughout the Pilbara, and has been recorded at localities such as Glen Ross Creek, Coondiner Pool, the Fortescue Marsh, Moreton Pool, Paradise Pool, Munreemya Billabong, Wackilina Creek Pool, West Peawah Creek Pool, Harding River Pool, and an un-named creek in Millstream (Watts and McRae 2010). Closer to the Project area, *H. pilbaraensis* was previously recorded from Red Hill Creek (WRM 2009).

5.5 Fish

5.5.1 Species composition and abundance

A total of 3,515 individual fish were caught, measured and released in the Project area; 1,578 from upstream reference sites (RRU1 - 6), and 1,937 from sites downstream of the Jimmawarruda-Robe confluence (RRD1 - 6). Seven true freshwater taxa were recorded, including the western rainbowfish, spangled perch, Pilbara tandan (eel-tailed catfish), Fortescue grunter, barred grunter, bony bream, and a hybridised form of Terapontidae (grunter) (Table 12). Four species captured were of estuarine/marine origin, including milkfish, tarpon (ox-eye herring) (Plate 8), mullet and banded scat (striped butterfish) (Plate 8) (Table 12). Each of the freshwater species, with the exception of bony bream, was recorded both upstream and downstream of the Jimmawarruda-Robe confluence (bony bream were only recorded upstream of the confluence) (Table 12). The marine vagrant tarpon and mullet were also recorded both upstream and downstream of the confluence; however, milkfish and banded scat were only recorded from the downstream reach (Table 12). Each of these species, except milkfish, was previously recorded from the Robe River by Morgan and Gill (2004) and Streamtec/UWA.

Table 12. Summary of freshwater and estuarine/marine vagrant fish species recorded in the Project area, including scientific and common names. ✓ = fish species was present.

Origin	Species	Common name	Downstream						Upstream

There was no significant difference in mean abundance of fish upstream and downstream of the Jimmawarruda-Robe confluence (one-way ANVOA, $p = 0.433$), nor was there any significant difference in mean abundance of any of the individual species between the upstream and downstream reaches (one-way ANOVA, $p < 0.05$). There was a significant difference in mean species richness between upstream and downstream sites, with mean richness significantly higher downstream of the Jimmawarruda-Robe confluence (one-way ANVOA, $p = 0.008$). This was mainly due to the greater presence of estuarine species such as banded scat, milkfish and tarpon at the downstream reach (Table 12).

Western rainbowfish were the most abundant fish of the Project area, with a total of 2,401 individuals captured. Western rainbowfish were present at all sites, with 1,019 recorded from upstream reference sites (42%), and 1,382 recorded from downstream sites (48%) (Figure 12). Fortescue grunter (685 individuals) and spangled perch (203 individuals) were the second and third most abundant species of the Project area, respectively. Fortescue grunter were collected from all sites, with similar numbers captured both upstream (320 individuals; 47%) and downstream (365 individuals; 53%) of the Jimmawarruda-Robe confluence (Figure 12). Spangled perch were also present at all sites, with the majority recorded at upstream sites (145 individuals; 71%) (Figure 12). Of the remaining freshwater species, Pilbara tandan (34 individuals) were recorded at upstream sites RRU1, RRU2, RRU3, RRU5, and downstream sites RRD2, RRD3 and RRD4; barred grunter (47 individuals) were recorded at upstream sites RRU5 and RRU6, and at downstream sites RRD3, RRD4 and RRD5. Terapontidae hybrids (12 individuals) were recorded at upstream sites RRU1, RRU3, RRU5 and RRU6, and downstream sites RRD2 and RRD5 (Figure 12). Bony bream (5 individuals) were only recorded at upstream site RRU2.

Of the estuarine/marine fish species, tarpon (39 individuals) (Plate 8) were recorded at upstream sites RRU2, RRU4 and RRU5, and all sites downstream of the Jimmawarruda-Robe confluence (Figure 12). Mullet (33 individuals) were recorded at upstream sites RRU2 and RRU4, and downstream sites RRD1 and RRD5 (Figure 12). Banded scat (53 individuals) (Plate 8) were only recorded downstream of the confluence, but were present at all sites within that reach (Figure 12). Milkfish (7 individuals) were only recorded from downstream sites RRD4 and RRD6 (Figure 12).

Plate 8. The banded scat *Selenotoca multifaciata* (left) and the tarpon *Megalops cyprinoides* (right), captured downstream of the Jimmawarruda-Robe confluence.

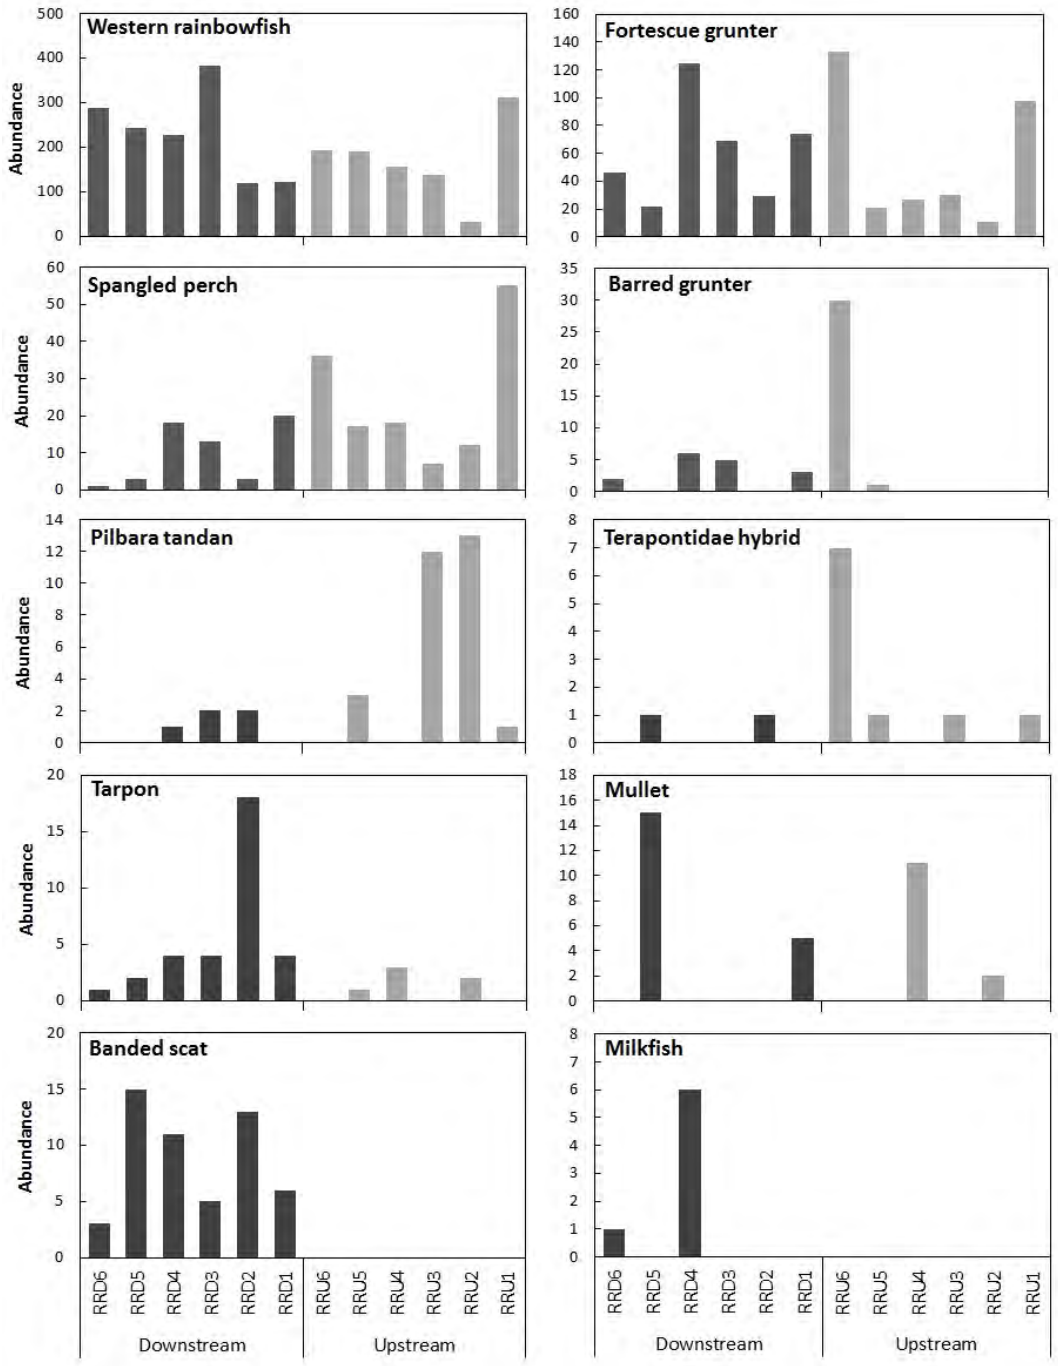

Figure 12. Abundance of each fish species recorded from upstream (RRU1 to 6) and downstream (RRD1 to 6) of the Jimmawurrada-Robe confluence. Note: bony bream (*Nematalosa erebi*) were also recorded from the Project area, but were not plotted due to low overall abundance of this species.

5.5.2 Conservation significance of fish species

One conservation listed freshwater fish species was recorded from the Project area; the Pilbara endemic Fortescue grunter (*Leipotherapon aheneus*). Currently, the Fortescue grunter is listed on the IUCN Red List of Threatened Species as Lower Risk/Near Threatened (IUCN 2016), and as a Priority 4 (P4) species on the Department of Parks and Wildlife (Parks and Wildlife) Priority Fauna List (Parks and Wildlife 2016). This species is only known from the Fortescue, Robe and Ashburton River systems (Allen *et al*. 2002, Morgan and Gill 2004); however, it is considered to be common within this range, as is evidenced

by the ubiquitousness of this species across the current Project area, being the second most abundant fish collected (685 individuals) and occurring at all sites both upstream and downstream of the Jimmawarruda-Robe confluence (Table 12 and Figure 12).

The following species are not listed for conservation significance, but are of some scientific interest:

Individuals which appeared to be hybridised forms of two of the three co-occurring Robe River Terapontidae species (spangled perch, barred grunter and/or Fortescue grunter; Plate 9) were recorded from RRU1, RRU3, RRU5, RRU6, RRD2 and RRD5 (Table 12 and Figure 12). Hybridised grunters have been recorded from other Pilbara systems by the authors and others, including the Fortescue, Murchison and Ashburton rivers (Morgan and Gill 2006, Morgan *et al.* 2009, WRM 2016, WRM unpub. data). Morgan and Gill (2006) propose hybridisation between closely related fish species is not uncommon; however, the hybridisation of grunters in Pilbara river systems is not fully understood, and is of some interest, particularly if hybridisation results in the loss of species through replacement with reproductively unviable individuals, or if there is evidence of incipient speciation (the formation of a new species). Loss or replacement of a species is especially important in the case of the Fortescue grunter, as it is a nationally and internationally listed species of conservation significance.

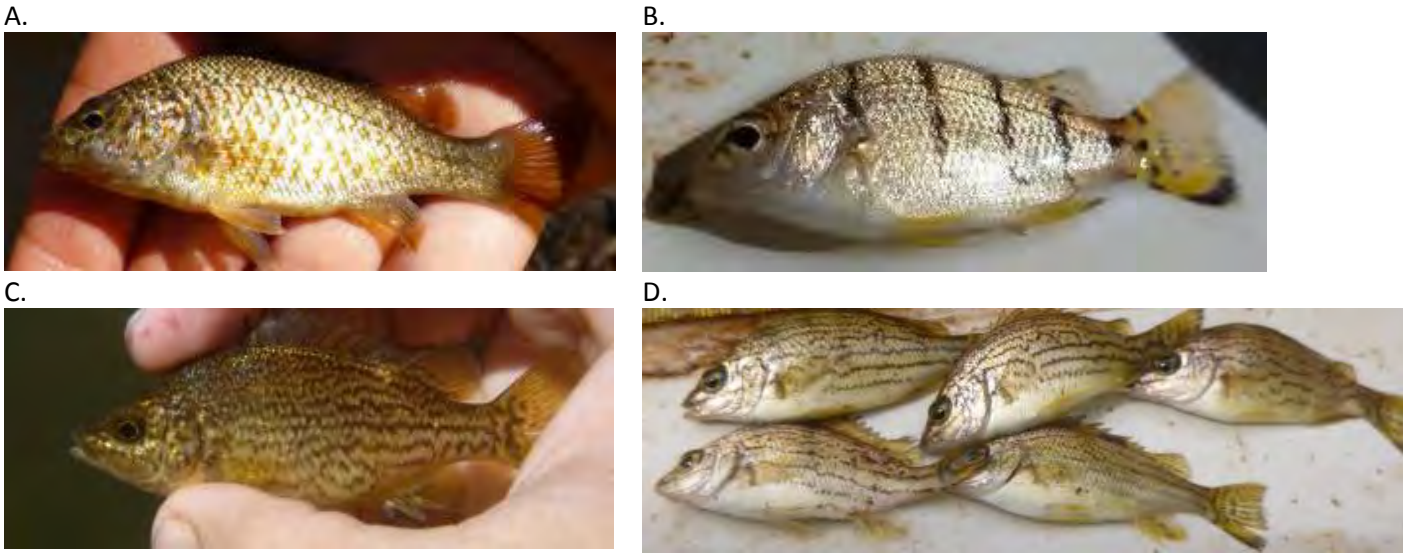

Plate 9. Terapontid hybridisation, illustrating (A) Spangled perch *Leiopotherapon unicolor,* (B) barred grunter *Amniataba percoides*, (C) Fortescue grunter *Leiopotherapon aheneus*, and (D) Terapontidae hybrids from RRU6, possibly sharing the features of barred and Fortescue grunter. Photographs by Chris Hofmeester (A, B and C)/WRM (D) ©.

None of the estuarine/marine fish species recorded in the Project area are endemic to the Pilbara region or currently listed for conservation significance. Milkfish (*Chanos chanos*) were not reported from the freshwater reaches of the Robe River by either Streamtec/UWA, Morgan and Gill (2004) or Antao and Braimbridge (2010). As such, collection of this species during the current study (along with its collection from further downstream) likely establishes a new record for the system. *Chanos chanos* is widely distributed across tropical and sub-tropical climes of the Indo-West Pacific region (Bagarinao 1994, Swanson 1998, Allen *et al.* 2002). This species is known to utilise fresh, brackish, oceanic and hypersaline lagoon environments (*i.e.* are euryhaline), being extremely efficient at osmoregulation during all life-history stages (Swanson 1998, Lin *et al.* 2003). In Australian waters, adult milkfish are pelagic schooling fish, inhabiting shallow, off-shore marine habitats. Spawning typically takes place offshore, following which juveniles migrate to sheltered estuaries. Sub-adult milkfish occasionally penetrate further upstream into freshwater reaches, before returning to the ocean to undergo sexual maturation and spawning (Bagarinao 1994, Allen *et al.* 2002).

5.5.3 Fish population structure

The reproductive strategies of freshwater fish species in the Pilbara are 'opportunistic' and 'periodic', reflecting the seasonal yet unpredictable nature of rainfall and streamflow in the region (Beesley 2006). Breeding of many species occurs during the wet season and during this time, multiple spawning events are known to occur (Beesley 2006). Further, the volume, hydrological regime and habitat complexity of Pilbara waterbodies can have a marked influence on fish population structure, with larger pools and more complex habitat considered generally advantageous for fish communities (Allen *et al.* 2002, Morgan *et al.* 2002, Morgan *et al.* 2009). Therefore, anthropogenically-induced alterations to streamflow patterns, water levels and water quality can have a discernible impact on life-history strategies and assemblage composition of local fish populations (Allen *et al.* 2002). Analysing population structure provides one means of characterising the health of fish assemblages at each site, and by extension the ecological processes driving aquatic communities within the waterbody. The presence of newly recruited and juvenile fish, for example, indicates recent spawning activity (and conditions conducive to such). Conversely, the presence of only sub-adult and adult (larger) fish may indicate a higher amount of predatory pressure on juvenile fish, and/or that conditions in pools are not conducive to spawning.

In order to examine population structures of the most ubiquitous freshwater fish of the Pilbara region (western rainbowfish, spangled perch and Pilbara tandan), length-frequency data for age-classes were estimated from published literature (*i.e.* Lake 1971, Bishop *et al.* 2001, Allen *et al.* 2002, Morgan *et al*. 2002, Beesley 2006; Table 13).

Table 13. Age-classes used in length-frequency analysis of Western rainbowfish, spangled perch and Pilbara tandan from the Project area. Age-classes are adapted from Lake (1971), Bishop *et al.* (2001), Allen *et al.* (2002), Morgan *et al*. (2002) and Beesley (2006).

Species	Age-class	Size mm SL
Western rainbowfish	New recruit	< 30
(*Melanotaenia australis*)	Juvenile	31-40
	Sub-adult	41-50
	Adult	> 51
Spangled perch	New recruit	< 30
(*Leiopotherapon unicolor*)	Juvenile	31-50
	Sub-adult	51-70
	Adult	> 71
Pilbara tandan	New recruit	< 30
(*Neosilurus* sp.)	Juvenile	31-70
	Sub-adult	71-90
	Adult	> 91

Western rainbowfish

Western rainbowfish breed throughout the year, with multiple spawning bouts that take full advantage of the region's intermittent rainfall and streamflow (Beesley 2006). Rainbowfish of the family Melanotaeniidae are usually sexually mature by the end of their first year (Allen *et al.* 2002). The size at sexual maturity can vary between river systems (typically around 50 mm SL), though western rainbowfish generally attain a maximum size of 110 mm total length (TL) (Allen *et al.* 2002).

The population structure of western rainbowfish at most upstream and downstream sites appeared to be healthy, with a variety of age-classes (new recruits, juveniles, sub-adults and adults) represented at RRU1, RRU4, RRU5, and RRD2 – RRD6 (Figure 13). New recruits and juveniles were particularly abundant at upstream site RRU4, and downstream sites RRD2, RRD4 and RRD6 (Figure 13), indicating spawning activity and good recruitment at these waterbodies. No western rainbowfish new recruits were recorded at RRD1, where sub-adults and adults (50 – 90 mm SL) dominated the population (Figure 13). Relatively low numbers of new recruits and juveniles (and low western rainbowfish numbers in general) were also recorded at RRU2 (Figure 13). Low recruitment of rainbowfish at RRD1 was possibly due to the small size of this pool, which also contained piscivorous species such as spangled perch, Fortescue grunter and barred grunter. Reduced depth and volume of small pools such as RRD1 inherently increases the risk of juvenile fishes to teleost (fish) and avian predation (Morgan *et al.* 2009). Conversely, low western rainbowfish abundance (and concurrent low abundance of new recruits and juveniles) recorded at RRU2 may have been related to the large size and volume of this pool, which would enable fish to avoid capture in seine and gill nets. Relatively low abundances of all fish species were recorded at RRU2, with the exception of Pilbara tandan, which are more commonly caught while electrofishing, rather than in seine and gill nets.

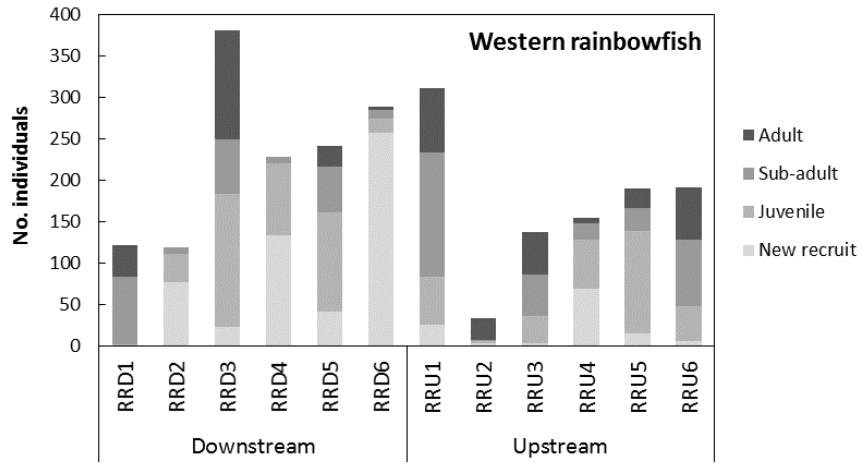

Figure 13. Abundance of western rainbowfish (*Melanotaenia australis*) age-classes recorded from each pool in the Project area.

Spangled Perch

Spangled perch are known to take advantage of wet season flooding to migrate upstream and breed (Bishop *et al.* 1995, Bishop *et al.* 2001, Pusey *et al.* 2004, Marsden and Power 2007). During this time, multiple spawning events are known to occur (Beesley 2006). In the Fitzroy River, Morgan *et al.* (2002) collected mature specimens at the beginning of the wet season, and larvae at the end of the wet season, indicating that spawning coincided with the flooding of the river. Spangled perch mature in their first year, at approximately 58 mm TL for males and 78 mm TL for females, and can reach a maximum size of 300 mm TL (Allen *et al.* 2002, Beesley 2006).

Spangled perch recruitment in the Project area appeared to be low, with new recruits (< 30 mm SL) only recorded at RRU1 and RRU2 upstream of the Jimmawarruda-Robe confluence, and RRD3 and RRD4 downstream of the confluence (Figure 14). Juveniles (31 - 60 mm SL) were also absent or recorded in low numbers at most sites (Figure 14). This reflects the high degree of variability in streamflow in the Project area, with low rainfall and streamflow leading up to the survey likely restricting spangled perch spawning activity. The exception was downstream site RRD3, where the spangled perch population comprised mainly juveniles (227 juveniles) (Figure 14). This suggests spangled perch may have spawned in or upstream of this pool recently following a flood event, with juveniles becoming isolated as waters

receded. RRD3 supported the highest abundance of spangled perch in the Project area (382 individuals), constituting 67% of all spangled perch caught during the survey; however, given the ubiquitousness of this species across the Pilbara, it is likely that larger populations reside at larger pools within the Project area. Catch per unit effort is likely reduced in these pools, such as RRU2, RRU4, RRU5, RRD4, RRD5 and RRD6, due to their size and depth, and presence of submerged debris (*e.g.* logs, branches, snags), which hinders seine and gill netting.

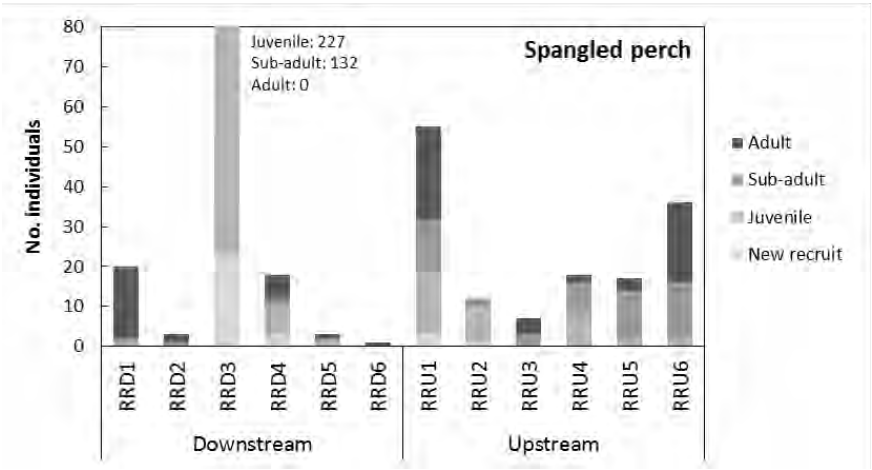

Figure 14. Abundance of spangled perch (*Leipotherapon unicolor*) age-classes recorded from each pool in the Project area. Note: column representing RRD3 is only partially displayed; the remainder of age-classes are given as text (new recruits are still displayed).

Pilbara tandan

Very little is known of the breeding ecology of the Pilbara tandan. Species of *Neosilurus* catfish usually attain a maximum size of only 200 mm SL, whereas similar species, such as *N. hyrtlii* and *N. ater*, can reach up to 400 mm TL (Lake 1971, Bishop *et al.* 2001). Breeding is thought to occur in the early wet season, where adults (> 91 mm SL) build their nests under large cobbles in flowing riffle zones (Bishop *et al*. 2001, Morgan *et al.* 2002). It is at this time when flooding increases the area and diversity of aquatic habitat available, while also initiating increases in plankton and other food sources (Bishop *et al.* 2001).

Pilbara tandan were collected in relatively low abundance throughout the Project area, with no new recruits (< 30 mm SL) recorded (Figure 15). Juvenile Pilbara tandan (31 – 70 mm SL) were only recorded at RRD2, RRU1 and RRU2 (Figure 15). Similar to spangled perch, low Pilbara tandan recruitment likely reflects the lack of streamflow in the Project area prior to the survey. Further, low overall catch rates of Pilbara tandan was likely due to the inherent difficulties in sampling this species. Like most other catfish, the Pilbara tandan is a benthic feeder, with techniques such as gill and seine netting generally limited in their ability to collect specimens due to the bottom-dwelling nature of these fish.

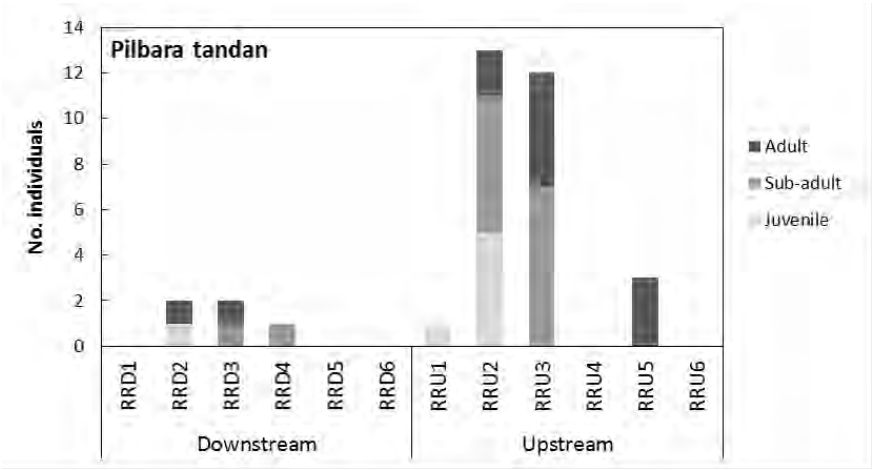

Figure 15. Abundance of Pilbara tandan (*Neosilurus* sp.) age-classes recorded from each pool in the Project area.

5.6 Other Fauna

No frogs or tadpoles were observed at any site in the current study. Although it is expected that some frogs do utilise pools within the Project area, the presence of large predatory fish, waterbirds and other predators (*e.g.* snakes) at these waterbodies would likely reduce survival rates of tadpoles in remnant pools.

No turtles were captured or observed in the Project area. EPA (1991) noted the native flat-shelled turtle, *Chelodina steindachneri,* was present at Gnieraoora and Martangkuna, but do not state the source of the records, which was possibly the 1991 survey by Streamtec/UWA for the Mesa J Project area.

6 SUMMARY AND CONCLUSIONS

This report summarises the results of wet season baseline sampling of aquatic ecosystems of the Robe River, both upstream and downstream of the proposed Mesa H development. The aim of the sampling program was to document the current ecological condition of the Robe River prior to the Mesa H development, which will require mine dewatering and surplus water discharge and may result in a surface discharge footprint along the Robe River. The current sampling program documents "current" ecological condition, moreso than "natural" condition due to the existing mine operations. In general, both water quality and aquatic fauna (microinvertebrate, hyporheic invertebrate, macroinvertebrate and fish) data indicated little ecological difference between "reference" sites upstream of the proposed development, and downstream sites that may be potentially exposed to dewatering discharge.

Water quality was highly variable amongst sites, with salinity levels ranging from fresh (592 µS/cm) to brackish (1,700 µS/cm), pH from circum-neutral (6.9) to slightly alkaline (7.9) and dissolved oxygen from hypoxic (14.5%) to supersaturated (134.9%). There were no obvious longitudinal gradients upstream or downstream of the Jimmawurrada-Robe confluence. Site RRU6, (~1 km upstream of the confluence) and the downstream sites, tended to have higher salinity (as EC and TDS), alkalinity, hardness and concentrations of associated ions, than sites upstream. This inter-site variability was attributed to differences in volume of the remnant pools sampled and evapoconcentration effects under recessional flows.

Exceedances of ANZECC/ARMCANZ default 95% TVs were recorded for nitrogen nutrients (N-total, N-NO_x and N-NH_3) at most sites upstream and downstream of the Jimmawurrada-Robe confluence. Elevated background levels of N-NO_3 and N-NH_3 within the Project area are unsurprising, given that the Robe River catchment is already effected by current and historic pastoral practices, with groundwaters also appearing to be enriched. Cattle, or evidence of high cattle use, were observed at a number of pools. Elevated N-total and N-NO_x downstream of the Jimmawurrada-Robe confluence may also reflect discharge of nitrogen-enriched groundwater from existing mine operations, though the relative contribution of anthropogenic and natural sources to nitrogen enrichment in surface waters of the Project area is unknown. With the exception of dissolved zinc at RRU5 and RRD3, no heavy metal analyte exceeded ANZECC/ARMCANZ default 95% TVs in the Project area.

A total of 81 microinvertebrate taxa were recorded from the Project area, of which 46 were present at potentially exposed sites downstream of the Jimmawurrada-Robe confluence, and 69 were recorded at upstream reference sites. The microinvertebrate fauna was generally typical of that commonly recorded from tropical/sub-tropical freshwater systems, comprising protists, rotifers, copepods, cladocerans (water fleas) and ostracods (seed shrimp), with Lecanidae dominating within the Rotifera. There were no significant differences in total mean microinvertebrate taxa richness between reference and potentially exposed sites, nor was there any significant difference in richness of any of the major microinvertebrate groups (protists, rotifers, micro-crustaceans) between these reaches.

Hyporheic sampling collected 59 taxa in total, the majority of which were species not specially adapted to groundwater environments (stygoxene); however, 8% were considered stygobitic (obligate groundwater inhabitants), 31% occasional hyporheic stygophiles (species that use the hyporheic zone seasonally or during early life history stages), and 2% possible hyporheic taxa. There were no obvious longitudinal gradients or patterns in hyporheic taxa richness between reference and potentially exposed sites, though hyporheic taxa richness was relatively high at RRD1, RRU6, RRD2 and RRU4, suggesting strong connectivity between ground- and surface- waters at these sites.

A total of 148 macroinvertebrate taxa were recorded from surface waters, with composition typical of freshwater systems throughout the world, being dominated by Insecta, in particular Diptera (true flies) and Coleoptera (aquatic beetles). There were no clear upstream/downstream gradients in

macroinvertebrate richness within the Project area, with no significant difference in mean total taxa richness, and mean richness of most major macroinvertebrate groups, between reference and potentially exposed sites. Similarly, multivariate analysis detected no distinguishable separation of reference or potentially exposed sites based on macroinvertebrate species assemblage structure.

3,515 individual fish, representing 11 species, were captured, measured and released in the Project area. True freshwater species included western rainbowfish, spangled perch, Pilbara tandan (eel-tailed catfish), Fortescue grunter, barred grunter, Terapontidae (grunter) hybrids and bony bream. Estuarine/marine vagrant fish species included milkfish, tarpon/ox-eye herring, mullet and banded scat/striped butterfish, the majority of which were recorded at downstream sites. The conservation listed Fortescue grunter (*Leipotherapon aheneus*; IUCN Lower Risk/Near Threatened; Parks and Wildlife Priority 4) was the second most abundant fish species of the Project area, recorded at all upstream and downstream sites. Similar to other fauna indices, there was no significant difference in mean total abundance of fish between upstream and downstream sites, nor was there any significant difference in mean abundance of each individual species between the reaches. Healthy (breeding) populations of western rainbowfish, the most abundant fish species of the Project area, were recorded from both the upstream and downstream reaches; however, spangled perch and Pilbara tandan recruitment appeared to be low throughout the Project area.

Including the Fortescue grunter, four species of conservation significance were recorded in the Project area, all of which were present at sites potentially exposed to dewatering discharge. These are summarised in Table 14 below:

Table 14. Summary of aquatic species of conservation significance (conservation listed or short range endemic) recorded from the Project area.

Species	Common name	Conservation significance	Occurrence within the Project area	Occurrence elsewhere
Microinvertebrates				
Eodiaptomus lumholtzi	Calanoid copepod	IUCN Vulnerable	RRD6	Koodaderi Spring, Homestead Trib., Mindy Mindy Ck., Cane R., NT & QLD.
Stygal / SRE invertebrates				
Nedsia spp.	Stygal amphipod	Potential short range endemic (data deficient)	RRD1 – 4, RRU3, RRU4 and RRU5	Uncertain, possibly bores within the Yarraloola Area
Macroinvertebrates				
Eurysticta coolawanyah	Pilbara pin damselfly	IUCN Near Threatened, Pilbara endemic	RRD3 and RRD4	Widespread throughout the Pilbara, though infrequently collected
Fish				
Leipotherapon aheneus	Fortescue grunter	IUCN Near Threatened, Parks and Wildlife Priority 4, Pilbara endemic	All sites	Robe R. catchment, Fortescue R. (below Fortescue Marsh); Ashburton R.

Current results indicate little ecological difference between "reference" sites upstream of the proposed Mesa H development, and downstream sites that may be potentially exposed to dewatering discharge operations. As such, these results provide a good starting point to enable the detection of potential ecological changes downstream of the Mesa H development caused by an altered abstraction and dewatering discharge regime. Data collected from reference sites upstream of Mesa H serve as the "control" for potentially exposed sites, while April/May 2016 data provide a snapshot of the "before"

condition, against which any future changes following mine development can be assessed. The premise being that if the degree of similarity between exposed and reference sites differs significantly over time (compared with pre-mine similarity), this would indicate mine-related response rather than stochastic variability due to factors such as climatic change.

Appendix 2. ANZECC/ARMCANZ (2000) trigger values

Table A2-1. ANZECC/ARMCANZ (2000) default trigger values for some physical and chemical stressors for tropical Australia for slightly disturbed ecosystems (TP = total phosphorus; FRP = filterable reactive phosphorus; TN = total nitrogen; NOx = total nitrates/nitrites; NH4+ = ammonium). Data derived from trigger values supplied by Australian states and territories, for the Northern Territory and regions north of Carnarvon in the west and Rockhampton in the east.

	TP ($\mu g\ L^{-1}$)	*FRP ($\mu g\ L^{-1}$)*	*TN ($\mu g\ L^{-1}$)*	*NOx ($\mu g\ L^{-1}$)*	*NH_4^+ ($\mu g\ L^{-1}$)*	*DO % saturation[f]*	*pH*
Aquatic Ecosystem							
Upland River[e]	10	5	150	30	6	90-120	6.0-7.5
Lowland River[e]	10	4	200-300[h]	10[b]	10	85-120	6.0-8.0
Lakes & Reservoirs	10	5	350[c]	10[b]	10	90-120	6.0-8.0
Wetlands[3]	10-50[g]	5-25[g]	350-1200[g]	10	10	90[b]-120[b]	6.0-8.0

b = Northern Territory values are 5µgL-1 for NOx, and <80 (lower limit) and >110% saturation (upper limit) for DO;
c = this value represents turbid lakes only. Clear lakes have much lower values;
e = no data available for tropical WA estuaries or rivers. A precautionary approach should be adopted when applying default trigger values to these systems;
f = dissolved oxygen values were derived from daytime measurements. Dissolved oxygen concentrations may vary diurnally and with depth. Monitoring programs should assess this potential variability;
g = higher values are indicative of tropical WA river pools;
h = lower values from rivers draining rainforest catchments.

Table A2-2. ANZECC/ARMCANZ (2000) Default trigger values for salinity and turbidity for the protection of aquatic ecosystems, applicable to tropical systems in Australia.

Aquatic Ecosystem		*Comments*
Salinity	***(µs/cm)***	
Upland & lowland rivers	20-250	Conductivity in upland streams will vary depending on catchment geology. The fist flush may result in temporarily high values
Lakes, reservoirs & wetlands	90-900	Higher conductivities will occur during summer when water levels are reduced due to evaporation
Turbidity	***(NTU)***	
Upland & lowland rivers	2-15	Can depend on degree of catchment modification and seasonal rainfall runoff
Lakes, reservoirs & wetlands	2-200	Most deep lakes have low turbidity. However, shallow lakes have higher turbidity naturally due to wind-induced re-suspension of sediments. Wetlands vary greatly in turbidity depending on the general condition of the catchment, recent flow events and the water level in the wetland.

Table A2-3. ANZECC/ARMCANZ (2000) default trigger values for toxicants at alternative levels of protection (µg/L).

	Trigger values for freshwater Level of protection (% species)			
Compound	***99%***	***95%***	***90%***	***80%***

Appendix 3. Water quality data

Results from spot measurement of surface water quality taken in conjunction with aquatic fauna sampling. ANZECC/ARMCANZ (2000) default TV for protection of 95% of freshwater species is also provided for comparison; ☐ ≥ default TV, ☐ ≥ 2x default TV, ☐ ≥ 10x default TV; note, for DO, values highlighted are less than the lower default TV.

* ANZECC/ARMCANZ (2000) provide only a low reliability TV for iron (Fe);

[A] Default TV shown is for AsV, as no default TV is provided for total arsenic;

[B] For bioaccumulating chemicals, ANZECC/ARMCANZ (2000) recommend using the default 99% species protection level TV;

[H] Default TV should be modified for water hardness using algorithms provided in Table 3.4.3 of ANZECC/ARMCANZ (2000);

[N] Default TV shown is for ammonium nitrogen, as N-NH_4^+, for protection against eutrophication. Default TV for protection against toxic effects of ammonia, as N-NH_3, is 0.9 mg/L.

Appendix 6. Hyporheic invertebrate data

Values are log_{10} abundance categories, where 1= 1 individual, 2 = 2-10 individuals, 3 = 11-100, 4 = 101-1000, and so on. Hyporheic fauna classifications (Class) followed those of Boulton (2001), where: X = stygoxene, O = occasional hyporheic stygophile, P = possible hyporheic taxa, S = stygobite and U = Unclassified.

(imm./dam) = taxa were too immature / damaged to be accurately identified to a lower taxonomic level.

(P) = taxa were in pupal form.

(L) = taxa were in larval form.

NB: some chironomid taxa are followed by their unique morphotype code (in parentheses).

Appendix 7. Macroinvertebrate data

Values are $\log_{10}$ abundance categories, where 1= 1 individual, 2 = 2-10 individuals, 3 = 11-100, 4 = 101-1000, and so on.

Executive Summary

Astron was engaged to undertake a desktop mesa façade ecological value assessment for the potential development of the Mesa H deposit. The purpose of the mesa façade assessment was to assist in determining which mesa façades should be prioritised for retention/avoidance if the Proposal proceeds. The Mesa H survey area is located adjacent to the existing Mesa J Operation, south-west of Pannawonica, Western Australia and is 4,930 hectares.

The mesa façade assessment area was 446.8 hectares and consisted of 48 assessment sites of approximately 500 metre long sections. The desktop assessment utilised the field data and literature already gathered and compiled during Level 2 flora, vegetation and fauna surveys completed by Astron and aligns with the Environmental Protection Authority's guideline for landforms. Each mesa section was scored for a number of ecological factors (flora and vegetation, vertebrate fauna and invertebrate fauna) and the total scores were used to determine the priority for retention rating. The priority for retention rating scales of high, moderate and low were determined using the mean and standard deviation of all mesa assessment sites.

Twenty per cent (91.2 ha) of the total area of mesa façades within the survey area were rated as high priority for retention, 56% (250.2 ha) as moderate priority for retention and 24% (105.4 ha) as low priority for retention. Ten of the 48 assessment sites were rated as high priority for retention (21%), 25 were rated as moderate priority (52%) and 13 were rated as low priority (27%). The 10 sites rated as high were found along the western façade near the Robe River and a small section along the northern façade that passes close to the Robe River within the Mesa H survey area. The western façade along the Robe River is characterised by structurally diverse habitats with high moisture retention, providing refuge and shelter sites for Matters of National Environmental Significance species such as the Ghost Bat, Northern Quoll and Pilbara Olive Python. In addition, vegetation analogous to the Priority 3 Priority Ecological Community '*Triodia sp. Robe River assemblages of mesas of the West* Pilbara' was present in these areas.

In accordance with the Environmental Protection Authority guideline on landforms, the mesa landforms within the survey area were assessed for their significance – rarity, variety, integrity and ecological importance. The mesas within the survey area are associated with the Robe land system, represented by only 0.7% of all land systems within the Pilbara bioregion; however, the survey area comprises only 0.3% of the land system occurrence within the Pilbara bioregion. Similar mesa landforms are common within the Robe Valley; although, a number of these are already approved or are proposed for mining, so the potential for cumulative impacts are increased. However, large sections of mesa façade are being retained along these mesas (currently approved or proposed for mining) to maintain the landscape geodiversity, important habitats, heritage values and visual amenity. The mesas do not appear to support any endemic or highly restricted terrestrial flora or fauna. The Robe land system is generally not susceptible to vegetation degradation or erosion as the mesa landforms are robust. Hence, if the façade is retained, while the mesa is mined, its condition and ecological function should be preserved.

1 Introduction

1.1 Project Background

Rio Tinto, on behalf of Robe River Mining Co. Pty. Ltd (the Proponent), engaged Astron to undertake a mesa façade ecological value assessment for the potential development of the Mesa H deposit (the Proposal), located adjacent to the existing Mesa J Operation, south-west of Pannawonica, Western Australia. The assessment is required to provide data on the ecological value of the mesa façades to assist in determining which mesa façades (or sections of mesa façades) should be retained if the Proposal proceeds. The Mesa H survey area is 4,930 ha and the mesa façade assessment area is 446.8 ha (Figure 1).

1.2 Scope and Objectives

The objective of the assessment was to undertake a mesa façade ecological value assessment to assist in determining which mesa façades to be prioritised for retention/avoidance if the Proposal proceeds. The specific scope of work was to undertake a desktop assessment using the field data and literature already gathered and compiled during the Level 2 flora, vegetation and fauna surveys completed by Astron (Astron Environmental Services 2017a, 2017c, 2017b, 2017d) and align it with the Environmental Protection Authority's (EPA) *Environmental Factor Guideline – Landforms* (Environmental Protection Authority 2016).

2 Methods

The EPA has recently released a bulletin detailing how a landform is considered in the Environmental Impact Assessment (EIA) processes (Environmental Protection Authority 2016). This guidance document will inform proponents as to the value a certain type of landform will have within an EIA process. A landform was described as 'a distinctive, recognisable physical feature of the earth's surface having a characteristic shape produced by natural processes' (Environmental Protection Authority 2016). In this case, the mesas of the survey area represent a distinct type of landform, although Mesa H is not as distinct as other mesas in the Robe Valley (John Cleary Planning 2005). Mesa H was described by John Cleary Planning (2005) as:

- a discrete mesa, although tends to blend into the adjacent landform in the south-east
- moderate-sized escarpment on the river/west side
- has a second tier in places
- shallow valleys and rounded tops on the south side
- long valley separates the two forms
- highly eroded with small mesas in the south-east
- eroded with rounded forms in the east
- stronger mesa formation in the north-east.

The mesa façades that were to be assessed within the survey area were defined and provided by Rio Tinto. The survey area provided captures 50 m of the mesa crest, breakaway and slope habitats, so the survey area does contain some areas that do not necessarily reflect just the high quality habitat. The mesa façade areas were divided into approximately 500 m sections of mesa façade for individual assessment (Figure 2). This assessment was only undertaken as a desktop assessment, and no specific field assessments beyond the field survey work for the Level 2 fauna and vegetation and flora surveys were conducted to assess the mesa façade within the Mesa H survey area.

A desktop assessment was undertaken to assess whether any listed flora and fauna species, introduced species, Short Range Endemic (SRE) invertebrate species, Priority Ecological Communities (PEC), Threatened Ecological Communities (TEC) or SRE communities have been recorded within the survey area and specifically on the mesas of the survey area. Background information (including database searches) and field data already gathered and compiled by Level 2 flora, vegetation and fauna surveys were used in the assessment. Specifically, all data previously compiled and collected from the following reports were used:

- Mesa H Level 2 Fauna Assessment – May 2016 (Astron Environmental Services 2017b)
- Mesa H Level 2 Vegetation and Flora Assessment – May 2016 (Astron Environmental Services 2017c)
- Mesa H Ghost Bat, *Macroderma gigas*, Contextual Study – September 2017 (Astron Environmental Services 2017a)
- Mesa H Riparian Community Assessment – June 2016 (Astron Environmental Services 2017d)

Each mesa section was scored for each ecological factor with a rating of 0 to 4 being applied as per the criteria in Table A.1 (Appendix A). The higher the value, the higher the ecological value was for that particular factor. Each mesa section assessed received a total score for the following factors:

- flora and vegetation ecological value (seven factors)
- vertebrate fauna ecological value (11 factors)
- invertebrate fauna ecological value (four factors)
- overall ecological value (22 factors).

The overall score of the mesa section determined the ecological façade rating as either a high, moderate or low priority for retention. The priority rating scales for high, moderate and low was determined by calculating the mean and standard deviation for all mesa assessment sites. One standard deviation (1SD) either side of the mean was considered to be the upper and lower bounds of a moderate rating. All scores 1SD above the mean received a high rating and all scores 1SD below the mean received a low rating. Overall scores for each mesa assessment site were checked manually to ensure sites with one or two highly significant attributes (e.g. Pilbara Olive Python den) were not rated as a lesser priority due to low scores for other attributes. The rating scales are summarised in Table A.2 (Appendix A).

3 Results

3.1 Mesa Assessment Sites

Forty-eight mesa façade assessments were undertaken by Astron, 27 assessments on the western side and 21 assessments on the eastern side of Mesa H (Figure 2 and Table B.1; Appendix B).

3.2 Flora and Vegetation

Vegetation considered to be analogous to the Priority (P) 3 PEC '*Triodia sp. Robe River assemblages of mesas of the West Pilbara*' was recorded in association with tops, breakaways and gullies of mesa landforms in the survey area (Astron Environmental Services 2017c). In addition, two conservation significant flora species were recorded within the mesa façade sections (Astron Environmental Services 2017c). *Triodia* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 was recorded across a number of mesa assessment sites in association with mesas, low hills and ranges, particularly favouring rocky ledges and breakaways in these habitats (Figure B.1; Appendix B). *Rhynchosia bungarensis* P4 was recorded in locations along the Robe River and was only recorded within mesa assessment site 7 (Figure B.1, Appendix B).

Seven mesa assessment sites (15, 24, 25, 26, 32, 33 and 34) were rated as high priority for flora and vegetation (Table B.1; Appendix B). This was primarily due to the inferred (not confirmed) presence of the P3 PEC '*Triodia sp. Robe River assemblages of mesas of the West Pilbara*', as well as the number of other Priority flora species recorded at these sites and the lack of weed species present (Figure B.1; Appendix B).

Mesa assessment sites 3, 4, 6, 28 and 30 were rated as low priority for flora and vegetation, mainly due to the lack of priority flora records as well as the presence of weed species. Mesa assessment site 28 was the only site that contained a weed species (Table B.1; Appendix B).

3.3 Vertebrate Fauna

Eleven mesa assessment sites (6, 7, 8, 9, 10, 11, 12, 13, 15, 16, and 40) were rated as high priority for vertebrate fauna (Table B.1; Appendix B). The high rating was generally due to records of species of Matters of National Environmental Significance (MNES), particularly the Ghost Bat, or contained a number of caves suitable for Ghost Bats and Pilbara Leaf-nosed Bats (Table B.1; Appendix B). A number of the assessments within the Mesa H survey area have focussed on roost habitat, specifically the presence of potential maternal and diurnal roosts, for conservation significant bat species, particularly the Ghost Bat (Astron Environmental Services 2017a, 2017b).

Mesa assessment sites 39 and 40 contained Pilbara Olive Python records (Figure B.1; Appendix B), but mesa assessment site 39 was only rated as moderate due to a lack of other MNES species records, significant caves and gorges/gullies. Given suitable habitat and its cryptic nature, it is likely that this species occurs more widely within the mesa assessment sites.

Twelve mesa assessment sites were rated as low priority for vertebrate fauna and were generally found along the eastern most façade of the mesa (sites 43 to 48), as well as mesa façade sections within the south of the Mesa H survey area (sites 1, 23, 27 to 30).

3.4 Invertebrate Fauna

Mesa assessment sites rated as high priority for SRE invertebrate fauna were generally the same sites as those for vertebrate fauna. Six assessment sites (5, 7, 8, 11, 12 and 13) were rated as high priority for invertebrate fauna (Table B.1; Appendix B) and were associated with two main gorges on

the western façade of the Mesa H survey area along the Robe River. This was due to the record of the potential SRE species *Buddelundia* '61' at site 7 (Figure B.1; Appendix B) and the presence of structurally diverse habitats with high moisture retention on south facing façades.

Fifteen mesa assessment sites were rated as low priority for invertebrate fauna and included most of the assessment sites along the eastern most façade of the mesa (sites 41 to 48) as well as mesa façade sections within the south of the Mesa H survey area.

3.5 Overall Ecological Value

Of the mesa façade assessments within the Mesa H survey area, 10 were rated as high priority for retention (21%), 25 were rated as moderate priority (52%) and 13 were rated as low priority (27%; Figure 3). The 10 sites rated as high were found within the two main gorges on the western façade along the Robe River (sites 6 to 13 and 15) and a small section of façade (site 40) along the northern section near the Robe River (Figure 3 and Table A.1; Appendix A). The 13 sites rated as low priority for retention were generally found along the eastern façades of both mesa façades (sites 23 and 27 to 30 and sites 42 to 48) as well as mesa assessment site 1 (Figure 3). Three of the mesa assessment sites (sites 5, 16 and 32) rated as moderate priority for retention had high overall rating scores of 41 and were close to being ranked as high priority for retention. These sites were generally found adjacent to those sites rated as high priority for retention (Figure 3).

Twenty per cent (91.2 ha) of the total area of mesa façades within the survey area were rated as high priority for retention, 56% (250.2 ha) as moderate priority for retention and 24% (105.4 ha) as low priority for retention (Figure 3 and Table B.1; Appendix B).

4 Conclusions

In accordance with the guidance statement (Environmental Protection Authority 2016), the criteria for assessing the significance of the mesa landforms within the survey area are detailed below. The criterion of Scientific and Social Importance is not discussed as this could not be addressed within the scope of this mesa façade assessment.

Rarity

The mesas within the survey area are all associated with the Robe land system (van Vreeswyk et al. 2004). The Robe land system represents only 0.7% of all land systems within the Pilbara bioregion (van Vreeswyk et al. 2004). However, the survey area comprises only 0.3% of the Robe land system occurrence within the Pilbara bioregion.

Variety

All the mesas occur within the Robe land system, and given that the survey area represents 0.3% of this land system within the Pilbara, similar landforms exist outside the survey area. The mesas found within the Mesa H survey area are not considered to represent a particularly good or important example of their type and other similar intact mesas currently exist outside the survey area.

Integrity

The Robe land system is not generally susceptible to vegetation degradation or erosion. Mesas are robust and have resisted a large amount of erosion and natural degradation process over time. Less resistant surrounding formations are eroded away on the surface into valleys, where they collect water drainage from the surrounding area, while the more resistant layers are left standing out and elevated in the landscape resulting in a mesa formation. Hence, if the façade is retained, while the mesa is mined, its condition and ecological function should be preserved.

The mesas within the Mesa H survey area were considered to still be intact and in good condition, although they are not in pristine condition (John Cleary Planning 2005). The Robe land system has been the target of considerable mining activity due to its geology (van Vreeswyk et al. 2004). A number of the mesas within the Robe Valley have been approved for, or are proposed for, mining, indicating that the potential for cumulative impacts on the mesa formations within the immediate area is relatively high. However, the majority of the mesa façades are being retained within these mesas (currently approved or proposed for mining) to maintain the landscape geodiversity, important habitats, heritage values and visual amenity.

Ecological Importance

Fifty-six per cent (250.2 ha) and 24% (105.4 ha) of the total area of mesa façades were rated as moderate and low priority for retention, respectively. Twenty per cent (91.2 ha) of the total area of mesa façades within the survey area were rated as high priority for retention.

The areas of mesa façades rated as high priority for retention were located along the western façade near the Robe River and a small section along the northern façade that passes close to the Robe River within the survey area. These areas are characterised by structurally diverse habitats with high moisture retention, providing refuge and shelter sites for MNES species such as the Ghost Bat, Pilbara Olive Python and Northern Quoll. In addition, vegetation analogous to the P3 PEC '*Triodia sp. Robe River assemblages of mesas of the West Pilbara*' was present in these areas. The mesas do not appear to support any endemic or highly restricted flora or fauna. The potential SRE species recorded within the mesa façade site 7 has also been collected from multiple habitats that extend far beyond the survey area.

Vertebrate fauna						
MNES fauna habitat suitability	**Pilbara Olive Python**	Recorded	**Potential shelter and foraging habitat**	**Suitable foraging and dispersal habitat**	**Limited foraging and dispersal habitat**	No suitable habitat
	Pilbara Leaf-nosed Bat	Recorded	**Potential shelter and foraging habitat**	**Suitable foraging and dispersal habitat**	**Limited foraging and dispersal habitat**	No suitable habitat
	Ghost Bat	Recorded	**Potential shelter and foraging habitat**	**Suitable foraging and dispersal habitat**	**Limited foraging and dispersal habitat**	No suitable habitat
	Northern Quoll	Recorded	**Potential shelter and foraging habitat**	**Suitable foraging and dispersal habitat**	**Limited foraging and dispersal habitat**	No suitable habitat
Threatened fauna		Recorded	Likely occurrence – suitable habitat and close proximity of previous records	Potential occurrence – suitable habitat or close proximity of previous records	Unlikely occurrence – no suitable habitat	Not present

Ecological factor	Rating score				
	(4)	(3)	(2)	(1)	(0)
Priority (or migratory) fauna	Recorded	Likely occurrence – suitable habitat and close proximity of previous records	Potential occurrence – suitable habitat or close proximity of previous records	Unlikely occurrence – no suitable habitat	Not present
Roosts/caves present	1 or more maternal roosts	1 or more diurnal roosts	>3 other caves(e.g. nocturnal feeding shelters)	1-2 other caves (e.g. nocturnal feeding shelters)	None present
Breakaway habitat present	Predominantly mapped as and south-facing	Predominantly mapped as breakaway but not south-facing	Partly mapped as breakaway and south-facing	Partly mapped as breakaway but not south-facing	Limited or no breakaway habitat mapped
Gorge/gullies present	>10	10 – 5	5 – 2	1	0
Permanent pools	≥2 within 500 m	1 within 500 m	≥2 within 1 km	1 within 1 km	None within 1 km
Distance to riverine habitat (i.e. Robe River)	<100 m	<250 m	<500 m	<1 km	>1 km
Invertebrate fauna					
Threatened and listed invertebrate fauna	Recorded	Likely occurrence based on proximity of previous records	Potential occurrence based on proximity of previous records	Unlikely occurrence – no or very few previous records	Not present
SRE fauna	Recorded	Likely occurrence based on proximity of previous records	Potential occurrence based on proximity of previous records	Unlikely occurrence – no or very few previous records	Not present

Ecological factor	Rating score				
	(4)	(3)	(2)	(1)	(0)
Relictual habitats	Structurally diverse habitats with high moisture retention ubiquitous (i.e. many deeply incised gullies and shaded runoffs)	Structurally diverse habitats with high moisture retention widespread but not ubiquitous (i.e. incised gorge present)	Less diverse habitat (one or two types) and limited moisture-holding capacity (i.e. shallow gullies)	Limited habitat suitability (i.e. flat and exposed, no moisture-holding capacity and limited ground cover)	No relictual habitats
Specialist habitats	Specialist habitats ubiquitous (i.e. rocky outcrops, fringing woodlands)	Specialist habitats widespread (i.e. rocky outcrops, fringing woodlands)	Specialist habitats present but not widespread or few types	Specialist habitats rare; area generally exposed and little diverse	No specialist habitats

Table A.2: Rating scale for the priority of retention for mesas or mesa sections.

Priority rating for retention	Flora and vegetation	Vertebrate fauna	Invertebrate fauna	Overall
High	≥13	≥24	≥7	≥42
Moderate	11-12	10-23	4-6	26-41
Low	≤10	≤9	≤3	≤25

Summary

The Rio Tinto Iron Ore GIS Team conducted the Visual Impact Assessment (VIA) for the proposed Mesa H Iron Ore Mine, located approximately 18km west of Pannawonica. Field work was undertaken in July and August of 2016 and the assessment was undertaken as part of the environmental impact assessment for the Proposed Mesa H Iron Ore Project.

The VIA was conducted in three phases:

- Desktop Assessment (Analysis)
- Field Assessment (Photo Locations)
- Visual Impact (Photo Montage)

Results show present, operational and closure photo montages to illustrate the indicative visual impact of the proposed operations at Mesa H.

Introduction

This report outlines the Mesa H VIA scope, methodology and results. The GIS Team was engaged to prepare a VIA report, which was developed in conjunction with several other environmental studies and reports to provide an overview of the likely impacts.

1.1 Objective & Scope

The overall objective was to assess the visual impact of the proposed mining operations at Mesa H and illustrate these impacts through photo montages. The key objectives were to:

- Analyse landscape within the development area
- Identify points of interest where potential impact may occur
- Conduct field trip to identified points to photograph
- Illustrate potential visual amenity impacts of mining stages through photo montages

1.3 Study Area

Mesa H is located approximately 18km west of Pannawonica and is adjacent to the existing Mesa J Mine (refer Figure 1).

The Pannawonica Access Road runs to the north Mesa H project area and provides access tracks to the area. This road is sealed and is the main access road to the town of Pannawonnica.

The Robe River lies immediately north and west of the project area, and Jimmawurrada Creek to the east of the project area (refer Figure 2).

1.4 Regulatory Context

The following regulatory documents and relevant sections within them were consulted as part of this work to provide context and guidance on completing a Visual Impact Assessment.

Environmental Projection Authority (EPA) and the Environmental Protection Act 1986
Amenity: “To ensure that impacts to amenity are reduced as low as reasonably practicable”.

The Western Australian Planning Commission’s (WAPC) State Planning Policy No. 2:
Environment and Natural Resource Policy for Western Australia (WAPC 2003)
“consider the need for a landscape or visual impact assessment for development proposals that may impact upon sensitive landscapes”.

The WAPC’s Pilbara Planning and Infrastructure Framework (WAPC 2012)
“protect and manage the region’s cultural heritage, arts including indigenous significant places, and landscapes of significance”.

Methodology

The methodology used to assess the impact to the landscape and visual amenity was conducted in three phases. This process included the following:

2.1 Desktop Assessment

The aim the desktop assessment was to produce a terrain model of the study area with the proposed infrastructure overlaid. This model was then used to conduct a viewshed analysis using the proposed infrastructure to identify potential visual impacts across the model domain. The viewshed analysis output was then combined with existing spatial data such as heritage, environment and cadastral layers to guide the selection of locations for capture of images.

Viewshed Analysis

To perform the viewshed analysis, the ArcGIS Viewshed tool within ArcMap was used. This tool can be found under Spatial Analyst > Surface > Viewshed within the Arc Toolbox.

A viewshed analysis identifies cells within a raster image (ASCII terrain model) that can be seen from any number of observer points or lines (infrastructure polylines). The identified cells are given a value of 1 for visible or 0 for not visible. This project had more than one observer point so more than 20 values have been entered. The viewshed analysis provides the starting point for all further visual impact assessment work.

The study area terrain model was created from LiDAR data and the proposed infrastructure data in Global Mapper and loaded into ArcGIS in ASCII format.

Figure 03: Viewshed Analysis Control Factors

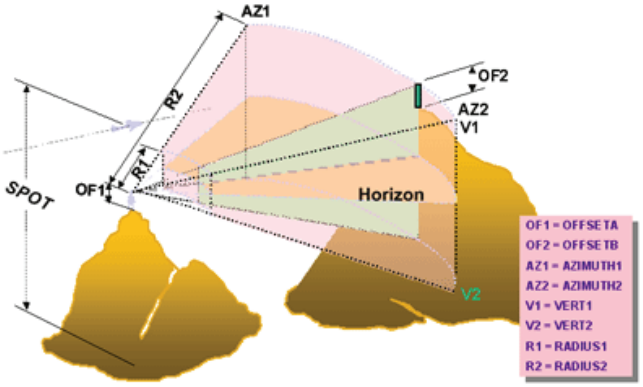

Figure 04: Viewshed Analysis Input vs Output

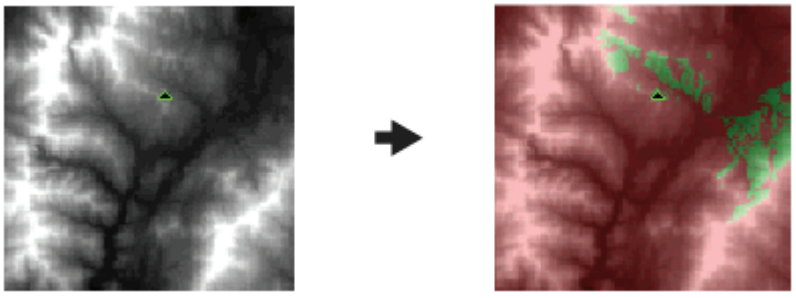

Input Surface with Observer Point

Output Viewshed

Output

The viewshed analysis output was then used to create a cartographic map for the study team to easily identify potential visual impacts and help determine the locations for capture of photographs.

Photo Location Selection

The study team consisted of Studies, Environment, Closure, Heritage and GIS. All teams worked together with GIS to identify and select locations for capture of images. Locations for the capture of images were selected based upon:

- proximity to significant heritage or environmental values
- line of sight to significant heritage or environmental values
- proximity to areas with public access

Traditional owner consultation was also undertaken to identify significant sites around the study area. Once all locations were selected, a field trip assessment was planned and undertaken over three days within the study area.

2.2 Field Assessment

A field assessment was conducted to capture data and photographs from selected locations around the study area, with the photographic views focusing on the proposed infrastructure such as dumps and stockpiles. Comprehensive data collection was undertaken at each location to allow for photo montages to be produced in the next phase.

Tools used in field work

Canon Digital Camera EOS 200 D
Accessories: Tripod, Stabiliser, Compass, Measuring Tape
ArcGIS Collector App (IOS Iphone)
Magellan GPS Unit
Paperwork (manual field notes)

Field Trip

Field work was undertaken in conjunction with another Rio Tinto project for the purpose of Visual Impact Assessment, this occurred in November 2017.

At each photograph location, assessment was made on the ground for accessibility and view aspect, which resulted in minor changes to photograph locations to ones agreed upon in desktop assessment. Once location and direction of photo was agreed, 3 photos of the same view were taken to reduce the risk of poor photo clarity and recorded both manually and digitally.

Data Collection

The data shown in Table 1 were collected from each photograph location to assist in the next phase of the assessment.

Table 1 - Data collected at each photograph location

Site No. and Name	Identified in desktop assessment
Date/Time	Date and time of day
Photo Number	Unique photo number as multiple taken from each point
GPS Co-ordinates	Actual photo location for GPS unit
Bearing	Direction of the photo with the aid of compass
Camera Height	Height of the camera from ground level
Atmospheric Conditions	Weather and lighting
Description of View	Vegetation cover and infrastructure within the area
Comments	Additional detail

Field Photos Review

Once field work was complete, the study team reviewed the adjusted photograph locations and selected photos that would best illustrate the potential visual impact.

2.3 Visual Impact Assessment process

Photo montages were generated from the photographs selected to best illustrate the potential visual impact of the proposed development. Generation of the photo montages involved a multistep process of data creation, view setup, image rendering, output and final mock up. Software required for this process were; Global Mapper, Microstation V8i, ArcGIS Desktop, Adobe Photoshop and Adobe InDesign.

The following sections outline the process to create the final photo montage showing the current view, operational view and closure view along with any relevant supporting data.

Data

The terrain model created desktop assessment was used in the final phase to create surface features, for the purpose of lining up these features in the montage view.

The first feature captured was the bearing of the photo point (field data collection); then a 3D profile of the surface along the bearing alignment was created in 3D DXF line format (see Figure 05 & 06). Additionally, landmark topography in each photo was captured from the terrain model in 3D Mesh DXF format to assist in the final alignment. All photos required the bearing and at least two 3D Mesh DXF models to successfully line up the photo.

Figure 05: Global Mapper Model Bearing

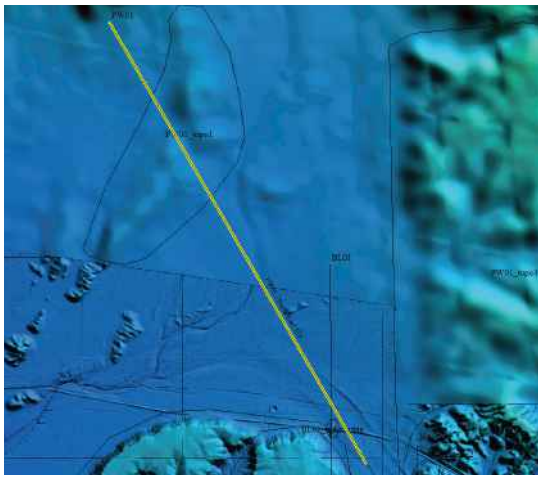

Figure 06: Global Mapper Model 3D Profile

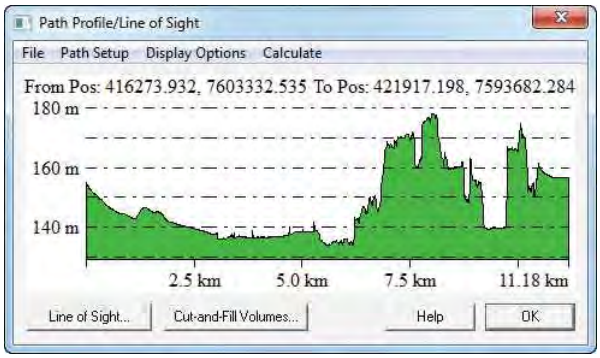
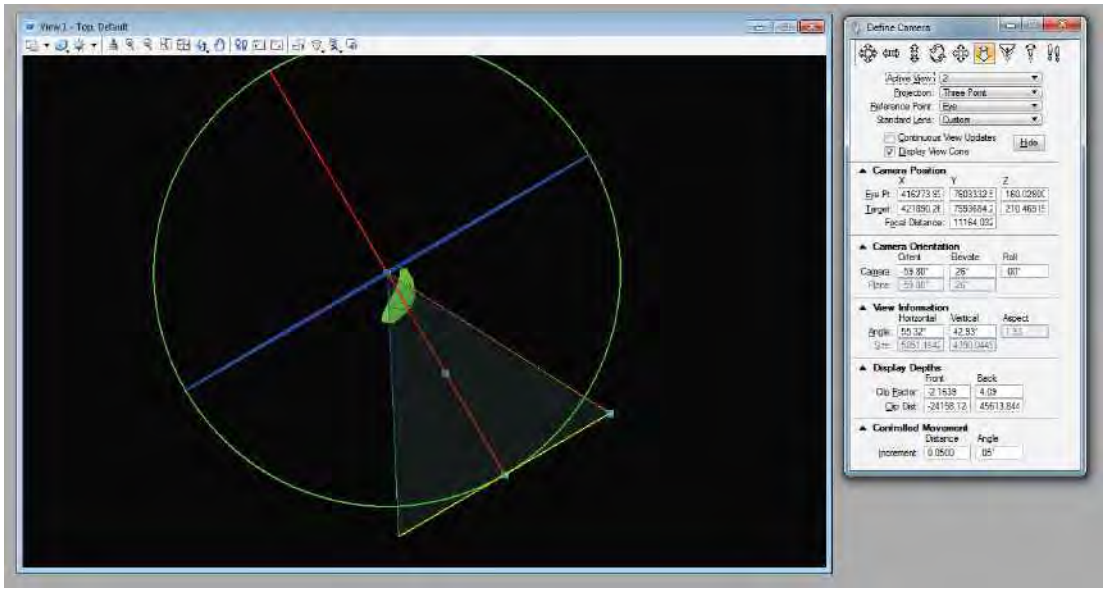


Montage Setup

Once data were captured in Global Mapper, a montage was created in Microstation. The photo size was kept proportional to actual size, then a view was created in the image by using the Define Camera alignment tools in the construction view (see Figure 07).

Figure 07: Microstation Construction View and Camera Define Tools



The Define Camera alignment tools allowed the montage view to be altered by units distance and degrees in all directions which gave more control to exactly line up features in the image.

Figure 08: Montage View - after alignment completed

Montage Rendering

The next step was to add the proposed infrastructure to the montage view in Microstation, these data were provided from the Mine Planning Engineers and converted to 3D Mesh DXF. The rendering tool was then applied to convert the proposed infrastructure line strings to surface areas (see Figure 09). The image was then exported from Microstation to a JPG format.

Figure 09: Rendered View

Montage Output

To create the final image, the original photo was loaded into Adobe Photoshop and the rendered image from Microstation was overlaid to show the location of the proposed infrastructure. A realistic texture (of proposed infrastructure) was then placed under the original image and parts of the image were erased to expose texture in the proposed infrastructure location (See Figure 10). The final image was then exported from Adobe Photoshop to JPG format. A closure version was also created to show rehabilitated infrastructure.

Figure 10: Texture Exposed on Original Image in Adobe Photoshop

Final Mock Up

The Current View, Operations View, Closure View were then combined into the final mock up in Adobe InDesign with location map and photo location details as the final output for the Visual Impact Assessment.

Results

The results section outlines a description of the maps and figures produced during the Visual Impact Assessment. The final output produced 15 figures showing the potential visual impact of the Mesa H mine development.

3.1 Desktop Assessment

The desktop assessment resulted in the output maps of the Planned Photo Locations and Viewshed Analysis. These assisted the team into the second phase of the Visual Impact Assessment.

Figure 11 - Planned Photo Locations

Figure 12 - Viewshed Analysis - Map shows the blue shaded area shows all locations where any component of the Mesa H mine development may be visible based on the topography of the area and the dimensions of the proposed infrastructure.

3.2 Field Assessment

Sites with the greatest potential for visual impact and sites of interest were selected from the view shed analysis for field assessment. The field assessment resulted in a map of actual photo locations taken on the ground. These altered slightly from planned location in some cases due to access or view aspect. This data was used in the final phase of the Visual Impact Assessment.

Figure 13 - Actual Photo Locations

3.3 Visual Impact

The final output from this assessment was to show the visual impact of the Mesa H mine development, the following figures outline how each view will be impacted visually.

Robe Valley Deposits Façade Stand-Off Distance Memo

Executive Summary

The Robe Valley is located in the Pilbara region of Western Australia and contains numerous Pisolite Mesa formations (also known as Channel Iron Deposits (CID)), which are characterised by steep 20-30 m high cliffs (façades) and flat tops. A number of these deposits have been mined, are active operations or are proposed for mining.

In order to protect environmental, heritage and visual amenity values associated with Mesa's particularly the façade fronting the Robe River during mining operations, a safe stand-off distance (the distance between the crest of the pit and that of the mesa's natural slope) is required to be determined to ensure the long term stability of the facade.

Since 2007 several Geotechnical studies have been carried out on the facade stability including internal Rio Tinto studies and external Consultant studies. The previous façade stability studies have recommended stand-off distances ranging between 10m to 50m. However, the current review identified that these results were based on different levels of orebody and geotechnical knowledge. An attempt was made to simplify and determine the appropriate stand-off distance to the Mesa façade. The current review utilized the following approach:

1. A review relevant Geotechnical reports relating to the Mesa façade stability (Sections 1 through 5),
2. A review of the pit slope performance of as-built slopes (Section 6), and
3. A review of the façade stability during closure (Section 7)

The outcome of this report can be used as a guideline for current and future mining operations in Robe Valley region.

1 Introduction

The current and proposed pits at Robe Valley Mesa deposits are generally shallow and are above the water table. As such, geotechnical hazards pose a relatively low risk to mine operations. The key focus of the assessment is to ensure preservation of the majority of the Mesa façades to protect associated environmental, heritage and visual amenity values particularly the façade fronting the Robe River.

A stand-off distance (the distance between the crest of the pit and that of the mesa's natural slope) based on a geotechnical assessment is required to ensure that the façades can be preserved and also allow for resource recovery.

This memorandum aims to recommend the minimum stand-off distance by reviewing historical geotechnical studies and based on the current pit wall performance.

2 Geology

Robe Valley is located in the Western Pilbara region of Western Australia. Mining commenced in 1972 from Middle Robe Valley and were relocated to the west as mining progressed. The locations of all the deposits are shown in Figure 1.

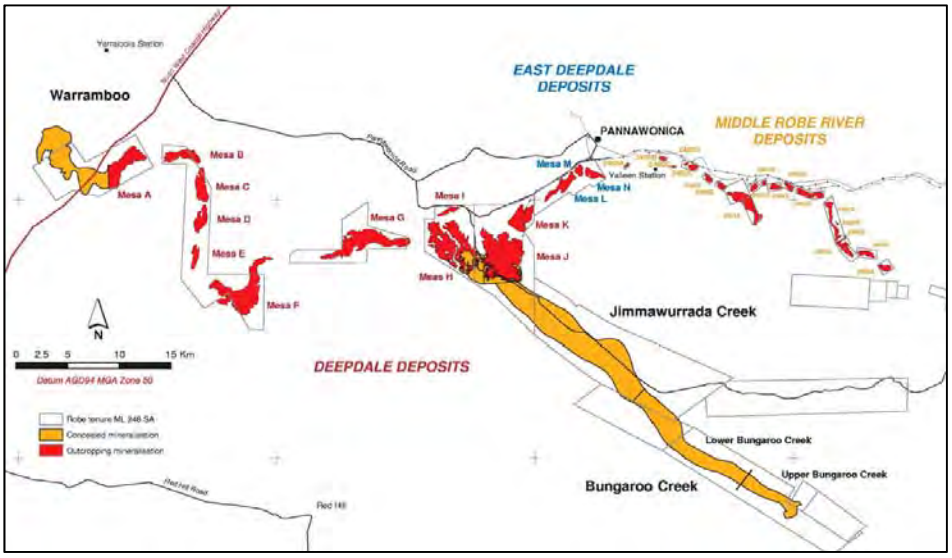

Figure 1. Location of Robe Valley Iron Ore Operations.

Mesa deposits are broad flat-topped hills with a number of deeply incised gullies. The deposit is bounded by 20-30 m high cliffs (façade). The channel at Mesa is incised through the Yarraloola Conglomerate into sediments interpreted to be part of the older Proterozoic Ashburton Formation, which forms the majority of the basement.

Mineralization within the Mesa deposits is generally hosted in the Tertiary Pisolite (TP) units. The TP has a pisolitic texture and is cemented together by a goethitic matrix. Internal zones of poorer quality material exist in the form of clay or as hydrated/denatured pisolite, but these are infrequent. Overlying the TP zone is the Semi-hardcap Tertiary Pisolite (HTP), which is a weathered/laterized form of the TP zone and contains secondary soils and silica. The transition between the HTP and TP is gradational and visually difficult to identify. Underlying the TP is the Mixed/Massive Sub-Grade Pisolite (TPM). This zone is also gradational from the TP. It is characterised by a limonitic, denatured/massive appearance and clay is common throughout. This contact is also visually difficult to identify due to its gradational nature. It is suggested that this zone has been subjected to a palaeo-water table, which has resulted in a significant hydration effects in comparison to the overlying TP.

The typical sequence of Mesa geological units are:

- Quaternary alluvium (variable thickness);
- HTP (Hardcap Tertiary Pisolite) (variable thickness);
- TPC (Tertiary Pisolites Clay) (variable thickness);
- TPM (Tertiary Pisolites Mixed) (variable thickness);
- TPH (Tertiary Pisolites Hard) (variable thickness); and
- TPB (Tertiary Pisolites Base) (variable thickness);

An in-situ geology sections and models are shown in Figure 2-5.

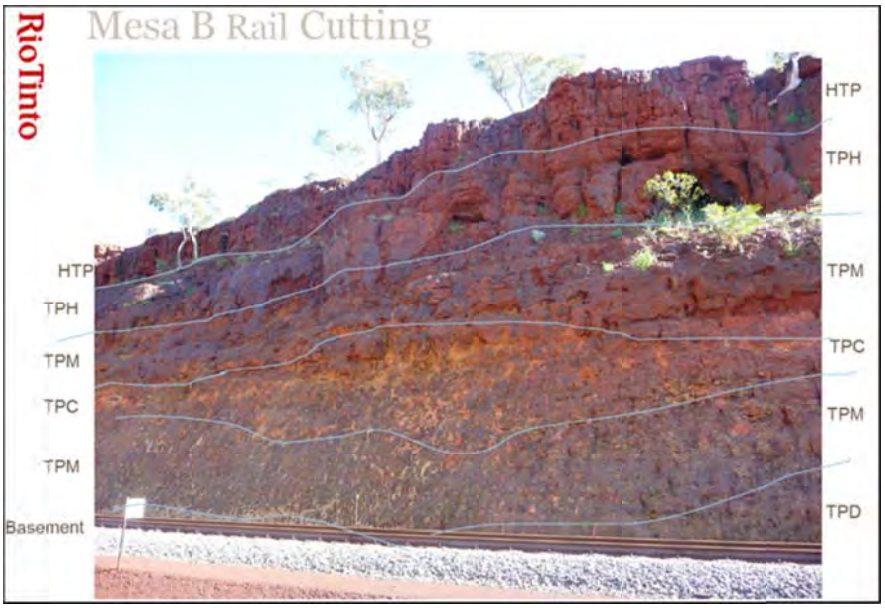

Figure 2. In-situ Geology Units Cross Section in Mesa B.

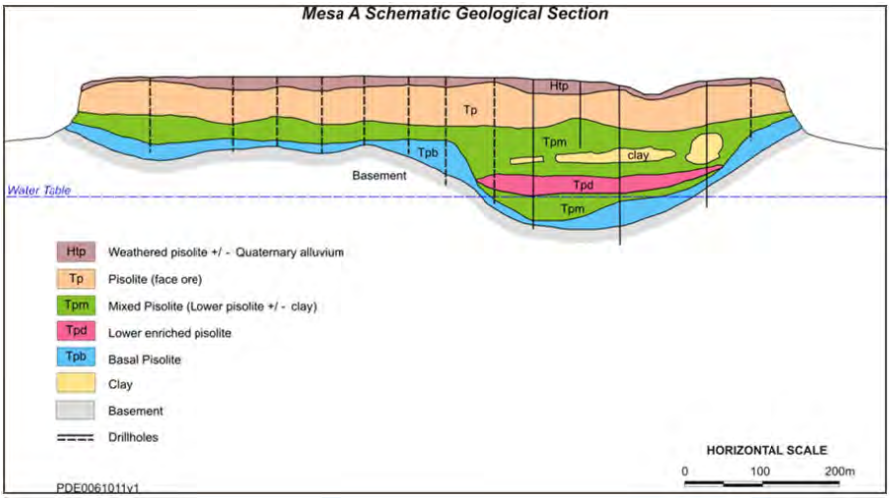

Figure 3. Geology Section of Mesa A.

Apart from other Robe Valley deposits, recent geology drilling indicated (refer Figure 4 and Figure 5) that unconsolidated alluvial cover (ALL) extends up to 15m in the upper most portion of the Mesa H and Mesa J deposit.

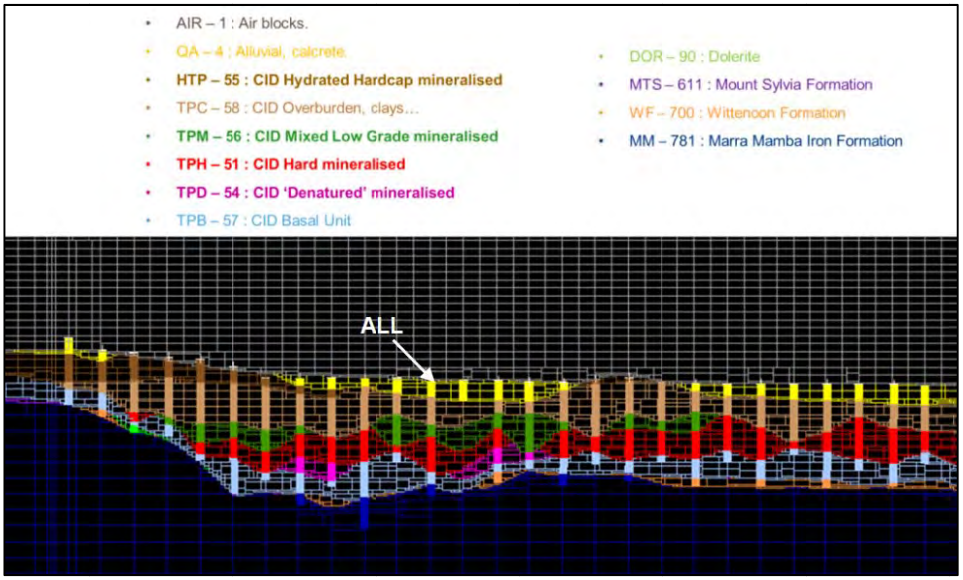

Figure 4. Mesa H Geology Cross Section.

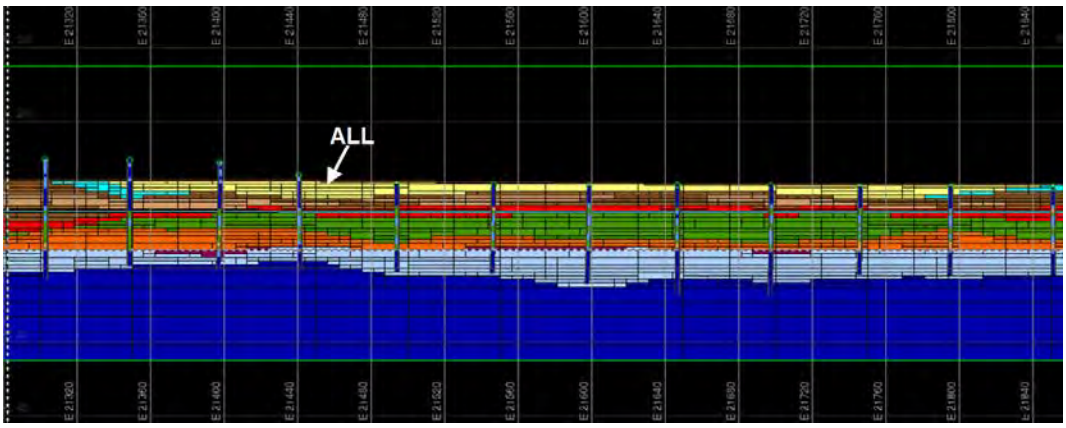

Figure 5. Mesa J Geology Cross Section.

3 Hydrology and Hydrogeology

Surface water and groundwater can impact the stability of façade. Most of the Robe deposits are above the groundwater table and the facade surrounding the Mesas further protect the mining operations from flooding of the Robe River.

3.1 Hydrology

The Robe Valley area is hot and persistently dry. Rainfall is also highly seasonal, with approximately 69% of the annual total occurring between December and April.

The Robe Valley deposits reviewed in this report are located on high ground, outside the 1% annual exceedance probability (AEP) floodplain of the Robe River. Riverine flooding of the deposits is not considered as a geotechnical issue. An example of the Mesa A, Mesa B, Mesa C, Mesa K and Mesa J 1% Annual Exceedance Probability (AEP) flood extent is shown in Figure 6, Figure 7 and Figure 8.

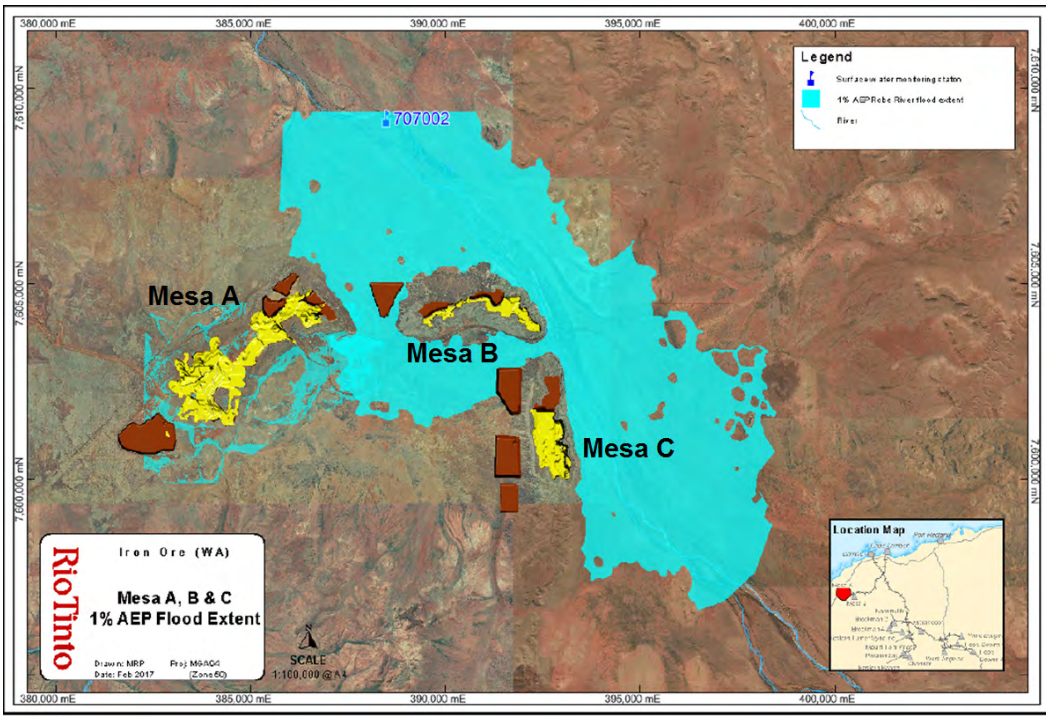

Figure 6. Mesa A, B and C Deposits in relation to the 1% AEP flood extent of the Robe River.

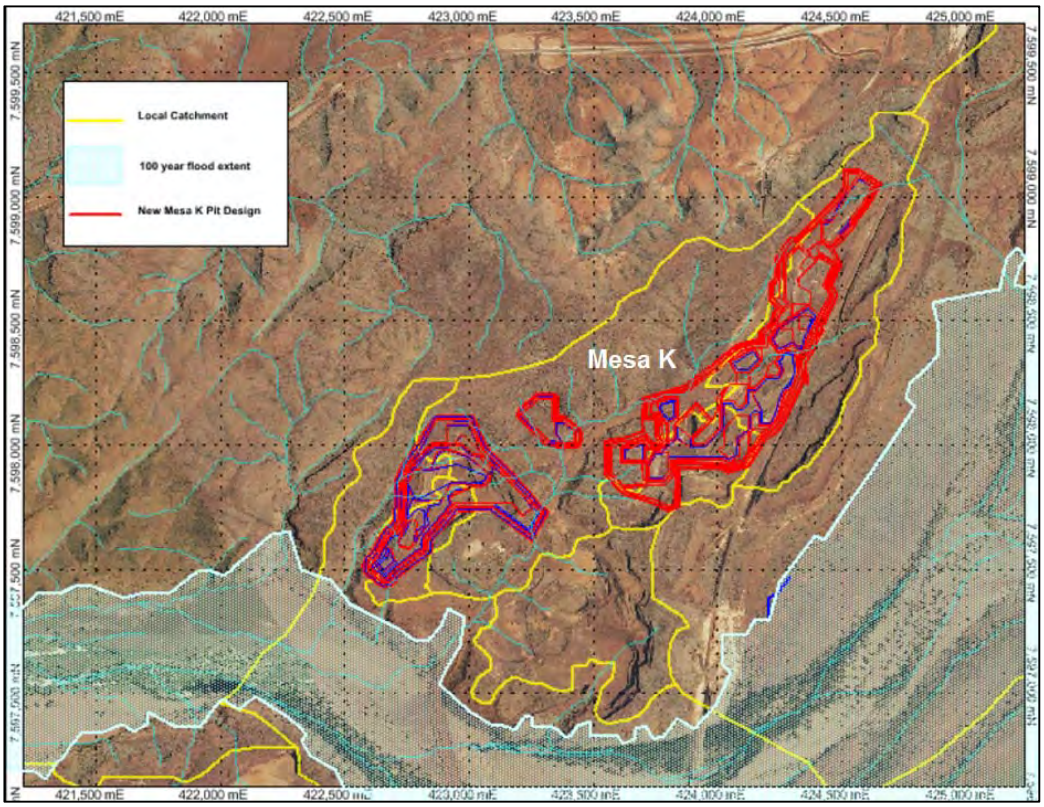

Figure 7. Mesa K Deposits in relation to the 1% AEP flood extent of the Robe River.

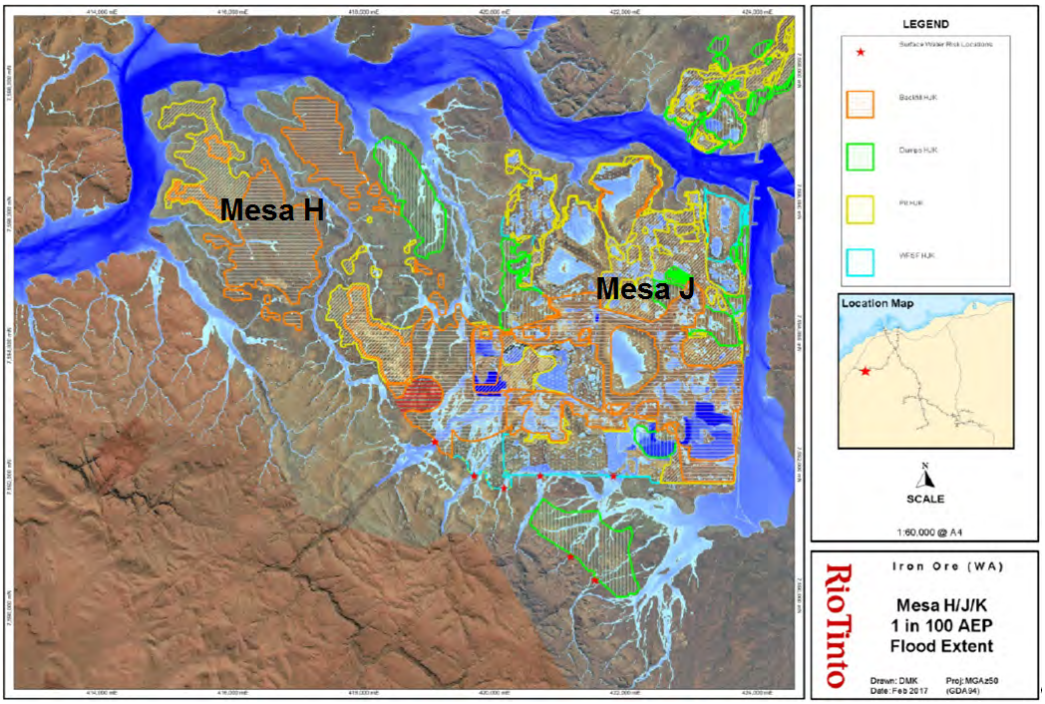

Figure 8.Mesa J and Mesa H Deposits in relation to the 1% AEP flood extent of the Robe River.

3.2 Hydrogeology

The key hydrogeological concepts at the Robe Valley are summarized based on groundwater investigations and groundwater modelling work summarised in Table 1: Dewatering is needed to mine the areas below pre-mining water table as shown from Figure 9 to Figure 13.

Table 1. Intersection Area between Robe Valley Pits and the Pre-Mining water Table.

Deposit	Pit Floor (mRL)	Benches	Pre-Mining Water Table (mRL)	Bench below Water Table
Mesa A	44	3	48.5	1
Mesa B	80	4	65	0
Mesa C	52	7	69	4
Mesa H	110	9	121	2
Mesa J	130	5	135	1
Mesa K	156	5	145	0

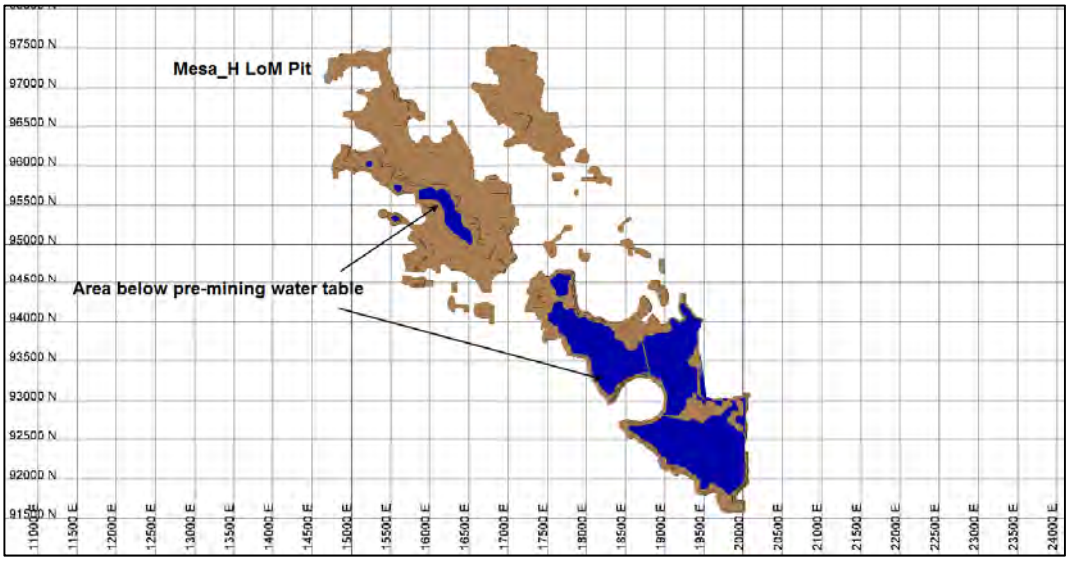

Figure 12. Areas in Mesa H Life of Mine (LoM) Pit Below Pre-mining Water Table

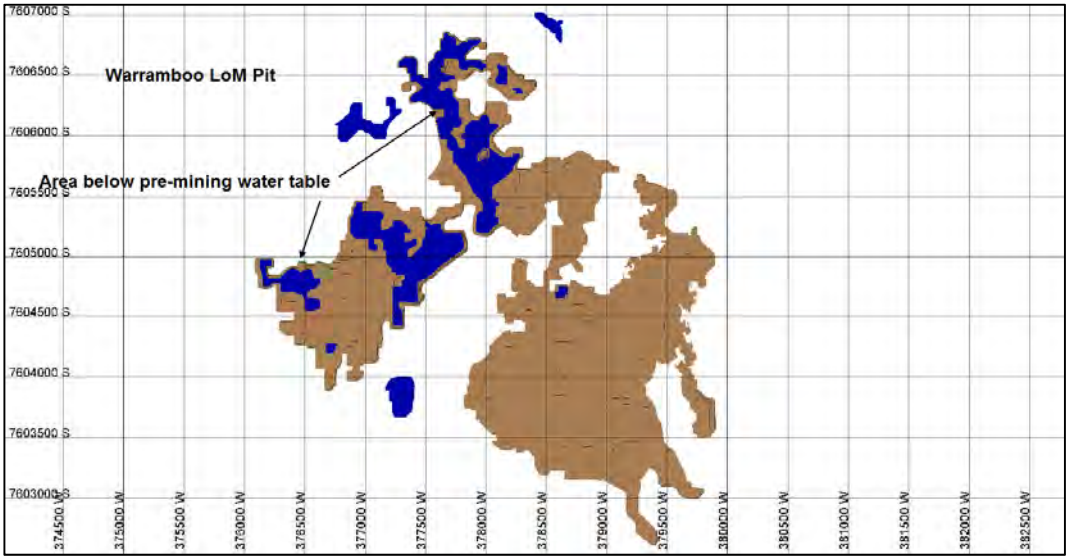

Figure 13. Areas in Warramboo Life of Mine (LoM) Pit Below Pre-mining Water Table

4 Geotechnical Field Investigation

The geotechnical site investigations have been undertaken at Robe Valley since 1999, Table 2 summarises all the completed geotechnical drilling to date and the drill hole locations are plotted in Figure 14, Figure 16, Figure 24, Figure 25 and Figure 26.

Table 2. Robe Valley Geotechnical Drilling Summary.

Year	Deposit	Drill Type	Actual Meters (m)	Number of Holes

2016	C	Diamond	749.7	10
2016	H	Diamond	900.1	12
Total			2873.2	51

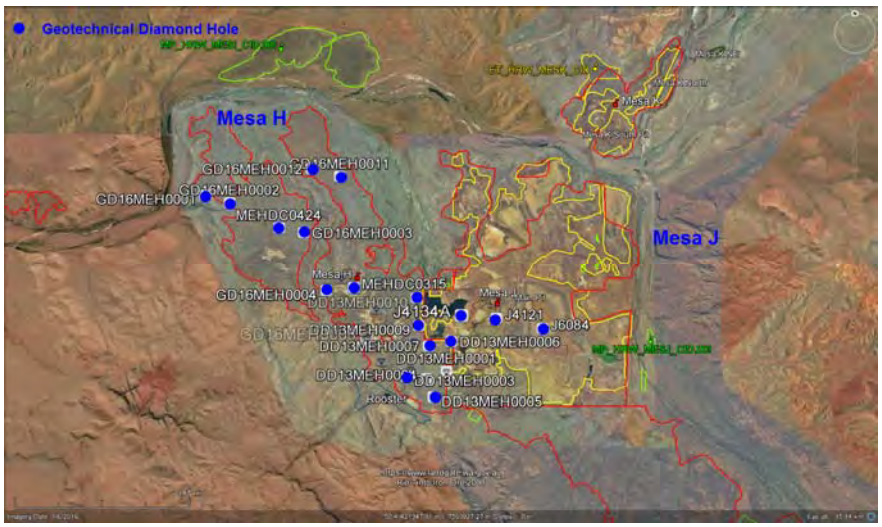

Figure 14. Historical Geotechnical Drill Holes in Mesa J and Mesa H.

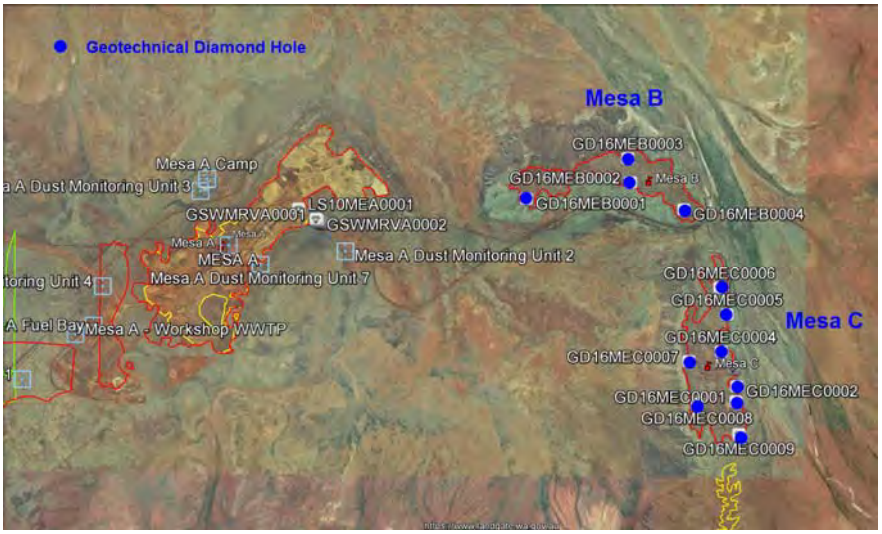

Figure 15. Historical Geotechnical Drill Holes in Mesa B.

5 Geotechnical Studies for Facades

Since 2007, several geotechnical studies were completed by Rio Tinto and external consultants, which included façade reviews. The results are summarised below.

5.1 Mesa A and Warramboo Geotechnical PFS (Snowden Mining Consulting, 2007)

Snowden undertook a review of the status of geotechnical knowledge and the proposed pit design criteria as part of the Warramboo and Mesa A pre-feasibility study (PFS) in 2007. This work was later substantiated by two programs of geotechnical investigations by PSM involving a total of 11 HQ3 diamond drill holes initially completed along the steeper and deeper sections of the proposed pit walls, and subsequently within the 50 m façade planned to be retained.

5.1.1 Site Investigation and Analysis Approach

Phase 2 of this project focused on investigating the stability of the 50 m wide façade. This program involved five vertical HQ3 diamond drill holes for a total of 195.52 m and was completed in December 2006 as shown in Figure 16.

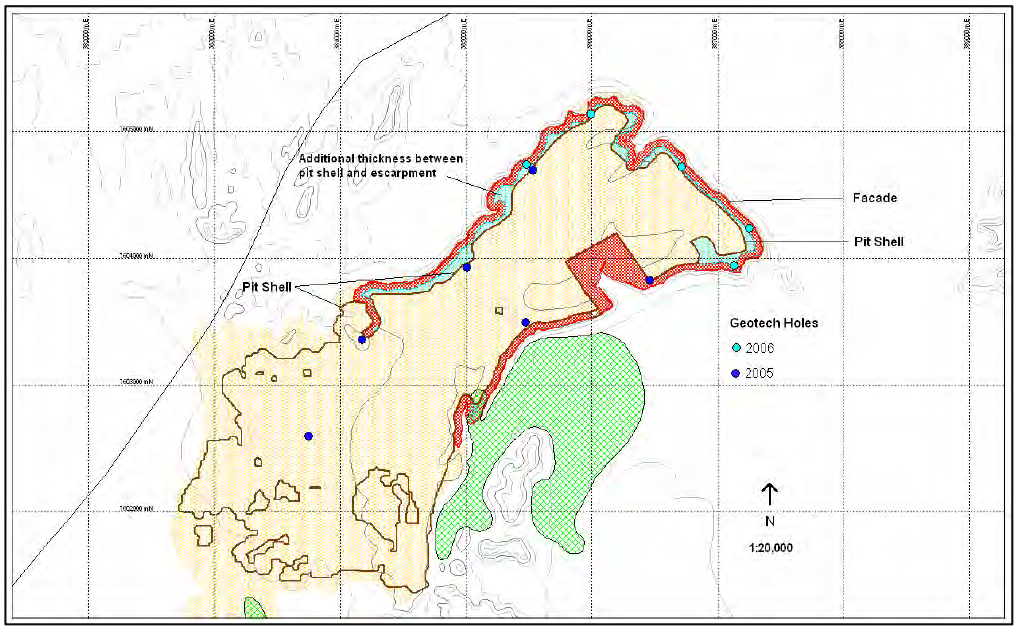

Figure 16. 2006 Snowden Façade Study Mesa A Geotechnical Drill Holes Locations.

The actual core data collection and collation was undertaken by Pells Sullivan Meynink Pty Ltd. Laboratory tests were carried out and the diamond cores were logged for geotechnical use. Snowden was engaged to undertake site visits to Mesa A, J, K and M to assess the conditions of natural and mined mesas in March 2007.

It was observed that visible blast damage typically extends 1 -2 m beyond the pit crest at Mesa J, K and M. Furthermore sections of 25-year-old remnant mesa only showed blast damage where the width of remnant façade was reduced to 15 m.

5.1.2 Results

- Mining operations adjacent to natural mesa facades have not caused large (face) scale instability of the natural slopes or escarpment at these sites;
- Visible damage from blast practices typically extends < 2m behind the slope crest; and
- Mesa A façade to have a probability of failure of 0.1%. It should be noted that none of the critical failure paths assessed involved the full 50m width of the façade.

5.2 Robe Valley Sustaining (Middle Robe, East Deepdale, Mesa B and Mesa C) Geotechnical Design Report (RTIO, 2015)

This report outlines the geotechnical slope design recommendations and mesa façade stand-off requirements associated with geotechnical risks.

5.2.1 Site Investigation and Analysis Approach

There was no specific geotechnical information, either measured or logged, for the Mesa B, Mesa C, East Deepdale or Middle Robe deposits and therefore for this study, geotechnical parameters were inferred from CID units found at Mesa A by Snowden in 2007.

To account for geological uncertainty and provide robust slope configurations, the entire slope was modelled using TPB/TPM strength parameters as a base case. A series of typical sections as shown from Figure 17 to Figure 20 were selected from Middle Robe, Deepdale, Mesa B and Mesa C for the 2D slope stability analysis.

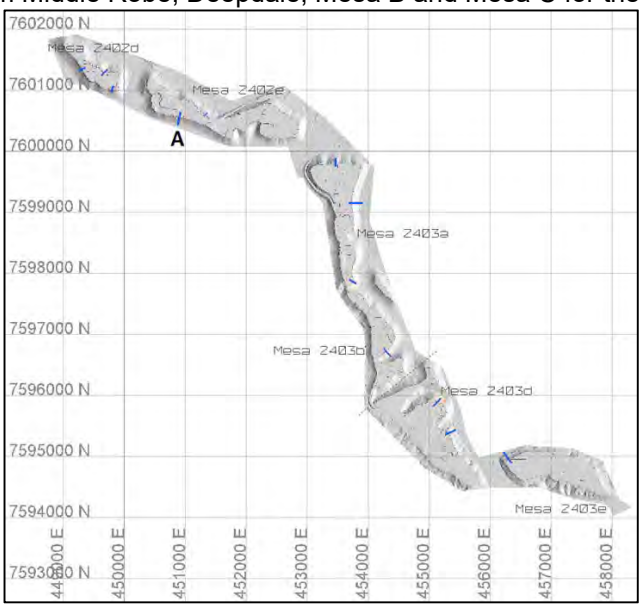

Figure 17. 2015 RTIO Robe Valley Pre-Feasibility Study (PFS) Middle Robe Section lines.

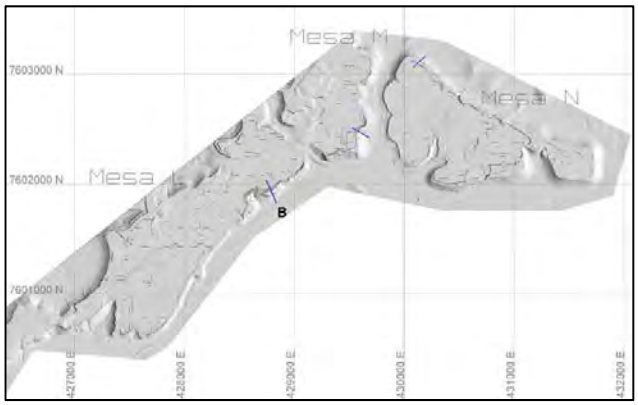

Figure 18. 2015 RTIO Robe Valley Pre-Feasibility (PFS) East Deepdale Section lines.

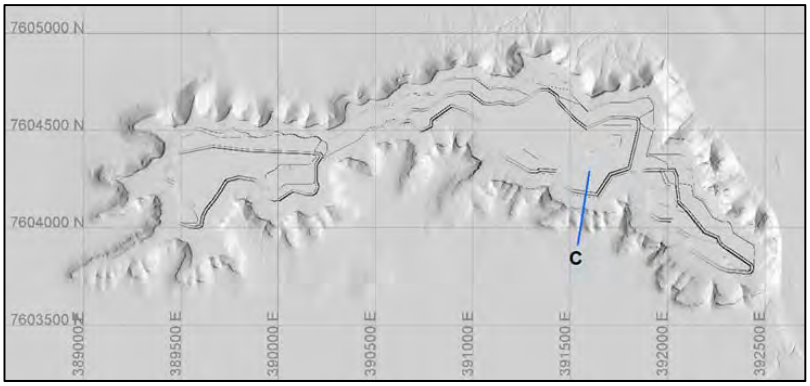

Figure 19. 2015 RTIO Robe Valley Pre-Feasibility Study (PFS) Mesa B Section lines.

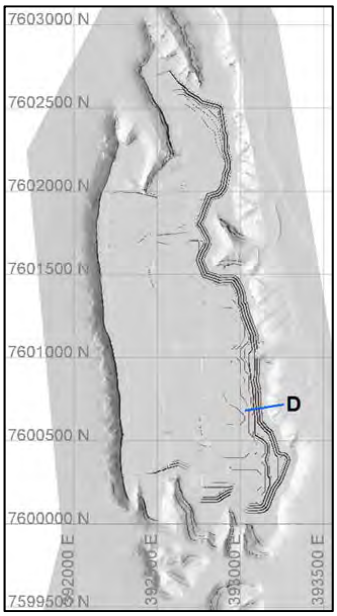

Figure 20. 2015 RTIO Robe Valley Pre-Feasibility Study (PFS) Mesa C Section lines.

5.2.2 Results

The façade stand-off distance recommendations were calculated based on the risk associated with different slope heights as outlined in Table 3.

Table 3. 2015 RTIO Robe Valley Slope Design Recommendations and Corresponding Minimum Mesa Facade Stand-Off Distance.

Deposit	Maximum Slope Height	Strand	Maximum IRA (°)	Maximum BFA (°)	Minimum Berm Width (m)	Max Bench Height (m)	Minimum Mesa Façade Stand-off (m)
Middle Robe / East Deepdale / Mesa B & C	20m high, AWT	HTP/ TPB/ TPM/ TPH/ TP	56	75	8	20	15
	40m high, AWT		56	75	8	20	20
East Deepdale	50m high, AWT		56	75	8	20	26
Mesa C	70m high, 13m BTW		52	75	10	20	35

5.3 Mesa H Pit crest/Façade Stand-off Distance Geotechnical Recommendations Update (RTIO, 2016)

A geotechnical assessment was undertaken in 2016 by Rio Tinto to review façade stand-off requirements.

5.3.1 Site Investigation and Analysis Approach

Review of the existing geotechnical data together with updated geological modelling and drilling data across the Robe Valley was undertaken and was analysed taking into consideration the distance to the 1.5 FOS failure surface in order to refine the stand-off distance from the pit crest to the mesa façade crests.

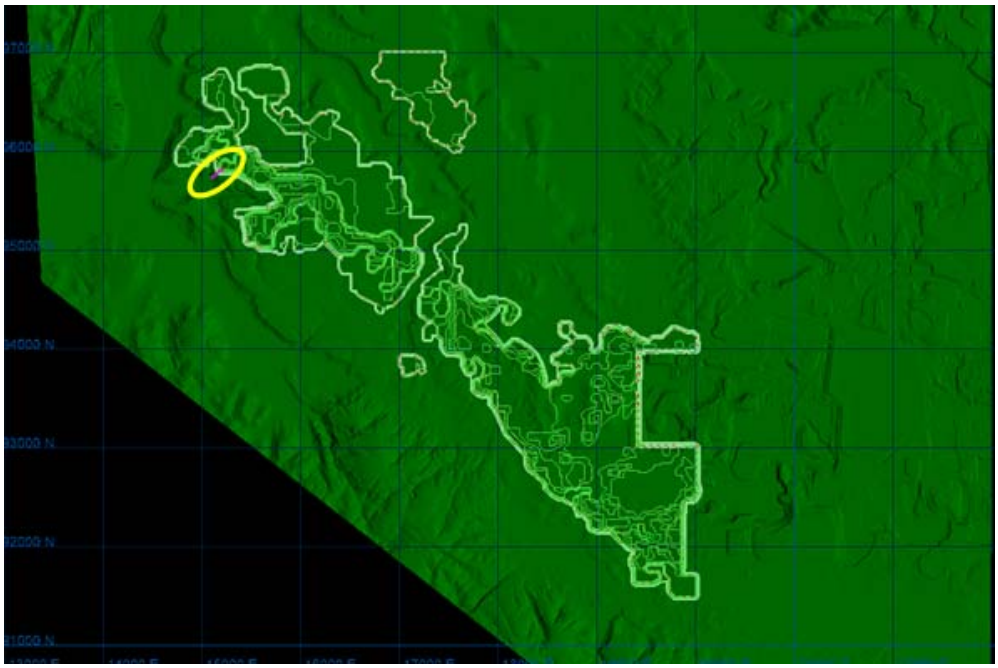

Figure 21. 2016 RTIO Mesa H Analysis Section.

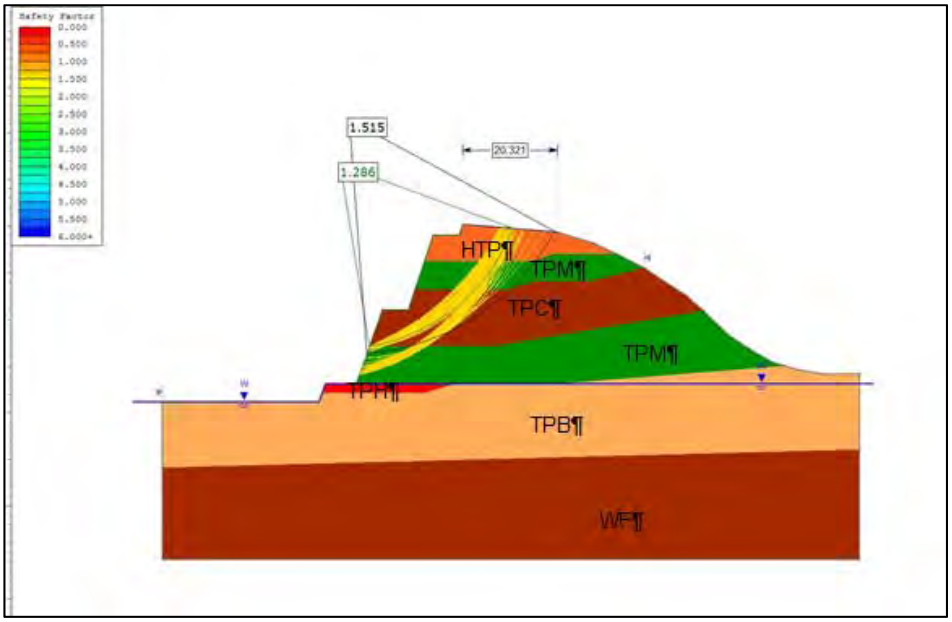

Figure 22. 2016 Mesa H Section Stability with 20m Stand-Off Distance on Pit Side (FoS=1.5).

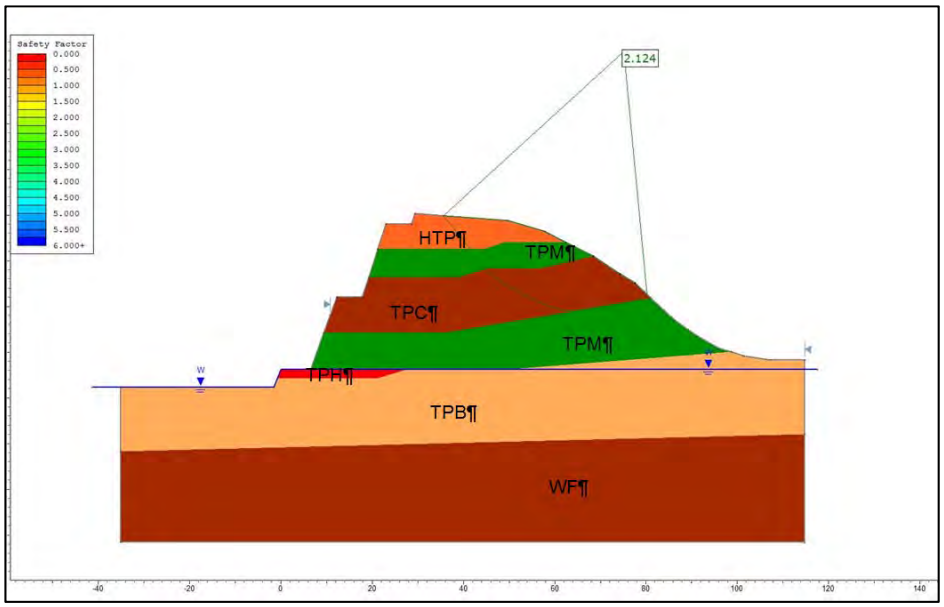

Figure 23. 2016 Mesa H Section Stability with 20m Stand-Off Distance on Façade Side (FoS>1.5).

5.3.2 Results

It was found that the FoS for the façade is below 1.5 using a 20m stand-off distance and above 1.5 with 30m stand-off distance. It was recommended that a minimum 30m stand-off is required between the Mesa H pit crest and façade crest.

5.4 Robe Valley mesa B, C and H Pits Geotechnical Feasibility Study, (3rd Rock Consulting, 2017)

3rd Rock Consulting (3RC) was commissioned to carry out a Life of Mine (LoM) geotechnical feasibility level design for Mesas B, C and H deposits.

5.4.1 Site Investigation and Analysis Approach

A total of 2690m of core were drilled and logged over seven drilling campaigns since 1999 with 1880m drilled in 2016 as shown in Figure 24, Figure 25 and Figure 26. A total of 435 geotechnical laboratory tests have been undertaken on core samples in the same period.

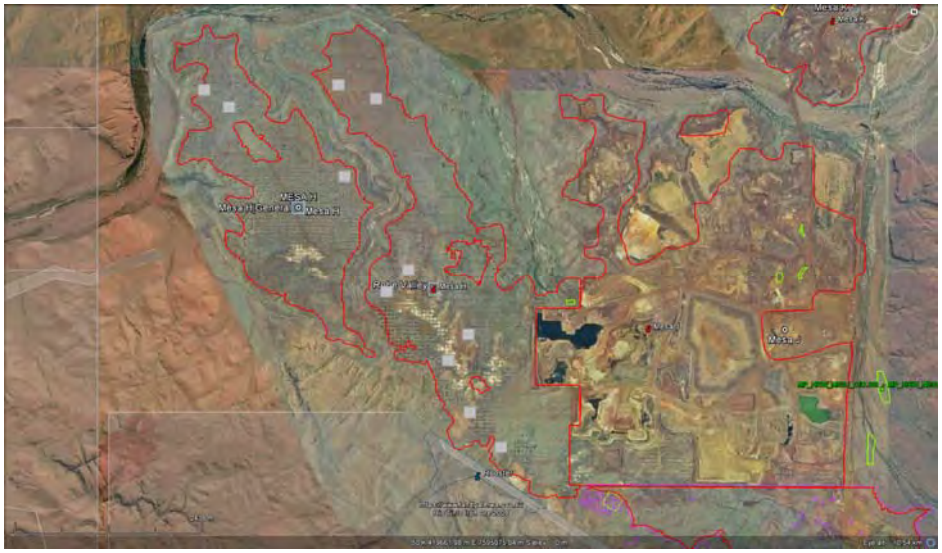

Figure 26. 2016 Mesa H Geotechnical Drill Hole Locations.

5.4.2 Results

3rd Rock developed material shear strengths which derived for both best-estimate and reduced (Lower Quartile) shear strengths for limit equilibrium stability analysis to meet Rio Tinto geotechnical Design Acceptance Criteria (DAC).

The SLIDE modelling results shown that the Factor of Safety meets the geotechnical DAC for both the estimated and lower quartile rock mass strength. The result also shows that the Factor of Safety of the façade is greater than 1.5 even with lower quartile rock mass strength and 30m stand-off distance as shown in Figure 27.

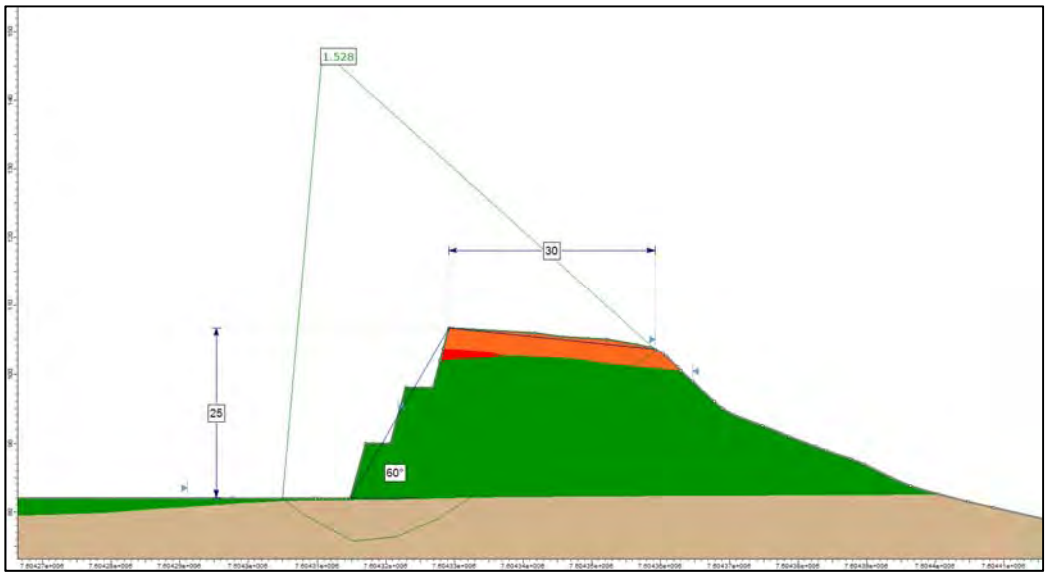

Figure 27. 2017 3rd Rock RV Study Mesa B Section A Facade Factor of Safety =1.53 with Lower Quartile Strength 30m from façade.

3rd Rock concluded:

- The slope stability results for Rio Tinto's designs for all three Mesas show that the Factor of Safety (FoS) for all sections are greater than Rio Tinto's Design Acceptance Criteria; in most cases significantly greater. This is because the final pit slopes are shallow and will perform well in competent cemented material; and
- The slopes were optimised in order to increase the overall slope angles and to reduce the façade width (that is the distance between the crest of the pit and that of the mesa's natural slope) to a minimum of 30m.

It has been implicitly assumed that best practise blasting methods will be used in order to minimise disturbance to the façade rock mass.

5.5 Robe Valley Operational Geotechnical Function Independent Review (Xstract, 2017)

Xstract Mining Consultants (Xstract) undertook an independent Operational Geotechnical review of the Mesa A and Mesa J mining areas at Robe Valley Operations in March 2017.

5.5.1 Site Investigation and Analysis Approach

This review mostly focused on the performance of the current slope, compliance to D3 standards by performing a desktop review, a site visit and discussion with key personnel.

5.5.2 Results

It was determined to be important to consider the likely depth of blast disturbance into the perimeter rock mass, behind the mined batters, which is generally taken as one to two mining bench heights but can be greater depending on the blasting methods used. Further, the impact of the blast disturbance on façade stability will be increased where the outer slope of the mesa forms a steep slope, forming a more slender perimeter "Pillar" as shown in Figure 28.

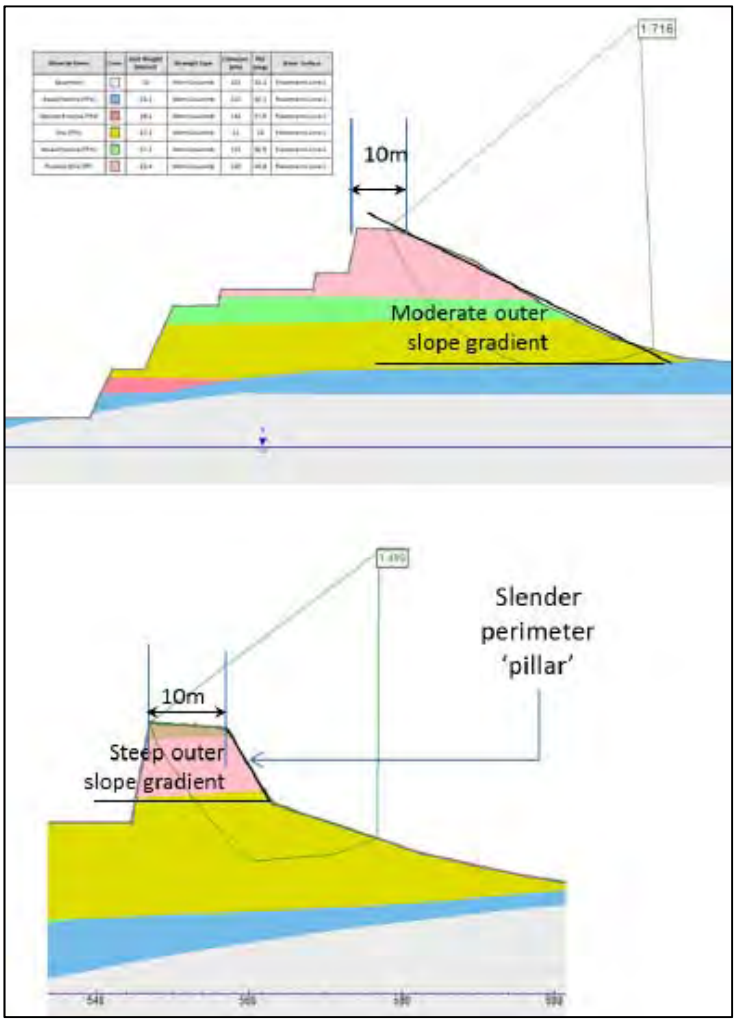

Figure 28. Example of Facade geometry in RTIO 2015 "Mesa B and C Façade Slope Stability Analysis for Closure" Report.

The long term stability of the mesa façade will be controlled, in part, by the level of blast damage and relaxation undergone by the perimeter material. Xstract recommended a minimum stand-off distance of 20m (i.e. approximately twice the standard mining bench height) be employed where the outer slope of the mesa is relatively steep (i.e. a 'slender' perimeter pillar may be formed).

6 Current Wall Performance

Current Mesa deposits wall performance was also evaluated to assist in deciding the minimum stand-off distance. The wall performance was evaluated in two ways:

- By reviewing wall condition utilizing UAV fly-over images (March, 2017) and
- By reviewing the prism monitoring data.

6.1 Wall Conditions

In Robe Valley, Mesa A, Mesa J and Warramboo are currently in an operational stage. Other deposits are currently under assessment. As there is no façade in Warramboo, only the current as-built slopes in Mesa A and Mesa J were reviewed. The existing walls have minimum stand-off distance of 50m as shown in Figure 29 and Figure 32.

In order to check geotechnical assumptions (design parameters) applied to the façade modelling, the installed prisms movements have been reviewed. The intent was to correlate the wall performance to the geotechnical parameters assuming the geotechnical parameters are not overly conservative.

The as-built wall conditions for Mesa A and Mesa J are shown in Figure 30, Figure 31, Figure 33 and Figure 34. Compared with Mesa J slope, the top benches in Mesa A demonstrated better performance. It was estimated that better wall performance in Mesa A contributed by more competent material intersected in the wall (HTP, TP TPM, and TPB). Mesa J has softer material (Alluvium and Colluvium) on the top benches. However, there were no indications that this condition has any impact on the façade.

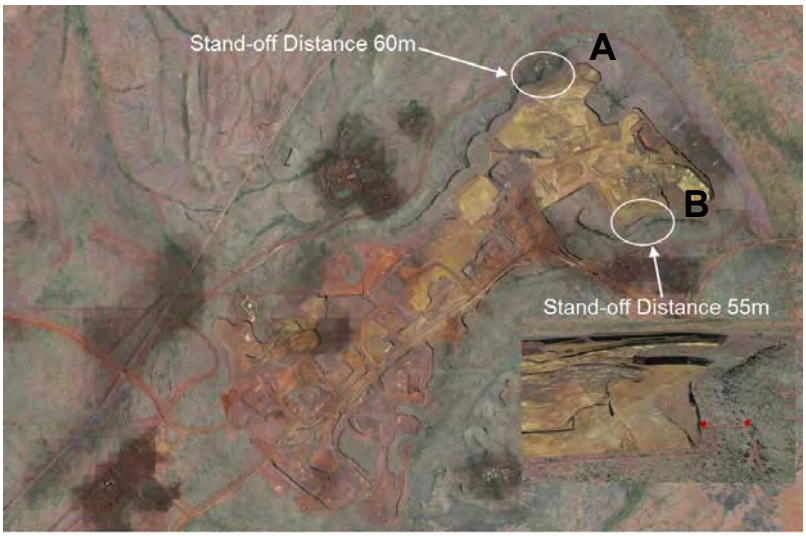

Figure 29. Mesa A As-Built Stand-Off Distance

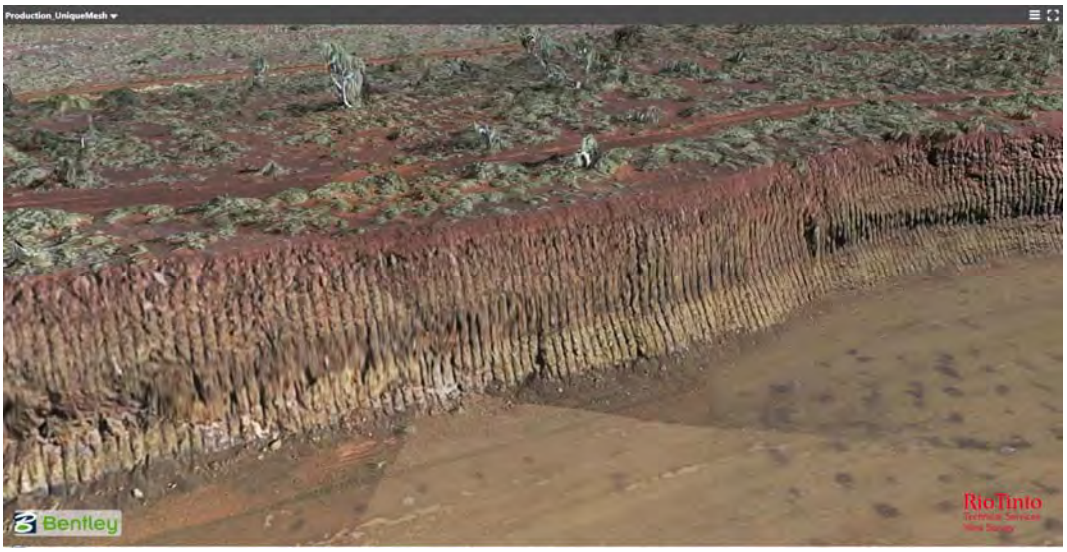

Figure 30. Mesa A Area A Wall Conditions.

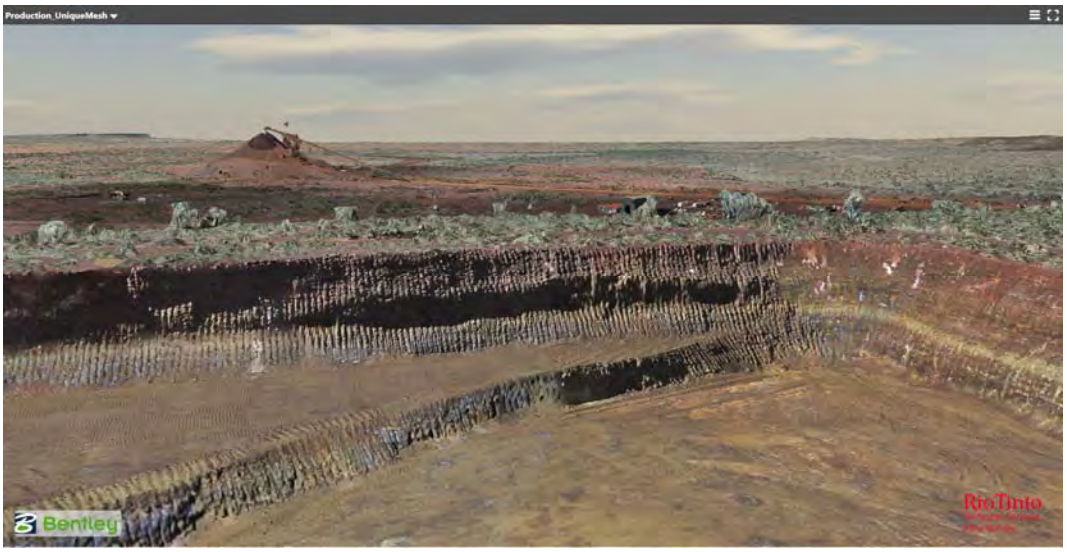

Figure 31.Mesa A Area B Wall Conditions.

Figure 32. Mesa J As Built Stand-Off Distance.

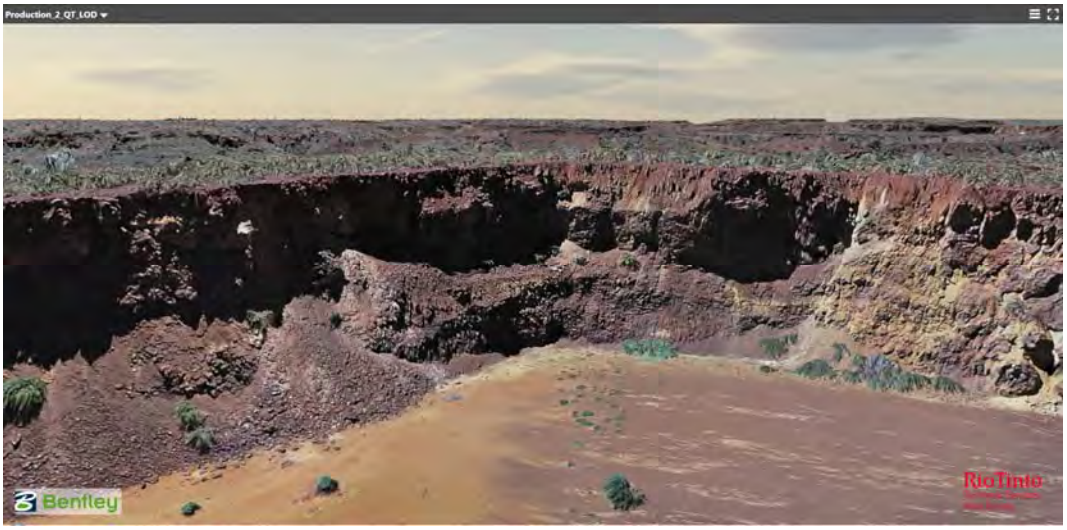

Figure 33.Mesa J Area A Wall Conditions.

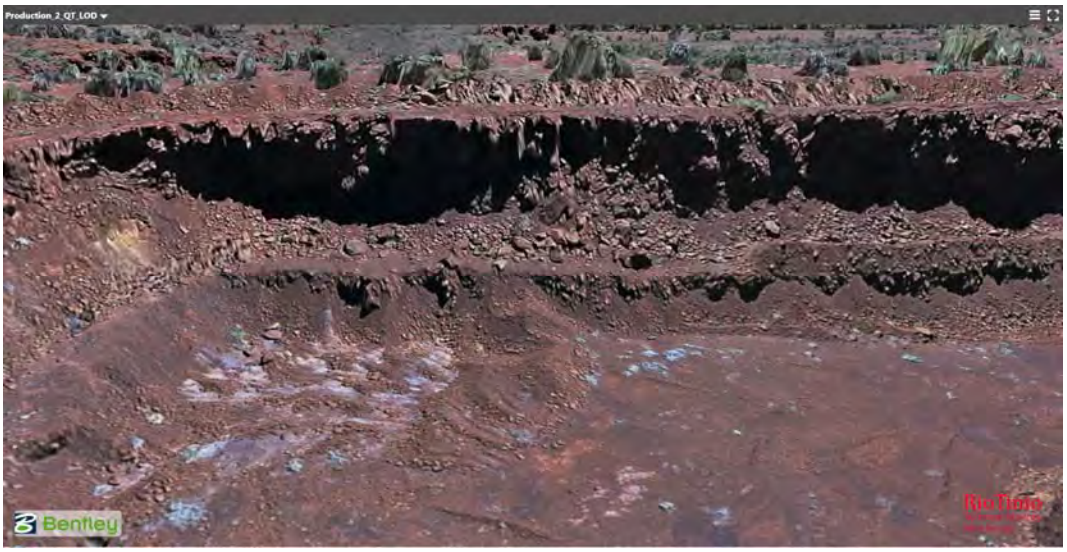

Figure 34.Mesa J Area B Wall Conditions.

6.2 Prism Monitoring Data

Based on the geotechnical risk assessment, prisms have been installed in several areas in Mesa A and Mesa J to monitor the wall performance. The prisms are monitored manually on a fortnightly basis.

The prisms 3D movements were used to analyse the current as-built wall stability.

6.2.1 Mesa A Prisms

Eight prisms were installed on the cut slopes crest close to the façade in Mesa A Breach area (5 on the North wall and 3 on the South wall) as shown in Figure 35. A cross section of the slopes with the geological setting is shown in Figure 36. The wall in this area intersected HTP, TPH, TPM and TPB with 25m slope height. The Inter Ramp Angle (IRA) is 30 degrees in the north wall and 48 degrees in the south wall. Both are still below the maximum IRA recommended by Snowden in the 2007 report.

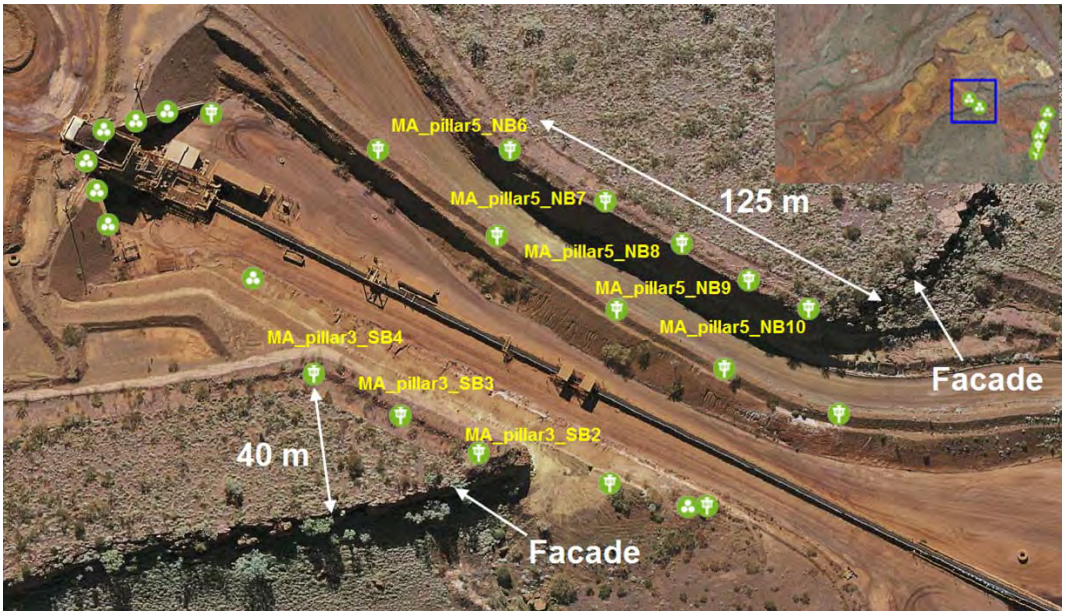

Figure 35. Prisms location in Mesa A Breach Area.

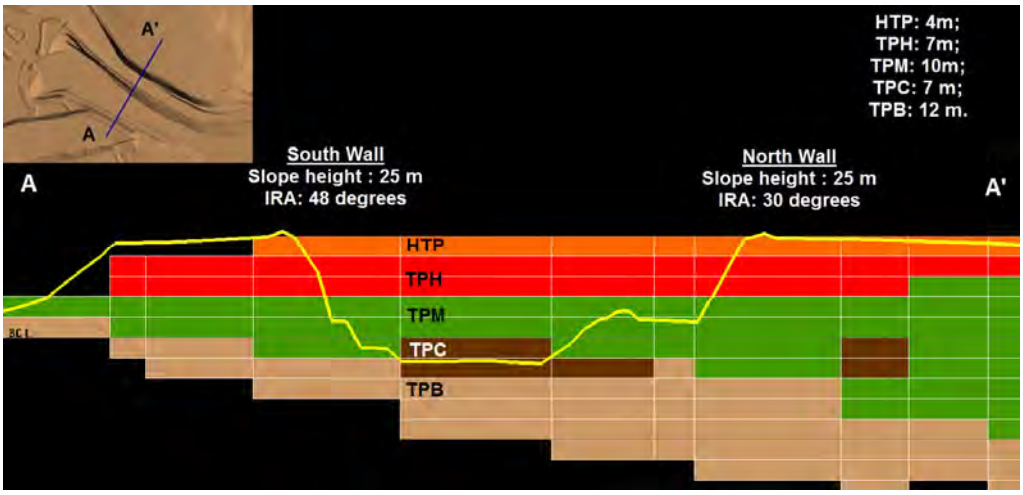

Figure 36. Mesa A Pit Cross Section where Prisms were installed.

The expected movement direction in the north wall prisms (NB6 toNB10) was south/south-west and north/north-east for the south wall prisms (SB2 to SB4). The prisms movements between May 2016 and April 2017 are summarized in Table 4.

Table 4. Mesa A Breach Area prisms movements summary

Deposit	Prism Name	3D Movement (mm/month)	Actual Movement direction	Expected movement direction	Note
Mesa A	SB2	-0.35	S-E	S / S-E / N / N-E / N-W	
Mesa A	SB3	-0.067	S-E	N-E / N / N-W	Invalid movement direction
Mesa A	SB4	0.00	N-E	N-E / N / N-W	
Mesa A	NB6	0.1	N	S / S-E / S-W	Invalid movement direction
Mesa A	NB7	0.00	N-W	S / S-E / S-W	Invalid movement direction
Mesa A	NB8	0.00	NA	S / S-E / S-W	
Mesa A	NB9	0.00	N-E	S / S-E / S-W	Invalid movement direction
Mesa A	NB10	0.00	N	S / S-E / S-W	Invalid movement direction

The recorded prism movement rates were minor. Five out of eight prisms movements also indicated invalid movement directions (moving towards the wall), possibly impacted by errors in the readings. Therefore, it was concluded that there was no apparent movement trend observed.
Mesa A prisms movement charts were included in Appendix A.

6.2.2 Mesa J Prisms

In order to check geotechnical assumptions (design parameters) applied to the façade modelling, the installed prisms movements have been reviewed. The intent is to correlate the wall performance to the geotechnical parameters assuming the geotechnical parameters are not overly conservative.

There is a Tailings Storage Facility (TSF4) behind the east wall of Pit 8 in Mesa J. The distance between the pit crest and the toe of TSF4 is around 25m. In total there are 17 prisms installed on the wall; 145mRL (prisms #17 and #18), 155mRL (prisms #10 to #16) and 161mRL (prisms 1 to 9) and monitored since February 2017 to monitor the impact of TSF4 to the pit 8 stability. The prisms locations are shown in Figure 37 and the as-built wall conditions are shown in Figure 38.

There is no façade near or might be impacted in this area. Monitoring results of this area is included to demonstrate stability of wall with worse conditions compared to most of the pit wall with façade in vicinity.

Prisms #1 to #9 are located in the tailing embankment to monitor the tailing slope stability. Therefore they were not included for analysing the slope stability. Only the prisms on the Pit 8 slope (#10 to 18) were investigated.

Figure 37. Mesa J TSF4 Prisms Locations.

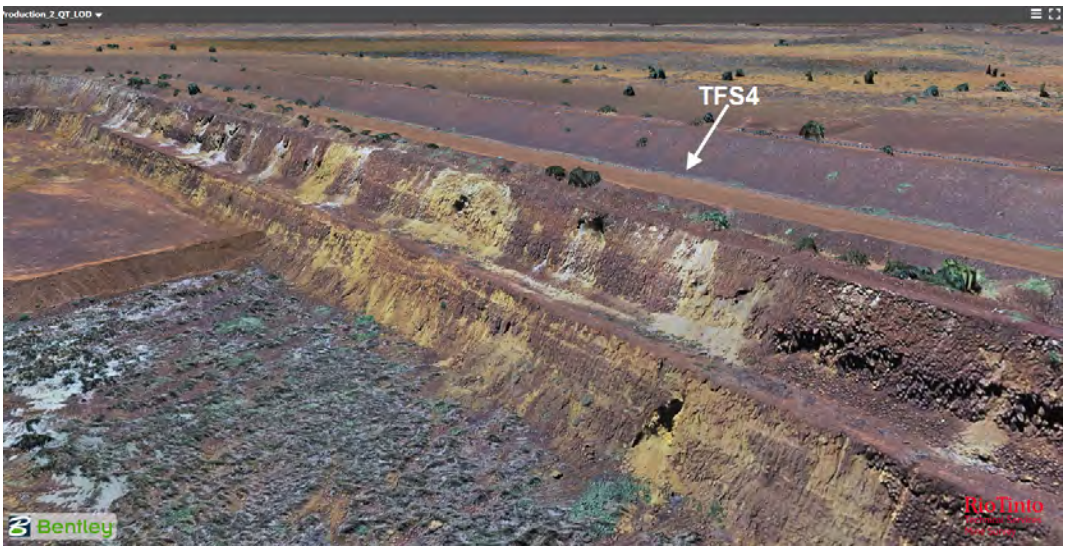

Figure 38. Mesa J Slope Under TFS4 Wall Conditions.

The slope intersected HTP (2m) and TPM (20m). The slope height is 25m with IRA 40 degrees as shown in Figure 39 which is lower than the maximum IRA recommended by 3rd Rock in their 2017 Mesa B, C and H FS report for similar material.

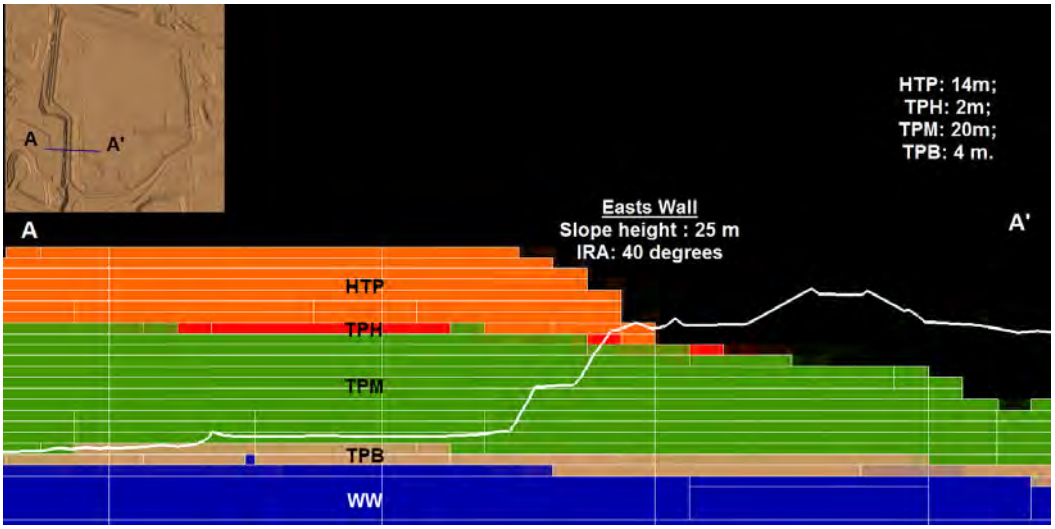

Figure 39. Mesa J South West Dump Cross Section Geology Setting.

Table 5.Mesa J TSF4 Area Prisms Movements Summary

Deposit	Prism Name	3D Movement (mm/month)	Actual movement direction	Expected movement direction	Note
Mesa J	10	1.40	S-E	W / N-W / N-E	Invalid movement direction
Mesa J	11	1.10	S-E	W / N-W / N-E	Invalid movement direction
Mesa J	12	0.00	N-E	W / N-W / N-E	No movement
Mesa J	13	1.10	S-E	W / N-W / N-E	Invalid movement direction
Mesa J	14	0.90	S-E	W / N-W / N-E	Invalid movement direction
Mesa J	15	1.20	S-E	W / N-W / N-E	Invalid movement direction
Mesa J	16	2.4	S-E	W / N-W / N-E	Invalid movement direction
Mesa J	17	1.80	S-E	W / N-W / N-E	Invalid movement direction

The recorded prism movement rates were minor with most of them showing invalid movement direction (moving towards the wall) Therefore, it can be concluded that there was no apparent trend of movement observed.
The Mesa J Pit 8 TFS4 prisms movement charts were included in Appendix A.

7 Façade Stability in Closure Stage

Stability of the mesa facades post closure had not been considered in historical Robe Valley Closure studies. There is a risk that the facade stability may be impacted if the water table returns to pre-mining levels. This risk must have been considered as part of the closure study.

7.1 Robe Valley Closure Plan

Closure studies have been completed for the Mesa A Hub (including Warramboo, Mesa A, B & C) and the Mesa J Hub (including Mesa J, K & H) by RTIO in 2017. The surface water, ground water and back fill plan are the factors which can affect the façade stability; therefore these parameters were reviewed in this report.

7.1.1 Surface Water

Flood modelling has been undertaken for the Robe Valley deposits as mentioned in Section 3.1. Mesa A and Mesa J hub deposits are not subject to riverine flooding from the Robe River. Waste Dumps currently proposed for a breakout flood area between Mesa A and Mesa B located in an area subject to infrequent and shallow flow. Flow velocities are less than 2 m/s and not expected to result in erosion of landforms (RTIO, 2017).

7.1.2 Ground Water

During mining, there will be a total of four deposits which will have the deepest part of their pit floors under the pre-mining ground water table level including: Mesa C, Mesa H, Mesa J and Warramboo. Predicted groundwater recovery levels and the modelled time to recovery are listed in Table 6.

Table 6. Predicted Ground water Level and Approximate time for Recovery (RTIO, 2017)

Deposit	Pre-mining Water Level (mRL)	Estimated water table level at mining stage(mRL)	Estimated maximum drawdown level (mRL)	Estimated recovery level (mRL)	Time (years)
Warramboo	25-50	18	18	25-50	100
Mesa A	48-50	No change-AWT mining	NA	NA	NA
Mesa B	55-58	No change-AWT mining	NA	NA	NA
Mesa C	67-70	47	20	TBC	TBC
Mesa H	120-144	110	34	120-144	30
Mesa J	142-155	110	45	142-155	30
Mesa K	144-146	No change-AWT mining	NA	NA	NA

7.1.3 Backfill Plan

The distribution of closure domains are illustrated in Figure 40, Figure 41 and summarized in Table 7.

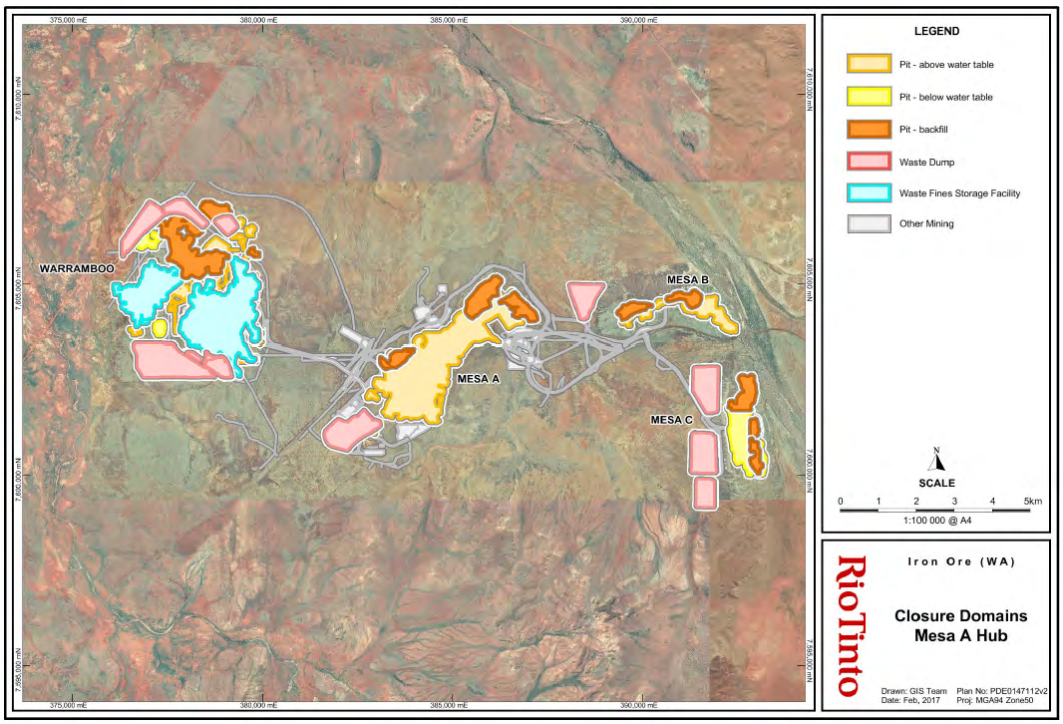

Figure 40. Robe Valley Mesa A, Mesa B, Mesa C and Warramboo Closure Domains.

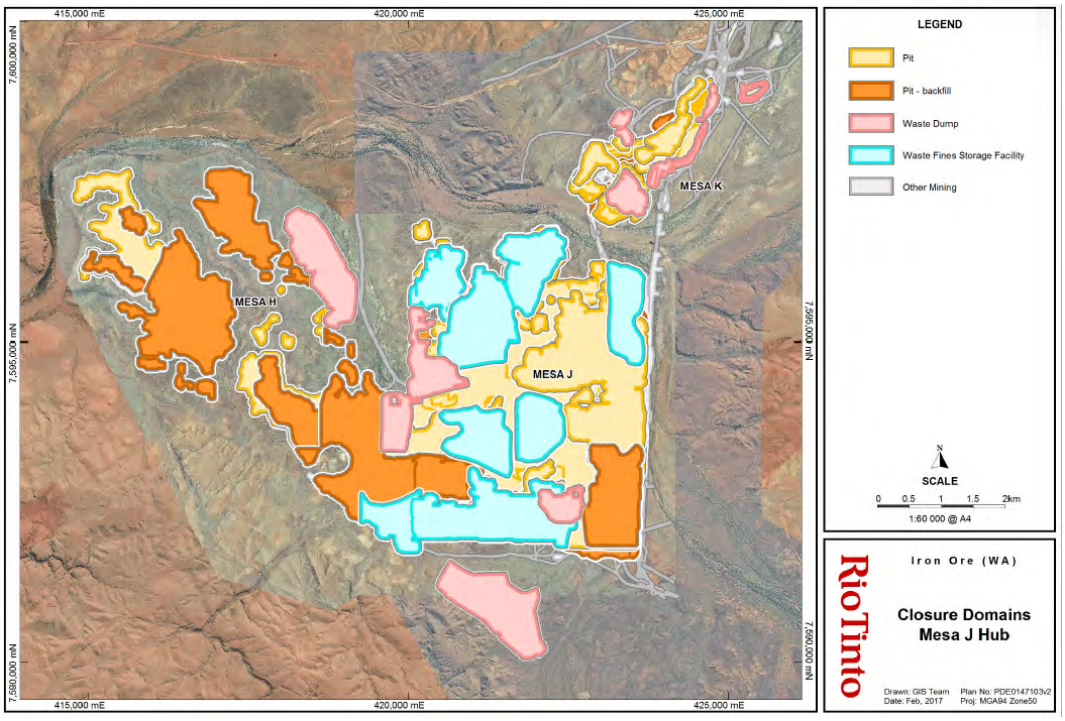

Figure 41.Robe Valley Mesa J, Mesa H and Mesa K Closure Domains

Table 7. Robe Valley Deposits Backfill Plan.

Deposits	Below/Above Water Table	Pits	Backfill Plan
Mesa J Mesa H Mesa K	AWT	Other pit except BWT pits	Pits may be partially backfilled
	BWT	Mesa H Pit 1 Mesa H Pit 3 Mesa H Pit 4 Mesa H Pit 5 Mesa H Pit 6 Mesa H Pit 7 Mesa J Pit 6 Mesa J Pit 11 Mesa J Pit 12 Mesa J Pit 15	Undertake opportunistic backfill during operations
		Mesa J Pit 15	Mesa J pit 15 will have an area partially left as a pit lake.
Mesa A Mesa B Warramboo	AWT	Other pits except BWT pits	Pits may be partially backfilled where possible to minimise the volume of waste in out of pit waste landforms
	BWT	Mesa C_pit01 Mesa C_pit02 Mesa C_pit03 Wboo_pit3	Undertake opportunistic backfill during operations

In order to assess the slope stability close the façade after ground water recovery, two sections were selected from Mesa C and Mesa H in the area where pit floors will be under the pre-mining water table as shown in Figure 42 and Figure 43. The pit floors will be 15m below pre-mining water table in section A Mesa C, and 10m below pre-mining water table in section J of Mesa H.

The closure plan has consequently prioritised these areas for backfill in the future. Additional stability analyses in these sections were intended to check the stability of the slopes prior to backfill.

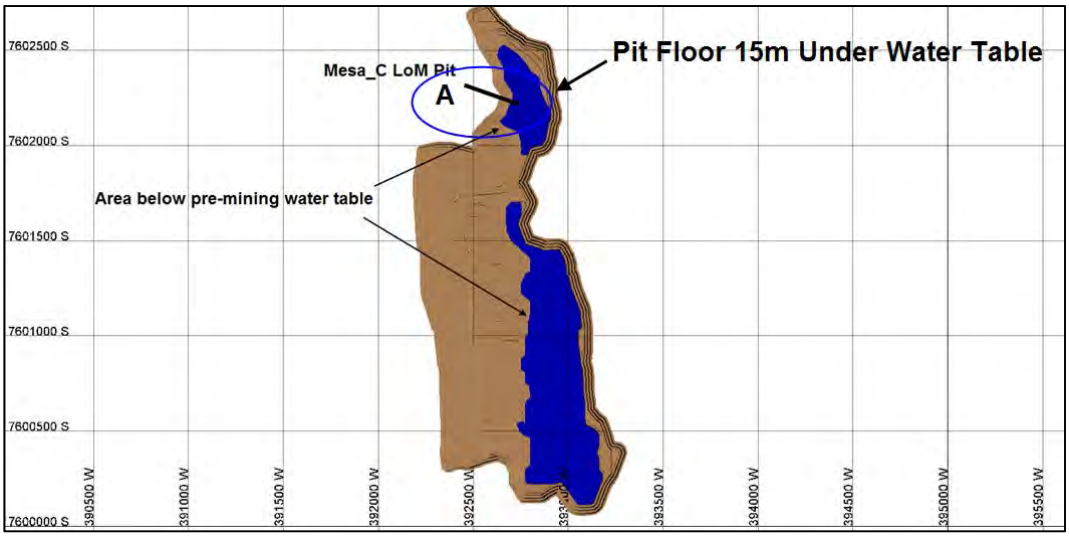

Figure 42. Closure Slope Stability Geotechnical Section in Mesa C.

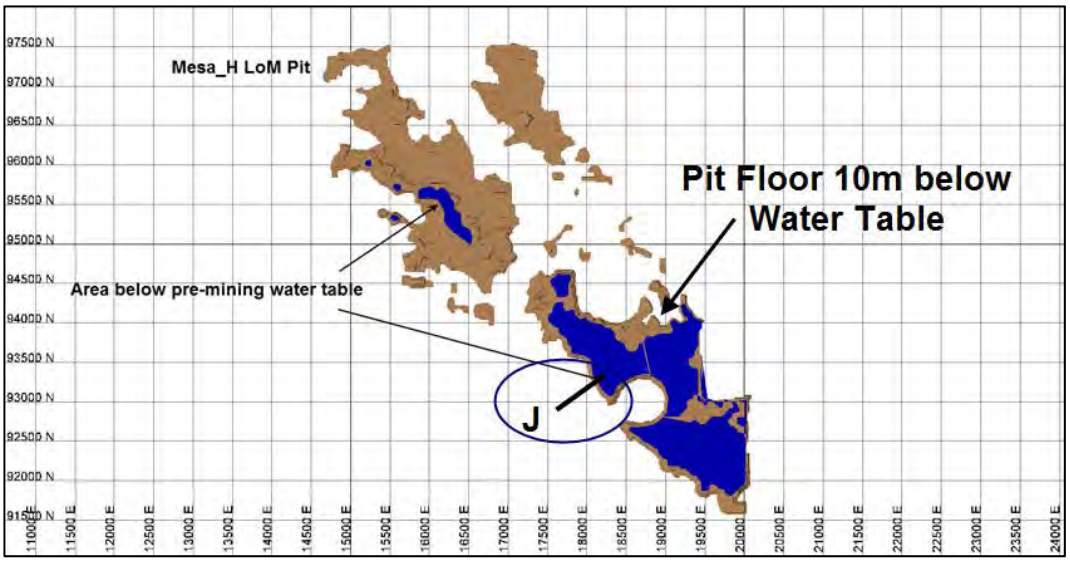

Figure 43.Closure Slope Stability Geotechnical Section in Mesa H.

The SLIDE models for the two sections used the rock mass parameters from 2017 3rd Rock study, and the pre-mining water table levels (69mRL in Mesa A and 135mRL in Mesa H). The results were plotted in Figure 44 and Figure 45.

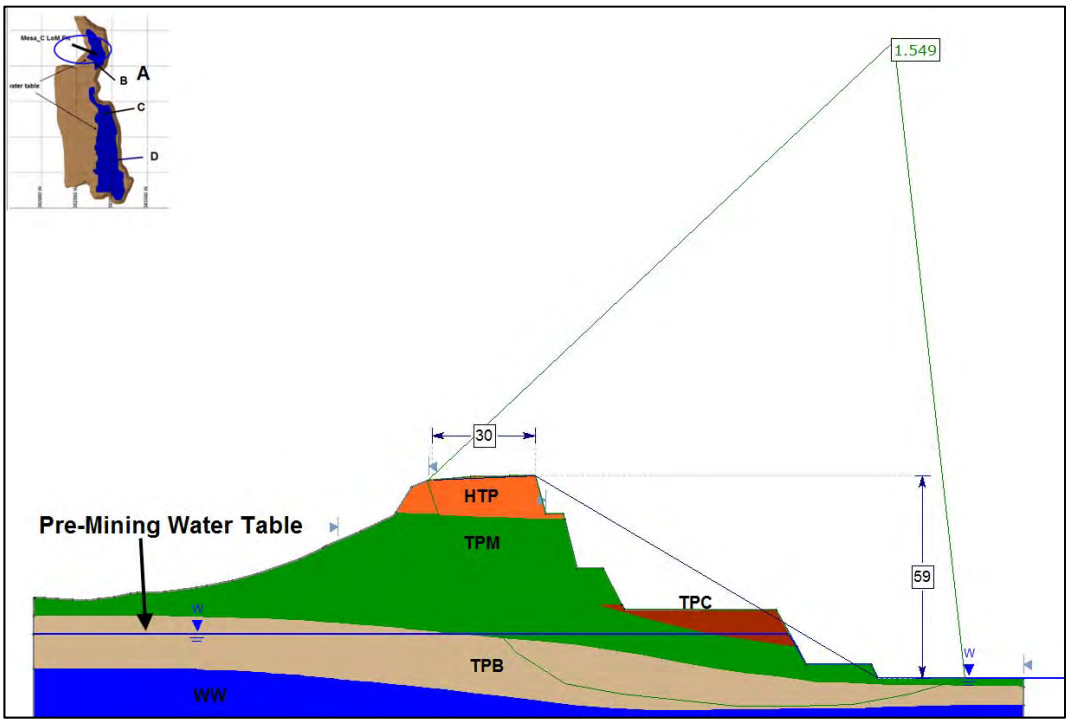

Figure 44. Section A Mesa C Slope Stability after Closure (FoS>1.5).

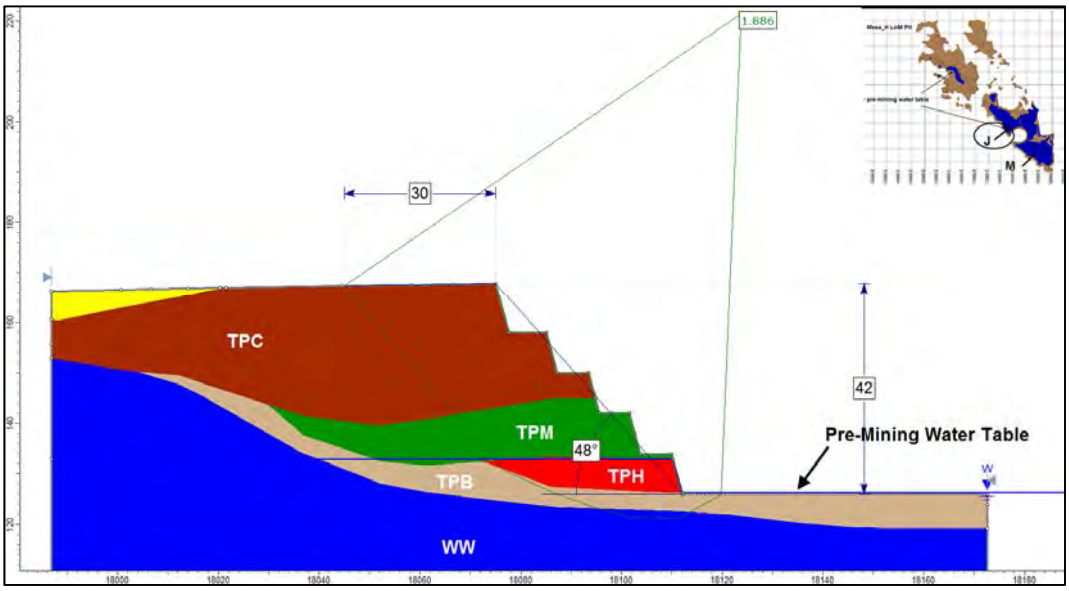

Figure 45.Section J Mesa H Slope Stability after Closure (FoS>1.5).

Both models show that the FoS in area within 30m from the pit crest were higher than Rio Tinto Design Acceptance Criteria (>1.5). Backfilling proposed in the closure plan will increase the wall stability. Therefore, it is concluded that a minimum 30m façade is considered as adequate from a stability perspective and to protect the identified environmental and heritage values.

8 Conclusions

The historical recommendations for the Robe Valley façade stand-off distances are summarized in Table 8.

Table 8. Recommendations for Facade Stand-Off Distance

Robe Valley Façade Stand-Off Distance Recommendation					
Report	**Completed by**	**Year**	**Geotechnical Drilling (m)**	**Number of used holes**	**Minimum Stand-Off Distance (m)**
Mesa A and Warramboo Geotechnical Review	Snowden	2007	507	14	50
Robe Valley Sustaining PFS Geotechnical Design Report	RTIO	2015	NA		15
Mesa H Pit crest/Façade Stand-off Distance Update	RTIO	2016	NA		30
Robe Valley Operational Geotechnical Function Independent Review	Xstract	2017	NA		20
Robe Valley mesa B, C and H Pits Geotechnical Feasibility Study	3rd Rock	2017	2873.2	51	30

Note. Snowden assessed stability for 50m stand-off distance but did not examine smaller distances (less than 50m).

Based on work undertaken in previous studies, and updated information available from new studies including: current wall performance and wall monitoring (with current prism monitoring data at Mesa A); additional drilling data; updated geological models; recent blasting data; and additional laboratory testing (including consideration of the lower quartile rock strength) have contributed to refining a minimum stable stand-off distance to protect the façade during mining operations and into closure.

From the work and studies undertaken to date, it is concluded that a minimum of 30m stand-off distance from the façade to the pit crest is adequate for maintaining the long term stability and integrity of the façade.

Sincerely,

Xuzheng Gao
Geotechnical Engineer
Mine Engineering Geotechnical, OKP
