GOVERNMENT OF WESTERN AUSTRALIA

Environmental Protection Authority

EPA Referral Form

Form for the referral of a proposal to the Environmental Protection Authority under Section 38 of the *Environmental Protection Act 1986*

Referrer information			
Who is referring this proposal?		X Proponent	
Name: Ivan Vella		**Signature:**	
Position	Director	Organisation	Robe River Mining Co. Pty. Limited
Email			
Address	152 – 158 St Georges Terrace		
	Perth	WA	6000
Date	June 2017		
Does the referrer request that the EPA treat any part of the proposal information in the referral as confidential? *Provide confidential information in a separate attachment.*		X No	

Referral declaration for organisations, proponents and decision-making authorities:

I, Ivan Vella, declare that I am authorised to refer this Proposal on behalf of Robe River Mining Co. Pty. Limited and further declare that the information contained in this form is true and not misleading.

Part A: Proponent and proposal description

Proponent information

Name of the proponent/s (including Trading Name if relevant)	Robe River Mining Co. Pty. Limited
Australian Company Number(s)	008 694 246
Contact for the proposal (if different from the referrer) *Please include: name; physical address; phone; and email.*	Melinda Brand Principal Advisor Environmental Approvals Rio Tinto 152-158 St Georges Tce, Perth WA 6000 Telephone (08) 6211 6991 Email: Melinda.brand@riotinto.com
Does the proponent have the legal access required for the implementation of all aspects of the proposal? *If yes, provide details of legal access*	X Yes Legal access to the Development Envelope is via ML248SA (section 104 and a portion of section 103) under the *Iron Ore (Robe River) Agreement Act 1964*.

authorisations / agreements / tenure. *If no, what authorisations / agreements / tenure is required and from whom?*	The Proposal overlaps with the co-existing Land Administration Act 1997 tenure: • Pastoral Lease N49500 held by Yarraloola Pastoral Station. Yarraloola Station is Robe Joint Venture (JV) controlled entity. • Pastoral Lease N49492 held by Yalleen Pastoral Station. Yalleen Station is held by Yalleen Pastoral Co. Pty. Limited which is a Robe Joint Venture (JV) controlled entity. Grants of additional tenure easements will be required for sections of infrastructure such as powerlines outside the existing ML248SA.
Proposal type	
What type of proposal is being referred? For a change to an approved proposal please state the Ministerial Statement number/s (MS No./s) of the approved proposal For a derived proposal please state the Ministerial Statement number (MS No.) of the associated strategic proposal	X significant – new proposal ☐ significant – change to approved proposal ☐ proposal under an assessed planning scheme ☐ strategic ☐ derived
For a significant proposal: • Why do you consider the proposal may have a significant effect on the environment and warrant referral to the EPA?	The Proposal may have a significant effect on the environment in the following ways: • Clearing of up to 2,200 ha of native vegetation generally in Good to Excellent condition. • Priority flora located in the Development Envelope including: - *Triodia* sp. Robe River [M.E. Trudgen et al. MET 12367] P3. - *Indigofera* sp. Bungaroo Creek (S. van Leeuwen 4301) P3. - *Rhynchosia bungarensis* P4. • Priority Ecological Communities occur within the Development Envelope: - *Subterranean invertebrate communities of mesas in the Robe Valley region* (P1). - *Subterranean invertebrate community of pisolitic hills in the Pilbara* (P1). • Removal of subterranean fauna habitat as a consequence of mining. • Dewatering of mine pits. • Surface discharge of surplus water.

For a proposal under an assessed planning scheme, provide the following details: • Scheme name and number For the Responsible Authority: • What new environmental issues are raised by the proposal that were not assessed during the assessment of the planning scheme? • How does the proposal not comply with the assessed scheme and/or the environmental conditions in the assessed planning scheme?	N/A
Proposal description	
Title of the proposal	Mesa H Proposal
Name of the Local Government Authority in which the proposal is located.	Shire of Ashburton
Location: a) street address, lot number, suburb, and nearest road intersection; or b) if remote the nearest town and distance and direction from that town to the proposal site.	16km south west of the township of Pannawonica (refer to Figure 1-1 of the Supplementary Information document)
Proposal description – including the key characteristics of the proposal *Provide as an attachment to the form*	Please refer to the attached supporting information document.
Have you provided electronic spatial data, maps and figure in the appropriate format? *Refer to instructions at the front of the form*	X Yes
What is the current land use on the property, and the extent (area in hectares) of the property?	The Proposal is located in the Shire of Ashburton. Existing land uses include pastoral activities (Yarraloola and Yalleen Stations), mineral exploration, mining activities and cultural / recreational activities (predominantly by Traditional Owners) such as camping, fishing and hunting.
Have you had pre-referral discussions with the OEPA? If so, quote the reference number and/or the OEPA contact.	Yes. OEPA contact is Peter Tapsell.
Part B: Environmental impacts	
Environmental factors	
What are the likely significant environmental factors for this proposal?	☐ Benthic Communities and Habitat ☐ Coastal Processes ☐ Marine Environmental Quality ☐ Marine Fauna

	X Flora and Vegetation ☐ Landforms X Subterranean Fauna ☐ Terrestrial Environmental Quality X Terrestrial Fauna X Hydrological Processes X Inland Waters Environmental Quality ☐ Air Quality X Social Surroundings ☐ Human Health

For the environmental factors identified above, complete the following table, or provide the information in a supplementary report. Please be sure to complete a separate table per factor identified above.

Potential environmental impacts

1	***EPA Factor***	Please refer to the attached supporting information document.
2	***EPA policy and guidance*** - What have you considered and how have you applied them in relation to this factor?	
3	***Consultation*** – Outline the outcomes of consultation in relation to the potential environmental impacts	
4	***Receiving environment*** - Describe the current condition of the receiving environment in relation to this factor.	
5	***Proposal activities*** – Describe the proposal activities that have the potential to impact the environment	
6	***Mitigation*** - Describe the measures proposed to manage and mitigate the potential environmental impacts.	
7	***Impacts*** - Assess the impacts of the proposal and review the residual impacts against the EPA objective.	
8	***Assumptions*** - Describe any assumptions critical to your assessment *e.g. particular mitigation measures or regulatory conditions.*	

Part C: Other approvals and regulation

State and Local Government approvals

Is rezoning of any land required before the proposal can be implemented? If yes, please provide details.	X No
If this proposal has been referred by a decision-making authority, what approval(s) are required from you?	

Proposal activities e.g. clearing, dewatering, mining, processing, dredging,	**Land tenure/access** e.g. Crown land – LA Act, Min Act, CALM Act specify type	**Type of approval** e.g. Native Vegetation Clearing Permit, licence, mining proposal,	**Legislation regulating the activity** e.g. *EP Act 1986* – Part V, *RiWI Act 1914*, *Mining Act 1979*
Clearing	State Agreement (ML248SA)	Native Vegetation Clearing Permit	*EP Act 1986* – Part V
Dewatering	State Agreement (ML248SA)	Licence	*RiWI Act 1914*
Mining	State Agreement (ML248SA)	State Agreement	*Iron Ore (Robe River) Agreement Act 1964*
Heritage	State Agreement (ML248SA)	Section 18 consent to disturb a protected site	*Aboriginal Heritage Act 1972*
Construction and operation of plant, camp and discharge of surplus water	State Agreement (ML248SA)	Works Approval and Licence	*EP Act 1986 – Part V*
Closure	State Agreement (ML248SA)	Closure Plan	*Mining Act 1978*

Commonwealth Government approvals

Does the proposal involve an action that may be or is a controlled action under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act)?	X Yes
Has the proposed action been referred? If yes, when was it referred and what is the reference number (EPBC No.)?	X No
If referred, has a decision been made on whether the proposed action is a controlled action? If 'yes', check the appropriate box and provide the decision in an attachment.	X No ☐ Decision – controlled action ☐ Decision – not a controlled action
Do you request that this proposal be assessed under the bilateral agreement or as an accredited assessment?	X Yes - Bilateral X Or Yes - Accredited
Is approval required from other Commonwealth Government/s for any part of the proposal? *If yes, describe.*	X No Approval:

1. INTRODUCTION

Robe River Mining Co. Pty. Limited (the Proponent) operates the Robe Valley mining operations, which includes iron ore mines at Mesa J, Mesa K, Mesa A and Warramboo. The Mesa J and Mesa K mines are located approximately 16 km south west of Pannawonica in the Pilbara region of Western Australia (Figure 1-1). The Mesa H deposit is located adjacent to the Mesa J mine. The Proponent is seeking to develop the Mesa H deposit to sustain iron ore production from the Robe Valley.

The following terminology is used throughout this document:

- **Mesa J operation** – The Mesa J mine as approved under Ministerial Statement 208 (MS 208)
- **Mesa H deposit –** pisolite iron ore formation occurring as a partial mesa landform (also known as a Channel Iron Deposit).
- **Proposal** – the proposed activities (as detailed in Section 3) incorporating above water table (AWT) and below water table (BWT) mining of the Mesa H deposit.
- **Development Envelope** - the proposed boundary within which the Proposal will be contained.

1.1 Purpose of this Document

This document has been prepared to support the referral of the Proposal under section 38 of the *Environmental Protection Act 1986* (EP Act). It provides information on the Proposal characteristics, existing environment, potential environmental impacts and proposed management commitments. This document has been prepared in accordance with Part IV Division 1 of the EP Act and the *Environmental Impact Assessment (Part IV Divisions 1 and 2) Administrative Procedures 2016*.

1.2 Proponent Details

The Proponent is the manager for the Robe River Iron Associates joint venture (RRIA) which is an unincorporated joint venture comprising the following participants:

- Robe River Mining Co. Pty. Limited (30% share);
- North Mining Limited (35% share);
- Mitsui Iron Ore Development Pty Ltd (20% share);
- Cape Lambert Iron Associates, a partnership carried on by Nippon Steel & Sumitomo Metal Australia Pty Ltd, Nippon Steel & Sumikin Resources Australia Pty Ltd and Mitsui Iron Ore Development Pty Ltd (5% share); and
- Pannawonica Iron Associates, a partnership carried on by Nippon Steel & Sumitomo Metal Australia Pty Ltd, Nippon Steel & Sumikin Resources Australia Pty Ltd (10% share).

The Rio Tinto contact person in relation to the environmental approvals process for the Proposal is:

Melinda Brand

Rio Tinto: Principal advisor environmental approvals

Telephone: (08) 6211 6991

Email: melinda.brand@riotinto.com

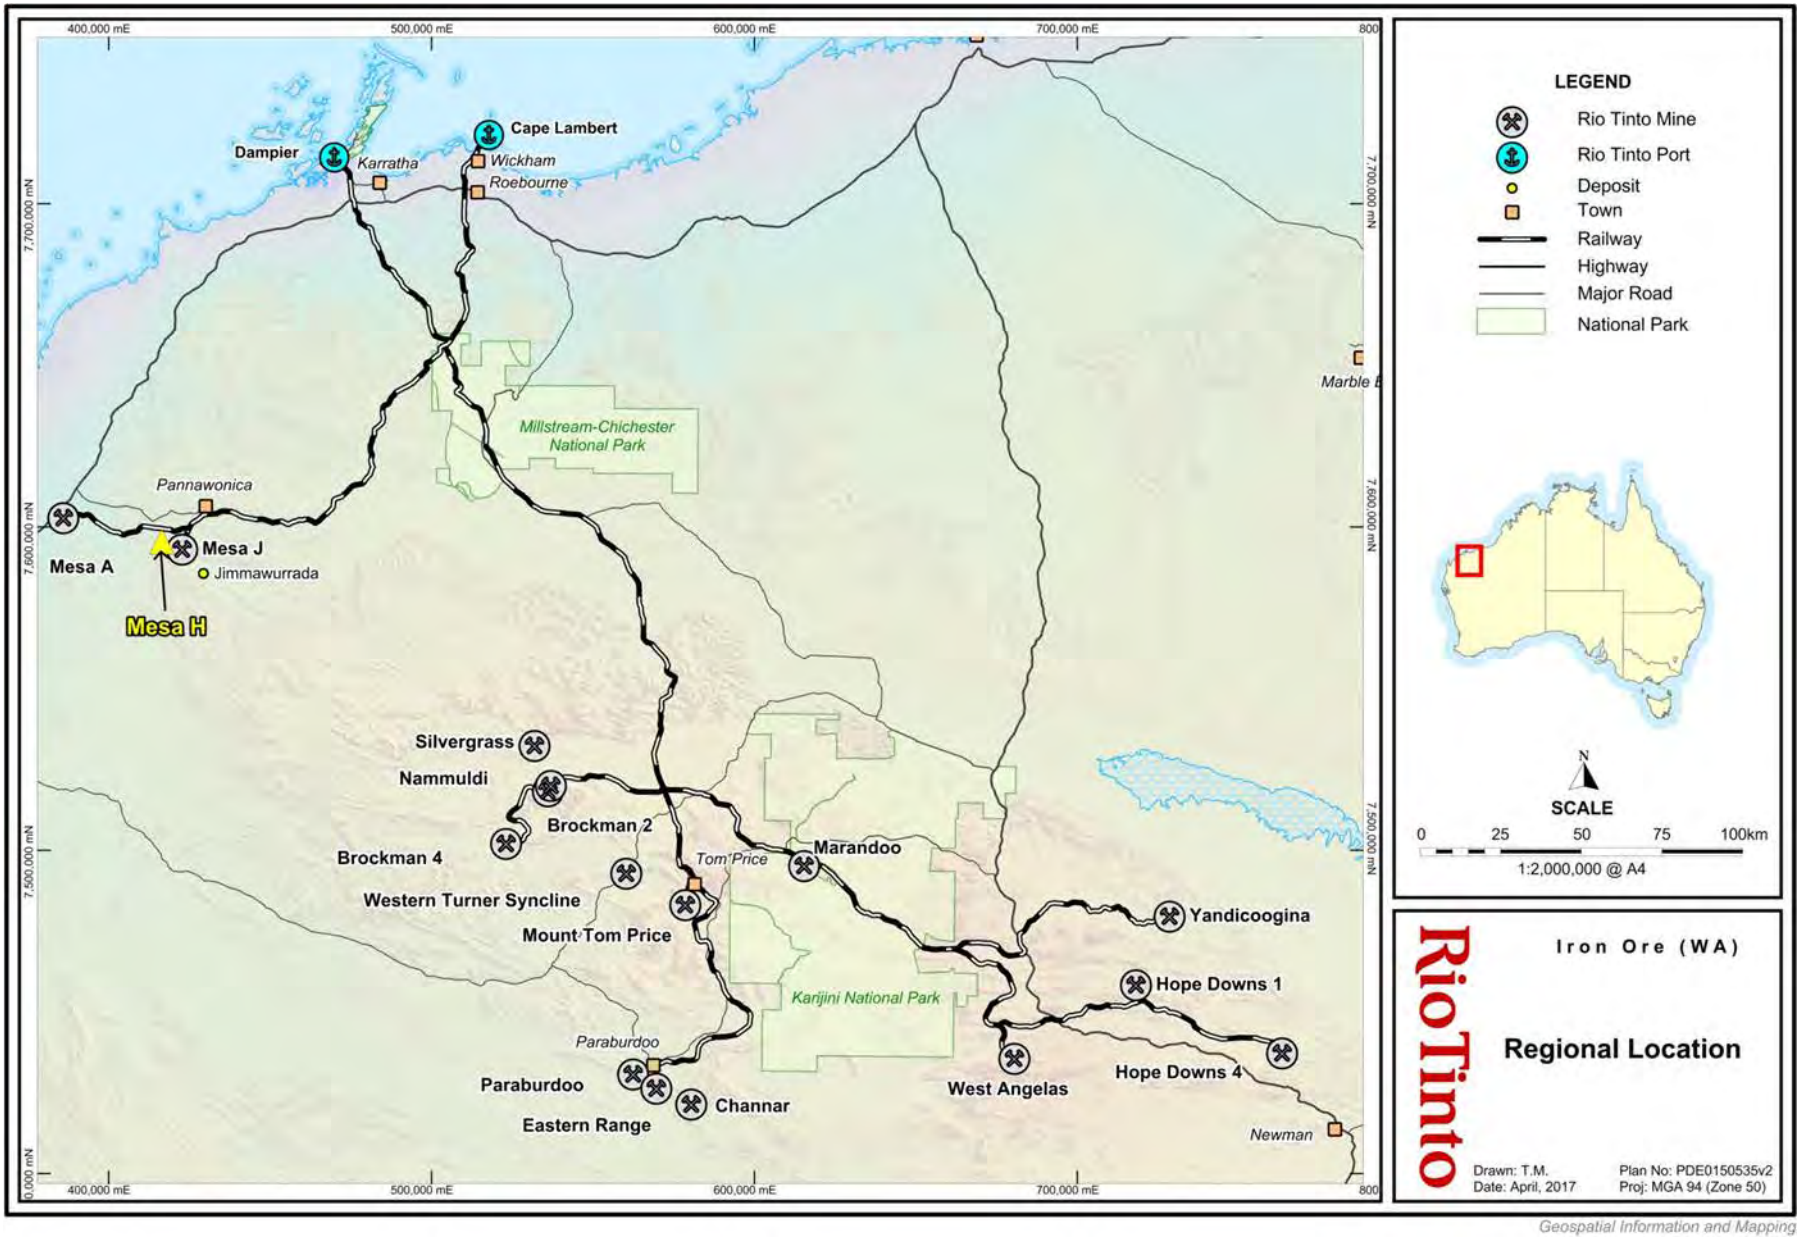

Figure 1-1: Regional Location

2. LAND USE AND TENURE

2.1 Land Use

The Proposal is located in the Shire of Ashburton, approximately 16 km south west of Pannawonica. Existing land uses in the Development Envelope include: pastoral activities (Yarraloola and Yalleen Stations); mineral exploration; mining activities; and cultural / recreational activities (predominantly by Traditional Owners) such as camping, fishing and hunting. The mesa landform / profiles of the Robe Valley are also used by Traditional Owners as landmarks when travelling though the countryside.

2.2 Tenure

The Robe Valley mining operations, including this Proposal, are predominantly located within the State Agreement Mineral Lease ML248SA granted pursuant to the *Iron Ore (Robe River) Agreement Act 1964*. ML248SA is appropriate tenure for mining and mining related infrastructure.

Existing tenure in and near the Development Envelope is shown in Figure 2-1. The Proposal pits, dumps and the majority of infrastructure are located within ML248SA (section 104 and a portion of section 103). A powerline to the east of Mesa J will require new tenure under the *Mining Act 1978*.

The main co-existing LAA tenure in the Development Envelope includes the Yarraloola Pastoral Station (Lease N49500) and the Yalleen Pastoral Station (Lease N49492). These pastoral leases are held by the RRIA.

2.3 Native Title

The Proposal lies within the Kuruma Marthudunera (K&M) Native Title Claim (WCD2016/006). The Proponent has a Participation Agreement and Indigenous Land Use Agreement with the K&M that includes an established consultation framework and ongoing engagement on relevant aspects of the Proponent's operations. These Agreements set obligations for processes such as: land access; tenure acquisition; heritage surveys; environmental management; mining benefit payments and reporting; and consultation and communication between the parties.

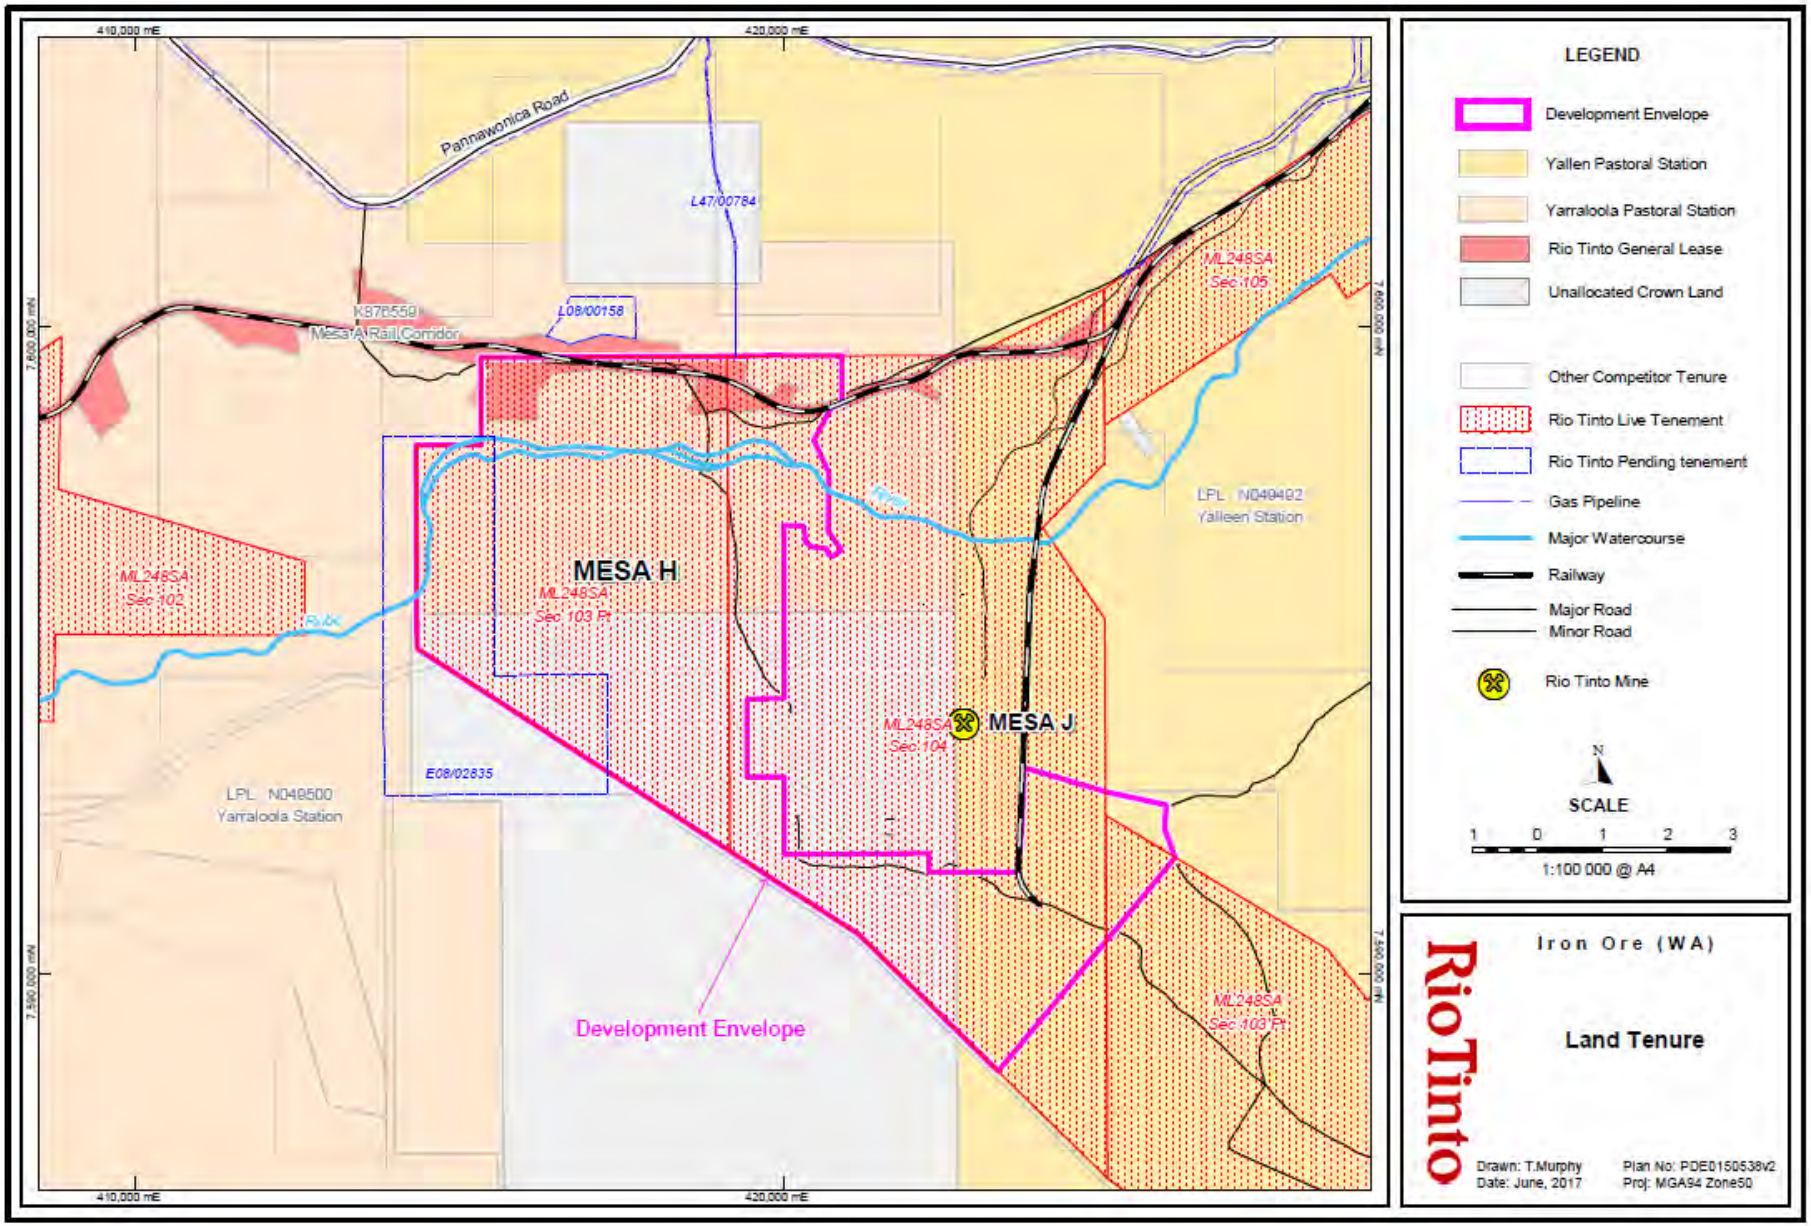

Figure 2-1: Land Tenure

3. MESA H PROPOSAL

3.1 Overview

A summary of the Proposal is provided in Table 3-1.

Table 3-1: Summary of the Proposal

Proposal Title	Mesa H Iron Ore Project
Proponent Name	Robe River Mining Co. Pty Limited
Short description	The Proposal is located approximately 16 km south west of Pannawonica in the Pilbara region of Western Australia, adjacent to the existing Mesa J mine. The Proposal includes development of above and below water table open cut iron ore pits and associated infrastructure, including water management infrastructure.

The Proposal consists of the following items and activities:

- **Mine pits** - development of open AWT and BWT iron ore pits
- **Dewatering and dewatering infrastructure** – including but not limited to bores, pipelines, and discharge outlet(s).
- **Surplus water management** – including but not limited to use in processing, on-site use and controlled discharge to the Robe River and tributaries.
- **Mineral waste management** – including but not limited to backfilling, ex-pit waste dumps, low grade ore dumps, topsoil and sub-soil stockpiles.
- **Processing facilities** – this Proposal will be supported by the existing processing facilities at Mesa J but may require other processing facilities including but not limited to waste fines storage facilities.
- **Support facilities** – including but not limited to workshops, power supply infrastructure, hydrocarbon storage, laydown areas, offices and waste water treatment plants.
- **Infrastructure for surface water management** – including but not limited to surface water diversion drains, levees and culverts.
- **Linear infrastructure** – including but not limited to heavy vehicle and light vehicle access roads, upgrades to existing vehicle access roads; pipelines and power (including sub-stations) and communications distribution networks.
- **Water supply** – utilising groundwater abstracted for dewatering, surface water that reports to pits, the existing Mesa J borefield (Southern Cutback borefield) and potentially additional bores.

Mined and processed ore will be railed to Rio Tinto's port operations at Dampier and/or Cape Lambert via the existing rail infrastructure.

The preliminary key characteristics for the Proposal are provided in Table 3-2.

An indicative conceptual mine layout is shown in Figure 3-1. Mine planning and engineering for the Proposal is currently still in progress therefore this layout is subject to change.

Table 3-2: Preliminary key characteristics of the Proposal

Element	Location	Proposed Extent
Physical Elements		
Mine and Associated Infrastructure	Figure 3-1	Clearing of no more than 2,200 ha within a Development Envelope of 4,930 ha.
Operational Elements		
Pit dewatering	-	Abstraction of no more than 10 GL/a of groundwater(including surface water run-off).
Surplus water management	-	Surplus water management options include use on site, and controlled discharge to the Robe River and tributaries.
Water supply	-	Supplied from an existing borefield within a current licence limit of 30 GL/a and surface water harvesting.
Ore Processing (waste)	-	In-pit disposal of waste fines at Mesa H and the adjacent Mesa J mine into in-pit waste fines storage facilities.

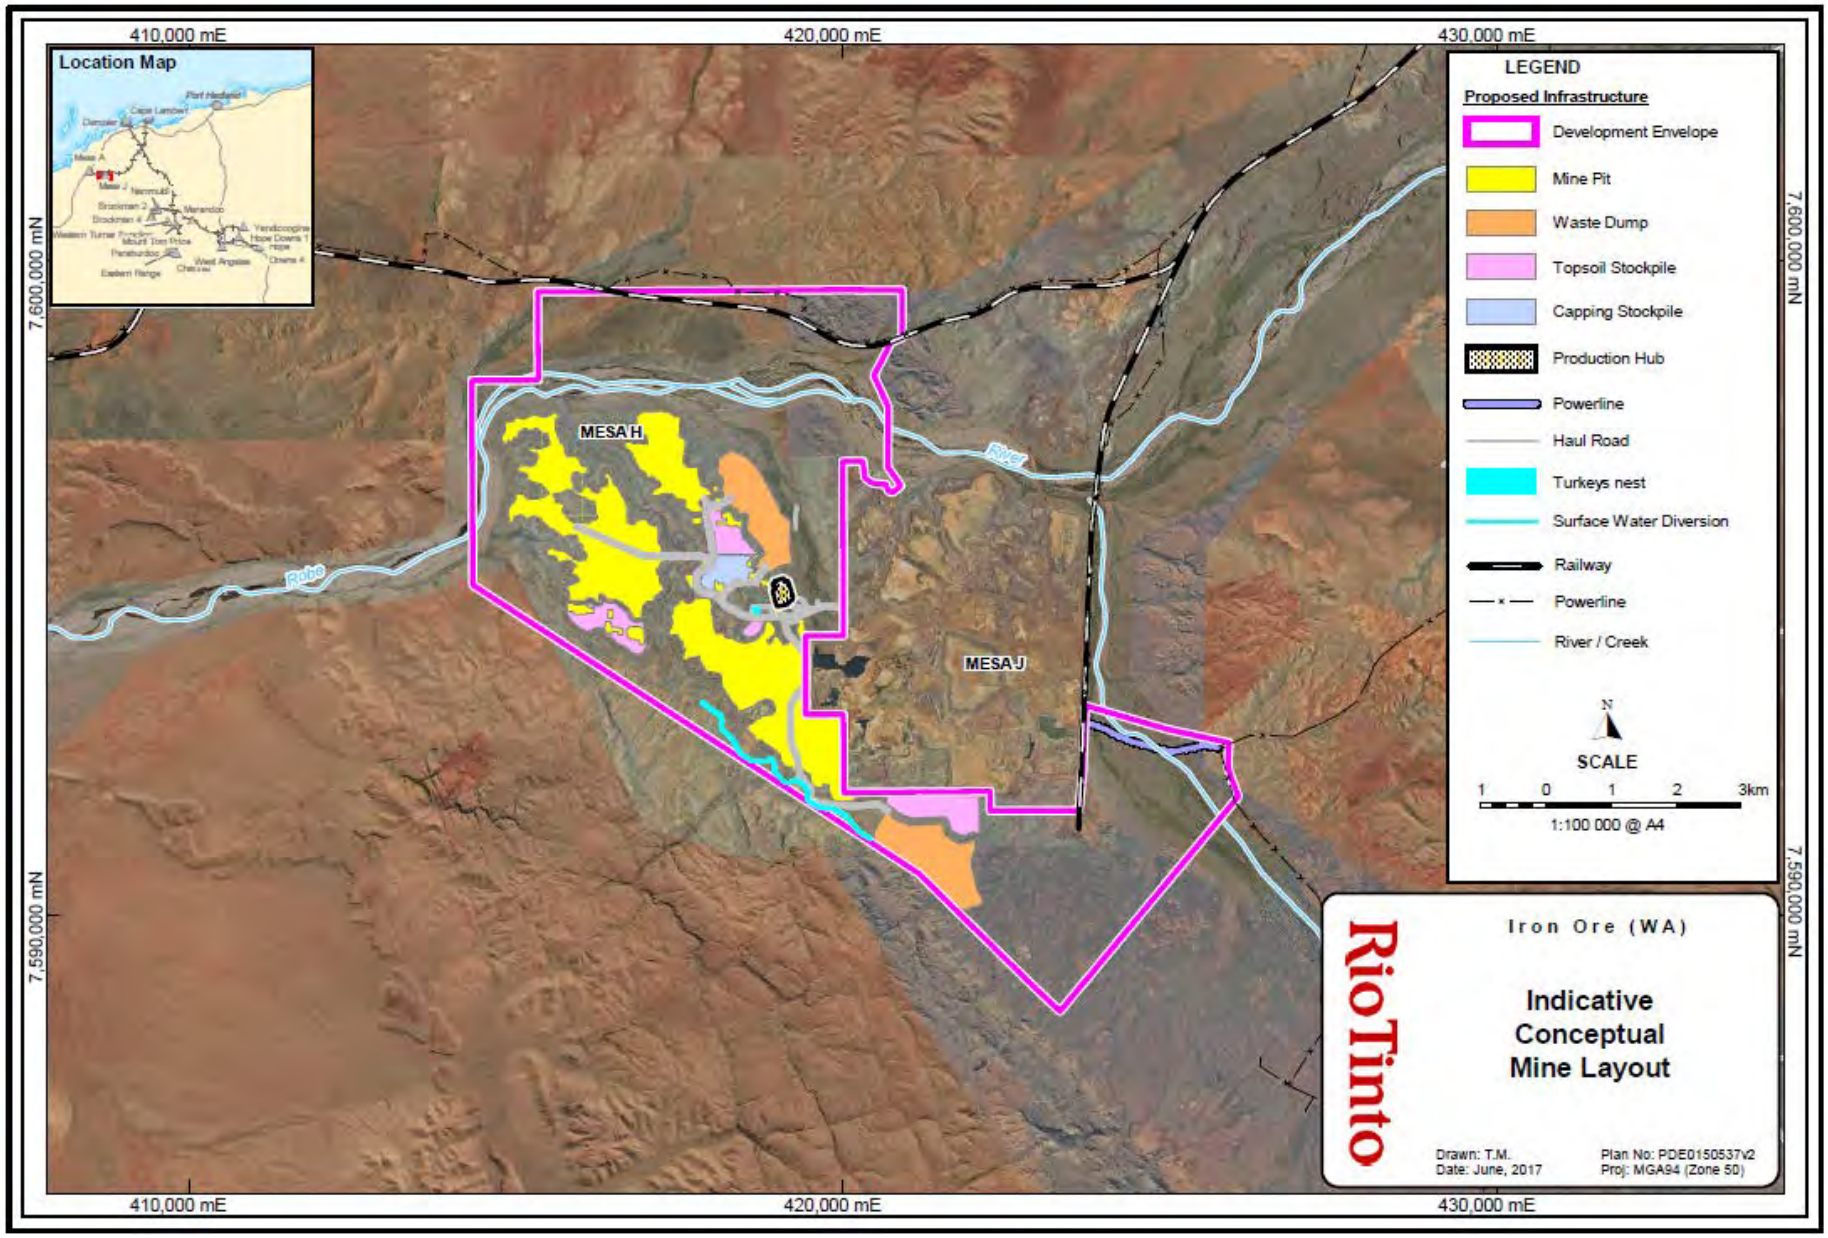

Figure 3-1: Indicative Conceptual Mine Layout

3.2 Proposal Description

3.2.1 Mining

The Mesa H deposit is a continuation of the Robe Pisolite iron ore deposit present at Mesa J, known more generally as a Channel Iron Deposit (CID).

The Proposal includes development of new open cut mine pits at Mesa H with approximately 20% of ore proposed for mining occurring BWT.

Ore will be mined using open cut mining methods comprising conventional drill, blast, load and haul as currently used in the adjacent Mesa J operations.

3.2.2 Exclusions

Exclusions from the scope of the Proposal comprise the following:

- Activities and additional infrastructure at the Mesa J operation approved under MS 208.
- Low impact activities within the Development Envelope prior to Part IV approval of the Proposal (to be subject to relevant provisions under Part V [Land Clearing] of the EP Act), including drilling and associated activities (such as upgrades to existing roads/tracks) for the purposes of resource evaluation, geotechnical assessment and hydrogeological investigation.
- Establishment of a construction camp to support the construction phase of the Proposal (to be subject to relevant provisions under Part V [Land Clearing and Works Approvals/Licensing] of the EP Act).
- Establishment of temporary services (communications, water supply, power), temporary concrete batch plant, site offices, access roads, laydown areas, and borrow pits to support establishment of a construction camp (to be subject to relevant provisions under Part V [Land Clearing and Works Approval/Licensing] of the EP Act).
- Facility upgrades in Pannawonica to support the expanded workforce.
- Power network upgrades at Pannawonica, and a 9 km section of overhead power line between the Pannawonica switchyard and the Mesa A/J tee-off (to be subject to relevant provisions under Part V [Land Clearing and Works Approval/Licensing] of the EP Act).

3.2.3 Ore handling and transport

Haul roads will be developed to enable haulage of ore from the Proposal to the Mesa J operation for dry and wet processing. Ore will then be transported to the ports via the existing Mesa J rail line.

3.2.4 Mineral waste

The Proposal mine plan has incorporated a pit sequence that enables progressive in-pit backfill of the majority of waste, using both the Proposal and the adjacent Mesa J pits. Where pit sequencing and scheduling do not allow waste to be used for backfilling, out-of-pit waste dumps will be utilised. Currently, two locations have been identified for out-of-pit waste dumps that minimise direct impact to significant environmental and heritage areas. Out-of-pit storage for competent material, low grade ore, sub-soil and topsoil will also be required.

Wet processing of low grade ore from the Proposal will generate waste fines. The mine plan will incorporate the use of pits within the Development Envelope and at the Mesa J operation for in-pit waste fines storage facilities (WFSF) over the life of the Proposal.

3.2.5 Surface water management

Surface water management will be required for the watercourses draining local catchments from the Buckland Hills south of the Proposal which intersect the southern pits. A drainage diversion is required during operations south of the southern pits, directing flow to the watercourse between the northwest and southern pits, and subsequently into the Robe River. The diversion will not be maintained post closure.

3.2.6 Pit dewatering

Approximately 20% of the ore proposed for mining at Mesa H is below the current water table. Dewatering to access the BWT ore is therefore required at an average rate of 3 GL/a and peak rate of 10 GL/a. Dewatering is currently expected to commence in approximately 2025 and will be via sump pumping, powered by diesel generators. Groundwater abstracted for dewatering purposes will contribute to meeting operational demands for the Proposal and Mesa J operation, primarily wet processing, however the timing for BWT pit dewatering and average dewatering rate will not be sufficient to meet these processing demands, hence an additional water supply will be required for the Proposal as detailed in Section 3.2.7.

3.2.7 Water supply and surplus water discharge

Water is required for the Proposal to enable:

- construction activities;
- general mining activities;
- dust suppression on haul roads; and
- potable water supply.

Mine pit dewatering for the Proposal of an average of 3 GL/a (peak up to 10 GL/a) will not be sufficient to meet operational demands, requiring continued operation of the existing Mesa J water supply borefield (Southern Cutback borefield) located immediately to the south of the Mesa J operations. The total abstraction from this water supply borefield (to include the requirements for this Proposal) is not expected to require an increase to the current abstraction licence limit.

The site water demand for the Proposal and continuation of the Mesa J operation is estimated to be approximately 11 GL/a, which is similar to the existing Mesa J water demand.

Based on water balance estimates, and depending on fluctuations in site water usage requirements and seasonal fluctuations, limited surplus water is expected to be generated from mine pit dewatering. After large rainfall events however, significant ponding would result in a requirement to discharge. In these circumstances, and combined with temporal variability in mine water use, up to a peak of 10 GL/a may be required to be discharged.

Any surplus water discharge will be predominantly via the existing Mesa J operation discharge points, in Jimmawurruda Creek east of Mesa J or West Creek, between the Proposal and the Mesa J operation. Additional discharge points may be established if required, pending further hydrological studies to support options to manage the identified values of the Robe River ecosystem.

3.2.8 Mine support facilities and infrastructure

Additional power supply to the Mesa J operation is required as part of the Proposal, comprising a powerline of approximately 2.5 km in length from the existing Coastal Water Supply powerline to Mesa J (Figure 3-1).

A production hub will be established at the Proposal comprising: truck park up; laydown; offices; ablutions; waste water treatment plant; and other facilities as required to support the operation. A power line will connect the production hub to the Mesa J power network.

A turkey's nest will be established near the production hub to provide water for dust suppression.

Communications systems will be extended to the Proposal including installation of fibre optic cables.

The Proposal will utilise the existing Mesa J rail infrastructure.

3.2.9 Workforce

The Proposal will be operated as an extension to the existing Mesa J operation and will require an increase in the operational workforce. The workforce will continue as mixed residential / FIFO workforce, housed in existing accommodation in Pannawonica. Some facilities in Pannawonica will be upgraded and expanded (not part of this Proposal).

The construction workforce is proposed to be accommodated in a 'dry hire' mobile construction camp north of the Proposal (not part of this proposal).

3.2.10 Timing

Under the current project schedule, construction activities are planned to commence in Quarter 4 2018 once all required internal and external approvals are granted.

4. ENVIRONMENTAL STUDIES

Environmental baseline studies and compliance monitoring have been completed in the vicinity of the Development Envelope as described in Table 4-1.

Table 4-1: Environmental studies completed in the vicinity of the Development Envelope

Study	Description
Flora and vegetation	
Biota Environmental Sciences (2011). *Baseline Flora and Vegetation Assessment of Robe Valley Mesas (Mesas B, C, D, E, F, H and I)*. Unpublished report prepared for Rio Tinto Iron Ore, April 2011.	Survey conducted in October 2010 documenting flora, vegetation units and conservation listed flora in the Development Envelope.
Astron (2016*). Mesa H Level 2 Vegetation and Flora Assessment.* Unpublished report prepared for Rio Tinto Iron Ore, May 2016.	Surveys conducted in September / October 2014 and May and July 2015 documenting vegetation units and conservation listed flora in the Development Envelope.
Astron (2016*). Mesa H Riparian Vegetation Baseline Monitoring.* Unpublished report prepared for Rio Tinto Iron Ore, June 2016.	Monitoring transects established across riverine vegetation in the Robe River in May-June 2016.
Astron (2016) *Mesa H Riparian Community Assessment*. Unpublished report prepared for Rio Tinto Iron Ore, June 2016.	Level 2 vegetation and flora assessment of the Robe River riparian community, and a Level 1 fauna assessment desktop assessment, including database searches and literature review of available resources, vegetation and flora assessment, fauna and fauna habitat assessment and baseline aquatic assessment.
Rio Tinto (2017). *Assessment of Groundwater Dependent Vegetation distribution on the Robe River - Targeted Riparian Vegetation Survey.* Unpublished report prepared by Rio Tinto Iron Ore, May 2017.	Detailed survey and spatial mapping of the distribution of Robe River Groundwater Dependent Vegetation (GDV). Interpretation of the significance and sensitivity of these communities to potential hydrological change – providing an interpreted risk map throughout the Development Envelope and immediate surrounds.
Other	
Various targeted surveys associated with Rio Tinto exploration and pastoral activities.	Flora/vegetation and fauna surveys conducted in localised areas subject to Native Vegetation Clearing Permit applications.
Terrestrial fauna	
Streamtec (1991 - 2016). Aquatic Ecosystems Study (annual monitoring).	Annual aquatic ecosystems monitoring survey to assess potential environmental impacts of the Mesa J Operation on the adjacent and downstream aquatic ecosystem. The survey is an integrated assessment of biological parameters including aquatic fauna (macroinvertebrates and fish), channel/pool morphology, riparian vegetation condition and water quality.

Study	Description
Biota Environmental Sciences (2011). *Robe Valley Mesas Fauna Report*. Unpublished report prepared for Rio Tinto Iron Ore, March 2011.	Survey conducted in October 2010 documenting terrestrial fauna, fauna habitats, species of conservation significance and habitats that may require specific management.
Astron (2015). *Level 2 Terrestrial Fauna Surveys: Mesa H*. Unpublished report prepared for Rio Tinto Iron Ore, November 2015.	Surveys conducted in May and September 2015 documenting terrestrial fauna, fauna habitats, species of conservation significance and habitats that may require specific management.
Astron (2016). *Mesa H Ghost Bat, Macroderma gigas – Contextual Study*. Unpublished report prepared for Rio Tinto Iron Ore, June 2016.	Contextual analysis for the conservation significant Ghost Bat (*Macroderma gigas*) within the vicinity of the Mesa H Development Envelope, including desktop review and field survey involving mapping of potential habitat and targeted survey for the Ghost Bat.
WRM (2017) Mesa H Project: Baseline Aquatic Ecosystem Survey. Wet Season Sampling 2016. Unpublished report prepared for Rio Tinto Iron Ore, April 2017.	Baseline wet season sampling program undertaken to document the current ecological condition of the Robe River for aquatic ecosystems, with a focus on permanent and semi-permanent pools and sampling of sites upstream and downstream of Mesa H.
Bat Call WA (2017). *Robe Valley Mesa H Ghost Bat roost cave assessment.* Unpublished report prepared for Rio Tinto, April 2017.	Extensive search for Ghost Bat presence at Mesa H conducted in April 2017, including assessment of the conservation value of caves associated with the presence of Ghost Bats.
Bat Call WA (2017). *Robe Valley Mesa A to Mesa 2405A, assessment of mining on Ghost Bat presence and activity.* Unpublished report prepared for Rio Tinto, April 2017.	Assessment of impact of mining on Ghost Bat viability in the broader Robe valley including a desktop and field review of historical mined areas, current mining operations and proposed mining developments.
Subterranean fauna	
Biota Environmental Sciences (2006). Mesa A and Robe Valley Mesas Troglobitic Fauna Survey. Unpublished report prepared for Robe River Iron Associates, March 2006).	Surveys conducted November 2004 to January 2005, April to May 2005, July to September 2005 documenting subterranean fauna and assessing subterranean fauna habitat.
Biota Environmental Sciences (2017). *Mesa H Subterranean Fauna Assessment.* Unpublished report prepared for Rio Tinto.	Surveys conducted June to August 2015 and August to October 2015 documenting subterranean fauna and assessing subterranean fauna habitat.
Hydrological Processes and Inland Waters Environmental Quality	
Rio Tinto (2016) *Mesa H Chemistry and Isotopes.* Unpublished report prepared by Rio Tinto Iron Ore, 2016.	Groundwater and surface water chemical and isotope analysis aiming to assess groundwater dependency of the Robe River pools.
Rio Tinto (2016) *Mesa H Chemistry and Isotopes.* Unpublished report prepared by Rio Tinto Iron Ore, 2016.	Groundwater and surface water chemical and isotope analysis aiming to assess groundwater dependency of the Robe River pools.
Rio Tinto (2016). *Mesa H 2016 Pre-Feasibility Study Hydrogeological Drilling Program Completion Report.* Unpublished report prepared by Rio Tinto Iron Ore, 2016.	Report detailing drilling and installation of 19 monitoring bores and 4 water bores, and test pumping of all completed water bores.
Rio Tinto (2016). *Mesa H Hydrogeological Conceptual Model Report.* Unpublished report prepared by Rio Tinto Iron Ore, 2016.	Mesa H hydrogeological conceptual model report to support the development of the groundwater numerical model.

Study	Description
Rio Tinto (2016). *Mesa H Dewatering, Water Supply and Impact Assessments*. Unpublished report prepared by Rio Tinto Iron Ore, 2016.	Groundwater numerical model to support the Mesa H Proposal assessing dewatering requirements, water supply strategy and impact prediction.
Rio Tinto (2016). *AMD Risk Assessment Summary for the Robe Valley.* Unpublished report prepared by Rio Tinto Iron Ore, 2016.	A review of the AMD risk assessment for the Robe Valley including Mesa H.
Rio Tinto (2016). *Mesa H Order of Magnitude Design Flood Estimation and Floodplain Mapping.* Unpublished report prepared by Rio Tinto Iron Ore, Feb 2016.	Investigation to provide design flood estimates and floodplain mapping for the Mesa H deposit to inform the development of surface water management options.
Rio Tinto (2017). *Mesa H PFS Surface Water Management.* Unpublished report prepared by Rio Tinto Iron Ore, March 2017.	Study describing the interaction between natural surface water runoff, the local environment and the Mesa H study area and proposed water management measures.
Rio Tinto (2017). *Surplus water discharge extent assessment: Mesa H*. Unpublished report prepared by Rio Tinto Iron Ore, March 2017.	Study was to estimate the extent of impact of surplus water discharge along the proposed watercourses based on discharge location options.
Rio Tinto (2017) Mesa H H3 Hydrogeological Level Assessment. Unpublished report prepared by Rio Tinto Iron Ore, 2017.	Report detailing the Mesa H and J hydrogeological conceptualisation, numerical model predictions, aquifer impact assessment, monitoring program and proposed GW management.

Environmental studies that are still in progress relevant to the Proposal are described in Table 4-2.

Table 4-2: Environmental studies in progress relevant to this Proposal

Study	Description
Flora and vegetation	
Astron.	Baseline Monitoring – Phase II (Monitoring transects established across riverine vegetation in the Robe River).
Rio Tinto (in prep).	Assessment of Groundwater Dependent Vegetation distribution on the Robe River - Targeted Riparian Vegetation Survey.
Subterranean fauna	
Biota Environmental Sciences (in prep).	Surveys conducted June to August 2015, August to October 2015 and January to March 2016 documenting subterranean fauna and assessing subterranean fauna habitat.
Aquatic fauna	
Streamtec Aquatic Ecosystems Study	Ongoing annual aquatic fauna monitoring as part of existing Mesa J Operations.
WRM.	Baseline Aquatic Fauna Monitoring – Phase II.
Visual impact assessment	
Rio Tinto (in prep).	Visual impact assessment considering vantage points along Pannawonica Road, the Robe River and sites of heritage significance.

5. ASSESSMENT OF PRELIMNARY KEY ENVIRONMENTAL FACTORS

The environmental factors and objectives adopted by the Environmental Protection Authority (EPA) are listed in the EPA's Statement of Environmental Principles, Factors and Objectives (EPA 2016). The Proponent has identified the following preliminary key environmental factors that are relevant to the Proposal:

- Flora and Vegetation
- Terrestrial Fauna
- Subterranean Fauna
- Hydrological Processes
- Inland Waters Environmental Quality
- Social Surroundings

The above factors are discussed in sections 5.1 to 5.5. The Proponent considers that the remaining environmental factors identified in (EPA 2016) are either not relevant to the Proposal or will not result in a significant impact (refer to Section 6).

5.1 Flora and Vegetation

5.1.1 EPA objective

The EPA objective for Flora and Vegetation is *to protect flora and vegetation so that biological diversity and ecological integrity are maintained.*

5.1.2 Potential environmental impact

Consideration of the potential impacts relevant to Flora and Vegetation is captured in Table 5-1.

Table 5-1: Consideration of potential environmental impacts – Flora and Vegetation

Potential environmental impacts	
EPA policy and guidance - What have you considered and how have you applied them in relation to this factor?	The following EPA guidelines and technical guidance have been considered for the proposal in relation to Flora and Vegetation in order to meet the EPA's objectives as outlined above: EPA Statement of Environmental Principles, Factors and Objectives (2016). • EPA Environmental Factor guideline (Land): *Environmental Factor Guideline – Flora and Vegetation* (2016). • EPA Technical Guidance (Land): *Flora and Vegetation Surveys for Environmental Impact Assessment* (2016). Flora and vegetation surveys have been, and will continue to be, undertaken consistent with The EPA's technical guidance for this factor. Any survey limitations relative to the technical guidance will be noted in the flora and vegetation survey report. The Proposal and supporting studies focus on presenting the current state of knowledge, and defines significant flora and vegetation communities within the Development Envelope and the immediate surrounding region. The Proposal has been designed such that activities and pathways which may have the potential to impact on priority flora or locally significant vegetation communities have been avoided or minimised where possible via the application of the mitigation hierarchy. Any survey limitations relative to the guidance will be noted in the flora and vegetation survey report.
Consultation – Outline the outcomes of consultation in relation to the potential environmental impacts	**Office of the Environmental Protection Authority (OEPA)** A summary of the Mesa H Proposal was provided pre-referral. • Proponent to complete studies and prepare referral documentation. • DMA consult to be undertaken with key agencies.
	Department of Parks and Wildlife (Parks and Wildlife) An outline of the scope of the Mesa H proposal was provided, including the status of surveys and an overview of survey results. • Proponent should seek confirmation from Parks and Wildlife whether the vegetation community that is analogous to the Triodia sp. Robe River PEC is actually the PEC or is possibly a new / subset of the PEC. • If the community is a PEC then further surveys may be required to define the community more rigorously.
	Department of Water (DoW) Refer to consultation notes summarised in Section 5-4.

Potential environmental impacts	
Receiving environment - Describe the current condition of the receiving environment in relation to this factor.	Numerous Flora and Vegetation surveys have been undertaken across the Development Envelope and surrounds. During the more recent two phase seasonal survey effort (2015-2016) across the Development Envelope, 38 vegetation associations were described, none of which represent a TEC. All but three vegetation associations recorded are well represented beyond the Development Envelope and do not support assemblages of species that are unique, on restricted landforms, or of high conservation significance. • One vegetation association is considered to represent the Priority 3 Priority Ecological Community (PEC) '*Triodia sp. Robe River assemblages of mesas of the West Pilbara'*. Vegetation representing this PEC accounted for 14.6 ha within the Development Envelope. • One vegetation association (ChAsppGOrGsppPlSsTeTw) contained all three of the recorded Priority flora species. This vegetation was associated with drainage lines comprising approximately 135 hectares (3%) of the Development Envelope. Similar vegetation has been recorded from other regional surveys. • The riparian vegetation association containing MaEcCv, represents approximately 174 hectares (3%) of the Development Envelope, and is considered a groundwater dependent ecosystem as it is characterised by the obligate phreatophyte *Melaleuca argentea*. MaEcCv was mapped on the fringes of permanent and semi-permanent water pools both in and outside the Development Envelope and the main flow channels of the Robe River, and as such supported a number of species that were unique to this habitat. Approximately 60% of the Priority 4 species *Rhynchosia bungarensis* P4 occurred in MaEcCv in the Development Envelope. The families and genera recorded in the Riverine and Drainage lines are typical of what would be expected in riparian vegetation of major drainage lines in the Pilbara. No Threatened taxa were recorded. There were 23 weed species recorded within the riparian habitats. None of the weed species recorded is listed as a declared pest for the Shire of Ashburton or a Weed of National Significance. Vegetation condition ranged from 'very poor' to 'excellent' with approximately 67% of the Development Envelope classified as being in 'excellent' condition. The area is also subject to a history of pastoral activity with cattle grazing evident on the plains, floodplains and drainage lines. There were 310 vascular flora species from 53 families and 150 genera recorded in the Development Envelope. The most represented families were Fabaceae, Poaceae and Malvaceae. No Threatened flora were recorded during the survey or are expected to occur. Three State-listed Priority flora were identified: *Indigofera* sp. Bungaroo Creek (S. van Leeuwen 4301) P3, *Triodia* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 and *Rhynchosia bungarensis* P4.
Proposal activities – Describe the proposal activities that have the potential to impact the environment.	The following aspects of the Proposal may affect flora and vegetation values: • Clearing of vegetation in mining and infrastructure development areas including vegetation communities of local significance and Priority Flora species. • Mining and ore transportation may increase dust emissions causing localised stress of adjacent vegetation. • Vehicle and earth movements may result in spread of existing weeds and/or introduction of new weeds. • Groundwater abstraction, surplus water discharge, and surface water diversions could potentially impact environmental values, including flora and vegetation, as discussed in section 5.4.

Potential environmental impacts	
Mitigation - Describe the measures proposed to manage and mitigate the potential environmental impacts.	Strategies to minimise the impacts to vegetation include: • Minimising the disturbance footprint during the study and mine planning phase. • Preferentially avoiding flora and vegetation of elevated conservation significance. • The mesa escarpment at Mesa H will be retained, through establishment of a Mining Exclusion Zone (MEZ). The majority of the '*Triodia sp. Robe River assemblages of mesas of the West Pilbara'*, occur along the margins of the Mesa escarpment, and will be protected from direct disturbance by the MEZ. • Minimal direct disturbance to the Robe River riparian vegetation which comprises the important Riverine habitat vegetation associations (ChAsppGOrGsppPlSsTeTw - containing all three of the recorded Priority flora species and MaEcCv). • The proposed development is located outside the 1% AEP (Annual Exceedance Probability) floodplain of the adjacent Robe River. • Conducting flora and vegetation surveys in all parts of the Development Envelope. • Detailed mapping of riparian vegetation and assessment of risk related to groundwater dependency to support water monitoring and water management approach. • Monitoring riparian vegetation along the Robe River for the duration of abstraction, discharge, and as required post closure during water table recovery. • Development of a monitoring and management plan, with trigger and threshold levels and actions, to ensure no significant detrimental impact to the identified environmental values of the Robe River ecosystem due to groundwater abstraction and discharge. This plan will consider precautionary mitigation options for groundwater drawdown, such as supplementary water supply to the Robe River ecosystem via controlled discharge. • Implementing vehicle hygiene procedures to prevent the introduction and spread of weeds. • Mapping and controlling weed species as necessary to protect conservation values. • Undertaking progressive rehabilitation where practicable.
Impacts - Assess the impacts of the proposal and review the residual impacts against the EPA objective.	The Proposal is expected to result in the progressive clearing of up to 2,200 ha of native vegetation. The Proposal is not expected to alter the conservation status or viability of any Priority Flora species or have a significant effect on the representation of vegetation at a local or regional level. No TECs, Environmentally Sensitive Areas or Declared Rare Flora will be affected by the Proposal as none have been recorded in the Development Envelope. Vegetation units of high local significance, associated with drainage lines (riparian habitat containing phreatophytic vegetation), are present along the Robe River. Dewatering at Mesa H may result in temporary, seasonal stress, particularly to the vegetation units containing obligate phreatophytic vegetation (e.g. *Melaleuca Argentea*) within the extent of drawdown. However, groundwater abstraction and surplus water discharge as a result of the Proposal are considered unlikely to have significant impacts on the identified environmental values of the Robe River and Jimmawurrada Creek ecosystems (including riparian vegetation), as discussed in section 5.4. The Proponent considers that the Proposal is likely to meet the EPA objective for Flora and Vegetation.

Potential environmental impacts	
Assumptions - Describe any assumptions critical to your assessment *e.g. particular mitigation measures or regulatory conditions.*	Key assumptions are related to the extent of information collected and degree of seasonal variability naturally experienced in an arid environment. The assessment of sensitivity of the riparian vegetation species to changes to water availability is based on scientific publications and responses recorded at other Rio Tinto mine sites. These assumptions are detailed in the supporting vegetation and flora studies. Assumptions regarding hydrogeological modelling, that informs assessment of the potential impacts of groundwater drawdown on the Robe River ecosystem are detailed in section 5.4. Surveys and studies have been undertaken by specialist consultants to ensure an appropriate level of independent rigour and ensure that EPA guidance, methodologies and industry standards have been adopted.

5.2 Terrestrial Fauna

5.2.1 EPA objective

The EPA objective for Terrestrial Fauna is *to protect terrestrial fauna so that biological diversity and ecological integrity are maintained.*

5.2.2 Potential environmental impact

Consideration of the potential impacts relevant to Terrestrial Fauna is captured in Table 5-2.

Table 5-2: Consideration of potential environmental impacts – Terrestrial Fauna

Potential environmental impacts	
EPA policy and guidance - What have you considered and how have you applied them in relation to this factor?	The following EPA guidelines and technical guidance have been considered for the proposal in relation to Terrestrial fauna in order to meet the EPA's objective as outlined above: • EPA Statement of Environmental Principles, Factors and Objectives (2016). • EPA Environmental Factor guideline (Land): *Environmental Factor Guideline – Terrestrial Fauna* (2016). • EPA Technical Guidance (Land): *Terrestrial Fauna Surveys* (2016). • EPA Technical Guidance (Land): *Sampling methods for terrestrial vertebrate fauna* (2016). • EPA Technical Guidance (Land): *Sampling of Short Range Endemic invertebrate fauna* (2016). Terrestrial Fauna surveys (including sampling for Short range endemic fauna) have been, and will continue to be, undertaken consistent with the EPA's technical guidance for this factor. Any survey limitations relative to the technical guidance will be noted in the terrestrial fauna survey report. The Proposal and supporting studies focus on presenting the current state of knowledge, defines significant terrestrial fauna species within the Development Envelope and surrounds. The Proposal has been designed such that activities which may have the potential to impact on significant fauna have been avoided or minimised where possible via the application of the mitigation hierarchy. Any survey limitations relative to the guidance will be noted in the terrestrial fauna survey report.
Consultation – Outline the outcomes of consultation in relation to the potential environmental impacts	**OEPA** A summary of the Mesa H proposal was provided pre-referral. • Proponent to complete studies and prepare referral documentation. • DMA consult to be undertaken with key agencies.
	Parks and Wildlife An outline of the scope of the Mesa H Proposal was provided, including the status of surveys and an overview of survey results. • Parks and Wildlife indicated that additional Ghost Bat work would be prudent to undertake (as planned) given the recent EPBC listing. Requested further information regarding the Pilbara Leaf-nose Bat roost location estimated 10km to the south (if this was the known 'super-roost') and habitat usage in the Robe River.

Potential environmental impacts	
Receiving environment - Describe the current condition of the receiving environment in relation to this factor.	**Vertebrate Fauna** Seven broad fauna habitat types were recorded in the Development Envelope: Riverine; Drainage Line; Gorge; Breakaway; Rocky Hills; Low Hills and Slopes; and Loamy/Stony Plain. The Gorge, Riverine and Breakaway habitats in the Development Envelope are considered important for fauna due to the microhabitats they provide such as caves and water pools; the Gorges and Breakaway habitats represent an important site of refuge due to their location close to the Robe River and as habitat for conservation listed fauna. There were 169 vertebrate fauna species recorded within the Development Envelope, including two amphibian species, 55 reptile species, 85 bird species and 27 mammal species (including four introduced species). The faunal assemblage recorded is considered typical of the Hamersley Range subregion extending from near Pannawonica to Mt Brockman. Eight conservation listed fauna species have been recorded in the Development Envelope: Pilbara Olive Python (VU; S3) (*Liasis olivaceus barroni*); Northern Quoll (EN; S2) (*Dasyurus hallucatus*); Pilbara Leaf-nosed Bat (VU; S3) (*Rhinonicteris aurantia*); Ghost Bat (VU; S3) (*Macroderma gigas*); Rainbow Bee-eater (Mi; S5) (*Merops ornatus*); Eastern Great Egret (Mi; S5) (*Ardea modesta*); Lined Soil-crevice Skink (P4) (*Notoscincus butleri*); and Western Pebble-mound Mouse (P4) (*Pseudomys chapmani*). Four of the eight recorded conservation listed species are classified under the *Environment Protection and Biodiversity Act* 1999 (EPBC Act) as Matters of National Environmental Significance (MNES) species: the Pilbara Olive Python; Northern Quoll; Ghost Bat; and Pilbara Leaf-nosed Bat. • A single juvenile Pilbara Olive Python and two Pilbara Olive Python scats were recorded within the Riverine and the Breakaway habitat type within the Development Envelope. • The Northern Quoll was recorded 27 separate times comprising: six capture records; 19 remote camera location records; and from two scats within the Breakaway, Riverine and Gorge habitat types in and immediately outside the Development Envelope. • The Ghost Bat was recorded twice through scat collections and acoustic recordings. Eleven caves were identified within the Development Envelope during the surveys during detailed assessments undertaken by Bat Call WA (2017), including two potential diurnal roost caves and nine nocturnal roost shelters based on their size, complexity and the presence of Ghost Bats and /or scats. The two diurnal caves were assessed as being maternity cave candidates although no evidence of intensive Ghost Bat use for this purpose was found during the survey. • The Pilbara Leaf-nosed Bat was recorded at eight of the 14 SM2 bat detector locations, all at low activity levels apart from one location (BAT 14) located outside the Development Envelope which recorded 257 calls. Further data and analysis of the BAT 14 sites confirmed that the Pilbara Leaf-nosed Bats originated from a known roost site approximately 10 kms south of the Development Envelope. Table 5-3 provides a summary of conservation listed species recorded or likely to be recorded in the Development Envelope.

Potential environmental impacts	
	Short Range Endemic Invertebrate Fauna The Loamy/Stony Plains habitat supported some Short Range Endemic (SRE) species however this habitat type is widespread in the Development Envelope and is considered unlikely to restrict dispersal in SRE fauna. The Breakaway, Gorge and Riverine habitats (most suited to SRE species), did not support rich SRE communities. Consequently, prospective SRE habitats within the Development Envelope are not considered restricted at the local, sub-regional or regional scale. A total of 36 specimens belonging to at least 14 invertebrate morphospecies were collected from the Development Envelope. Scorpions were the most diverse group with seven species and 12 specimens, followed by slaters (three species; 16 specimens), pseudoscorpions (two species; four specimens) and spiders (two species; four specimens). No centipedes, harvestmen, millipedes or snail specimens (aquatic or terrestrial) were collected during the current survey. No listed invertebrate species were collected during the survey. Nine of the species (64%) were not considered to be, or are unlikely to be, SRE's. No confirmed SRE species were collected; however, five species (36%) were classified as potential SRE species, primarily in the scorpion (three species), spider (two species) and slater (one species) faunas.
Proposal activities – Describe the proposal activities that have the potential to impact the environment	The following aspects of the Proposal may affect terrestrial fauna values: • Clearing of vegetation in mining and infrastructure development areas will directly disturb fauna habitat and may result in the loss of individuals. • Vibration from mining operations may damage the integrity of Ghost Bat roosts on Mesa H. • Noise and dust from mining and ore transportation may disturb Ghost Bat roosts. • Vehicle movements may result in the loss of individuals. • Groundwater abstraction, surplus water discharge, and surface water diversions could potentially impact environmental values, including fauna habitat, as discussed in section 5.4.
Mitigation - Describe the measures proposed to manage and mitigate the potential environmental impacts.	Strategies to minimise the impacts to terrestrial fauna include: • Minimising the disturbance footprint during the mine planning phase. • The mesa escarpment at Mesa H will be retained, through establishment of a MEZ. The majority of the important Gorge and Breakaway Habitats, and all of the Ghost Bat roosts, occur in the Mesa escarpment, and will be protected from direct disturbance by retention of the MEZ. • Similarly, the Northern Quoll and Pilbara Olive Python habitats (Gorge, Breakaway and Riverine) will be protected by retention of the MEZ and limited disturbance to the creekline. • Minimal direct disturbance to the Robe River riparian vegetation which comprises the important Riverine habitat. • Maintaining appropriate speed limits for vehicles.

Potential environmental impacts	
Impacts - Assess the impacts of the proposal and review the residual impacts against the EPA objective.	The Proposal is expected to result in the progressive clearing of up to 2,200 ha of native vegetation (incorporating fauna habitat). It is recognised that the escarpments of Mesa H adjacent to the Robe River are some of the most significant habitat features in the Development Envelope for both vertebrates and SREs. The mesa escarpment adjacent to the Robe River will be retained through establishment of a MEZ, ensuring that these habitats continue to be available to a range of fauna. Note that Mesa landform only occurs in the northern area of the deposit. Refer to Section 6. Semi-permanent and permanent pools and riparian vegetation of the Robe River adjacent to Mesa H are considered significant habitat features. Groundwater abstraction and surplus water discharge as a result of the Proposal are considered unlikely to have significant impacts on the identified environmental values of the Robe River and Jimmawurrada Creek ecosystems (including terrestrial fauna habitat), as discussed in section 5.4. The area of potential impact is a small proportion of the total terrestrial fauna habitat on these creekline ecosystems. Based on the above considerations, it is unlikely that the Proposal will significantly affect the regional distribution of terrestrial fauna habitat or the conservation status of any fauna species. The Proponent considers that the Proposal is likely to meet the EPA objective for Terrestrial Fauna.
Assumptions - Describe any assumptions critical to your assessment *e.g. particular mitigation measures or regulatory conditions.*	Key assumptions are related to the extent of information collected and seasonal variability – these assumptions are detailed in the supporting terrestrial fauna studies. Assumptions regarding hydrogeological modelling, that informs assessment of the potential impacts of groundwater drawdown on the Robe River ecosystem are stated in section 5.4. These surveys and studies have been undertaken by specialist consultants to ensure an appropriate level of independent rigour and ensure that EPA guidance, methodologies and industry standards have been adopted. Where significant uncertainty exists, a ‘worst case scenario’ will presented in the impact assessment and options of mitigation will be considered.

Table 5-3: Conservation listed species recorded or likely to be recorded in the Development Envelope

Common name	Scientific name	Conservation status		Likelihood of occurrence
		WC Act	EPBC Act	
Northern Quoll	*Dasyurus hallucatus*	S 2	Endangered	Confirmed
Pilbara Leaf-nosed Bat	*Rhinonicteris aurantia* (Pilbara form)	S 3	Vulnerable	Confirmed
Pilbara Olive Python	*Liasis olivaceus barroni*	S 3	Vulnerable	Confirmed
Ghost Bat	*Macroderma gigas*	S 3	Vulnerable	Confirmed
Western Pebble-mound Mouse	*Pseudomys chapmani*	P 4	-	Confirmed
Lined Soil-crevice Skink	*Notoscincus butleri*	P 4	-	Confirmed
Rainbow Bee-eater	*Merops ornatus*	S 5	Migratory	Confirmed
Eastern Great Egret	*Ardea modesta*	S 5	Migratory	Confirmed
Blindsnake	*Anilios ganei*	P 1	-	High
Cattle Egret	*Ardea ibis*	S 5	Migratory	Moderate
Fork-tailed Swift	*Apus pacificus*	S 5	Migratory	Moderate
Letter-winged Kite	*Elanus scriptus*	P 4	-	Moderate
Australian Painted Snipe	*Rostratula benghalensis (sensu lato)*	S 5	Endangered	Moderate
Common Sandpiper	*Actitis hypoleucos*	S 5	Migratory	Moderate
Sharp-tailed Sandpiper	*Calidris acuminata*	S 5	Migratory	Moderate
Wood Sandpiper	*Tringa glareola*	S 5	Migratory	Moderate
Common Greenshank	*Tringa nebularia*	S 5	Migratory	Moderate
Oriental Pratincole	*Glareola maldivarum*	S 5	Migratory	Moderate
Long-tailed Dunnart	*Sminthopis longicaudata*	P 4	-	Moderate
Short-tailed Mouse, Karekanga	*Leggadina lakedownensis*	P 4	-	Moderate
Brush-tailed Mulgara	*Dasycercus blythi*	P 4	-	Moderate
Greater Bilby, Dalgyte	*Macrotis lagotis*	S 3	Vulnerable	Low
Northern Marsupial Mole	*Notoryctes caurinus*	-	Endangered	Low
Eastern Osprey	*Pandion cristatus*	S 5	Migratory	Low
Oriental Plover	*Charadrius veredus*	S 5	Migratory	Low
Greater Sand Plover	*Charadrius leschenaultii*	S 5	Migratory	Low
Whimbrel	*Numenius phaeopus*	S 5	Migratory	Low
Barn Swallow	*Hirundo rustica*	S 5	Migratory	Low

5.3 Subterranean Fauna

5.3.1 EPA objective

The EPA objective for subterranean fauna is *to protect subterranean fauna so that biological diversity and ecological integrity are maintained*.

5.3.2 Potential environmental impacts

Consideration of the potential impacts relevant to Terrestrial Fauna is captured in Table **5-4**

Table 5-4: Consideration of potential environmental impacts – Subterranean Fauna

Potential environmental impacts	
EPA policy and guidance - What have you considered and how have you applied them in relation to this factor?	The following EPA guidelines and technical guidance have been considered for the proposal in relation to Subterranean fauna in order to meet the EPA's objective as outlined above: • EPA Statement of Environmental Principles, Factors and Objectives (2016). • EPA Environmental Factor guideline (Land): *Environmental Factor Guideline – Subterranean Fauna* (2016). • EPA Technical Guidance (Land): *Sampling methods for subterranean fauna* (2016). • EPA Technical Guidance (Land): *Subterranean Fauna Survey* (2016). Subterranean fauna surveys are being undertaken consistent with the EPAs technical guidance for this factor. The design of the subterranean fauna surveys is consistent with the requirements of the EPA technical guidance as is the level of survey effort. Vouchering and lodgement of specimens is underway consistent with the guidance. The Proposal and supporting studies focus on presenting the current state of knowledge and defines subterranean species within the Development Envelope and surrounds. The Proposal has been designed to minimise impact to and maintain viable habitat for subterranean fauna via the application of the mitigation hierarchy. Any survey limitations relative to the technical guidance will be noted in the subterranean fauna survey report.
Consultation – Outline the outcomes of consultation in relation to the potential environmental impacts	**OEPA (Terrestrial Ecosystems Branch)** An outline of the scope of the Mesa H proposal was provided, including a summary of troglofauna sampling and results; conceptual proposed troglofauna habitat retention areas; and singleton avoidance areas. • Justification for the areas, volumes and widths selected as habitat retention zones in terms of suitability for troglofauna to be included in the EIA. • Clearly show which holes were sampled during each of the 6 phases of sampling including null results and which holes were resampled. • Data from troglofauna sampling at Mesa A and analysis of habitat aspects (downhole humidity and temperature data) would help to support approach to habitat retention.
	Parks and Wildlife An outline of the scope of the Mesa H Proposal was provided, including the status of surveys and an overview of survey results, and a discussion of the subterranean fauna PEC's. Parks and Wildlife suggested that there may be a need to context troglofauna habitat cumulatively between Mesas H and J.
	DMP An outline of the scope of the Mesa H Proposal for closure was provided. Clarification sought whether different or similar subterranean fauna species recorded on each mesa and whether contextual survey work for subterranean fauna and other fauna had been undertaken on remaining mesas. Contextual information to be provided in the EIA and considered in the closure plan.
	DoW Refer to consultation notes summarised in Section 5.4.

Potential environmental impacts	
Receiving environment - Describe the current condition of the receiving environment in relation to this factor.	Three Priority 1 PECs relevant to subterranean fauna are present in (or overlap with) the Development Envelope namely: • *Subterranean invertebrate communities of mesas in the Robe Valley region*; • *Subterranean invertebrate community of pisolitic hills in the Pilbara*; and • *Stygofaunal Community of the Bungaroo Aquifer.* **Troglofauna** Subterranean fauna assessments have identified troglofauna from the proposed mining area. Some species recorded at Mesa H appear to be restricted to the mesa. A total of 27 troglobitic taxa recorded from the survey at Mesa H are regarded as potential SRE fauna. Of these, 19 taxa are represented by singleton records. Two potential SRE species recorded from a previous survey occur within the Mesa H development envelope, *Paradraculoides* sp. nov. 'Mesa H' and *Troglarmadillo* sp. 1. Three taxa have been recorded from both inside and outside of the Development Envelope, with the remaining 24 taxa recorded only from within the Mesa H Development Envelope. **Stygofauna** Stygofauna have been recorded in the Development Envelope and the surrounding area. A total of 337 stygofauna specimens were recorded over the four phases of sampling, comprising at least 34 species-level taxa, with 6 taxa representing singleton records. Two Amphipoda species of conservation significance have been recorded within the Development Envelope during previous surveys: *Nedsia hurlberti* and *Nedsia sculptilis*, both of which are Schedule 3 species. An additional species of conservation significance was also recorded from a previous survey within 1 km of the Mesa H Development Envelope: Blind Cave Eel (*Ophisternon candidum* – Vulnerable; Schedule 3). All but 4 of the 15 potential SRE stygofauna taxa recorded are known to occur outside Development Envelope and impact area.
Proposal activities – Describe the proposal activities that have the potential to impact the environment.	The following aspects of the Proposal may affect subterranean fauna values: • Mining will result in physical loss and or degradation of a proportion of troglofauna habitat within the Development Envelope and loss of individuals. • Groundwater abstraction will temporarily reduce stygofauna habitat. • Surplus water discharge may temporarily increase the extent and connectivity of stygofauna habitat. • Spills of hydrocarbons or waste water may degrade the subterranean environment. • Localised seepage from placement of waste fines in-pit at Mesa H may result in minor local loss or impact to stygofauna habitat.

Potential environmental impacts	
Mitigation - Describe the measures proposed to manage and mitigate the potential environmental impacts.	Strategies to minimise the impacts to subterranean fauna include: • Characterising the troglofauna and stygofauna habitat present in the conceptual footprint. • Characterising the local and regional conservation significance of troglofauna and stygofauna in the impact area and Development Envelope. • Establishing Mining Exclusion Zones (MEZ) to retain troglofauna habitat. • Undertaking further troglofauna sampling. • Maintaining groundwater and surface water quality by managing erosion, sedimentation and contamination (e.g. hydrocarbon spills). • Undertaking monitoring of stygofauna habitat (via hydrological parameters) through the life of the mine. • Undertaking backfilling of mine pits to assist in protecting troglofauna habitat retention zones.
Impacts - Assess the impacts of the proposal and review the residual impacts against the EPA objective.	The Proposal may result in direct mortality and reduction in available habitat due to pit excavation and groundwater drawdown. Potential impacts will be localised to the proposed pit area and the groundwater drawdown zone during mining operations – however is not expected to significantly impact subterranean fauna species persistence. The risk of pollutants being transported into the subterranean habitat is low and is likely to be locally restricted. The connectivity of the habitat maintained in the alluvial aquifers together with proposed habitat retention in the CID maintains habitat viability for subterranean fauna populations during and post mining. **Troglofauna** Loss of troglofauna habitat will occur as a consequence of excavation from mining. Many troglofauna recorded appear to be restricted to Mesa H and are unlikely to occur more widely. Significant volumes of troglofauna habitat at Mesa H is proposed to be retained via establishment of a MEZ. Examples of existing and historical mining operations and the ongoing representation of troglofauna species has been investigated at Mesa K and ongoing sampling at Mesa A (currently still in operation) supports this approach. **Stygofauna** Dewatering of pits and abstraction of groundwater water will temporarily reduce stygofauna habitat in the CID until the water table recovers following cessation of water abstraction. The majority of the stygofauna taxa recorded at Mesa H are known to occur outside the Development Envelope and additional habitat is present in the alluvials and basement aquifers. The results of hydrogeological modelling will provide greater certainty regarding the extent of potential impacts. Based on the proposed management approach and the anticipated residual impacts, the Proponent considers that the Proposal is likely to meet the EPA objective for Subterranean Fauna.

Potential environmental impacts	
Assumptions - Describe any assumptions critical to your assessment *e.g. particular mitigation measures or regulatory conditions*.	Key assumptions are related to the extent of information collected and seasonal variability, and limitations of sampling in the subterranean environment – these assumptions are detailed in the supporting subterranean fauna studies. These surveys and studies have been undertaken by specialist consultants to ensure an appropriate level of independent rigour and ensure that EPA guidance, methodologies and industry standards have been adopted. Outcomes of the subterranean fauna habitat characterisation work at the nearby Mesa K and Mesa A Projects are considered analogous and applicable to the Mesa H Proposal based on having the same geology and habitat features.

5.4 Hydrological Processes and Inland Water Environmental Quality

5.4.1 EPA objective

The EPA objective for Hydrological Processes is *to maintain the hydrological regimes of groundwater and surface water so that environmental values are protected*.

The EPA Objective for Inland Waters Environmental Quality is *to maintain the quality of groundwater and surface water so that environmental values are protected.*

5.4.2 Potential environmental impacts

Consideration of the potential impacts relevant to Hydrological Processes and Inland Waters Environmental Quality is captured in Table 5-5.

Table 5-5: Consideration of potential environmental impacts – Hydrological Processes and Inland Waters Environmental Quality

Potential environmental impacts	
EPA policy and guidance - What have you considered and how have you applied them in relation to this factor?	The following EPA guidelines have been considered for the proposal in relation to Hydrological Processes and Inland Waters Environmental Quality in order to meet the EPA's objectives as outlined above: EPA Statement of Environmental Principles, Factors and Objectives (2016). EPA Environmental Factor guideline (Water): Environmental Factor Guideline – Hydrological Processes (2016). • EPA Environmental Factor guideline (Water): *Environmental Factor Guideline – Inland Waters Environmental Quality* (2016). The Proposal identifies the environmental values supported by hydrological processes and inland waters environmental quality, and their significance including water dependent ecosystems, amenity, cultural values, recreation, and agricultural use of water, and the chemical, physical, biological and aesthetic characteristics of inland waters. The Proposal and supporting studies focus on presenting the current state of knowledge, defines environmentally significant water dependant ecosystems and focusses on activities and pathways that can impact on hydrological processes and inland waters environmental quality – with the application of the mitigation hierarchy in the design of the Proposal in order to avoid and minimise impacts to hydrological processes / inland waters environmental quality and associated environmental values, where possible.
Consultation – Outline the outcomes of consultation in relation to the potential environmental impacts	**OEPA** A summary of the Mesa H Proposal was provided pre-referral. Proponent to complete studies and prepare referral documentation. DMA consult to be undertaken with key agencies.
	DoW A summary of the hydrogeological drilling and monitoring program in the Robe Valley was presented including conceptual hydrogeological models for Mesa H. A field trip to the Robe Valley was also completed. • The proposed consultant for peer review of the hydrogeological models was discussed and agreed. • H3 report to be included with the EIA. • Cumulative impact assessment required for the lower Robe River in the EIA. • Further conceptualisations and testing of the connectivity between the CID and the alluvium. • Quantification of impacts to stygofauna in the drawdown impact area and cumulatively. • Quantification of impacts to riparian vegetation from both drawdown and discharge and current monitoring and management program. • Discussion of limited impacts to the semi-permanent and permanent pools predicted, and proposed mitigation options (if required) to address any significant uncertainties in the modelling to be presented in the EIA.
	DMP An outline of the scope of the Mesa H Proposal for closure was provided. Clarification sought whether the diversion controls being considered will apply for operation only or will they remain post closure, and if pooling/damming of surface flow occur. Further modelling and consideration being undertaken for closure requirements.

Potential environmental impacts	
Receiving environment - Describe the current condition of the receiving environment in relation to this factor.	Mesa H lies within the Robe River catchment which has a catchment area of approximately 7,500 km^2. Major watercourses occurring within the catchment include the Robe River and the Jimmawurrada, Bungaroo and Mungarathoona Creek's. The major water courses generally flow from the southeast to the northwest through high relief areas of the Hamersley Ranges on to the more gently sloping areas of the coastal plain before discharging into the ocean approximately 150 km south of Dampier. For the majority of its course, the Robe River is ephemeral with a wide, shallow flood plain which carries a significant underflow in its alluvial bed. This sub-surface flow maintains permanent pools in the river channel, and these pools play an important role in the river ecosystem. During the dry season water is often restricted to a series of permanent pools that are maintained by sub-surface flow (Bowman *et al* 1991). Surface water and groundwater in the Mesa H locality has been modified and managed for a number of years (since the mid 1990s) by the Mesa J mining operation. This includes pit dewatering and groundwater abstraction, and discharge of surplus water to Jimmawurrada Creek.
Proposal activities – Describe the proposal activities that have the potential to impact the environment	The following aspects of the Proposal may affect hydrological processes and inland waters environmental quality: **Groundwater abstraction:** • Modelling has considered the cumulative impact of dewatering and groundwater abstraction for this Proposal, the Mesa J operation and the Coastal Water Supply borefield. • Groundwater abstraction for water supply and pit dewatering will result in localised groundwater drawdown in the CID and basement aquifers that may have some connectivity to the Robe River alluvial aquifer and the Jimmawurrada creek alluvial aquifer. • Hydrogeological modelling indicates the potential for limited reduction in water levels in the Robe River alluvial aquifer and pools, with recovery of the groundwater table over time once water abstraction ceases. The predicted limited reduction in water levels in the alluvial aquifers is considered unlikely to have significant impacts on the identified environmental values of the Robe River, including riparian vegetation, terrestrial and aquatic fauna, and associated habitats. • Hydrogeological modelling indicates that ongoing dewatering and groundwater abstraction for the Proposal may potentially further extend drawdown in the Jimmawurrada Creek and will extend the timeframe for the predicted groundwater recovery once water abstraction ceases. This may result in changes to structure and composition of riparian vegetation and temporary localised impacts to aquatic and stygofauna; however riverine ecosystem function is expected to be maintained. • Further hydrogeological investigations and modelling will be undertaken to confirm findings to date. **Discharge:** • Discharge of surplus water may be required from Mesa H into an existing discharge point in Jimmawurrada Creek, and /or the Robe River and tributaries. • Discharge is modelled to extend no further than 8 km from the discharge point under natural no-flow conditions (or ~19km during discharge during flood events). • Discharge could potentially reduce water quality via increased sediment loads and contamination via hydrocarbons. • Discharge could result in stress in riparian vegetation due to waterlogging, and increase in distribution and proliferation of weeds. However discharge water is expected to be of similar quality, and of lower volumes, than has historically occurred from the Mesa J mine, which ongoing monitoring indicates has not had significant impacts on the identified environmental values of the Robe River ecosystem. **Minor creek diversions and flood protection structures:** • Alteration to natural surface drainage regimes has the potential to affect downstream vegetation. Of the three local catchments diverted, two are already intersected by pits at Mesa J operation.

Potential environmental impacts	
Mitigation **-** Describe the measures proposed to manage and mitigate the potential environmental impacts.	Strategies to minimise the impacts to Hydrological Process and Inland Environmental Waters Quality include: • Minimal direct disturbance to the Robe River and Jimmawurrada Creek. • Infrastructure and pit designs avoid disruption of natural flood flows where possible. • Undertaking further hydrogeological investigations and modelling to improve understanding of the potential impacts of groundwater abstraction, including the cumulative effects of the Mesa J mine (including the Southern Cutback Borefield) and the Coastal Water Supply Borefield. • Monitoring groundwater water levels and abstraction rates during operations with ongoing validation of the hydrogeological modelling. • Undertaking aquatic fauna surveys in the Robe River pools, and ongoing monitoring during operations. • Establishing a baseline of seasonal water levels and water quality in the Robe River pools, and ongoing monitoring during operations. • Groundwater to be discharged to the Robe River is generally of good quality; additional water samples will be collected to confirm water quality. • Limiting surplus water discharge to the Robe River by preferential use on site for operational purposes. Preferential use of existing Mesa J discharge outlets, if new discharge locations are required, surface water management structures will be installed to prevent erosion and sediment transport. • Hydrocarbon bunding and hydrocarbon treatment facilities will be installed to prevent hydrocarbons contaminating surface water and groundwater. • Development of a monitoring and management plan, with trigger and threshold levels and actions, to ensure no significant detrimental impact to the identified environmental values of the Robe River and Jimmawurrada creek ecosystems due to groundwater abstraction and discharge. This plan will consider precautionary mitigation options for groundwater drawdown, such as supplementary water supply to the Robe River ecosystem via controlled discharge. Management strategies for potential impacts to flora and vegetation, terrestrial fauna, subterranean fauna and social surrounds arising from hydrological processes are discussed in sections 5.1, 5.2, 5.3, and 5.5.

Potential environmental impacts	
Impacts - Assess the impacts of the proposal and review the residual impacts against the EPA objective.	**Groundwater abstraction:** Modelling has considered the cumulative impact of dewatering and groundwater abstraction for the Mesa H Proposal, the Mesa J mine and the Coastal Water Supply Borefield. Modelling has adopted a conservative approach to current hydrogeological uncertainties, generally applying more pessimistic parameters to test a 'worst case' scenario. Dewatering for water supply and pit dewatering will result in localised groundwater drawdown in the CID and basement aquifers that may have some connectivity to the Robe River alluvial aquifer and the Jimmawurrada Creek alluvial aquifer. Hydrogeological modelling indicates the potential for limited reduction in water levels in the Robe River alluvial aquifer and pools, with recovery of the groundwater table over time once water abstraction ceases. The predicted reduction in groundwater levels in the alluvial aquifer is considered unlikely to have significant impacts on the identified environmental values of the Robe River ecosystem (including riparian vegetation and terrestrial and aquatic fauna). Hydrogeological modelling indicated that ongoing dewatering and groundwater abstraction for the Proposal may potentially further extend drawdown in the Jimmawurrada Creek area, and extend the timeframe for predicted groundwater recovery once groundwater abstraction ceases. This may result in changes to structure and composition of riparian vegetation, and temporary, localised impacts to aquatic and stygofauna, however riverine ecosystem function may be maintained. The predicted reduction in water levels due to the Proposal is not considered to have significant impacts on the identified environmental values of the Jimmawurrada Creek ecosystem. Further hydrogeological investigations and modelling will be undertaken to confirm findings to date. **Discharge:** Discharge of surplus water may be required from Mesa H into the Robe River and tributaries. Discharge will extend no further than 8 km from the discharge point under natural no-flow conditions, and 19km if emergency discharge, resulting from surface water flooding of the pits, is required. Discharge is expected to be of similar quality, and of lower volumes, than has historically occurred from the Mesa J mine, that ongoing monitoring indicates has not had significant impacts on the identified environmental values of the Robe River ecosystem (including riparian vegetation, and terrestrial and aquatic fauna). **Drainage:** Acid rock drainage risk has been assessed as low due to the geology. Site drainage will be designed to minimise or eliminate surface runoff into areas where activities with a potential risk of hydrocarbon contamination occur. Management of waste dumps will ensure that risks of contamination of surface and groundwater are minimised. Anticipated residual impacts to flora and vegetation, terrestrial fauna, subterranean fauna and social surrounds arising from hydrological processes are discussed in sections 5.1, 5.2, 5.3 and 5.5. The Proponent considers that the Proposal is likely to meet the EPA objective for Hydrological Processes and Inland Environmental Water Quality.
Assumptions - Describe any assumptions critical to your assessment *e.g. particular mitigation measures or regulatory conditions.*	Key assumptions are related to the extent of information collected and calibration of existing systems to support hydrogeological and hydrological conceptualisations – these assumptions are detailed in the supporting hydrogeological / hydrological studies. These studies have been peer reviewed to ensure appropriate methodologies and industry standards in approach have been adopted. Hydrogeological modelling has adopted a conservative approach to current uncertainties, generally applying more pessimistic parameters to test a 'worst case' scenario to inform the environmental impact assessment. The Proposal assumes no 3rd party changes to the local hydrogeological regime.

5.5 Social Surroundings

5.5.1 EPA objective

The EPA objective for Social Surroundings is *to protect social surroundings from significant harm.*

5.5.2 Potential environmental impacts

Consideration of the potential impacts relevant to Social Surroundings is captured in Table 5-6.

Table 5-6: Consideration of potential environmental impacts – Social Surroundings

Potential environmental impacts	
EPA policy and guidance - What have you considered and how have you applied them in relation to this factor?	The following EPA guidelines and technical guidance have been considered for the proposal in relation to Subterranean fauna in order to meet the EPA's objective as outlined above: • EPA Statement of Environmental Principles, Factors and Objectives (2016). • EPA Environmental Factor guideline (People): *Environmental Factor Guideline – Social Surroundings* (2016). The Proposal and supporting studies focus on presenting the current state of knowledge and defines the aesthetic, cultural (physical and biological), economic and/or social values which may be impacted within the Development Envelope. The Proposal has been designed to minimise impact to social surroundings via the application of the mitigation hierarchy. Any limitations relative to the work undertaken will be noted in the impact assessment and supporting studies.
Consultation – Outline the outcomes of consultation in relation to the potential environmental impacts.	**Traditional Owners (Kuruma Marthudunera)** The Proponent maintains ongoing regular consultation with the K&M through multiple forums, including the Local Implementation Committee (LIC) meetings, KMAC Heritage Sub-Committee (HSC) meetings, and heritage surveys. The Proponent has provided a copy of this referral to the K&M people concurrently with this submission; The Mesa H proposal has been discussed on multiple occasions with the K&M, and consultation will continue. Key outcomes of consultation to date comprise: • The highly significant ethnographic site *Jirti Thalu*, and a significant quarry site, will be protected. • The mesa escarpment has significant cultural value, particularly where adjacent to the Robe River, and will be retained via a MEZ. • The proposed location and design (height restricted) of the northern waste dump location was agreed as the preferred option to minimise visual impact. • Agreement to obtain precautionary Section 18 consents under the *Aboriginal Heritage Act 1972* (Heritage Act) for rock shelters in the mesa escarpment that may be impacted by blasting vibrations. • The Robe River and pools are of high cultural significance, and are regularly used for cultural and recreational activities. • Watercourses other than the Robe River are also of cultural importance. • Agreement to retain the central watercourse through the mesa and main gullies on the western side of the mesa (protected by establishment of a MEZ). • The project footprint will directly impact multiple archaeological sites as discussed with the K&M. Consent under the Heritage Act will be required to disturb these sites. **Yarraloola and Yalleen Stations** • Further consultation as part of existing subleasing arrangement; and • Update on Mesa H Proposal, planned activities, scope of the proposal and dates/ timeframes.

Potential environmental impacts	
Receiving environment - Describe the current condition of the receiving environment in relation to this factor.	Existing land uses in the Development Envelope include pastoral activities (Yarraloola and Yalleen Stations), mineral exploration, mining activities and cultural / recreational activities (predominantly by Traditional Owners) such as camping, fishing and hunting. The mesa landform / profiles are also used by Traditional Owners as landmarks when travelling though the countryside. The Proposal falls within the K&M native title claim (WCD2016/006). The K&M People have a Claim Wide Participation Agreement and Indigenous Land Use Agreement with Rio Tinto. The agreements commit Rio Tinto and the K&M People to work together to manage and maintain the areas in which Rio Tinto operates. The agreements set clear requirements for processes such as land access, tenure, heritage and environmental approvals, mining benefit payments and reporting and communication requirements. All of the archaeological survey work and the majority of the ethnographic survey work has been completed for the Proposal. Heritage sites of high significance in the vicinity of the Proposal Area and broader Development Envelope are ethnographic sites (including mythological locations, named pools and places of importance due to current use); the Robe River, and the mesa profiles which are used as landmarks within the landscape. The Proposal is located at the centre of a series of pisolite mesa formations associated with the Robe River. These mesas punctuate a landform of plains and low angle talus slopes that generally fall away to the Ashburton Plain in the west. In the Development Envelope, the land rises into the adjacent Hamersley Ranges, where more robust formations create more rugged and highly dissected landforms. Mesa H forms a mesa ridge on its north west margin where it abuts the Robe River, and merges into the footslope of the Buckland Hills in the south-east, with a smaller less prominent gully dissecting central part of the formation. The Pannawonica Road is the main travel route though the area, that is used predominantly by Robe Valley mining operations personnel to access Pannawonica (a closed town) and the Mesa J Operation. Other roads are generally unformed pastoral access roads. Long distance views of the surrounding country are available at certain locations along the Pannawonica Road, due to the open nature of the landforms and sparse vegetation; however views become confined close to, and between, mesa formations, in gullies and near the riverine vegetation. Mesa H is approximately 5 km south of the Pannawonica Road and is visible in the distance from approximately a 6.8 km section of the road. Mesa H lies within the Robe River catchment with major watercourses including the Robe River and the Jimmawurrada, and Mungarathoona Creek's. The Robe River is the major watercourse in the Development Envelope which contains semi-permanent and permanent pools in the river channel. The pools and the riparian ecosystem within the Development Envelope are utilised by the K&M for cultural and recreational activities, by the public for recreation, and by Yaraloola and Yalleen Stations. Surface water and groundwater in the Mesa H locality has been modified and managed for a number of years (since the mid 1990s) by the Mesa J Operations. The Proposal also overlaps with the Yarraloola and Yalleen Pastoral Leases which are currently active pastoral stations running cattle in the lower plains and riverine areas.
Proposal activities – Describe the proposal activities that have the potential to impact the environment	• Ground disturbance for the Proposal could directly impact heritage sites. • Blasting vibrations could indirectly impact heritage sites. • Groundwater abstraction and surplus water discharge could potentially have limited impact on water levels in the Robe River alluvial aquifer and pools, however significant impacts on the identified environmental values of the Robe River ecosystem are considered unlikely, as discussed in section 5.4. • Mining activities will result in external waste dumps retained in the landscape and will remove the central core of the mesa formation.

Potential environmental impacts	
Mitigation **-** Describe the measures proposed to manage and mitigate the potential environmental impacts.	• Biological survey work for the Proposal, and more generally in the Robe Valley, has included K&M involvement. • Heritage surveys are undertaken with participation of the K&M. • Heritage sites will be avoided where practicable. Where heritage sites cannot practically be avoided, the Proponent will consult with the K&M and seek appropriate approval under the Heritage Act. • The Proponent has an established internal system for managing all ground disturbing activities to ensure compliance with heritage commitments and regulatory requirements. • The project footprint has been modified to protect the highly significant ethnographic site *Jirti Thalu*, and a significant quarry site, in consultation with the K&M. • The culturally significant mesa escarpment will be retained via establishment of a MEZ, as discussed with the K&M. Pit designs will incorporate the outcomes of geotechnical investigations to ensure the long-term stability of the retained escarpment, and appropriate blast management will be applied during operations. • The proposed location and design (height restricted) of the northern waste dump location was agreed with the K&M as the preferred option to minimise visual impact. • Rockshelters within the mesa escarpment will not be directly impacted by mining but may be impacted by blasting vibration, requiring Heritage Act consents as agreed with the K&M. • Additional hydrogeological investigations and modelling will be undertaken to confirm the current predictions of limited impact due to this Proposal on the Robe River alluvial aquifer and pools and the Jimmawurrada Creek area. • The central watercourse through the mesa and main gullies on the western side of the mesa are protected from direct mining impacts by the MEZ. • Groundwater abstraction and surplus water discharge from the Proposal are considered unlikely to have significant impacts on the identified environmental values of the Robe River and Jimmawurrada ecosystems. A monitoring and management plan, with trigger and threshold levels and actions will ensure no significant detrimental impact to the identified environmental values of the Robe River and Jimmawurrada Creek ecosystems. This plan will consider precautionary mitigation options for groundwater drawdown, such as supplementary water supply to the Robe River ecosystem via controlled discharge.

Potential environmental impacts	
Impacts - Assess the impacts of the proposal and review the residual impacts against the EPA objective.	**Heritage values** • The project footprint has been modified to protect the highly significant ethnographic site *Jirti Thalu*, and a significant quarry site, in consultation with the K&M. • The culturally significant mesa escarpment will be excluded from mining as discussed with the K&M. • Rockshelters within the mesa escarpment will not be directly impacted by mining but may be impacted by blasting vibration, requiring Heritage Act consents as agreed with the K&M. • The project footprint will directly impact multiple archaeological sites. Consent under the Heritage Act will be required to disturb these sites. • Groundwater abstraction and surplus water discharge as a result of the Proposal are considered unlikely to have significant impacts on the identified environmental values of the Robe River and Jimmawurrada ecosystems. Further hydrogeological investigations and modelling will be undertaken to confirm findings to date. • Further consultation will be undertaken with the K&M regarding the physical and biological cultural values of the Robe River and Jimmawurrada Creek ecosystems and how these interrelate with management of the identified environmental values. **Visual Amenity** • The Proposal will not have a significant impact to visual amenity due to the retention of the mesa escarpment, and location and design (height restriction) of external waste dumps. **Pastoral** • The mine pit is located in an area not normally utilised by cattle for grazing activities, hence limited impacts to pastoral activities are anticipated. The Proponent considers that the Proposal is likely to meet the EPA objective for Social Surroundings.
Assumptions - Describe any assumptions critical to your assessment *e.g. particular mitigation measures or regulatory conditions.*	Key assumptions are related to the extent of consultation and information collected in combination with the degree of seasonal variability naturally experienced in an arid environment – these assumptions are detailed in the supporting studies. Assumptions regarding the potential for impacts of groundwater drawdown on the Robe River ecosystem are outlined in previous sections. Consultation has been undertaken with the K&M regarding cultural values of the Robe River and pools, and the impact assessment considers cultural values in the context of where they relate to the identified physical and biological values of the ecosystem. Further discussion will be undertaken with the K&M on this relationship. Surveys and studies have been undertaken by specialists in conjunction with key K&M group representatives to ensure an appropriate level of rigour and ensure that EPA guidance, methodologies and industry standards have been adopted. Where significant uncertainty exists, a 'worst case scenario' will be considered in the impact assessment and mitigation options to prevent significant impacts will be provided.

6. OTHER ENVIRONMENTAL FACTORS

The following factors, although not considered key, are relevant to the Proposal:

- Landforms
- Air Quality

Table 6-1 outlines the consideration of the above factors relevant to the Proposal.

All other factors (Benthic Communities and Habitat, Coastal Processes, Marine Environmental Quality, Marine Fauna, Terrestrial Environmental Quality and Human Health) are not considered to be relevant to the Proposal.

Table 6-1: Consideration of factors unlikely to be key environmental factors

EPA Objective & policy / Guideline consideration	Potential impact	Management	Anticipated residual impact
Air Quality			
To maintain air quality and minimise emissions so that environmental values are protected. The following EPA guidelines and technical guidance have been considered for the proposal in relation to Air in order to meet the EPA's objective as outlined above: • EPA Statement of Environmental Principles, Factors and Objectives (2016). • EPA Environmental Factor guideline (Air): *Environmental Factor Guideline – Air Quality* (2016).	• Dust will be generated by construction, mining, processing, ore handling and transportation and vehicle movements • Greenhouse gas emissions will be generated by the Proposal. Estimates are currently being calculated, however it is anticipated that emissions will be reduced due to utilisation of existing infrastructure and facilities at the Mesa J Operations.	• Use of dust extraction, water sprays and dust suppressants as applicable. • Clearing work areas only where required. • Rehabilitation of disturbed areas, especially following construction activities, to reduce potential dust lift-off from open areas. • Designing and operating the Proposal to maximise energy efficiency and minimise greenhouse gas emissions.	No significant dust impacts are anticipated due to the proposed management controls and remote location of the Proposal. Greenhouse gas emissions are not considered to be significant and will partly replace the current greenhouse gas emissions from the Mesa J mine as mining transitions from Mesa J to Mesa H. The Proponent considers that the Proposal is likely to meet the EPA objective for Air Quality.
Landforms			
To maintain the variety and integrity of distinctive physical landforms so that environmental values are protected. • EPA Statement of Environmental Principles, Factors and Objectives (2016). • EPA Environmental Factor guideline (Land): Environmental Factor Guideline – Landforms (2016).	• There is limited potential for impact to the mesa landforms as the Mesa H landform comprises escarpments only on the NW margins, adjacent to the Robe River. This escarpment will be retained / avoided during mining.	• Retention of the mesa escarpment. • location and design (height restriction) of external waste dumps to minimise visual • Pit designs will incorporate the outcomes of geotechnical investigations to ensure the long-term stability of the retained escarpment, and appropriate blast management will be applied during operations. • Continuing to locate infrastructure in previously disturbed areas where possible.	The Development Envelope is adjacent to an existing mining operation at Mesa J with similar components to those of the Proposal. No significant additional impacts are anticipated. The Proponent considers that the Proposal is likely to meet the EPA objective for Landforms.

7. PRINCIPLES OF ENVIRONMENTAL PROTECTION

The principles of environmentally sustainable development are incorporated into Section 4A of the EP Act. These principles have been considered for the Proposal as summarised in Table 7-1.

Table 7-1: Environmental principles of the EP Act

Principle	Consideration given in the Proposal
1. Precautionary principle Where there are threats of serious or irreversible damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation. In the application of the precautionary principle, decisions should be guided by: (a) Careful evaluation to avoid, where practicable, serious or irreversible damage to the environment; and (b) An assessment of the risk-weighted consequences of various options.	Comprehensive biological surveys have already been undertaken and others are well underway. The results of the biological surveys are being used to guide the design phase of the Proposal. Where significant potential environmental impacts are identified measures have been, and will continue to be, incorporated into the Proposal design and management to avoid or minimise these impacts where practical.
2. Intergenerational equity The present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.	The Proposal will make a long-term contribution to the economic prosperity of Western Australia. The Proposal will not compromise current or foreseeable future land use options in the area. The Proposal can be effectively managed through avoidance, management and mitigation measures to ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations.
3. Improved valuation, pricing and incentive mechanisms (a) Environmental factors should be included in the valuation of assets and services. (b) The polluter pays principle – those who generate pollution and waste should bear the cost of containment, avoidance or abatement. (c) The users of goods and services should pay prices based on the full life cycle costs of providing goods and services, including the use of natural resources and assets and the ultimate disposal of any wastes. (d) Environmental goals, having been established, should be pursued in the most cost-effective way, by establishing incentives structures, including market mechanisms, which enable those best placed to maximise benefits and/or minimise costs to develop their own solutions and responses to environmental problems.	The Proposal will be subject to a Mine Closure Plan prepared in accordance with the DMP and EPA *Guidelines for Preparing Mine Closure Plans* (May 2015) and the Rio Tinto Closure Standard. This will provide the basis for ensuring that post-mining land use objectives are identified (through a consultative process) and can be met. The Proponent will undertake land rehabilitation activities to underpin the mine closure process.

Principle	Consideration given in the Proposal
4. Conservation of biological diversity and ecological integrity. Conservation of biological diversity and ecological integrity should be a fundamental consideration.	Comprehensive biological surveys have already been undertaken and others are other are underway to identify aspects of the environment that are of conservation significance. Where significant potential environmental impacts are identified measures have been, and will continue to be, incorporated into the Proposal design and management to avoid or minimise these impacts where practical. The Proponent's HSECQ Management System has established rehabilitation procedures for restoring disturbed environments.
5. Waste minimisation All reasonable and practicable measures should be taken to minimise the generation of waste and its discharge into the environment.	Application of the Proponent's management policies, systems and procedures, in combination with the Mine Closure Plan, will provide the basis for minimising the generation of waste and its discharge into the environment. Mine planning objectives to minimise stripping ratios, thereby reducing mineral waste materials volumes, will assist in meeting the aims of this principle.

Dear Mr Vella

MESA H PROPOSAL (REVISION TO MESA J IRON ORE DEVELOPMENT) – ASSESSMNET NO: 2121

The Environmental Scoping Document (ESD) dated 31 October 2017 (DWERDA-010464) specifying the scope and content of the Environmental Review Document (ERD) for the above proposal was considered by the Environmental Protection Authority at Meeting No. 1106 on 19 October 2017. The ESD has been approved as providing an acceptable basis for the preparation of the ERD.

During the preparation of the ERD you are encouraged to consult with the Office of the Environmental Protection Authority assessment officer for the proposal, Matt Spence, who can be contacted on telephone number 6364 6805. Please quote the above "Our Ref" on any further correspondence.

Yours sincerely

Dr Robert Harvey
DEPUTY CHAIRMAN

31 October 2017

Encl. Environmental Scoping Document – Mesa H Proposal (Revision to Mesa J Iron Ore Development)

DRAFT ENVIRONMENTAL SCOPING DOCUMENT

Proposal name:	**Mesa H Proposal (Revision to the Mesa J Iron Ore Project)**
Proponent:	**Robe River Mining Co. Pty. Ltd.**
Assessment number:	**2121**
Location:	**16 kilometres south west of Pannawonica in the Pilbara region of Western Australia**
Local Government Area:	**Shire of Ashburton**
Public review period:	**Environmental Review Document – 2 weeks**
EPBC Reference No:	**2017/8017**

1. Introduction

The Environmental Protection Authority (EPA) has determined that the above Proposal is to be assessed under Part IV of the *Environmental Protection Act 1986* (EP Act).

The purpose of the Environmental Scoping Document (ESD) is to define the form, content, timing and procedure of the environmental review, required by s. 40(3) of the EP Act. Robe River Mining Co. Pty. Ltd. (the Proponent) has prepared this draft ESD according to the procedures in the EPA's *Procedures Manual.*

Form

The EPA requires that the form of the report on the environmental review required under s. 40 (Environmental Review Document, ERD) is completed according to the *Environmental Review Document template.*

Content

The EPA requires that the environmental review includes the content outlined in sections **2** to **6** of this ESD.

Timing

Table 1 sets out the timeline for the assessment of the Proposal agreed between the Proponent and the EPA.

Table 1: Assessment timeline

Key assessment milestones	Completion Date
EPA approves Environmental Scoping Document	19 October 2017
Proponent submits first draft Environmental Review Document	5 February 2018
EPA provides comment on first draft Environmental Review Document *(6 weeks from receipt of ERD)*	19 March 2018
Proponent submits revised draft Environmental Review Document	30 April 2018
EPA authorises release of Environmental Review Document for public review *(2 weeks from EPA approval of ERD)*	14 May 2018
Proponent releases Environmental Review Document for public review for 2 weeks	28 May 2018
Close of public review period	11 June 2018
EPA provides Summary of Submissions *(3 weeks from close of public review period)*	2 July 2018
Proponent provides Response to Submissions	13 August 2018
EPA reviews the Response to Submissions *(4 weeks from receipt of Response to Submissions)*	10 September 2018
EPA prepares draft assessment report and completes assessment *(6 weeks from EPA accepting Response to Submissions)*	22 October 2018
EPA finalises assessment report (including two weeks consultation on draft conditions) and gives report to Minister *(6 weeks from completion of assessment)*	10 December 2018

*The Assessment Timeline is yet to be agreed to between the Proponent and the EPA. This will be confirmed once the EPA has endorsed the final ESD.

Procedure

The EPA requires the Proponent to undertake the environmental review according to the procedures in the *Administrative Procedures* and the *Procedures Manual*. This ESD has not been released for public review. The ESD will be available on the EPA website (www.epa.wa.gov.au) upon endorsement and must be appended to the ERD.

Assessment as an accredited assessment

The Proposal has been referred to the Commonwealth Department of Environment and Energy and has been determined to be a controlled action under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act). The Proposal is being assessed as an accredited assessment. The relevant matters of national environmental significance (MNES) for this proposal are:

- Listed threatened species and communities (Sections 18 and 18A).

This ESD includes work required to be carried out and reported on in the ERD document in relation to MNES. The ERD will also address the matters in Schedule 4 of the *Environment Protection and Biodiversity Conservation Regulations 2000*.

MNES that may be impacted by the Proposal will be identified and the potential impacts on these matters addressed within each relevant preliminary environmental factor as identified in Table 4. The ERD will include a separate section which summarises the potential impacts on MNES and describes, to the extent practicable, any feasible alternatives to the proposed action and possible mitigation measures. Proposed offsets to address significant residual impacts on MNES are also to be discussed.

2. The Proposal and Regional Context

2.1 The Proposal

The subject of this ESD is the proposed development of the Mesa H Proposal (the Proposal) by Robe River Mining Co. Pty. Ltd. (Joint Venture entities include: Robe River Mining Co. Pty. Ltd., North Mining Limited, Mitsui Iron Ore Development Pty. Ltd., Cape Lambert Iron Associates, a partnership carried on by Nippon Steel & Sumitomo Metal Australia Pty Ltd, Nippon Steel & Sumikin Resources Australia Pty Ltd and Mitsui Iron Ore Development Pty Ltd and Pannawonica Iron Associates, a partnership carried on by Nippon Steel & Sumitomo Metal Australia Pty Ltd, Nippon Steel & Sumikin Resources Australia Pty Ltd).

The Mesa H Proposal is located approximately 16 kilometres (km) south-east of Pannawonica in the Pilbara region of Western Australia. The Proposal is to sustain production from the existing Mesa J Operation [approved under Ministerial Statement 208 (MS 208)] and includes development of above and below water table mine pits and associated infrastructure, waste dumps, stockpiles and associated infrastructure, as well as processing facilities and water management infrastructure. The Proposal will utilise and integrate with existing infrastructure and facilities of the Mesa J Operation including ore processing facilities, water management infrastructure, power, and rail.

The regional location of the Proposal is shown in Figure 1 and the Development Envelope encompassing the physical elements of the Proposal is delineated in Figure 2.

The key characteristics of the Proposal are set out in Tables 2 and 3. The key Proposal characteristics may change during the EIA process as a result of the findings of studies and investigations conducted and the application of the mitigation hierarchy by the Proponent.

The Mesa H Proposal is predominantly located on Mineral Lease ML248SA granted pursuant to the Iron Ore (Robe River) Agreement Act 1964. The Proposal pits, dumps and the majority of infrastructure are located within ML248SA (section 104 and a portion of section 103). A powerline to the east of Mesa J will require new tenure under the Mining Act 1978. Grant of Land Administration Act 1997 (LAA) tenure for this area will be required prior to construction of the powerline connection.

The main co-existing LAA tenure in the Development Envelope includes the Yarraloola Pastoral Station (Lease N49500) and the Yalleen Pastoral Station (Lease N49492). These pastoral leases are held by the Robe River Iron Associates.

The Mesa J Operation was referred under Part IV of the EP Act and was assessed as Consultative Environmental Review. The EPA published its Report and

Recommendations (Bulletin 574) in August 1991 which described the environmental aspects considered by the EPA, as:

- riparian vegetation communities (Vegetation and Flora);
- groundwater drawdown and surface water discharge (Hydrological Processes and Inland Environmental Water Quality); and
- rehabilitation.

The Minister for Environment approved implementation of the Mesa J Proposal, subject to the conditions of MS 208, on 16 January 1992.

A number of s45c's have been submitted and approved during the life of the Mesa J Operation during 2005 - 2007. These related to rail works and fibre optic cable and one clarified the Part IV disturbance area boundary.

The existing approved environmental management plan for the Mesa J Operation will continue to be implemented and will be updated, in addition to new management plans developed, specifically relating to Mesa H, subject to approval.

2.2 Regional Context

The Proposal is located in the Robe River valley which has a catchment area of approximately 7,500 km^2. Major watercourses occurring within the catchment include the Robe River and creek systems of the Jimmawurrada, Bungaroo, and Mungarathoona Creeks. Groundwater and surface water systems in the area are complex, variable, and linked. For the majority of its course the Robe River is ephemeral with a wide, shallow flood plain that carries a significant underflow in its alluvial bed.

The escarpment of the Robe River valley provides habitat for listed threatened species, including the Northern Quoll, Pilbara Leaf-nosed Bat, Ghost Bat, and the Pilbara Olive Python. Furthermore, riparian habitat containing groundwater dependent vegetation (e.g. *Melaleuca Argentea*) of high local significance are associated with drainage lines along the Robe River.

Surface water and groundwater in the Proposal's locality has been modified and managed for a number of years (since the mid-1990s). This includes pit dewatering and groundwater abstraction, and discharge of surplus water to Jimmawurrada Creek, to allow below water-table mining at the Mesa J operations. Other operating mines located within the catchment include the Mesa A Hub, comprising existing Mesa A operations and the proposed future mining of nearby deposits, including the Mesa B and Mesa C deposits, which will sustain the Mesa A operation.

Noting the above, the cumulative impacts of the Proposal need to be considered in the ERD, in the regional context of the existing and proposed mining activities in the Robe River catchment.

Table 2: Summary of the Proposal

Proposal title	Mesa H Proposal (Revision to the Mesa J Iron Ore Project)
Proponent name	Robe River Mining Co. Pty. Ltd.
Short description	The Proposal is located 16 km south-west of Pannawonica in the Pilbara region of Western Australia. The Proposal is to develop the Mesa H deposit adjacent to the existing Mesa J Iron Ore Project utilising the adjacent Mesa J infrastructure including but not limited to the development of above and below water table open cut iron ore pits and associated infrastructure, including ore processing facilities, waste dumps, waste fines storage facilities, water management infrastructure and rail.

Table 3: Location and proposed extent of physical and operational elements

Element	Location	Existing approval (MS 208)	Proposed Extent (This Proposal)	Proposed Extent (Revised Proposal)
Physical Elements				
Mine and associated infrastructure	Figure 2	Clearing of up to 1,800 ha for mine development.	Clearing of up to 2,200 ha (within a Development Envelope of 4,930 ha).	Clearing of up to 4,000 ha (within a Development Envelope of 6,730 ha).
Rail / Linear Infrastructure	Figure 1	Single gauge railway line with sidings and a voice and radio data communications system with fibre optic cable from Cape Lambert.	N/A.	Single gauge railway line with sidings and communications system with fibre optic cable from Cape Lambert.
Operational Elements				
Pit dewatering	–	Not specified.	Up to 5 GL/annum.	Up to 10 GL/a.
Surplus Water Management	–	Not specified. Surplus water management includes use on site and controlled discharge to the environment at discharge points in Jimmawurrada Creek and a tributary west of Mesa J.	Controlled surface discharge to extend along Jimmawurrada Creek / Robe River no further than 8 km downstream of the discharge point under natural no-flow conditions. Surplus water management options include use on site and discharge to the environment or alternative means of disposal.	Controlled surface discharge to extend along Jimmawurrada Creek / Robe River no further than 8 km downstream of the discharge point under natural no-flow conditions. Surplus water management options include use on site and discharge to the environment or alternative means of disposal.
Water supply	–	Not specified.	Up to 10 GL/annum from a water supply borefield.	Up to 10 GL/annum from a water supply borefield.

3. Preliminary key environmental factors and required work

The preliminary key environmental factors for the environmental review are:

1. Flora and Vegetation.
2. Subterranean Fauna.
3. Terrestrial Fauna.
4. Hydrological Processes and Inland Waters Environmental Quality.
5. Social Surrounds.
6. Air Quality.

Table 4 outlines the work required for each preliminary key environmental factor and contains the following elements for each factor:

- **EPA factor** and **EPA objective** for that factor.
- **Relevant activities** – the Proposal activities that may have a significant impact on that factor.
- **Potential impacts and risks** to that factor.
- **Required work** for that factor.
- **Relevant policy and guidance** – EPA (and other) guidance and policy relevant to the assessment.

Table 4: Preliminary key environmental factors and required work

Flora and Vegetation	
EPA objective	To protect flora and vegetation so that biological diversity and ecological integrity are maintained.
Relevant activities	Clearing of native vegetation, groundwater abstraction, potential alteration of surface water flows, and potential discharge of excess mine dewater.
Potential impacts and risks	• Disturbance to up to 2,200 ha of native vegetation. • Disturbance to riparian vegetation units considered to be of local significance that are present in the Development Envelope and discharge footprint. • Disturbance to three Priority Flora taxa recorded in the Development Envelope: o *Triodia* sp. Robe River (M.E. Trudgen et al. MET 12367) (Priority 3); o *Indigofera* sp. Bungaroo Creek (S. van Leeuwen 4301) (Priority 3); and o *Rhynchosia bungarensis* (Priority 4).
Required work	1. Identify and characterise flora and vegetation in accordance with the requirements of EPA 2016 Technical Guidance – *Flora and Vegetation Surveys for Environmental Impact Assessment*. The survey should take into account areas that are likely to be directly or indirectly impacted as a result of the Proposal. 2. Map weed occurrences in areas likely to be directly or indirectly impacted by the Proposal.

3. Describe the vegetation and conservation significant flora species present and likely to be present within the Development Envelope and indirect disturbance areas outside of the Development Envelope. Include an assessment of the relevance of any vegetation and conservation significant flora species in a local and regional context.
4. Provide an analysis of any additional potential impacts from the Proposal in relation to dewatering and discharge activities, including consideration of potential impacts from waste fines storage facilities.
5. Provide a detailed description of the cumulative impacts associated with the Proposal, including direct impacts from clearing, and indirect impacts such as groundwater drawdown, altered drainage, changes in water quality, spread of weeds, fragmentation of vegetation, altered fire regime, and dust.
6. Provide tables and maps of the proposed clearing and predicted indirect impact to vegetation and conservation significant flora species, including but not limited to threatened and/or priority ecological communities, threatened flora, Priority flora or new flora species.
7. Discuss, and determine significance of, potential direct, indirect (such as dust, weeds and downstream impacts) and cumulative impacts to conservation listed flora and vegetation as a result of the Proposal at a local and regional level (i.e. the Robe Valley).
8. Demonstrate that all practical measures have been taken to reduce the area of the proposed disturbance footprint based on progress in the Proposal design and understanding of the environmental impacts.
9. Discuss proposed objectives, management, monitoring and mitigation methods to be implemented demonstrating that the design of the Proposal has addressed the mitigation hierarchy to avoid and minimise impacts to flora and vegetation.
10. Review and revise the existing Mesa J environmental management plan to apply to the Proposal. The objective of the plan is to ensure the protection of conservation significant vegetation communities within the Development Envelope and areas of indirect impact. The following should be addressed in the plan:
    - Invasive species control – control of weeds, in particular through transport and/or entry and exit points, and in areas of vegetation units considered to have high local significance.
    - Monitoring program – to monitor the health of conservation listed vegetation communities including (but not limited to) the protection of obligate phreatophytic communities that will be impacted by the Proposal.
11. Prepare a Mine Closure Plan consistent with DMP and EPA *Guidelines for Preparing Mine Closure Plans* (2015) which considers the proposed rehabilitation methodologies to achieve successful progressive rehabilitation of all areas disturbed by mining with vegetation composed of native species of local provenance.
12. Predict the inherent and residual impacts before and after applying the mitigation hierarchy and identify whether the residual impacts are significant by applying the Significant Residual Impact Model in the WA Environmental Offsets Guideline.
13. Quantify any significant residual impacts by completing the Offset Template, spatially defining the area of 'good' to 'excellent' native vegetation that will be disturbed as a result of this proposal (excluding the approved Mesa J Operation), and propose an appropriate offsets package that demonstrates application of the WA Environmental Offsets Policy and Guideline.
14. Demonstrate and document in the ERD how the EPA's objective for this factor can be met.

Relevant policy and guidance	<u>EPA Policy and Guidance</u> Advice of the Environmental Protection Authority to the Minister for Environment under Section 16 of the *Environmental Protection Act 1986*, *Cumulative environmental impacts of development in the Pilbara region.* EPA *Statement of Environmental Principles, Factors and Objectives* (2016). EPA *Environmental Factor Guideline: Flora and Vegetation* (2016). EPA *Technical Guidance: Flora and Vegetation Surveys for Environmental Impact Assessment* (2016). EPA *Instructions on how to prepare Environmental Protection Act 1986 Part IV Environmental Management Plans* (2016). DMP and EPA *Guidelines for Preparing Mine Closure Plans* (2015). <u>Other policy and guidance</u> Department of Water *Western Australian Water in Mining Guideline* (2013). Government of Western Australia *WA Environmental Offsets Policy* (2011). Government of Western Australia *WA Environmental Offsets Guidelines* (2014).
Subterranean Fauna	
EPA objective	To protect subterranean fauna so that biological diversity and ecological integrity are maintained.
Relevant activities	Mining (excavation), groundwater abstraction, surplus water discharge and disposal of waste fines.
Potential impacts and risks	Reduction in troglofauna habitat and loss of individuals from mine pit development. Reduction in stygofauna habitat due to abstraction of groundwater. Reduction in subterranean fauna habitat from seepage from waste fines placed in-pit. Reduction in the quality of subterranean habitat due to contaminants (e.g. spills of hydrocarbons). Potential impacts and risks to the EPBC Act listed vulnerable Blind Cave Eel (*Ophisternon candidum*) including the loss of individuals and loss or degradation of habitat due to mining activity and associated abstraction of groundwater.
Required work	15. Conduct Level 2 fauna surveys within areas to be impacted and in surrounding areas in accordance with EPA 2016 Environmental Factor Guideline – Subterranean Fauna. 16. Present the results of the subterranean fauna surveys and discuss the potential for direct, indirect and cumulative impacts to subterranean fauna and habitat including consideration of altered water regimes and water quality as a result of the Proposal, and other operating/planned mining operations within the Robe River Valley. 17. Assess any impacts to subterranean fauna with reference to relevant impacts from the Proposal (including taking into consideration any relevant guidelines, policies, plans and statutory provisions). For species which are likely to be impacted, including MNES listed species (Blind Cave Eel), provide information, including maps on habitat extent and an appropriate explanation of the likely distribution of species within those habitats, including information to support habitat connectivity. 18. Provide a detailed description of the cumulative impacts to conservation significant and other species within the Development Envelope and on a regional scale.

	19. Discuss proposed objectives, management, monitoring and mitigation methods to be implemented demonstrating that the design of the Proposal has addressed the mitigation hierarchy to avoid and minimise impacts to subterranean fauna. 20. Develop a Subterranean fauna management plan(s) to apply to the Proposal. The objective of the plan is to ensure the protection of conservation listed subterranean fauna species within the Development Envelope and areas of indirect impact. 21. Prepare a Mine Closure Plan consistent with DMP and EPA Guidelines for Preparing Mine Closure Plans (2015) which delineate and considers the use of Mining Exclusion Zones (MEZ) to protect troglofauna habitat and takes into consideration groundwater recovery to support stygofauna habitat. 22. Predict the inherent and residual impacts before and after applying the mitigation hierarchy and identify whether the residual impacts are significant by applying the Significant Residual Impact Model in the WA Environmental Offsets Guideline. 23. Quantify any significant residual impacts by completing the Offset Template and propose an appropriate offsets package that demonstrates application of the WA Environmental Offsets Policy and Guideline. 24. Demonstrate and document in the ERD how the EPA's objective for this factor can be met.

Government of Western Australia *WA Environmental Offsets Policy* (2011). Government of Western Australia *WA Environmental Offsets Guidelines* (2014).
Terrestrial Fauna	
EPA objective	To protect terrestrial fauna so that biological diversity and ecological integrity are maintained.
Relevant activities	Clearing of native vegetation, abstraction of groundwater, discharge of surplus dewater into Jimmawurrada Creek and / or the Robe River, vehicle strike, generation of noise, vibration and dust.

	Work may also include installation of infrastructure/use of equipment (including vehicles) incorporating lighting and/or fencing (with reference to bat species).
Potential impacts and risks	• Loss of individuals due to vehicle strikes and as a result of construction and operation of the mine. • Reduction in fauna habitat and loss of individuals due to clearing of native vegetation and development of mine pits and associated infrastructure. • Direct and indirect fragmentation of habitat. • Indirect impacts to fauna due to: o altered fire regimes due to clearing of native vegetation; o altered surface and groundwater regimes; o changes to feral animal populations; o introduction or spread of weed species; and o mine related changes / restrictions to habitat (e.g. light, fencing).
Required work	25. Provide a desktop review and analysis of all surveys of the Development Envelope undertaken in accordance with EPA Policy and Assessment, Survey guidelines for Australia's threatened mammals. 26. The study should include: o a justification of how those surveys are relevant and representative of the Development Envelope and if they were carried out using methods consistent with the EPA policy; and o a comprehensive listing of vertebrate fauna and short range endemic (SRE) invertebrate fauna known or likely to occur in the habitats present, and identification of conservation significant fauna species likely to occur in the area. 27. Conduct Level 2 terrestrial fauna and SRE invertebrate surveys (including aquatic fauna) in areas not previously surveyed that are likely to be directly or indirectly impacted as a result of the Proposal. Surveys are to be undertaken in accordance with technical guidance statements and, where available, species-specific survey guidelines for relevant species listed under the *Wildlife Conservation Act 1950* and the *Environment Protection and Biodiversity Conservation Act 1999*. 28. Conduct additional targeted surveys for conservation significant fauna that are known to or likely to occupy habitats in the Development Envelope if demonstrated to be required based on the results of the desktop study and Level 2 surveys. 29. Specify MNES being assessed as part of the accredited assessment. 30. Investigate and provide a description of any potential bat populations, and habitat (including foraging habitat) in the Development Envelope, and potential impacts from the Proposal. 31. For each relevant conservation significant fauna, including MNES (Northern Quoll, Pilbara Olive Python, Pilbara Leaf-nosed Bat, and Ghost Bat) recorded or likely to occur within the Development Envelope, provide where possible: • baseline information on their distribution (including known occurrences), ecology, and habitat preferences at the site level; • information on the conservation value of each habitat type from a local and regional perspective; • if a population of a conservation significant species is present on the site, its size and the importance of that population from a local and regional perspective; and

	• maps illustrating the known recorded locations of conservation significant species and short-range endemic invertebrates in relation to the proposed disturbance and areas to be impacted. 32. Identify the fauna habitat types within and outside the areas of impact. Consider habitat types that provide important ecological function within the Development Envelope. 33. Discuss known existing threats to conservation significant fauna, whether or not attributable to the Proposal, with reference to relevant impacts from the Proposal (including taking into consideration any relevant guidelines, policies, plans and statutory provisions). 34. Provide a detailed description of the potential direct, indirect and cumulative impacts to conservation significant fauna within the Development Envelope on a local and regional scale. Propose areas of key significance that may be considered for mine exclusion zones (including cave habitats, rocky outcrops and pools). 35. For all conservation significant fauna that are not likely to be impacted by the Proposal, but for which suitable habitat is present, demonstrate that an impact on the species will not or is unlikely to occur. 36. Discuss proposed objectives, management, monitoring and mitigation methods to be implemented demonstrating that the design of the Proposal has addressed the mitigation hierarchy to avoid and minimise impacts to terrestrial fauna. 37. Develop a conservation significant fauna management plan to apply to the Proposal. The objective of the plan is to ensure the protection of threatened species that will be impacted by the Proposal and their habitat within the Development Envelope. 38. Prepare a Mine Closure Plan consistent with DMP and EPA *Guidelines for Preparing Mine Closure Plans* (2015), which addresses the need for progressive rehabilitation of habitat for conservation significant species. 39. Predict the inherent and residual impacts before and after applying the mitigation hierarchy and identify whether the residual impacts are significant by applying the Significant Residual Impact Model in the WA Environmental Offsets Guideline. 40. Quantify any significant residual impacts by completing the Offset Template, spatially defining the habitat area for each significant fauna species that will be disturbed as a result of this proposal (excluding the approved Mesa J Operation), and propose an appropriate offsets package that demonstrates application of the WA Environmental Offsets Policy and Guideline. 41. Demonstrate and document in the ERD how the EPA's objective for this factor can be met. Note: Conservation significant fauna are defined as species that are listed under the *Environment Protection and Biodiversity Conservation Act 1999* and *Wildlife Conservation Act 1950*, and the Department of Biodiversity, Conservation and Attractions Priority Species that are likely to have their conservation status changed by the proposal.

Hydrological Processes and Inland Waters Environmental Quality	
EPA objective	To maintain the hydrological regimes of groundwater and surface water so that environmental values are protected. To maintain the quality of groundwater and surface water so that environmental values are protected.
Relevant activities	Abstraction of groundwater. Discharge of surplus dewater into Jimmawurrada Creek / Robe River. Alteration of surface water flows through the Development Envelope.
Potential impacts and risks	Groundwater drawdown due to mine pit dewatering and abstraction for operational water use (processing, dust management, potable water) may result in: • reduction to water levels in semi-permanent and permanent pools in the Robe River; and

	• reduction in groundwater levels in Jimmawurrada Creek. The discharge of surplus dewater into Jimmawurrada Creek / Robe River will result in surface flow downstream of the discharge point under natural no-flow conditions and could lead to erosion of the creek bank, alteration to fauna habitat. The discharge of surplus dewater into Jimmawurrada Creek / Robe River may reduce water quality. Surface water flows through the Development Envelope may become contaminated (e.g. by sediment or hydrocarbon spills).
Required work	42. Characterise the baseline hydrology and hydrogeological regimes and water quality, both in a local and regional context, including but not limited to, water levels, water chemistry, stream flows, flood patterns, and water quantity and quality. 43. Provide a detailed description of the design and location of the Proposal with the potential to impact surface water or groundwater. A figure should be provided in the ERD which depicts the predicted location of the wetting front (under natural no-flow conditions). 44. Provide a conceptual model of the surface and groundwater systems including the extent of connectivity between surface and groundwater systems and demonstrate that there will be no migration of seepage from infrastructure towards the Bungaroo Creek P1 Water Reserve. 45. Provide a conceptual mine water balance over the life of the Proposal to discuss the capacity to reuse surplus mine dewater. 46. Provide a geochemical risk characterisation of the waste material to be backfilled in pit which may be exposed to groundwater. 47. Discuss the potential environmental impacts and benefits of identified surplus water management options (i.e. discharge of excess mine dewater, reuse on site, local water supply, aquifer recharge etc.) and discuss the most appropriate water management strategy for the Proposal. 48. Analyse, discuss and assess surface water and groundwater impacts, including alternatives options to water management and the feasibility of each option: • changes in groundwater levels and changes to surface water flows associated with the Proposal; • the nature, extent, and duration of impacts; • cumulative impacts with other projects and referred proposals in the Robe Valley, for which relevant information is publicly available; and • impacts on the environmental values of significant receptors including but not limited to the Robe River catchment. 49. Demonstrate application of the mitigation hierarchy to avoid and minimise impacts to Hydrological Processes and Inland Waters Environmental Quality. 50. Prepare a Mine Closure Plan consistent with DMP and EPA *Guidelines for Preparing Mine Closure Plans* (2015) which addresses the development of completion criteria to maintain of the hydrological regimes and the quality of groundwater and surface water so that environmental values are maintained post closure. Specify whether the below water table pits will be backfilled to a level to prevent post-closure exposure of the groundwater table and the formation of permanent pit lakes. 51. Demonstrate and document in the ERD how the EPA's objective for this factor can be met.
Relevant policy and guidance	<u>EPA Policy and Guidance</u> EPA *Statement of Environmental Principles, Factors and Objectives* (2016).

Social Surroundings	
EPA objective	To protect social surroundings from significant harm.
Relevant activities	Clearing and excavation for mining activities. Abstraction of groundwater for mining and related activities. Discharge of surplus dewater. Alteration to hydrological processes.
Potential impacts and risks	Disturbance of sites of cultural significance. Prevention or change to access to a site. Changes to the physical and biological attributes of the environment which would impact on sites of heritage significance.
Required work	52. Characterise the heritage and cultural values of proposed disturbance areas and any other areas that may be indirectly impacted to identify sites of significance and their relevance within a wider regional context. 53. Conduct Aboriginal heritage surveys in conjunction with the native title claim (WCD2016/006) holders Kuruma Marthudunera and other local people to identify Aboriginal sites of significance and identify concerns in regard to impacts from proposed mining operations. 54. Provide a description of the heritage values within the Development Envelope and proposed disturbance. 55. Assess the impacts of the Proposal on heritage sites and/or cultural associations as a result of implementation of the Proposal, including those arising from changes to the environment which may impact on ethnographic and archaeological heritage significance. 56. Demonstrate the application of the mitigation hierarchy to avoid and minimise impacts to social surroundings. 57. Provide detail on consultation that will be undertaken with Traditional Owners in preparing the mine closure plan, particularly in relation to water management. 58. Prepare a Mine Closure Plan consistent with DMP and EPA *Guidelines for Preparing Mine Closure Plans* (2015), which addresses the need to protect the social surrounds from significant harm post closure. 59. Demonstrate and document in the ERD how the EPA's objective for this factor can be met.
Relevant policy and guidance	<u>EPA Policy and Guidance</u> EPA *Statement of Environmental Principles, Factors and Objectives* (2016).

	EPA *Environmental Factor Guideline: Social surroundings* (2016). EPA *Instructions on how to prepare Environmental Protection Act 1986 Part IV Environmental Management Plans* (2016). Air Quality	
EPA objective	To maintain air quality and minimise emissions so that environmental values are protected.
Relevant activities	Clearing of native vegetation. Mining and ore processing activities.
Potential impacts and risks	Increase in Greenhouse Gas Emissions due to additional mining activities. Increase in dust to sensitive receptors due to blasting, excavation and haulage of ore.
Required work	60. Characterise the greenhouse gas emission key sources from the Proposal and estimation of expected Scope 1 (direct) and Scope 2 (energy indirect) greenhouse gas emissions. 61. Analysis of greenhouse gas intensity (i.e. quantity of CO2-e generated per tonne of product produced). 62. Demonstrate and document in the ERD how the EPA's objective for this factor can be met.
Relevant policy and guidance	EPA Policy and Guidance EPA *Statement of Environmental Principles, Factors and Objectives* (2016). EPA Environmental Factor Guideline: *Air quality* (2016). Other policy and guidance *Clean Energy Act 2011.* *National Greenhouse and Energy Reporting Act 2007.*

4. Other environmental factors or matters

The EPA has identified the following other environmental factor or matter relevant to the proposal that must be addressed during the public environmental review and discussed in the ERD:

1. Landforms

There is potential for significant cumulative impacts on landforms (particularly the mesa structures) within the Robe River valley. Taking into consideration Section 2.1 – Regional Context, the cumulative impacts on the mesa structures of the Robe River valley should be considered and detailed in the ERD, including the following required work:

- A description of the geology and morphology of the landforms within the Robe River valley;

- Spatially define the significant mesa habitat (including rocky ridge, gorge and breakaway habitat) along the Robe River, and the location of the operating and proposed mining operations; and
- Describe the cumulative impacts on the landforms from historic and reasonably foreseeable future developments.

It is also important that the Proponent be aware that other factors or matters may be identified during the course of the environmental review that were not apparent at the time that this ESD was prepared. If this situation arises, the Proponent must consult with the EPA to determine whether these factors and/or matters are to be addressed in the ERD, and if so, to what extent.

5. Stakeholder consultation

The Proponent must consult with stakeholders who are affected by, or are interested in the Proposal. This includes the decision-making authorities (see section 6), other relevant state (and Commonwealth) government agencies and local government authorities, the local community, and environmental non-government organisations.

The Proponent must document the following in the ERD:

- identified stakeholders;
- the stakeholder consultation undertaken and the outcomes, including decision-making authorities' specific regulatory approvals and any adjustments to the Proposal as a result of consultation; and
- any future plans for consultation.

6. Decision-making authorities

At this stage, the EPA has identified the authorities listed in Table 6 as decision-making authorities (DMAs) for the Proposal. Additional DMAs may be identified during the course of the assessment.

Table 6: Decision-making authorities

Decision-making authority	Relevant legislation
1. Minister for State Development.	*Iron Ore (Robe River) Agreement Act 1964.*
2. Minister for Mines and Petroleum.	*Mining Act 1978.*
3. Minister for Lands.	*Land Administration Act 1997.*
4. Minister for Environment.	*Wildlife Conservation Act 1950.*
5. Chief Executive Officer, Department of Water and Environmental Regulation.	*Environmental Protection Act 1986.*
6. Executive Director: Environment, Department of Mines, Industry, Regulation and Safety.	*Mining Act 1978.*
7. State Mining Engineer, Department of Mines, Industry, Regulation and Safety.	*Mines Safety and Inspection Act 1994.*
8. Chief Executive Officer: Department of Mines, Industry, Regulation and Safety.	*Dangerous Goods Safety Act 2004.*
9. Department of Water and Environmental Regulation.	*Rights in Water and Irrigation Act 1914.*
10. Minister for Aboriginal Affairs.	*Aboriginal Heritage Act 1972.*

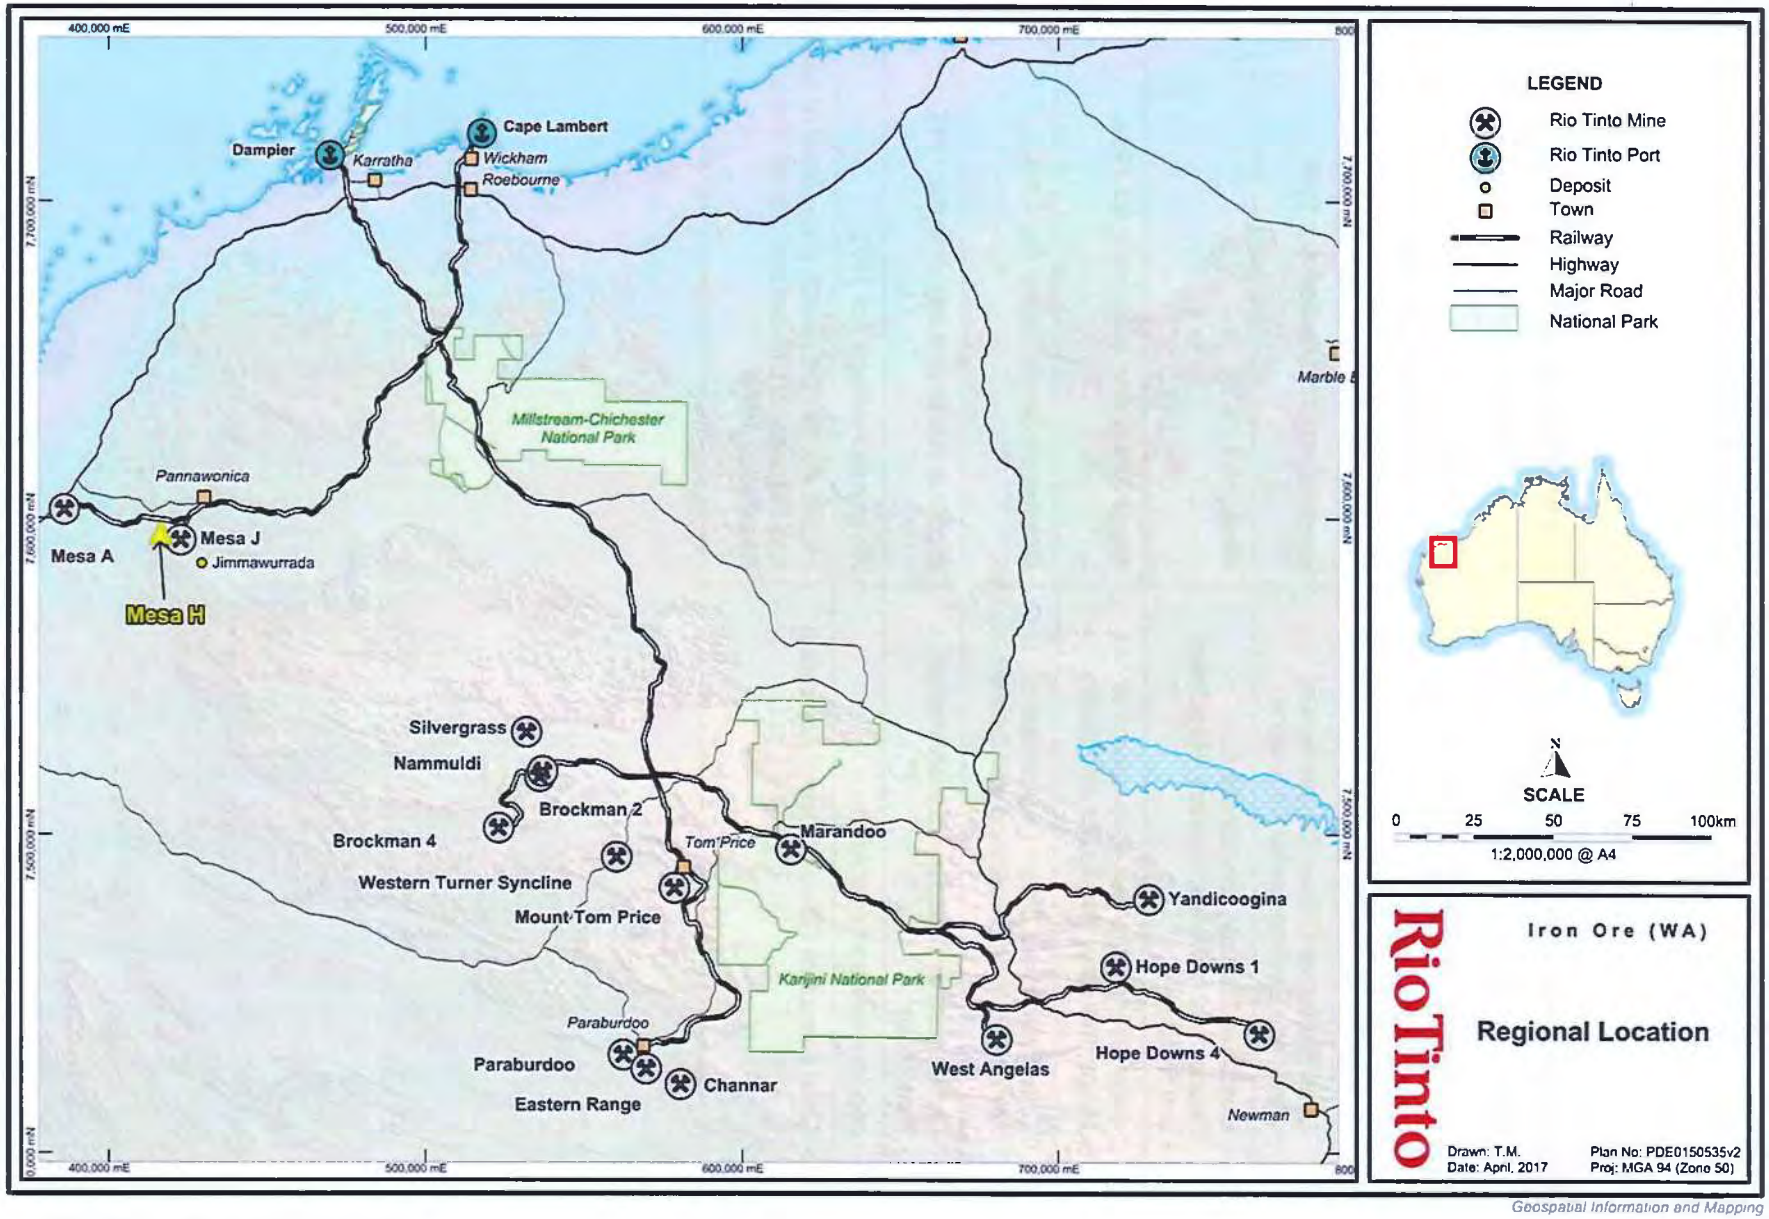

Figure 1 – Regional location

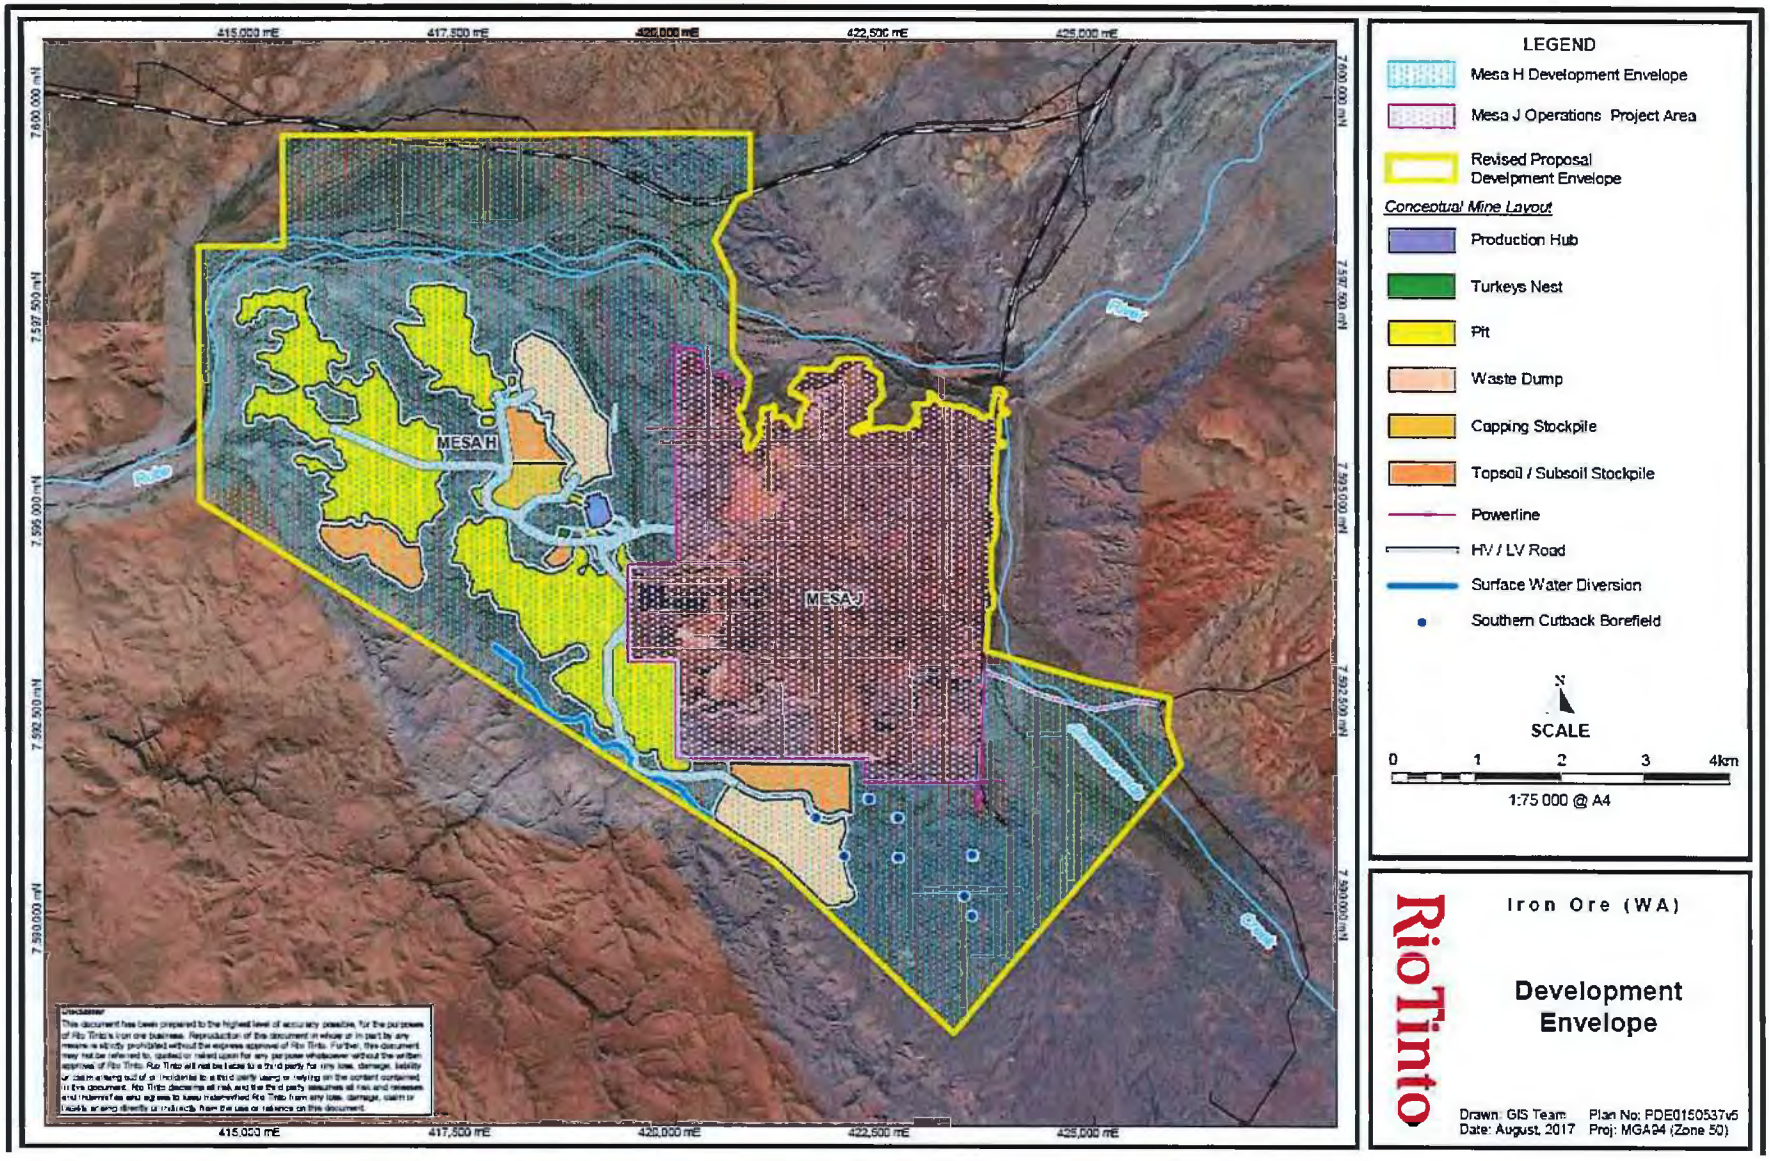

Figure 2 – Revised Development Envelope

Mesa H Proposal (Revision to the Mesa J Iron Ore Development)

Proposed Ministerial Conditions

The existing Mesa J Iron Ore Development, the subject of MS 208 is managed via nine existing Ministerial conditions:

1. Proponent Commitments
2. Implementation
3. Environmentally Significant Areas
4. Drainage Management
5. Dewatering Management
6. Rehabilitation
7. Environmental Management Programme
8. Proponent
9. Time limit on Approval

The Proponent has undertaken a review of these existing Ministerial conditions and proposes that, subject to approval, these Ministerial conditions be amended as follows:

- Conditions shall be updated to reflect contemporary wording and format, consistent with other recent Ministerial Statements for the Proponent's Pilbara iron ore operations.
- Development of conditions which reflect the requirement for Condition Environmental Management Plans to meet environmental outcomes for key environmental factors (inland waters, flora and vegetation, subterranean fauna, and terrestrial fauna) consistent with the EP Act, EPA guidance (*Statement of Environmental Principles, Factors and Objectives*, 2016) and other recent Ministerial Statements for the Proponent's Pilbara iron ore operations.
- Removal of redundant conditions, or conditions that are managed under other regulatory processes and as such, do not require regulation under Part IV the EP Act, where this can be justified.

The proposed Ministerial conditions of the Mesa H Project (revision to the Mesa J Iron Ore Development) include the following:

1. Proposal Implementation
2. Contact Details
3. Compliance Reporting
4. Public Availability of Data
5. Condition Environmental Management Plan

6. Inland Waters and Flora and Vegetation – Groundwater abstraction, discharge, riparian vegetation and pool ecosystems
7. Terrestrial Fauna - Conservation significant fauna species; Ghost Bat (*Macroderma gigas*) and Northern Quoll (*Dasyurus hallacatus*),
8. Subterranean fauna – troglofauna
9. Subterranean fauna - stygofauna (including the Blind Cave Eel: *Ophisternon candidum*)
10. Rehabilitation and Decommissioning
11. Offsets

Table 1 provides the proponents rationalisation for the proposed changes.

The proposed Ministerial conditions are closely aligned to the existing Ministerial conditions and will maintain the overall level of protection of environmental values and the required standard of management of key environmental factors. The Proponent proposes that these conditions be adopted for the new Ministerial Statement that, subject to approval, will supersede the existing MS208.

DRAFT ENVIRONMENTAL CONDITIONS

STATEMENT THAT A REVISED PROPOSAL MAY BE IMPLEMENTED (PURSUANT TO THE PROVISIONS OF SECTION 46 OF THE *ENVIRONMENTAL PROTECTION ACT 1986*)

MESA H PROJECT (REVISION TO THE MESA J IRON ORE DEVELOPMENT)

Revised Proposal:	The Mesa H Project is a revision of the existing Mesa J Iron Ore Development, the subject of Ministerial Statement 208, dated 16 January 1992. The Revised Proposal includes the existing Mesa J Iron Ore Project and a revision to include Mesa H which involves additional above and below water table mine pits and the construction and operation of associated infrastructure, waste dumps and water management infrastructure, located approximately 16 kilometres west of Pannawonica in the Pilbara region of Western Australia, as documented in Schedule 1 of this Ministerial Statement.
Proponent:	Robe River Mining Co. Pty. Ltd. Australian Company Number 008 694 246
Proponent Address:	152-158 St Georges Terrace PERTH WA 6000 GPO Box A42, PERTH WA 6001
Assessment Number:	**2121**

Report of the Environmental Protection Authority: xxxx

Previous Report of the Environmental Protection Authority: 574

Previous Ministerial Statement Number: 208

Pursuant to section 45, read with section 45B of the *Environmental Protection Act 1986,* it has been agreed that:

1. the Revised Proposal described and documented in Schedule 1 of this Statement may be implemented; and
2. from the date of this Statement, the implementation of the Revised Proposal is subject to the following revised implementation conditions which replace and supersede all previous conditions of Ministerial Statement 208.

Table 1: Rationalisation of Conditions of MS 208

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
1	**Proponent Commitments**		**1**	**Proposal Implementation**
	In implementing the proposal, the proponent shall fulfil the commitments (which are not inconsistent with the conditions or procedures contained in this statement) made in the proponent's Consultative Environmental Review (a copy of the commitments is attached).	This Condition is still relevant and should be retained; however, it has been updated to reflect contemporary wording and format, consistent with other recent Ministerial Statements for the Proponent's Pilbara iron ore operations.	1-1	When implementing the Revised Proposal, the proponent shall not exceed the authorised extent of the Revised Proposal as defined in Table 2 in Schedule 1 of this Statement, unless amendments to the Revised Proposal and the authorised extent of the Revised Proposal have been approved under the *Environmental Protection Act 1986*.
2	**Implementation**			
	Subject to these conditions, the manner of detailed implementation of the proposal shall conform in substance with that set out in any designs, specifications, plans or other technical material submitted by the proponent to the Environmental Protection Authority with the proposal. Where, in the course of that detailed implementation, the proponent seeks to change those designs, specifications, plans or other technical material in any way that the Minister for the Environment determines on the advice of the Environmental Protection Authority, is not substantial; those changes may be effected.	This Condition is still relevant and should be retained; however, it has been updated to reflect contemporary wording and format, consistent with other recent Ministerial Statements for the Proponent's Pilbara iron ore operations.		
8	**Proponent**		**2**	**Contact Details**
	Prior to any transfer of ownership, control or management of the project being effected which would give rise to the need for the replacement of the proponent, the Minister for the Environment shall be advised of the name and details of the transferee and invited to nominate a replacement proponent	This Condition is still relevant and should be retained; however, it has been updated to reflect contemporary wording and format, consistent with other recent Ministerial Statements for the Proponent's Pilbara iron ore operations.	2-1	The proponent shall notify the Chief Executive Officer (CEO) of any change of its name, physical address or postal address for the serving of notices or other correspondence within twenty eight (28) days of such change. Where the proponent is a corporation or an association of persons, whether incorporated or not, the postal address is that of the principal place of business or of the principal office in the State.

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
	If the Minister nominates a replacement proponent, a copy of this statement endorsed with an undertaking by the replacement proponent to carry out the project in accordance with the conditions and procedures set out in the statement shall be delivered to the Minister and thereupon the former proponent shall be released from the conditions of this statement to the extent of its interest transferred.			
3	**Compliance Reporting**		**3**	**Compliance Reporting**
		New contemporary condition.	3-1	The proponent shall prepare, submit and maintain a Compliance Assessment Plan to the satisfaction of the CEO prior to the first Compliance Assessment Report required by condition 3-6, or as agreed in writing by the CEO.
			3-2	The Compliance Assessment Plan shall indicate: 1. the frequency of compliance reporting; 2. the approach and timing of compliance assessments; 3. the retention of compliance assessments; 4. the method of reporting of potential non-compliances and corrective actions taken; 5. the table of contents of Compliance Assessment Reports; and 6. public availability of Compliance Assessment Reports.
			3-3	After receiving notice in writing from the CEO that the Compliance Assessment Plan satisfies the requirements of condition 3-2, the proponent shall assess compliance with conditions in accordance with the Compliance Assessment Plan required by condition 3-1.

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
			3-4	The proponent shall retain reports of all compliance assessments described in the Compliance Assessment Plan required by condition 3-1 and shall make those reports available when requested by the CEO.
			3-5	The proponent shall advise the CEO of any potential non-compliance within seven (7) days of that non-compliance being known.
			3-6	The proponent shall submit to the CEO the first Compliance Assessment Report by 30 April each year addressing compliance in the previous calendar year, or as agreed in writing by the CEO. The first Compliance Assessment Report shall be submitted by 30 April 2019 addressing the compliance for the period from the date of issue of this Statement, notwithstanding that the first reporting period may be less than 12 months. The Compliance Assessment Report shall: 1. be endorsed by the proponent's Chief Executive Officer or a person delegated to sign on the Chief Executive Officer's behalf; 2. include a statement as to whether the proponent has complied with the conditions; 3. identify all potential non-compliances and describe corrective and preventative actions taken; 4. be made publicly available in accordance with the approved Compliance Assessment Plan; and 5. indicate any proposed changes to the compliance assessment plan required by condition 3-1.

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
4	**Public Availability of Data**		**4**	**Public Availability of Data**
4-1		This Condition is still relevant and should be retained; however, it has been updated to reflect contemporary wording and format, consistent with other recent Ministerial Statements for the Proponent's Pilbara iron ore operations.	4-1	Subject to condition 4-2, within a reasonable time period approved in writing by the CEO of the issue of this Statement and for the remainder of the life of the Revised Proposal, the proponent shall make publicly available, in a manner approved in writing by the CEO, all validated environmental data (including sampling design, sampling methodologies, empirical data and derived information products e.g. maps) required under this Statement.
4-2			4-2	If any data referred to in condition 4-1 contains particulars of: 1. a secret formula or process; or 2. confidential commercially sensitive information; the proponent may submit a request for approval from the CEO to not make this data publicly available. In making such a request the proponent shall provide the CEO with an explanation and reasons why the data should not be made publicly available.
7	**Environmental Management Program**		**5**	**Condition Environmental Management Plans**
7	A comprehensive management programme for the project should be prepared to integrate the various components referred to in conditions 4, 5 and 6 above. This will allow reporting for the various aspects of the project to, be done in one document.			
7-1	Prior to construction, the proponent shall prepare an interim report outlining the key components of a comprehensive environmental management programme to the satisfaction of the Minister for the Environment on advice of the Environmental Protection Authority. The programme shall include but not necessarily be limited to: 1. drainage;	This Condition is still relevant and should be retained; however, it has been updated to reflect contemporary wording and format, consistent with other recent Ministerial Statements for the Proponent's Pilbara iron ore operations.	5-1	Within 6 months of the issue of this Statement, the proponent shall prepare and implement a Condition Environmental Management Plan to the satisfaction of the CEO. This plan shall demonstrate that the **environmental outcomes** specified in in condition 6-1, 7-1 and 8-1 and the **environmental objectives** specified in conditions 7-2, 8-2 and 9-2 will be met.

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
	2. rehabilitation; and 3. dewatering.			
7-2	Subsequent to condition 7-1 and prior to the commencement of mining, the proponent shall prepare a comprehensive environmental management programme to the satisfaction of the Minister for the Environment on advice of the Environmental Protection Authority. Whilst initial reporting would be to the Environmental Protection Authority, future reporting could be done under the Iron Ore (Robe River) Agreement Act. The programme shall include but not necessarily be limited to: ' 1. the plan for drainage management required by condition 4-1; 2. the plan for rehabilitation required by condition 6-1; and 3. a status report on the plan for dewatering management as per condition 5-1.		5-2	For outcome based provisions, the Condition Environmental Management Plan shall: 1. specify the **environmental outcomes** to be achieved, as specified in condition 5-1; 2. specify **trigger criteria** that must provide an early warning that the threshold criteria may not be met; 3. specify **threshold criteria** to demonstrate compliance with the environmental outcomes specified in condition 5-1. Exceedance of the threshold criteria represents non-compliance with these conditions; 4. specify **monitoring** to determine if trigger criteria and threshold criteria are exceeded; 5. specify **trigger level actions** to be implemented in the event that trigger criteria have been exceeded; 6. specify **threshold contingency actions** to be implemented in the event that threshold criteria are exceeded; and 7. provide the format and timing for the reporting of monitoring results against trigger criteria and threshold criteria to demonstrate that condition 5-1 has been met over the reporting period in the Compliance Assessment Report required by condition 3-6.

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
				For management based provisions, the Condition Environmental Management Plan shall: (1) specify the **environmental objectives** to be achieved, as specified in condition 5-1; (2) specify **management actions** to meet the environmental objective; (3) specify **management targets**; (4) specify **monitoring** to determine if management targets are being met (5) provide the format and timing for the reporting of monitoring results against management targets to demonstrate that condition 5-1 has been met over the reporting period in the Compliance Assessment Report required by condition 3-6.
			5-3	After receiving notice in writing from the CEO that the Condition Environmental Management Plan satisfies the requirements of condition 5-2 the proponent shall: 1. implement the Condition Environmental Management Plan; and 2. continue to implement the Condition Environmental Management Plan until the CEO has confirmed by notice in writing that the proponent has demonstrated the objectives specified in condition 5-1 have been met.

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
			5-4	In the event that the monitoring indicates an exceedance of the threshold criteria specified in the Condition Environmental Management Plans, the proponent shall: 1. report the exceedance in writing to the CEO within seven (7) days of the exceedance being identified; 2. implement the threshold level contingency actions specified in the Condition Environmental Management Plans within 24 hours and continue implementation of those actions until the CEO has confirmed by notice in writing that it has been demonstrated that the threshold criteria are being met and the implementation of the threshold contingency actions is no longer required; 3. investigate to determine the cause of the threshold criteria being exceeded; 4. investigate to provide information for the CEO to determine potential environmental harm that occurred due to the threshold criteria being exceeded; and 5. provide a report to the CEO within twenty one (21) days of the exceedance being reported as required by condition 5-6(1). The report shall include; a. details of threshold contingency actions implemented; b. the effectiveness of the threshold contingency actions implemented, against the threshold criteria; c. the findings of the investigations; d. measures to prevent the threshold criteria being exceeded in the future;

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
			5-4	e. measures to prevent, control or abate the environmental harm which may have occurred; and f. justification of the threshold remaining, or being adjusted based on better understanding, demonstrating that outcomes would continue to be met.
			5-5	The proponent: 1. may review and revise the Condition Environmental Management Plan, or 2. shall review and revise the Condition Environmental Management Plan as and when directed by the CEO.
4	**Drainage Management**		**6**	**Inland Waters and Flora and Vegetation – Groundwater abstraction, discharge, riparian vegetation and pool ecosystems**
4	The Robe River - Jimmawurrada Creek system needs to be protected from pollution and unacceptable sedimentation, recognising the requirements of mining and ore transport.	This Condition is still relevant and should be retained; however, it has been updated to reflect contemporary wording and format, consistent with other recent Ministerial Statements for the Proponent's Pilbara iron ore operations.	6-1	The proponent shall manage the implementation of the Revised Proposal to meet the following environmental outcomes: (1) No irreversible impact, as a result of the proponent's water abstraction, to the health of groundwater dependent vegetation within the Robe River. (2) No irreversible impact, as a result of the proponent's water abstraction, to the health of riparian vegetation communities within Jimmawurrada Creek. (3) No irreversible impact, as a result of the Proponent's discharge of surplus water, to the health of riparian vegetation communities of Jimmawurrada Creek and the Robe River. (4) No irreversible impact, as a result of the Proponent's drawdown and discharge, to the pool ecosystems of the Robe River.
4-1	Prior to construction at the site, the proponent shall prepare a Drainage Management Programme, to protect the Robe River - Jimmawurrada Creek system from the deleterious impacts of sedimentation and pollution from the project, to the satisfaction of the Minister for the Environment on advice of the Environmental Protection Authority, the Department of Conservation and Land Management and the Water Authority of Western Australia. The plan is to include but is not necessarily limited to:			

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
	1. a monitoring programme to detect impacts; 2. procedures for protecting the ecology of the system; 3. procedures for reporting on the programme; and 4. a commitment to ameliorate environmental impacts to the satisfaction of the Environmental Protection Authority if impacts are detected which are deemed unacceptable by the Environmental Protection Authority.			
4-2	Subsequent to condition 4-1, the proponent shall implement the approved Drainage Management Programme to the satisfaction of the Environmental Protection Authority on advice of the Water Authority of Western Australia and the Department of Conservation and Land Management.			
5	**Dewatering Management**			
5	The permanent pools and vegetation of the Robe River - Jimmawurrada Creek system are to be protected from unacceptable environmental impacts, recognising the requirements of mining and ore transport.			
5-1	Prior to the commencement of dewatering, the proponent shall prepare a Dewatering Management Programme, to protect the Robe River - Jimmawurrada Creek system, to the satisfaction of the Environmental Protection Authority on advice of the Department of Conservation and Land Management and the Water Authority of Western Australia. The plan is to include but is not necessarily limited to: 1. a monitoring programme to detect impacts;			

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
	2. procedures for protecting the ecology and water quality of the permanent pools and associated vegetation; 3. procedures for reporting on the programme; and 4. a commitment to ameliorate environmental impacts to the satisfaction of the Environmental Protection Authority if impacts are detected which are deemed unacceptable by the Environmental Protection Authority.			
5-2	Subsequent to condition 5-1, the proponent shall implement the approved Environmental Management Programme to the satisfaction of the Environmental Protection Authority on advice of the Water Authority of Western Australia and the Department of Conservation and Land Management.			
			7	**Terrestrial Fauna - Conservation significant fauna species; Ghost Bat (*Macroderma gigas*), and Northern Quoll (*Dasyurus hallacatus*)**
		New environmental factor condition for Mesa H		The proponent shall manage the implementation of the Revised Proposal to meet the following environmental outcomes: (1) No irreversible impact, as a result of the proponent's activities to Breakaways and Gullies habitat retained in the escarpments of Mesa H Mining Exclusion Zone, other than existing and authorised disturbance. The proponent shall manage the implementation of the Revised Proposal to meet the following environmental objective: (1) The proponent shall improve knowledge of the Ghost Bat population and utilisation of high value habitat in the Robe Valley in order to assist in maintaining biological diversity and ecological

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
				integrity.
			8	**Subterranean Fauna - Troglofauna**
		New environmental factor condition for Mesa H	8-1	The proponent shall manage the implementation of the Revised Proposal to meet the following environmental outcome: (1) No irreversible impact, as a result of the proponent's activities, to the troglofauna habitat retained within the Mesa H MEZ The proponent shall manage the implementation of the Revised Proposal to meet the following environmental objective: (1) The Proponent shall protect the biological diversity and ecological integrity of the troglofauna assemblages of Mesa H by minimising impacts as far as practicable.
			9	**Subterranean Fauna - Stygofauna**
		New environmental factor condition for Mesa H	9-1	The proponent shall manage the implementation of the Revised Proposal to meet the following environmental outcome:

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
				(1) No irreversible impact, as a result of the proponent's water management activities to the stygofauna habitat within the alluvial aquifer habitats of Jimmawurrada Creek and the Robe River. The proponent shall manage the implementation of the Revised Proposal to meet the following environmental objective: (1) The Proponent shall protect the biological diversity and ecological integrity of the stygofauna assemblages within the Robe River and Jimmawurrada alluvial aquifer habitats by minimising impacts as far as practicable.
6	**Rehabilitation**		**10**	**Rehabilitation and Decommissioning**
6-1	Rehabilitation is an integral part of the project and requires management throughout the life of the project. Within 12 months of the date of this statement, the proponent shall prepare a Rehabilitation Management Programme to the satisfaction of the Environmental Protection Authority on advice of the Department of' Mines and the Department of Conservation and Land Management. The programme shall include but not necessarily be limited to: 1 . proposals for rehabilitation of the project area; and 2. a monitoring programme to determine success of the rehabilitation.	This Condition is still relevant and should be retained; however, it has been updated to reflect contemporary wording and format, consistent with other recent Ministerial Statements for the Proponent's Pilbara iron ore operations.	10-1	The proponent shall manage the implementation of the Revised Proposal to meet the following environmental objective: (1) Ensure that the Revised Proposal is rehabilitated and decommissioned in an ecologically sustainable manner. (2) Ensure that closure planning and rehabilitation are undertaken in a progressive manner.
6-2	The initial programme shall be submitted to the Environmental Protection Authority, with subsequent programmes for the project to be updated annually in		10-2	Within 12 months of the issue of this Statement or as otherwise agreed in writing from the CEO, the proponent shall prepare and submit a Mine Closure Plan in accordance with the Guidelines for Preparing Mine Closure Plans, May 2015 (or any subsequent

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
	conjunction with reporting requirements under the Iron Ore (Robe River) Agreement Act.			revisions of the guidelines), to the requirements of the CEO, on advice of the Department of Mines, Industry Regulation and Safety and the Department of Water and Environmental Regulation.
6-3	At least twelve months prior to decommissioning, the proponent shall prepare a plan for decommissioning and rehabilitating the site, to the satisfaction of the Environmental Protection Authority on advice of the Department of Mines and the Department of Conservation and Land Management.		10-3	The proponent shall review and revise the Mine Closure Plan required by condition 10-2 at intervals not exceeding three years, or as otherwise specified by the CEO, and submit the plan to the CEO at the agreed interval.
6-4	Subsequent to conditions 6-1 and 6-3, the proponent shall implement the approved programmes for rehabilitating and decommissioning the site; to the satisfaction of the Environmental Protection Authority on advice of the Department of Mines and the Department of Conservation and Land Management.		10-4	The proponent shall implement the latest revision of the Mine Closure Plan, which the CEO has confirmed by notice in writing, satisfies the requirements of condition 10-2.
10	**Offsets**		**11**	**Offsets**
		New contemporary condition	11-1	In view of the residual impacts and risks as a result of implementation of the Revised Proposal, the proponent shall contribute funds to offset: • clearing of Northern Quoll core habitat • clearing of 'good to excellent' condition native vegetation in the Hamersley IBRA subregion, • clearing of riparian vegetation in the Hamersley IBRA subregion • clearing within areas defined as Priority Ecological Communities: the *Subterranean invertebrate community of pisolitic hills* and the *Subterranean invertebrate community of mesas in the Robe Valley region*

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
				• direct impact to the subterranean Blind Cave Eel habitat within the Priority Ecological Community: *Stygofaunal community of the Bungaroo Aquifer* The offset shall be calculated pursuant to condition 11-2 subject to any reduction approved by the CEO under condition 11-7. This funding shall be provided to a government established conservation offset fund or an alternative offset arrangement providing an equivalent outcome as determined by the Minister.
			11-2	The proponent's contribution to the initiative identified in condition 11-1 shall be paid biennially, the first payment due two years after ground disturbance. The amount of funding will be made on the following basis in accordance with the approved Impact Reconciliation Procedure required by condition 11-4: • $ 3,000 AUD (excluding GST) per hectare of clearing within Northern Quoll core habitat; • $750 AUD (excluding GST) per hectare of clearing of "good to excellent" condition native vegetation cleared within the delineated Figure x as Area x within the Hamersley IBRA subregion; $1500 AUD (excluding GST) per hectare of clearing of riparian vegetation and Priority Ecological Communities, the *Subterranean invertebrate community of pisolitic hills* and the *Subterranean invertebrate community of mesas in the Robe Valley region*; and • $1500 AUD (excluding GST) per hectare of the *Stygofaunal community of the Bungaroo Aquifer* delineated in the drawdown Zone 3 in Jimmawurrada Creek.
			11-3	The clearing of 1800 ha of native vegetation previously authorised under statement MS 208, is exempt from the requirement to offset under condition 11-2.

Ministerial Conditions of MS 208		Proposed Change / Rationale	Proposed New Ministerial Conditions	
			11-4	Within twelve months of the date of this statement develop an Impact Reconciliation Procedure that: (1) Includes a methodology to identify clearing of 'Good to Excellent' condition native vegetation, riparian vegetation and Priority Ecological Communities in the Development Envelope; (2) Includes a methodology for calculating the amount of clearing undertaken during each biennial time period; and (3) States dates for the commencement of the biennial time period and for the submission of results of the Impact Reconciliation Procedure, to the satisfaction of the CEO.
			11-5	The proponent shall implement the Impact Reconciliation Procedure required by condition 11-4.
			11-6	The real value of contributions described in condition 11-2 will be maintained through indexation to the Perth Consumer Price Index, (CPI) with the first adjustment to be applied to the first contribution.
			11-7	The proponent may seek the written approval of the CEO to reduce all or part of the contribution payable under condition 11-2 where: (1) a payment has been made to satisfy a condition of an approval under the *Environment Protection and Biodiversity Conservation Act 1999* in relation to the Revised Proposal; (2) the payment counterbalances impacts of the Revised Proposal on matters of national environmental significance; and (3) the payment counterbalances the significant residual impacts to the environmental values identified in condition 11-2.

Schedule 1

The Proponent proposes that, subject to approval, the summary of the Revised Proposal and the location and authorised extent of operational elements of Schedule 1 will be amended to consolidate the existing Ministerial Statement and this Revised Proposal, to read as follows:

Table 1: Summary of the Revised Proposal

Revised Proposal title	Mesa H Project (Revision to the Mesa J Iron Ore Development)
Proponent name	Robe River Mining Co. Pty. Ltd.
Short description	The Revised Proposal is located approximately 16 km south west of Pannawonica in the Pilbara region of Western Australia (Figure 1). The Revised Proposal includes development of above and below water table open cut pits at Mesa J and Mesa H, ore processing facilities, waste dumps, ore, topsoil and subsoil stockpiles and associated infrastructure, including water management infrastructure. This Revised Proposal utilises infrastructure including processing facilities (subject to upgrades), waste fines storage facilities and rail from the existing Mesa J operations.

Table 2: Location and authorised extent of physical and operational elements of the Revised Proposal

Element	Location	Existing approval (Ministerial Statement/s and other regulatory approvals)	Proposed change (This Proposal)	Proposed extent (Revised Proposal) *[total of existing approval + proposed change] [total of existing approval + proposed change]*
Physical Elements				
Mine and associated infrastructure	Figure 2	Total disturbance area (vegetation clearing) of up to 1,800 ha	Clearing of up to 2,200 ha of native vegetation within the Development Envelope of 6,638ha. Disturbance in the Mesa H Mining Exclusion Zone in accordance with the Environmental Management Plan.	Clearing of up to 4,000 ha of native vegetation within the Development Envelope of 6,638 ha. Disturbance in the Mesa H Mining Exclusion Zone in accordance with the Environmental Management Plan.
Rail	Figure 1	Single gauge railway line with sidings and a voice and radio data communications system with Fibre optic cable, from Cape Lambert.	N/A	Remove as not environmentally relevant

Element	Location	Existing approval (Ministerial Statement/s and other regulatory approvals)	Proposed change (This Proposal)	Proposed extent (Revised Proposal) *[total of existing approval + proposed change] [total of existing approval + proposed change]*
Operational Elements				
Groundwater abstraction for water supply, ore processing and pit dewatering	-	Not specified in MS 208 Annual water entitlement of 30 GL/a (Approved under *Rights in Water and Irrigation Act 1914* (RiWI) licence GWL107678(13))	No change	Groundwater abstraction up to 30 GL/a, including from: • Water supply from Southern Cutback Borefield • Pit dewatering
Surplus Water Management	-	Not specified in MS 208. Discharge of mine dewater at designated discharge points in Jimmawurrada Creek and a tributary of Robe River (Approved under Part V Operating Licence L6820/1993/12)	No change	Controlled surface discharge to extend along Jimmawurrada Creek / West Creek and into the Robe River no further than 8 km downstream of the discharge point under natural no-flow conditions.

Referral of proposed action

Proposed action title:	Mesa H Proposal

1. Summary of proposed action

1.1	**Short description:** Robe River Mining Co. Pty. Limited (the Proponent), as manager and agent for the Robe River Iron Associates joint venture (RRIA), is seeking to extend the existing Mesa J operations by developing the adjacent iron ore deposit at Mesa H. The Mesa H Proposal is located approximately 16 km south west of Pannawonica in the Pilbara region of Western Australia (refer Attachment 1). This Proposed Action will involve development of additional mine pits, mineral waste dumps and associated infrastructure, processing facilities and water management infrastructure to sustain the Robe Valley Operations ore feed at 35 Mt/annum.
1.2	**Latitude and longitude** Nodes are provided in Table 1 below.

Table 1: Nodes for the area subject to the Proposed Action

Location point	Latitude			Longitude		
	degrees	minutes	seconds	degrees	minutes	seconds
1	-21	42	20.68	116	10	53.24

1.3	**Locality and property description:** The Proposed Action is located approximately 16 km south west of Pannawonica and 130 km south-west of Karratha in the Pilbara region of Western Australia (refer Attachment 1). The area subject to the Proposed Action (the Development Envelope) is distant from major public population centres and significant tourist attractions. The Pannawonica access road runs to the north of the Development Envelope. Existing land uses include iron ore mining, mineral exploration, pastoral activities (Yarraloola and Yalleen Stations) and traditional owner activities such as camping, fishing and hunting.	
1.4	**Size of the development footprint or work area (hectares)**	The Proposed Action will involve clearing of up to 2,200 ha within the Development Envelope of 4,930 ha.
1.5	**Street address of the site**	Not applicable
1.6	**Lot description** The Proposed Action is centred on deposits located within State Agreement Mineral Lease ML248SA granted pursuant to the *Iron Ore (Robe River) Agreement Act 1964* held by Robe River Ltd and sub-leased to RRIA (refer Attachment 2). The Proposed Action is also situated on the Yarraloola and Yalleen Pastoral Stations Leases (N49500 and N49492 respectively) held by entities associated with members of the RRIA.	

1.7	**Local Government Area and Council contact (if known):** The Proposed Action is located in the Shire of Ashburton. The main Shire offices are located in the town of Tom Price and the relevant council contact is: Mr Neil Hartley Chief Executive Officer Shire of Ashburton PO Box 567 Tom Price, WA 6751 Telephone: (08) 9188 4457 Fax: (08) 9189 2090		
1.8	**Time frame:** The Proposed Action has an estimated operational mine life of approximately 17 years. Under the current project schedule, construction activities are planned to commence in Quarter 4 2018 once all required internal and external approvals are granted.		
1.9	**Alternatives to proposed action:** Were any feasible alternatives to taking the proposed action (including not taking the action) considered which are not proposed?	✓	No. The Proposed Action is centred on substantial iron ore deposits that are critical to sustaining the existing Mesa J Operation.
1.10	**Alternative time frames, locations or activities:** Does the proposed action include alternative time frames, locations or activities?	✓	No
1.11	**Commonwealth, State or Territory assessment:** Is the action subject to other a Commonwealth, State or Territory environmental impact assessment?	✓	Yes, refer to section 2.5
1.12	**Component of larger action:** Is the proposed action a component of a larger action?	✓	No
1.13	**Related actions/proposals:** Is the proposed action related to other actions or proposals in the region?	✓	Yes: The Proposed Action involves mining, ore handling, processing, water abstraction and disposal that are inter-related with the infrastructure and activities of the existing Mesa J Operation. The Mesa J Operation has been in operation since 1992.

1.14	**Australian Government funding:** Has the person proposing to take the action received any Australian Government grant funding to undertake the proposed action?	✓	No
1.15	**Great Barrier Reef Marine Park** Is the proposed action inside the Great Barrier Reef Marine Park?	✓	No

2. Detailed description of proposed action

2.1 Description of proposed action

The Proposed Action includes development of additional mine pits, new mineral waste dumps and associated infrastructure, water treatment facilities, processing facilities and water management infrastructure. An indicative conceptual mine layout is shown in Attachment 3.

Mining

The Mesa H deposit is a continuation of the Robe Pisolite iron ore deposit present at Mesa J and Mesa K, known more generally as a Channel Iron Deposit (CID).

The Proposed Action includes development of new open cut mine pits at Mesa H with approximately 20% of ore proposed for mining occurring below water table (BWT).

Ore will be mined using open cut mining methods comprising conventional drill, blast, load and haul as currently used in the adjacent Mesa J Operation.

Exclusions

Exclusions from the scope of the Proposed Action comprise the following:

- Activities and additional infrastructure at the Mesa J Operation approved under Ministerial Statement 208 (MS 208).
- Low impact activities within the Development Envelope required prior to Part IV of the Environmental Protection Act 1986 (EP Act) approval of the Proposal. These activities will be subject to relevant provisions under Part V [Land Clearing] of the EP Act) and will include drilling and associated activities (such as upgrades to existing roads/tracks) for the purposes of resource evaluation, geotechnical assessment and hydrogeological investigation.
- Establishment of a construction camp to support the construction phase of the Proposed Action. This will be subject to relevant provisions under Part V [Land Clearing and Works Approvals/Licensing] of the EP Act.
- Establishment of temporary services (communications, water supply, power), temporary concrete batch plant, site offices, access roads, laydown areas, and borrow pits to support establishment of a construction camp. These will be subject to relevant provisions under Part V [Land Clearing and Works Approval/Licensing] of the EP Act.
- Facility upgrades in Pannawonica to support the expanded workforce.
- Power network upgrades at Pannawonica, and a 9 km section of overhead power line between the Pannawonica switchyard and the Mesa A/J tee-off. These will be subject to relevant provisions under Part V [Land Clearing and Works Approval/Licensing] of the EP Act.

Ore handling and transport

Haul roads will be developed to enable haulage of ore from the Proposed Action to the adjacent Mesa J Operation for dry and wet processing. Ore will then be transported to the Cape Lambert/Dampier ports via the existing Mesa J rail line.

Mineral waste

The Mesa H mine plan has incorporated a pit sequence that enables progressive in-pit backfill of the majority of waste, using both the Mesa H and the adjacent Mesa J pits. Where pit sequencing and scheduling do not allow waste to be used for backfilling, out-of-pit waste dumps will be utilised. Currently, two locations have been identified for out-of-pit waste dumps that minimise direct impact

to significant environmental and heritage areas. Out-of-pit storage for competent material, low grade ore, sub-soil and topsoil will also be required.

Wet processing of low grade ore at Mesa H will generate waste fines. The mine plan will incorporate the use of pits within the Development Envelope and at the Mesa J operation for in-pit waste fines storage facilities (WFSF) over the life of the Proposal.

Pit Dewatering

Approximately 20% of the ore proposed for mining at Mesa H is BWT. Dewatering to access the BWT ore is therefore required at an average rate of 3 GL/a and peak rate of 10 GL/a. Dewatering is currently expected to commence in approximately 2025 and will be via sump pumping, powered by diesel generators. Groundwater abstracted for dewatering purposes will contribute to meeting operational demands for the Proposed Action and Mesa J operation, primarily wet processing, however the timing for BWT pit dewatering and average dewatering rate will not be sufficient to meet these processing demands, hence an additional water supply will be required for the Proposed Action.

Surface water management

Surface water management will be required for the watercourses draining local catchments from the Buckland Hills south of the Proposed Action which intersect the southern pits. A drainage diversion is required during operations south of the southern pits to direct flow to the watercourse between the northwest and southern pits, and subsequently into the Robe River. The diversion will not be maintained post closure.

Water supply and surplus water discharge

Water is required for the Proposed Action to enable:

- construction activities;
- general mining activities;
- dust suppression on haul roads; and
- potable water supply.

Mine pit dewatering for the Proposal of an average of 3 GL/a (peak up to 10 GL/a) will not be sufficient to meet operational demands, requiring continued operation of the existing Mesa J water supply borefield (Southern Cutback borefield) located immediately to the south of the Mesa J Operation. The total abstraction from this water supply borefield (to include the requirements for this Proposed Action) is not expected to require an increase to the current Mesa J abstraction licence limit (which is 30GL/a).

The site water demand for the Proposed Action and continuation of the Mesa J Operation is estimated to be approximately 11 GL/a, which is similar to the existing Mesa J water demand.

Based on water balance estimates, and depending on fluctuations in site water usage requirements and seasonal fluctuations, limited surplus water is expected to be generated from mine pit dewatering. After large rainfall events however, significant ponding would result in a requirement to discharge. In these circumstances, and combined with temporal variability in mine water use, up to a peak of 10 GL/a may be required to be discharged.

Any surplus surface water discharge will be predominantly via the existing Mesa J Operation discharge points, in Jimmawurruda Creek east of Mesa J or West Creek, between the Proposal and the Mesa J operation. Additional discharge points may be established if required, pending further hydrological studies to support options to manage the identified values of the Robe River ecosystem.

Mine support facilities and infrastructure

Additional power supply to the Mesa J Operation is required as part of the Proposed Action, comprising a powerline of approximately 2.5 km in length from the existing Coastal Water Supply powerline to Mesa J (Attachment 3).

A production hub will be established at Mesa H comprising: truck park up; laydown; offices; ablutions; waste water treatment plant; and other facilities as required to support the operation. A power line will connect the production hub to the Mesa J power network.

A turkey's nest will be established near the production hub to provide water for dust suppression.

Communications systems will be extended to the Proposed Action including installation of fibre optic cables.

The Proposed Action will utilise the existing Mesa J rail infrastructure.

Workforce

The Proposed Action will be operated as an extension to the existing Mesa J operation and will require an increase in the operational workforce. The workforce will continue as mixed residential Fly In / Fly Out (FIFO) workforce, housed in existing accommodation in Pannawonica.

The construction workforce is proposed to be accommodated in a 'dry hire' mobile construction camp north of Mesa H (not part of the Proposed Action).

Timing

Under the current schedule, construction activities are planned to commence in Quarter 4 2018 once all required internal and external approvals are granted.

2.2 Feasible alternatives to taking the proposed action

No alternative iron ore deposits have been identified as being suitable for development within the timeframe required to maintain both the type of iron ore product and to sustain the existing Mesa J Operation.

2.3 Alternative locations, time frames or activities that form part of the referred action

Other than the options described in this document (e.g. water sources for wet processing), no alternative locations, timeframes, methods or activities have been identified for undertaking the Proposed Action.

2.4 Context, including any relevant planning framework and state/local government requirements

The Proposed Action is subject to the provisions of the *Iron Ore (Robe River) Agreement Act 1964.* The Proposed Action is subject to the Western Australian environmental approval requirements listed in Table 2.

Table 2: Western Australian legislation relevant to the Proposed Action

Agency/authority	Approval required
Environmental Protection Authority (EPA) / Minister for Environment.	Proposal approval under Part IV of the *Environmental Protection Act 1986* (WA) (EP Act).
Department of Jobs, Tourism, Science and Innovation / Minister for Jobs, Tourism, Science and Innovation.	Proposal approval under the *Iron Ore (Robe River) Agreement Act 1964*
Department of Water and Environment Regulation.	Project environmental impact assessment under Part IV of the EP Act. Works approvals and licences under Part V of the EP Act. Permits and licences to interfere with the bed and banks of a watercourse, take water and manage its use and construct and alter wells under the *Rights in Water and Irrigation Act 1914* (WA).
Department of Mines, Industry Regulation and Safety.	Native Vegetation Clearing Permits under Part V of the EP Act. Mining Proposals under the *Mining Act 1978* (WA).
Department of Planning, Lands and Heritage.	Protection of Aboriginal sites under the *Aboriginal Heritage Act 1972* (WA).
Shire of Ashburton.	Development approval under the Shire Town Planning Scheme No. 7.

2.5 Environmental impact assessments under Commonwealth, State or Territory legislation

The Proposed Action is subject to the Western Australian environmental impact assessment process under the EP Act. The Proposed Action was referred to the Western Australian EPA under section 38 of the EP Act on 29 June 2017. The level of assessment was set as a Public Environmental Review (PER) with a 2 week public review period. Completed and planned environmental studies associated with this referral are summarised in Table 3 and Table 4 respectively.

Table 3: Completed environmental studies relevant to the Proposed Action

Study	Description
Flora and vegetation	
Biota Environmental Sciences (2011). *Baseline Flora and Vegetation Assessment of Robe Valley Mesas (Mesas B,C,D,E,F,H and I).* Unpublished report prepared for Rio Tinto Iron Ore, April 2011.	Survey conducted in October 2010 documenting flora, vegetation units and conservation listed flora in the Development Envelope.
Astron (2016b). *Mesa H Level 2 Vegetation and Flora Assessment.* Unpublished report prepared for Rio Tinto Iron Ore, May 2016.	Surveys conducted in September / October 2014 and May and July 2015 documenting vegetation units and conservation listed flora in the Development Envelope.
Astron (2016). *Mesa H Riparian Vegetation Baseline Monitoring.* Unpublished report prepared for Rio Tinto Iron Ore, June 2016.	Monitoring transects established across riverine vegetation in the Robe River in May-June 2016.

Study	Description
Astron (2016) *Mesa H Riparian Community Assessment*. Unpublished report prepared for Rio Tinto Iron Ore, June 2016.	Level 2 vegetation and flora assessment of the Robe River riparian community, and a Level 1 fauna assessment desktop assessment, including database searches and literature review of available resources, vegetation and flora assessment, fauna and fauna habitat assessment and baseline aquatic assessment.
Rio Tinto (2017). *Assessment of Groundwater Dependent Vegetation distribution on the Robe River - Targeted Riparian Vegetation Survey.* Unpublished report prepared by Rio Tinto Iron Ore, May 2017.	Detailed survey and spatial mapping of the distribution of Robe River Groundwater Dependent Vegetation (GDV). Interpretation of the significance and sensitivity of these communities to potential hydrological change – providing an interpreted risk map throughout the Development Envelope and immediate surrounds.
Terrestrial fauna	
Streamtec (1991 - 2016). Aquatic Ecosystems Study (annual monitoring).	Annual aquatic ecosystems monitoring survey to assess potential environmental impacts of the Mesa J Operation on the adjacent and downstream aquatic ecosystem. The survey is an integrated assessment of biological parameters including aquatic fauna (macroinvertebrates and fish), channel/pool morphology, riparian vegetation condition and water quality.
Biota Environmental Sciences (2011). *Robe Valley Mesas Fauna Report*. Unpublished report prepared for Rio Tinto Iron Ore, March 2011.	Survey conducted in October 2010 documenting terrestrial fauna, fauna habitats, species of conservation significance and habitats that may require specific management.
Astron (2016a). *Level 2 Terrestrial Fauna Surveys: Mesa H*. Unpublished report prepared for Rio Tinto Iron Ore, November 2015.	Surveys conducted in May and September 2015 documenting terrestrial fauna, fauna habitats, species of conservation significance and habitats that may require specific management.
Astron (2017). *Mesa H Ghost Bat, Macroderma gigas – Contextual Study*. Unpublished report prepared for Rio Tinto Iron Ore, July 2017.	Contextual analysis for the conservation significant Ghost Bat (*Macroderma gigas*) within the vicinity of the Mesa H Development Envelope, including desktop review and field survey involving mapping of potential habitat and targeted survey for the Ghost Bat.
WRM (2017) Mesa H Project: Baseline Aquatic Ecosystem Survey. Wet Season Sampling 2016. Unpublished report prepared for Rio Tinto Iron Ore, April 2017.	Baseline wet season sampling program undertaken to document the current ecological condition of the Robe River for aquatic ecosystems, with a focus on permanent and semi-permanent pools and sampling of sites upstream and downstream of Mesa H.
Bat Call WA (2017a). *Robe Valley Mesa H Ghost Bat roost cave assessment.* Unpublished report prepared for Rio Tinto, April 2017.	Extensive search for Ghost Bat presence at Mesa H conducted in April 2017, including assessment of the conservation value of caves associated with the presence of Ghost Bats.
Bat Call WA (2017b). *Robe Valley Mesa A to Mesa 2405A, assessment of mining on Ghost Bat presence and activity*. Unpublished report prepared for Rio Tinto, April 2017.	Assessment of impact of mining on Ghost Bat viability in the broader Robe valley including a desktop and field review of historical mined areas, current mining operations and proposed mining developments.
Subterranean fauna	
Biota Environmental Sciences (2006). Mesa A and Robe Valley Mesas Troglobitic Fauna Survey. Unpublished report prepared for Robe River Iron Associates, March 2006).	Surveys conducted November 2004 to January 2005, April to May 2005, July to September 2005 documenting subterranean fauna and assessing subterranean fauna habitat.
Biota Environmental Sciences (2017). *Mesa H Subterranean Fauna Assessment.* Unpublished report prepared for Rio Tinto.	Surveys conducted June to August 2015 and August to October 2015 documenting subterranean fauna and assessing subterranean fauna habitat.

Study	Description
Hydrological Processes and Inland Waters Environmental Quality	
Rio Tinto (2016) *Mesa H Chemistry and Isotopes.* Unpublished report prepared by Rio Tinto Iron Ore, 2016.	Groundwater and surface water chemical and isotope analysis aiming to assess groundwater dependency of the Robe River pools.
Rio Tinto (2016) *Mesa H Chemistry and Isotopes.* Unpublished report prepared by Rio Tinto Iron Ore, 2016.	Groundwater and surface water chemical and isotope analysis aiming to assess groundwater dependency of the Robe River pools.
Rio Tinto (2016). *Mesa H 2016 Pre-Feasibility Study Hydrogeological Drilling Program Completion Report.* Unpublished report prepared by Rio Tinto Iron Ore, 2016.	Report detailing drilling and installation of 19 monitoring bores and 4 water bores, and test pumping of all completed water bores.
Rio Tinto (2016). *Mesa H Hydrogeological Conceptual Model Report.* Unpublished report prepared by Rio Tinto Iron Ore, 2016.	Mesa H hydrogeological conceptual model report to support the development of the groundwater numerical model.
Rio Tinto (2016). *Mesa H Dewatering, Water Supply and Impact Assessments*. Unpublished report prepared by Rio Tinto Iron Ore, 2016.	Groundwater numerical model to support the Mesa H Proposal assessing dewatering requirements, water supply strategy and impact prediction.
Rio Tinto (2016). *AMD Risk Assessment Summary for the Robe Valley.* Unpublished report prepared by Rio Tinto Iron Ore, 2016.	A review of the AMD risk assessment for the Robe Valley including Mesa H.
Rio Tinto (2016). *Mesa H Order of Magnitude Design Flood Estimation and Floodplain Mapping.* Unpublished report prepared by Rio Tinto Iron Ore, Feb 2016.	Investigation to provide design flood estimates and floodplain mapping for the Mesa H deposit to inform the development of surface water management options.
Rio Tinto (2017). *Mesa H PFS Surface Water Management.* Unpublished report prepared by Rio Tinto Iron Ore, March 2017.	Study describing the interaction between natural surface water runoff, the local environment and the Mesa H study area and proposed water management measures.
Rio Tinto (2017). *Surplus water discharge extent assessment: Mesa H*. Unpublished report prepared by Rio Tinto Iron Ore, March 2017.	Study was to estimate the extent of impact of surplus water discharge along the proposed watercourses based on discharge location options.
Rio Tinto (2017) Mesa H H3 Hydrogeological Level Assessment. Unpublished report prepared by Rio Tinto Iron Ore, 2017.	Report detailing the Mesa H and J hydrogeological conceptualisation, numerical model predictions, aquifer impact assessment, monitoring program and proposed GW management.
Other	
Various targeted surveys associated with Rio Tinto exploration and pastoral activities.	Flora/vegetation and fauna surveys conducted in localised areas subject to Native Vegetation Clearing Permit applications.

Table 4: Environmental studies relevant to the Proposed Action that are in progress

Study	Description
Flora and vegetation	
Astron Environmental Services.	Baseline Monitoring – Phase II (Monitoring transects established across riverine vegetation in the Robe River).
Rio Tinto (in prep).	Assessment of Groundwater Dependent Vegetation distribution on the Robe River - Targeted Riparian Vegetation Survey.
Subterranean fauna	
Biota Environmental Sciences (in prep).	Surveys conducted June to August 2015, August to October 2015 and January to March 2016 documenting subterranean fauna and assessing subterranean fauna habitat.
Aquatic fauna	
Streamtec Aquatic Ecosystems Study	Ongoing annual aquatic fauna monitoring as part of existing Mesa J Operations.
Wetland Research and Management (WRM)	Baseline Aquatic Fauna Monitoring – Phase II.
Visual impact assessment	
Rio Tinto (in prep).	Visual impact assessment considering vantage points along Pannawonica Road, the Robe River and sites of heritage significance.

2.6 Public consultation (including with Indigenous stakeholders)

The Proponent has undertaken consultation on the Proposed Action as summarised in Table 5. The Proponent will continue to consult with relevant stakeholders during the environmental assessment process and during project implementation. Identified key stakeholders include:

- Department of Water and Environmental Regulation - EPA Services and Compliance and Regulation;
- Department of the Environment and Energy;
- Department of Biodiversity, Conservation and Attractions - Parks and Wildlife Services;
- Department of Mines, Industry Regulation and Safety;
- Department of Jobs, Tourism, Science and Innovation;
- Department of Planning, Lands and Heritage;
- Shire of Ashburton; and
- Traditional Owners, the Kuruma Marthudunera.

Table 5: Summary of completed stakeholder consultation for the Proposed Action

Stakeholder	Date	Topics/issues raised
Department of Water and Environmental Regulation (DWER) EPA Services	15 June 2016	Scope of the Proposed Action, summary of the biological survey results and likely key environmental factors for assessment.
	25 May 2017	Update of the scope of the Proposed Action, summary of the latest biological survey results, likely key environmental factors for assessment and timeframes.
Department of Water and Environmental Regulation (DWER) EPA Services – Terrestrial Ecosystems Branch	1 May 2017	Outline of the scope of the Proposed Action. A summary of troglofauna sampling and results was provided. Conceptual proposed troglofauna habitat retention areas / approach and avoidance areas.
Department of Water and Environmental Regulation (DWER) Department of Water	14 February 2017	Presentation of the Proposed Action hydrogeological conceptualisation, approach and key assumptions undertaken in the modelling.
Department of Water and Environmental Regulation (DWER) Department of Water	11-12 April 2017	Site trip to the Robe Valley to provide context and scale of the current operations and Proposed Action. Update of current understanding and conceptualisation of the hydrology and hydrogeology for all of the Robe Valley operations and Proposed Action. The field visit also included visits to the Robe River including a number of semi-permanent pools.
Department of Water and Environmental Regulation (DWER) Department of Water	4 July 2017	Presentation of the updated results from the hydrogeological modelling and the preliminary environmental impact assessment related to modelled hydrogeological drawdown – focussing on the modelled changes to the Robe River and Jimmawurrada Creek.
Department of Mines, Industry Regulation and Safety	30 June 2016	Scope of the Proposed Action, tenure, likely key environmental factors for assessment and closure planning.
	24 January 2017	Overview of the key elements of the Closure Plan being prepared for the Proposed Action.
Department of Jobs, Tourism, Science and Innovation	30 June 2016	Brief summary of the Proposed Action and status of study. Confirmation that a Proposal requesting approval for the Proposed Action will be submitted to the Department of Jobs, Tourism, Science and Innovation following funding approval and environmental approvals.
Department of Biodiversity, Conservation and Attractions (DBCA) Parks and Wildlife Services	24 March 2017	Scope of the Proposed Action, summary of the biological survey results, and likely key environmental factors for assessment. Discussion of occurrence of listed species (Northern Quoll, Pilbara Olive Python, Pilbara Leaf-nosed Bat and Ghost Bat) and nearest Priority Ecological Community (PEC).
Kuruma Marthudunera (K&M)	4 April 2016	Robe Valley Operations update including environmental monitoring and environmental status. Update of Life of Mine Planning – to include the Mesa H study progress (Proposed Action).
	25-26 May 2016	Scope of the Proposed Action and discussion of key heritage sites and important heritage values / concerns in the Development Envelope.
	23 August 2016	Discussion of key cultural heritage sites in the Development Envelope.

Stakeholder	Date	Topics/issues raised
	5-6 October 2016	Scope of the Proposed Action, update of proposed water management, discussion of protection of a key cultural heritage site via a change to the mine plan.
	15-16 May 2017	Field trip with K&M and independent anthropologist to discuss mine plan / waste dump locations and proposed management in respect of culturally sensitive areas.
	27 June 2017	Presentation of the results from the hydrogeological modelling and the preliminary environmental impact assessment related to modelled hydrogeological changes.

2.7 A staged development or component of a larger action

Not applicable.

2.8 Related actions

The Proposed Action involves mining, ore handling, water abstraction and disposal that utilise infrastructure and share activities of the existing adjacent Mesa J Operation.

The Mesa J Operation was assessed under Part IV of the EP Act with environmental approval for the project granted in 1992 subject to the conditions of Ministerial Statement 208 (MS 208). The project pre-dated the *Environment Protection and Biodiversity Conservation Act* (1999) (EPBC Act) and hence was not referred.

3. Description of environment & likely impacts

3.1 Matters of national environmental significance

3.1 (a) World Heritage Properties

Not applicable.

3.1 (b) National Heritage Places

Not applicable.

3.1 (c) Wetlands of International Importance (declared Ramsar wetlands)

Not applicable.

3.1 (d) Listed threatened species and ecological communities

Description

An EPBC Act Protected Matters search (21 November 2016, Attachment 4) identified 10 Listed Threatened Species as potentially occurring within the Development Envelope and surrounds, of which two are migratory species. The remaining eight species are listed in Table 6 (with migratory species listed in Table 7). In addition, the Blind Cave Eel (*Ophisternon candidum)* has been recorded within 1.1 km of the Development Envelope.

Table 6: Outputs of Protected Matters search relevant to the Proposed Action

Species	Status	Type of Presence
Mammals		
Northern Quoll *Dasyurus hallucatus*	Endangered	Species or species habitat known to occur within area
Ghost Bat *Macroderma gigas*	Vulnerable	Species or species habitat likely to occur within area
Greater Bilby *Macrotis lagotis*	Vulnerable	Species or species habitat may occur within area
Pilbara Leaf-nosed Bat *Rhinonicteris aurantia* (Pilbara form)	Vulnerable	Roosting known to occur within area
Reptiles		
Pilbara Olive Python *Liasis olivaceus barroni*	Vulnerable	Species or species habitat known to occur within area
Birds		
Night Parrot *Pezoporus occidentalis*	Endangered	Species or species habitat may occur within area
Australian Painted Snipe *Rostratula australis*	Endangered	Species or species habitat may occur within area
Plants		
Hamersley Lepidium *Lepidium catapycnon*	Vulnerable	Species or species habitat likely to occur within area
Fish		
Blind Cave Eel* *Ophisternon candidum*	Vulnerable	Species or species habitat likely to occur within area

* Not an output of the EPBC Protected Matters Search.

The most recent fauna and flora/vegetation surveys (Astron 2016a, Attachment 5 and Astron 2016b, Attachment 6 respectively) assessed the likelihood of the listed species occurring in the Development Envelope as either 'Confirmed', 'High', 'Moderate' or 'Low'. The results of the assessment are summarised in Table 7.

Table 7: Likelihood of occurrence of Listed Threatened Species in the Development Envelope

Species	Status	Habitat description and distribution	Likelihood of occurrence
Plants			
Hamersley Lepidium *Lepidium catapycnon*	Vulnerable	Rocky hilltop areas and breakaway slopes. Nearest known location of this taxon is 190 km south-east of the Development Envelope.	**Low** Unlikely to occur as the Development Envelope is outside the distribution of this taxon.
Mammals			
Northern Quoll *Dasyurus hallucatus*	Endangered	In the Pilbara, ironstone ridges, scree slopes of sandstone or ironstone and granite boulders and outcrops (van Dyck and Strahan 2008). Rio Tinto has recorded the Northern Quoll over a range of approximately 345 km extending from the Mesa A mine site to the Koodaideri mine site to the east-south-east (Rio Tinto 2016). Rio Tinto has recorded the Northern Quoll over 180 times in the Robe Valley (Rio Tinto 2016), with the majority of records associated with the mesas to the east of Mesa J, many of which have been historically mined.	**Confirmed**
Ghost Bat *Macroderma gigas*	Vulnerable	Caves, rock piles and abandoned mines (Menkhorst and Knight 2014). Will travel 2 km from roost to hunt (Churchill 2008). Can disperse up to 50 km during non-breeding season. Ghost bats utilise three main types of roosts: nocturnal roosts or feeding sites; diurnal / day roosts that may be permanent or semi-permanent sites; and maternity roosts that are diurnal roosts with the range of characteristics allowing regular or permanent occupancy (Bat Call 2017b). The Ghost Bat has been recorded throughout the Pilbara with a population estimated at 1,500 – 2,000. Locally within the Robe Valley, the population has been estimated at around 150, which include current records from historically mined mesa areas (Bat Call 2017b, Attachment 12).	**Confirmed**
Greater Bilby *Macrotis lagotis*	Vulnerable	Variety of habitats on soft soils including spinifex hummock grassland, *Acacia* shrubland, open woodland and cracking clays (Burrows et al. 2012). Nearest record located >70 km east of the Development Envelope (Parks and Wildlife 2015).	**Low** Unlikely to occur due to lack of suitable habitat and distance to nearest record.

Species	Status	Habitat description and distribution	Likelihood of occurrence
Pilbara Leaf-nosed Bat *Rhinonicteris aurantia* (Pilbara form)	Vulnerable	Roost in caves with high humidity (95%) and temperature (32 °C). Forage in humid caves and along waterbodies with fringing vegetation (Armstrong 2001). Rio Tinto has recorded the Pilbara Leaf-nosed Bat over a range of approximately 360 km extending from the Warramboo mine site to the east-south-east at Koodaideri and to the south-east towards Newman. The Pilbara Leaf-nosed Bat has been recorded along the length of the Robe Valley; suitable foraging and dispersal habitat is known to be available along the length of the Robe River.	**Confirmed**
Reptiles			
Pilbara Olive Python *Liasis olivaceus barroni*	Vulnerable	Watercourses and areas of permanent water in rocky gorges, escarpments and gullies (Pearson 1993).	**Confirmed**
Birds			
Night Parrot *Pezoporus occidentalis*	Endangered	Known to inhabit treeless or sparsely wooded long unburnt spinifex hummock plains often interspersed with chenopods (Davis and Metcalf 2008, Pyke and Ehrlich 2014) (Parks and Wildlife 2017) One unpublished record within 36 km of the survey area recorded in 1967 (Department of Parks and Wildlife 2015).	**Low** Unlikely to occur due to the absence of recent records from the locality and a lack of preferred habitat. Indicated as a Medium priority for Survey (Parks and Wildlife 2017)
Australian Painted Snipe *Rostratula australis*	Endangered	Inhabits shallow terrestrial freshwater wetlands, temporary/permanent lakes, swamps and claypans with emergent grass, sedges, rushes and samphire (Astron 2016a). The nearest record is located 100km to the north of the Proposed Action (Naturemap 2011).	**Moderate**
Fish			
Blind Cave Eel* *Ophisternon candidum*	Vulnerable	Inhabits groundwater systems in subterranean caves, transmissive geological formations, fissures and wells (Humphreys 2001). Utilises a range of habitats including cave floor sediments, karst aquifers and alluvial aquifers overlying channel iron deposits in the western Pilbara (Biota 2013). The nearest records occur 1.1 km and 5 km from the eastern extent of the Proposed Action's Development Envelope, in Jimmawurrada Creek and Bungaroo Creek.	**High**

Nature and extent of likely impact

Attachment 7 shows the records of Matters of National Environmental Significance (MNES) in the Development Envelope. Species profiles relevant to the Proposed Action for species that are likely or known to occur in the Development Envelope are summarised in Table 8 to Table 12.

Assessment against the Significant Impact Criteria for each species likely or known to occur in the Development Envelope is provided in Table 13 to Table 16.

Table 8: Species profile for the Northern Quoll (*Dasyurus hallucatus*) (Endangered)

Description and context with respect to the Proposed Action
The Northern Quoll was historically common across northern Australia, occurring almost continuously from the Pilbara, Western Australia, to near Brisbane, Queensland; however, its distribution and abundance has declined over the last 50 years. The Northern Quoll now occurs in five regional populations across Queensland, the Northern Territory and Western Australia both on the mainland and on offshore islands (Department of the Environment and Energy 2016a). In the Pilbara, the species is considered to favour the Rocklea, Macroy and Robe land systems (Biota 2008). These land systems comprise basalt hills, mesas (and buttes of limonites), high and low plateaux, lower slopes, occasional tor fields and stony plains supporting either hard or soft spinifex grasslands (van Vreeswyk *et al.* 2004). The Northern Quoll has also been recorded in other land systems which comprise sandstone and dolomite hills and ridges, shrublands, sandy plains, clay plans and tussock grasslands and coastal fringes including dunes islands and beaches (Biota 2008). Factors currently thought to threaten the species include: • mortality resulting from consumption of cane toads (*Bufo marinus*) (Woinarski et al. 2014); • removal, degradation and fragmentation of habitat associated with development and pastoralism; • inappropriate fire regimes (and subsequent predation by introduced fauna following fire (Hill and Ward 2010); and • invasive species (feral cat (*Felius catus*) and European red fox (*Vulpes vulpes*)) either through direct predation or competition for food. The Robe Valley, in which the Development Envelope is located, spans a distance of over 100 km and contains 34 named mesas as well as numerous un-named minor mesa formations and breakaways (refer Attachment 9). The Robe Valley contains habitat regarded as suitable for the Northern Quoll. The escarpments of the mesas in the Robe Valley, particularly those areas with deep gullies that are associated with drainage lines and water courses, are considered to represent core habitat for the Northern Quoll. Areas potentially containing core Northern Quoll habitat in the Development Envelope are mapped as the Gorge and Breakaway Habitat (~2% of the Development Envelope) in Attachment 10. Potentially suitable foraging and dispersal habitat consisted of Riverine and Rocky Hills habitats (~4% of the Development Envelope) particularly where these habitats were in close association with the Gorge and Breakaway Habitat (Astron 2016a). Evidence of the Northern Quoll has been recorded 27 times in the vicinity of Mesa H during the most recent targeted surveys, comprising six capture records (five confirmed separate individuals), 19 remote camera location recordings and two scats, tracks and/or trace records (Astron 2016a). The majority of these records were found in the Breakaway Habitat; however some records occurred within Riverine and Gorge habitat types. All records were in close proximity to rocky substrate associated with the escarpments of Mesa H and the adjacent Robe River. No Northern Quoll records to date have been recorded within the indicative clearing footprint of the Proposed Action. The Proposed Action includes retention of the mesa escarpments at Mesa H (except where cuts through lower value habitat are required to allow vehicle access) and will ensure that core Northern Quoll habitat continues to be available. Groundwater abstraction for water supply and pit dewatering will result in localised groundwater drawdown in the Mesa H and basement aquifers that may have some connectivity to the Robe River alluvial aquifer and the Jimmawurrada creek alluvial aquifer. The modelling indicates the potential for minor reduction in water levels in the Robe River alluvial aquifer and semi-permanent and permanent pools (<1 m), with recovery of the groundwater table over time once water abstraction ceases. Groundwater abstraction for water supply from the existing Southern Cutback Borefield may potentially increase groundwater drawdown in Jimmawurrada Creek and also extend the timeframe for the predicted groundwater recovery once water abstraction ceases. This may result in localised vegetation changes; however no semi-permanent or permanent pools are known to occur in the Jimmawurrada area and the riverine ecosystem function is expected to be maintained. Numerous pools exist along the Robe River outside the potential impact area near Mesa H as presented in Attachment 14. Any temporary changes to groundwater water levels in Jimmawurrada Creek and the permanent and semi-permanent pools of the Robe River near Mesa H are, therefore, unlikely to significantly impact Northern Quoll foraging habitat.

Table 9: Species profile for the Ghost Bat (*Macroderma gigas*) (Vulnerable)

Description and context with respect to the Proposed Action
The Ghost Bat is believed to be a geographically relictual species in southern, arid landscape, present only because caves provide suitable roost microclimates (Threatened Species Scientific Committee 2016). Since European settlement, the distribution of the Ghost Bat has contracted northwards. The current range of the Ghost Bat is discontinuous, with geographically disjunct colonies occurring in the Pilbara, Kimberley, Northern Territory, the Gulf of Carpentaria, coastal and near coastal eastern Queensland and western Queensland (Threatened Species Scientific Committee 2016). Population genetic studies indicate that females appear to remain in or return to the individual's birthplace. The genetic isolation of sub-populations suggests areas are unlikely to be recolonised if local extinction occurs (Threatened Species Scientific Committee 2016). Ghost Bats move between a number of caves seasonally. Roost sites include caves, rock crevices and disused mine adits. Ghost Bats use three types of roost regularly: • Nocturnal roosts (or feeding sites) are used only at night, either habitually or for transitory visits. They are typically shallow, poorly insulated caves and shelters that are well lit during the day (Bat Call WA 2017a). Ghost Bats hunt at night and use nocturnal caves to consume prey they have captured in the surrounding area. • Diurnal roosts (or day roosts) are caves and mine adits that are deeper and more complex than nocturnal roosts. They typically have one or more large chambers at or beyond the twilight area with additional fissures or chambers at the rear in the fully dark regions. They have a minimum roof height in the chambers of 2 to 3 m providing protection from attack by terrestrial predators. They are often at mid-levels or lower in the strata making them well insulated. The stable temperature and elevated humidity of these caves relative to the ambient conditions create physiologically benign conditions (McKenzie and Bullen 2009). • Maternity roosts are diurnal roosts that usually include an interior chamber that rises toward the rear, trapping warmer, more humid air at the top. To persist in an area, Ghost Bats require a group of caves/shelters that provide diurnal and nocturnal sites and a gully or gorge system that opens onto a plain or riparian line that provides good foraging opportunities. The persistence of the species in the Pilbara is believed to depend on the availability of diurnal roosts that have stable temperature and humidity (Threatened Species Scientific Committee 2016). The current population size in the Pilbara is estimated to be between 1500 and 2000 individuals, with colonies in the Hamersley sub-region containing between five and 25 individuals (Bat Call WA 2017a). The key threat to the Ghost Bat is believed to be destruction of, or disturbance to, roost sites and nearby areas (Woinarski et al. 2014). In the Pilbara, most known breeding sites are confined to underground gold/copper mines that are now collapsing or being converted into open cut mines and to caves in banded ironstone that may be mined in the future (Threatened Species Scientific Committee 2016). Other threats to the Ghost Bat include mortality resulting from the consumption of cane toads, modification to foraging habitat, disturbance at breeding sites through human visitation and collision with barbed-wire fences. There is evidence to demonstrate that Ghost Bats will continue to use a roost despite nearby mining activities. This is reflected in Process Minerals International Poondano Iron Ore Project near Port Hedland, which originally recorded the presence of Ghost Bats in Cave 26 on Mesa 3 in 2009. A buffer zone in excess of 50 m from Cave 26 was put in place to protect the fauna habitat and mining progressed such that by September 2012, mining of Mesa 3 was well underway (Process Minerals International 2013). Ghost Bats were subsequently recorded in Cave 26 in 2012, 2013, 2014 and 2015, demonstrating a continued presence of a substantial colony of Ghost Bats in Cave 26 following during mining. Visual observations of the Ghost Bat and the presence of Ghost Bat cave middens have been recorded on the various mesas within and adjacent to the Development Envelope (Bat Call WA 2017a). A recent desktop assessment and contextual field survey (Bat Call 2017b) indicated that the Ghost Bat is common and widespread in the Robe Valley. Caves are present on the escarpments of mesas, including Mesa H and throughout the Robe Valley. Detailed characterisation of the caves at Mesa H was undertaken by Bat Call WA (2017a) (refer Attachment 11). Eleven sites in the Development Envelope were assessed as being suitable for roosting by Ghost Bats including two diurnal roost caves and nine nocturnal roost shelters. The two diurnal caves were assessed as being maternity cave candidates, although no evidence of intensive Ghost Bat use for this purpose was found during the surveys (Bat Call WA 2017a). The assessment confirmed no *permanent* Ghost Bat presence at Mesa H. Roost locations at Mesas H and contextual Ghost Bat habitat mapping are shown in Attachment 13. No Ghost Bat roosts have been found within the indicative clearing footprint of the Proposed Action. High quality habitat for Ghost Bat was defined by locations where diurnal roosts or potential maternal roosts were identified or likely to be identified. High quality habitat was assessed as being restricted to the gorge habitat in the Robe Valley, which encompasses 0.2% of the Mesa H Development Envelope (Astron 2017). The Proposed Action includes retention of

Description and context with respect to the Proposed Action
the mesa escarpments and these associated gorges, where this high quality habitat occurs. Mine pits and waste dumps / infrastructure have been designed to avoid the highest value habitat for the Ghost Bat. The Proposed Action includes retention of the mesa escarpments (except where cuts through lower value habitat are required to allow vehicle access) to retain nocturnal and potential diurnal/maternal roost caves. The depths of the diurnal/potential maternal caves at Mesas H are up to 30m. The conceptual mine designs incorporate a 40 m mining exclusion zone between the back of each diurnal/potential maternal roost cave and the proposed mine pit to protect the integrity of the diurnal/potential maternal roosts. The Proposed Action also includes retention of the nocturnal roost caves. Nocturnal roost caves that form part of roost complexes (i.e. nocturnal roost caves that are in the same gullies as the diurnal/ potential maternal roosts) are considered to be an important factor in the persistence of Ghost Bats in an area, and range from 5 – 19 m in depth at Mesa H (Bat Call WA 2017). For each nocturnal cave that is part of a roost complex, the mine designs will incorporate a mining exclusion zone of 40 m from the cave entry to the proposed mine pit. The Proponent operates within a blast management framework underpinned by the best practice approaches identified in AS 2187.2 (the prescribed standard for use of explosives in Western Australia) to protect environmental and cultural heritage values. The Proponent has an established record of successfully managing drill and blast operations to minimise harm to sensitive sites (including bat roosts). Current and previous blasting programmes for sensitive sites across Pilbara mines provide a baseline for future work. Drill and blast management plans for specific areas will be risk-based and may prescribe one or more of the following additional controls: • a blast vibration monitoring and control programme; • reduced drill hole size, reduced charge weights and modified blast timing to minimise ground vibrations and 'air-blast' disturbance; and • use of leading-edge technology such as 'seed hole' analysis and modelling supported by electronic initiation systems to control vibrations. The Ghost Bat forages across the Development Envelope as well as more widely in the Robe Valley, particularly along the Riverine Habitat. The Proposed Action will involve clearing of up to 2,200 ha with the majority of this occurring on the surface of the mesas and on the plain adjacent to Mesa H. However, the mesa escarpments and associated major gullies will be retained and no significant clearing will be undertaken along the Robe River under the Proposed Action. The potential increase in water availability in the Robe River due to surplus water discharge may locally increase available foraging habitat for the duration of the discharge. Groundwater abstraction for water supply and pit dewatering will result in localised groundwater drawdown in the Mesa H and basement aquifers that may have some connectivity to the Robe River alluvial aquifer and the Jimmawurrada creek alluvial aquifer. The modelling indicates the potential for minor reduction in water levels in the Robe River alluvial aquifer and semi-permanent and permanent pools (<1 m), with recovery of the groundwater table over time once water abstraction ceases. Groundwater abstraction for water supply from the existing Southern Cutback Borefield may potentially increase groundwater drawdown in Jimmawurrada Creek and also extend the timeframe for the predicted groundwater recovery once water abstraction ceases. This may result in localised changes to structure and composition of riparian vegetation in the Jimmawurrada area; however no semi-permanent or permanent pools are known to occur in the Jimmawurrada locality and the riverine ecosystem function is expected to be maintained. Numerous pools exist along the Robe River outside the potential impact area near Mesa H as presented in Attachment 14. Any temporary changes to groundwater water levels in Jimmawurrada Creek and the permanent and semi-permanent pools of the Robe River near Mesa H are considered unlikely to significantly impacts on Ghost Bat foraging habitat. The Proponent requires personnel to comply with strict guidelines regarding cave entry for safety reasons as well as protection of heritage and environmental values. The Proponent will continue to apply these guidelines. Disturbance to Ghost Bats resulting from human visitation to caves is, therefore, unlikely to result in any significant changes to the Ghost Bat populations in the Robe Valley. Barbed-wire fences will only be installed under the Proposed Action where there is a statutory requirement to do so (e.g. *Electricity (Licensing) Regulations 1991* (WA)). Where barbed-wire is necessary, reflectors will be installed to deter the bats. The Proponent has several decades of experience mining adjacent to environmentally sensitive areas, including at the West Angelas mine site, where the use of barbed wire is strictly limited (only when there is a statutory requirement) specifically to protect Ghost Bats. Dust controls will be in place in the Development Envelope as part of standard management practices. Dust and light are unlikely to have a significant impact on the Ghost Bat as the aspect of the diurnal/potential maternal caves is such that they face away from the mining areas, into protected gullies, and thus are protected from direct dust ingress into the caves.

Table 10: Species profile for the Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*) (Pilbara form) (Vulnerable)

Description and context with respect to the Proposed Action
The Pilbara Leaf-nosed Bat is restricted to caves and mine adits (horizontal shafts) with stable, warm and humid microclimates because of its poor ability to thermoregulate and retain water (Armstrong 2001). Roosts are usually over pools of water in deeper mines, or deep within the mine or cave structure in an area that maintains elevated temperature and humidity. Simple vertical shafts are not used and shallow caves beneath mesa bluffs are also unlikely roost sites (Armstrong 2001). Colonies of the Pilbara Leaf-nosed Bat are found in three distinct areas: in the mines of the eastern Pilbara; scattered throughout the Hamersley Range in smaller colonies; and in sandstone formations south of the Hamersley Range in a small number of significant colonies (Armstrong 2001). Habitat favoured by the Pilbara Leaf-nosed Bat for foraging is diverse, ranging from *Triodia* hummock grasslands to eucalypt woodlands along watercourses (Armstrong 2001). Typically, they exhibit a preference for foraging in the open spaces in watercourses and gorges, and over *Triodia* grassland, with a usual foraging range up to 20 km from the primary roost cave (Bullen 2013). It also appears that the Pilbara Leaf-nosed Bat spreads from primary roosts to satellite roosts when wet season conditions allow and consolidates back to permanent sites during dry periods (Bat Call WA 2016). Threats to the persistence of the Pilbara Leaf-nosed Bat are mainly related to the susceptibility of the species to dehydration and hypothermia which limits the availability of suitable roosts in the Pilbara. Many roost sites comprise old mine workings, which can degrade over time with collapses and flooding rendering them unusable. Disturbance factors associated with human activities include mine development and rehabilitation of old mine sites where roost sites are disturbed. The species is also vulnerable to collisions with vehicles as it tends to fly relatively low and displays a curiosity for light sources; a busy road located close to a roost or foraging site could contribute to a local population decline (Department of the Environment and Energy 2016b). Astron (2016a) completed 27 systematic and targeted bat recording nights in the Development Envelope. In addition, Rio Tinto completed 61 targeted bat recording nights in the vicinity of the Development Envelope. Echolocation records of the Pilbara Leaf-nosed Bat in the Development Envelope indicate that this species forages generally across the Development Envelope with the Robe River providing the main foraging habitat. The echolocation records also indicate that the Pilbara Leaf-nosed Bats foraging in the area originate from a roost located approximately 10 km to the south of Mesa H, outside the Development Envelope (Bat Call 2017a). Detailed characterisation of the caves on Mesas H (Rio Tinto 2016, Bat Call WA 2017a) showed no evidence of Pilbara Leaf-nosed Bat presence in any cave or shelter on these mesas. The Pilbara Leaf-nosed Bat forages across the Development Envelope as well as more widely in the Robe Valley, particularly along the Riverine Habitat. The Proposed Action will involve clearing of up to 2,200 ha and the majority of this clearing will be on the surface of the mesas and on the plain adjacent to Mesa H. The mesa escarpments and associated major gullies will be retained (except where cuts through lower value habitat are required to allow vehicle access) and no significant clearing will be undertaken along the Robe River and Jimmawurrada Creek under the Proposed Action. The potential increase in water availability in the Robe River may locally increase available foraging habitat for the duration of the discharge. Groundwater abstraction for water supply and pit dewatering will result in localised groundwater drawdown in the Mesa H and basement aquifers that may have some connectivity to the Robe River alluvial aquifer and the Jimmawurrada creek alluvial aquifer. The modelling indicates the potential for minor reductions in water levels in the Robe River alluvial aquifer and semi-permanent and permanent pools (<1 m), with recovery of the groundwater table over time once water abstraction ceases. Groundwater abstraction for water supply from the Southern Cutback Borefield may potentially extend drawdown in Jimmawurrada Creek and extend the timeframe for the predicted groundwater recovery once water abstraction ceases. This may result in localised changes to structure and composition of riparian vegetation; however no semi-permanent or permanent pools are known to occur in this area and the riverine ecosystem function is expected to be maintained. Attachment 14 shows numerous pools that are present along the Robe River within the 20 km foraging range of the Pilbara Leaf-nosed Bat. The Proposed Action is, therefore, unlikely to significantly impact Pilbara Leaf-nosed Bat foraging habitat. Dust controls will be in place in the Development Envelope so dust is unlikely to have a significant impact on any roosts located to the south-east of the Development Envelope. It is also considered that, given that the closest permanent roost is estimated to be located approximately 10 km away, that light, noise and vibration from the Proposed Action are unlikely to have an impact on the roost.

Table 11: Species profile for the Pilbara Olive Python (*Liasis olivaceus barroni*) (Vulnerable)

Description and context with respect to the Proposed Action
The Pilbara Olive Python has a known distribution that coincides roughly with the Pilbara bioregion, where it is widespread. The species is considered stable and is present in sizable numbers at some sites (Pearson 2003). A large portion of the Pilbara Olive Python habitat is conserved in Karijini National Park (Pearson 1993). The Pilbara Olive Python prefers escarpments, gorges and water holes in the ranges of the Pilbara region (Pearson 1993; Wilson and Swan 2003). Radio-telemetry has shown that individuals are usually in close proximity to water and rock outcrops that attract suitable sized prey species (Pearson 2003). The range of the male Pilbara Olive Python is approximately 4 km (Department of the Environment and Energy 2016c). Factors recognised as threats to the Pilbara Olive Python include major fire events, predation by foxes, declines in prey species and habitat destruction associated with mining developments (Department of the Environment and Energy 2016c). Major gullies at Mesa H contain breeding habitat for the Pilbara Olive Python and the Robe River and Jimmawurrada Creek provides foraging habitat and a potential dispersal route (Astron 2016a). One Pilbara Olive Python was recorded in the Riverine Habitat of the Robe River during the 2015 surveys and numerous records of the species exist within 50 km of the Development Envelope in similar riverine habitats (Astron 2016a). The Proposed Action includes retention of the mesa escarpments (except where cuts through lower value habitat are required to allow vehicle access). The proposed cuts through the escarpments will impact only a small proportion (<5%) of the escarpment on each mesa and have been designed to avoid the highest value habitat for the Pilbara Olive Python. Retention of the escarpments will ensure that Pilbara Olive Python habitat continues to be available. The potential increase in water availability in the Robe River due to surplus water discharge may locally increase available foraging habitat for the duration of the discharge. Groundwater abstraction for water supply and pit dewatering will result in localised groundwater drawdown in the Mesa H and basement aquifers that may have some connectivity to the Robe River alluvial aquifer and the Jimmawurrada Creek alluvial aquifer. The modelling indicates the potential for limited reduction in water levels in the Robe River alluvial aquifer and semi-permanent and permanent pools (<1 m), with recovery of the groundwater table over time once water abstraction ceases. Groundwater abstraction for water supply from the Southern Cutback Borefield may potentially further extend drawdown in the Jimmawurrada Creek and will extend the timeframe for the predicted groundwater recovery once water abstraction ceases. This may result in localised changes to structure and composition of riparian vegetation; however no semi-permanent or permanent pools are known to occur in the Jimmawurrada area and the riverine ecosystem function is expected to be maintained. The area of potential disturbance in the vicinity of Mesa H due to dewatering is a small proportion of the Pilbara Olive Python foraging habitat available along the Robe River and Jimmawurrada Creek. There are a number of pools present in the Robe River the vicinity of Mesa H that are within the individual range of the Pilbara Olive Python (refer Attachment 14), so individuals may relocate to nearby suitable habitat if necessary.

Table 12: Species profile for the Blind Cave Eel (Ophisternon candidum) (Vulnerable)

Description and context with respect to the Proposed Action
The Blind Cave Eel (*Ophisternon candidum*) is a depigmented, subterranean fish growing up to 40 cm in length and is the world's longest cavefish with a long slender body, no eyes, and a thin rayless membrane around the tip of the tail (DSEWPaC 2008). The Blind Cave Eel is one of only three vertebrate animals known from Australia that are restricted to subterranean waters (Humphreys 2001). The Blind cave eel inhabits groundwater systems in subterranean caves, transmissive geological formations, fissures and wells (Humphreys 2001). It is known to utilise cave floor sediments at Cape Range, Karstic Aquifers on Barrow Island, and alluvial aquifers in association with Channel Iron Deposits (Biota 2013). They are also known to occur in a range of water qualities at Cape Range, ranging from fresh to brackish (0-16 ppt) and generally neutral pH (6.8-7.6) (Biota 2013). Two records of the Blind Cave Eel have been recorded in the Pilbara region, both from the Jimmawurrada Creek aquifer in the Bungaroo area, approximately 1.1 km and 5 km from the Development Envelope. Given these specimens were obtained from the major aquifer system of this area, this implies the presence of a population in this system (Biota 2013). Genetic analysis has also demonstrated that the species present at Bungaroo is the same as that on Cape Range, suggesting that it is likely that the species occurs further downstream, and is probably also associated with the regional aquifer of the Robe River (to which Jimmawurrada Creek is a tributary). This is supported by distribution patterns in other stygofauna species, with some taxa known from Cape Range and Barrow Island also present in the headwaters of the Robe River (Biota 2013). Factors presenting threats to the Blind Cave Eel include sedimentation from mining; water abstraction; and point source pollution (Humphreys 2001). The Robe River and Jimmawurrada Creek alluvial aquifers provide subterranean habitat and provide a potential dispersal route. The Proposed Action includes retention of the Robe River and Jimmawurrada Creek subterranean habitat by avoiding excavation of the primary alluvial habitat. Retention of the alluvial substrate and flow paths of the river systems will ensure that the Blind Cave Eel habitat connectivity is maintained. The potential increase in water availability in the Robe River due to surplus water discharge may locally increase available dispersal habitat for the duration of the discharge. Groundwater abstraction for water supply and pit dewatering will result in localised groundwater drawdown in the Mesa H and basement aquifers that may have some connectivity to the Robe River alluvial aquifer and the Jimmawurrada Creek alluvial aquifer. The modelling indicates the potential for limited reduction in water levels in the Robe River alluvial aquifer and semi-permanent and permanent pools (<1 m), with recovery of the groundwater table over time once water abstraction ceases. Groundwater abstraction for water supply from the Southern Cutback Borefield may potentially extend drawdown in Jimmawurrada Creek and extend the timeframe for the predicted groundwater recovery once water abstraction ceases. This will result in localised changes to groundwater levels across a ~9 km stretch of Jimmawurrada Creek, which encompasses the area of one of the Blind Cave Eeel records (1.1 km from the Development Envelope), however the alluvials will continue to be seasonally recharged following large rainfall events and the area of potential disturbance in the vicinity of Mesa H due to dewatering is a limited proportion (<7%) of the potential Blind Cave Eel habitat available along the Robe River and Jimmawurrada Creek.

Table 13: Assessment against the significant impact criteria for the Northern Quoll

Significant impact criteria	Comment
Is there a real chance or possibility the action will lead to a long-term decrease in the size of a population	**No.** Management strategies for avoiding and reducing impacts to the Northern Quoll will be implemented as outlined in Section 5.1. The escarpments of the mesas in the Robe Valley, particularly those areas with deep gullies that are associated with drainage lines and water courses, are considered to represent core habitat for the Northern Quoll. The mesa escarpments will be retained and the continued presence of the Northern Quoll has been observed in both historical and currently active mining areas where mesa escarpments have been retained (e.g. Mesa A, Middle Robe and East Deepdale). There are also numerous other mesas in the Robe Valley (refer Attachment 9) that provide core habitat for the Northern Quoll. The Proposed Action is unlikely to have a significant impact on Northern Quoll foraging habitat as proposed clearing will impact only a small proportion of available foraging habitat.
Is there a real chance or possibility the action will reduce the area of occupancy of the species	**No**. The escarpments of the mesas in the Robe Valley, particularly those areas with deep gullies that are associated with drainage lines and water courses, are considered to represent core habitat for the Northern Quoll. The mesa escarpments will be retained (except where cuts through lower value habitat are required to allow vehicle access).
Is there a real chance or possibility the action will fragment an existing population into two or more populations	**No.** Core habitat connectivity will be maintained by retention of the escarpments, particularly along the Robe River. The Proposed Action minimise impacts by utilising existing Mesa J linear infrastructure (e.g. road, rail) which will not prevent passage of individuals.
Is there a real chance or possibility the action will adversely affect habitat critical to the survival of a species	**No.** The escarpments of the mesas in the Robe Valley, particularly those areas with deep gullies that are associated with drainage lines and water courses, are considered to represent core habitat for the Northern Quoll. The mesa escarpments will be retained. There are also numerous other mesas in the Robe Valley (refer Attachment 9) that provide core habitat for the Northern Quoll.
Is there a real chance or possibility the action will disrupt the breeding cycle of a population	**No.** Denning habitat is contained within the escarpments of the mesas in the Robe Valley, particularly those areas with deep gullies that are associated with drainage lines and water courses. The mesa escarpments will be retained (except where cuts through lower value habitat are required to allow vehicle access). There are also numerous other mesas in the Robe Valley (refer Attachment 9) that provide core habitat for the Northern Quoll.
Is there a real chance or possibility the action will modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline	**No.** The escarpments of the mesas in the Robe Valley, particularly those areas with deep gullies that are associated with drainage lines and water courses, are considered to represent core habitat for the Northern Quoll. The mesa escarpments will be retained (except where cuts through lower value habitat are required to allow vehicle access). There are also numerous other mesas in the Robe Valley (refer Attachment 9) that provide core habitat for the Northern Quoll. Temporary minor reduction in water levels in a number of adjacent semi-permanent and permanent pools may seasonally affect individuals but would not result in species decline due to the continued presence of the pools and presence of other nearby pools on the Robe River.

Significant impact criteria	Comment
Is there a real chance or possibility the action will result in invasive species that are harmful to a critically endangered or endangered species becoming established in the endangered or critically endangered species' habitat	**No.** The cane toad is considered to be the main invasive species that poses a threat to the Northern Quoll. The cane toad is not currently established in the Pilbara. Discharge to the Robe River may result in additional water being present which may locally increase suitable habitat for cane toads for the duration of the discharge, should the cane toad spread to the Pilbara. However, permanent water is already available in the locality (permanent pools on the Robe River). The Proposed Actions will not, therefore, alter the possibility of cane toads becoming established in the area. The feral cat is also considered to pose a threat to the Northern Quoll. There is little opportunity for the Proposed Action to result in increases to the feral cat population. Feral cat control will continue to be undertaken by the Proponent in the areas where the Proponent operates.
Is there a real chance or possibility the action will introduce disease that may cause the species to decline	**No.**
Is there a real chance or possibility the action will interfere with the recovery of the species	**No.** Offset actions are being undertaken as part of the approved Yandicoogina Threatened Species Offset Plan (TSOP) on parts of Yarraloola Pastoral Station. Yarraloola Pastoral Station underlies and surrounds the Development Envelope. The TSOP specifically recognises that mineral resources in the offset area will be developed and accounts for this through selection of a land management area that is much larger than the area of habitat to be impacted by the Yandicoogina Project. The Proposed Action will, therefore, not interfere with the offset actions of the TSOP. The EPBC Act referral guideline for the Northern Quoll (Department of the Environment 2016) includes in the definition of 'populations important for the long-term survival of the Northern Quoll' populations which are, 'being monitored by government agencies or universities or subject to reintroductions or translocations.' The TSOP is implementing landscape-scale land management to improve habitat for Matters of National Environmental Significance through de-stocking and cat baiting. The Yarraloola area was selected as an area that would benefit from improved land management and as an area where it is logistically feasible to undertake land management; the selection was not based on an assessment of the importance of the Northern Quoll population. Although the TSOP was developed in partnership with the WA Department of Biodiversity, Conservation and Attractions - Parks and Wildlife Service and includes some monitoring of Northern Quoll, it does not specifically include monitoring of the Northern Quoll population by government agencies or universities, nor is the population subject to reintroductions or translocations. The monitoring at Yarraloola is focused on monitoring of land condition with monitoring of Northern Quolls used as a tool to validate the land condition gains achieved through implementation of the land management actions. It is, therefore, considered that the Northern Quoll population in the Development Envelope does not meet the definition of a population important for the long-term survival of the Northern Quoll.

Table 14: Assessment against the significant impact criteria for the Ghost Bat

Significant impact criteria	Comment
Is there a real chance or possibility the action will lead to a long-term decrease in the size of an important population of the species	**No**. Management strategies for avoiding and reducing impacts to the Ghost Bat will be implemented as outlined in Section 5.2. The Robe Valley Ghost Bat population occurs towards the western extent of the Ghost Bat's range so may be considered an 'important population' as defined by the Department of the Environment (2013). The key threat to the Ghost Bat is believed to be destruction of, or disturbance to, roost sites and nearby areas (Woinarski *et al*. 2014). As the Proposed Action will retain the two diurnal roosts (which contain potential features for maternal roosts), it is considered unlikely to lead to a long-term decrease in the size of the Ghost Bat population in the Robe Valley. There are also four confirmed maternal Ghost Bat roosts and > 10 confirmed diurnal Ghost Bat roosts elsewhere in the Robe Valley. Given that potential changes to foraging habitat associated with the Robe River will be temporary and represent only a small proportion of Ghost Bat foraging habitat available in the Robe Valley, the Proposed Action is unlikely to result in a long-term decrease in the size of the Ghost Bat population in the Robe Valley.
Is there a real chance or possibility the action will reduce the area of occupancy of an important population	**No.** There may be a minor, temporary reduction in the area of occupancy if Ghost Bats vacate the retained roosts due to noise and vibration while mining operations are underway. There are, however, other roosts and roost complexes available throughout the Robe Valley (including a large maternal roost approximately 20 km west). The retention of diurnal (and potential maternal) roosts, availability of alternative roosts and the evidence of continued Ghost Bat presence in the roost at the Poondano mine site and in historical mining areas of Robe Valley (including the Deepdale area) indicate that it is unlikely that the Proposed Action will permanently reduce the area of occupancy of the Robe Valley population.
Is there a real chance or possibility the action will fragment an existing important population into two or more populations	**No.** The Proposed Action will not alter the movement of individuals so will not cause any fragmentation of the Ghost Bat population in the vicinity of the Development Envelope.
Is there a real chance or possibility the action will adversely affect habitat critical to the survival of the species	**No.** The Proposed Action includes retention of all nocturnal roosts and all potential diurnal/maternal roosts with appropriate mining exclusion zones to protect the integrity of the roosts.
Is there a real chance or possibility the action will disrupt the breeding cycle of an important population	**No.** There may be a temporary disruption to the breeding cycle of individuals in the Development Envelope if Ghost Bats vacate the retained diurnal (potential maternal) roosts due to noise and vibration while mining operations are underway. There are, however, other roosts available throughout the Robe Valley (including a large maternal roost approximately 20 km west). The retention of diurnal/maternal roosts, availability of alternative roosts and the evidence of continued Ghost Bat presence in the roost at the Poondano mine site and in historical mining areas of Robe Valley (including the Deepdale area) indicate that it is unlikely that the Proposed Action will disrupt the breeding cycle of the Ghost Bat population in the Robe Valley.

Significant impact criteria	Comment
Is there a real chance or possibility the action will modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline	**No.** The Proposed Action includes retention of all nocturnal roosts and all potential diurnal/maternal roosts with appropriate mining exclusion zones to protect the integrity of the roosts. Given that potential changes to foraging habitat associated with the Robe River will be temporary and represent only a small proportion of Ghost Bat foraging habitat available in the Robe Valley, the Proposed Action is unlikely to result in a long-term decrease in the size of the Ghost Bat population in the Robe Valley.
Is there a real chance or possibility the action will result in invasive species that are harmful to the vulnerable species becoming established in the vulnerable species' habitat	**No.** The cane toad is considered to be an invasive species that poses a threat to Ghost Bats as Ghost Bats may prey on cane toads. The cane toad is not currently established in the Pilbara. Discharge to the Robe River may result in permanent water being present which may locally increase suitable habitat for cane toads for the duration of the discharge, should the cane toad spread to the Pilbara. However, permanent water is already available in the locality (permanent pools on the Robe River). The Proposed Action will not, therefore, alter the possibility of cane toads becoming established in the area.
Is there a real chance or possibility the action will introduce disease that may cause the species to decline	**No.**
Is there a real chance or possibility the action will interfere substantially with the recovery of the species	**No.**

Table 15: Assessment against the significant impact criteria for the Pilbara Leaf-nosed Bat

Significant impact criteria	Comment
Is there a real chance or possibility the action will lead to a long-term decrease in the size of an important population of the species	**No.** Management strategies for avoiding and reducing impacts to the Pilbara Leaf-nosed Bat will be implemented as outlined in Section 5.3. Survey data indicate that a permanent Pilbara Leaf-nosed Bat roost is not present in the Development Envelope. Given that potential changes to foraging habitat will be temporary and represent only a small proportion of foraging habitat available in the Robe Valley within the range of the Pilbara Leaf-nosed Bat, the Proposed Action is unlikely to result in a long-term decrease in the size of the Pilbara Leaf-nosed Bat population in the Robe Valley.
Is there a real chance or possibility the action will reduce the area of occupancy of an important population	**No.** Survey data indicate that a permanent Pilbara Leaf-nosed Bat roost is not present in the Development Envelope.
Is there a real chance or possibility the action will fragment an existing important population into two or more populations	**No**. The Proposed Action will not alter the movement of individuals so will not cause any fragmentation of the Pilbara Leaf-nosed Bat population in the vicinity of the Development Envelope.
Is there a real chance or possibility the action will adversely affect habitat critical to the survival of the species	**No.** Survey data indicate that a permanent Pilbara Leaf-nosed Bat roost is not present in the Development Envelope. Given that potential changes to foraging habitat represent only a small proportion of foraging habitat available in the Robe Valley within the range of the Pilbara Leaf-nosed Bat, the Proposed Action is unlikely to adversely affect habitat critical to the survival of the species.
Is there a real chance or possibility the action will disrupt the breeding cycle of an important population	**No.** Survey data indicate that a permanent Pilbara Leaf-nosed Bat roost is not present in the Development Envelope (Astron 2016a, Bat Call 2017a). Given that the closest permanent roost is estimated to be approximately 10 km from the Proposed Action and that dust controls will be in place, the effects of dust, light, noise and vibration are unlikely to have a significant impact on the roost or the breeding cycle of Pilbara Leaf-nosed Bats in the roost.
Is there a real chance or possibility the action will modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline	**No** Survey data indicate that a permanent Pilbara Leaf-nosed Bat roost is not present in the Development Envelope.
Is there a real chance or possibility the action will result in invasive species that are harmful to the vulnerable species becoming established in the vulnerable species' habitat	**No.**

Significant impact criteria	Comment
Is there a real chance or possibility the action will introduce disease that may cause the species to decline	**No.**
Is there a real chance or possibility the action will interfere substantially with the recovery of the species	**No.**

Table 16: Assessment against the significant impact criteria for the Pilbara Olive Python

Significant impact criteria	Comment
Is there a real chance or possibility the action will lead to a long-term decrease in the size of an important population of the species	**No.** Management strategies for avoiding and reducing impacts to the Pilbara Olive Python will be implemented as outlined in Section 5.4. The Robe Valley Pilbara Olive Python population occurs towards the western extent of the python's range so may be considered an 'important population' as defined by the Department of the Environment (2013). Major gullies contain breeding habitat for the Pilbara Olive Python. The Proposed Action will retain the escarpments and associated gullies (except where cuts through lower value habitat are required to allow vehicle access). The Robe River provides foraging habitat and a potential dispersal route for the Pilbara Olive Python (Astron 2016a). The Proposed Action may disturb foraging habitat due to abstraction of groundwater which is modelled to result in localised groundwater drawdown in the Mesa H and basement aquifers that may have some connectivity to the Robe River alluvial aquifer and the Jimmawurrada creek alluvial aquifer. However modelling indicates that the potential drawdown impacts to the semi-permanent and permanent pools of the Robe River is expected to be <1 m, with recovery of the groundwater table over time once water abstraction ceases. Groundwater abstraction for water supply from the Southern Cutback Borefield may potentially further extend drawdown in the Jimmawurrada Creek and will extend the timeframe for the predicted groundwater recovery once water abstraction ceases, however no semi-permanent or permanent pools are known to occur in this area – refer to Attachment 14. The potential disturbance to foraging habitat would, however, be temporary and would represent only a small proportion of the foraging habitat available in the Robe Valley. Given retention of the escarpments and the wider availability of foraging habitat in the Robe Valley it is unlikely that the Proposed Action will lead to a long-term decrease in the size of the Robe Valley Pilbara Olive Python population.
Is there a real chance or possibility the action will reduce the area of occupancy of an important population	**No.** The Proposed Action will retain the escarpments and associated gullies (except where cuts through lower value habitat are required to allow vehicle access). Given that potential disturbance to foraging habitat will be temporary and represents only a small proportion of foraging habitat available in the Robe Valley, it is unlikely that the Proposed Action will reduce the area of occupancy of the Robe Valley Pilbara Olive Python population.
Is there a real chance or possibility the action will fragment an existing important population into two or more populations	**No.** Proposed infrastructure will not prevent passage of individuals.

Significant impact criteria	Comment
Is there a real chance or possibility the action will adversely affect habitat critical to the survival of the species	**No.** The Proposed Action will retain the escarpments and associated gullies (except where cuts through lower value habitat are required to allow vehicle access). Given that potential disturbance to foraging habitat will be temporary and represents only a small proportion of foraging habitat available in the broader Robe Valley, it is unlikely that the Proposed Action will adversely affect habitat critical to the survival of the species.
Is there a real chance or possibility the action will disrupt the breeding cycle of an important population	**No.** The Proposed Action will retain breeding habitat through retention of the escarpments and associated gullies (except where cuts through lower value habitat are required to allow vehicle access).
Is there a real chance or possibility the action will modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline	**No.** The Proposed Action will retain breeding habitat through retention of the escarpments and associated gullies (except where cuts through lower value habitat are required to allow vehicle access). Any disturbance to foraging habitat would be temporary and would represent only a small proportion of the foraging habitat available in the broader Robe Valley.
Is there a real chance or possibility the action will result in invasive species that are harmful to the vulnerable species becoming established in the vulnerable species' habitat	**No.** The cane toad is considered to be an invasive species that poses a threat to Pilbara Olive Pythons as Pilbara Olive Pythons may prey on cane toads. The cane toad is not currently established in the Pilbara. Discharge to the Robe River may result in permanent water being present which may locally increase suitable habitat for cane toads for the duration of the discharge, should the cane toad spread to the Pilbara. However, permanent water is already available in the locality (permanent pools on the Robe River). The Proposed Actions will not, therefore, alter the possibility of cane toads becoming established in the area. The feral cat is also considered to pose a threat to juvenile Pilbara Olive Pythons. There is little opportunity for the Proposed Action to result in increases to the feral cat population. Feral cat control will continue to be undertaken by the Proponent in the areas where the Proponent operates.
Is there a real chance or possibility the action will introduce disease that may cause the species to decline	**No.**
Is there a real chance or possibility the action will interfere substantially with the recovery of the species	**No.** Offset actions are being undertaken as part of the TSOP on parts of Yarraloola Pastoral Station. Yarraloola Pastoral Station underlies and surrounds the Development Envelope. The TSOP recognises that mineral resources in the offset area will be developed and accounts for this through selection of a land management area that is much larger than the area of habitat impacted by the Yandicoogina Project. The Proposed Action will, therefore, not interfere with the offset actions under the TSOP.

Table 17: Assessment against the significant impact criteria for the Blind Cave Eel

Significant impact criteria	Comment
Is there a real chance or possibility the action will lead to a long-term decrease in the size of an important population of the species	**No.** Management strategies for avoiding and reducing impacts to the Blind Cave Eel will be implemented as outlined in Section 5.5. The alluvial aquifers overlying CID formation in Jimmawurrada Creek contains known habitat for the Blind Cave Eel. Jimmawurrada Creek forms an upstream tributary which intersects the Robe River to the east of the Proposed Action. These creek systems are interconnected and provide a potential dispersal route for the Blind Cave Eel. The Proposed Action will retain the alluvial aquifer habitat and flow paths of the creeks, however may result in a localised reduction in habitat due to the lowering of the groundwater table due to abstraction of groundwater for water supply and mine pit dewatering. The hydrogeological modelling indicates the potential for minor reduction in water levels in the Robe River alluvial aquifer and semi-permanent and permanent pools (<1 m), with recovery of the groundwater table over time once water abstraction ceases. Groundwater abstraction for water supply from the Southern Cutback Borefield may potentially extend groundwater drawdown in Jimmawurrada Creek over a 9 km section, which would encompass a known Blind Cave Eel record (located 1.1 km from the Development Envelope) and extend the timeframe for the predicted groundwater recovery once water abstraction ceases. However wet season flows are expected to continue to provide seasonal connectivity of the alluvial habitat through these creek systems. Any temporary changes to groundwater levels in the alluvial aquifer of Jimmawurrada Creek and the Robe River near Mesa H are, therefore, unlikely to significantly impact habitat for the Blind Cave Eel and would represent only a small proportion of the habitat available in the broader Robe Valley. Given that the creek flow lines and alluvial substrate will remain largely physically undisturbed, and the interconnected nature of Jimmawurrada creek and the Robe River, the availability of core habitat remains extensive in the broader Robe Valley. The potential impact from reduction in habitat due to groundwater drawdown is considered temporary. In any case, mitigation options for groundwater drawdown, such as supplementary water supply to the river ecosystems via controlled discharge would be considered for the Proposed Action should monitoring indicate a requirement to protect significant values. Therefore it is considered unlikely that the Proposed Action will lead to a long-term decrease in the size of the Blind Cave Eel population.
Is there a real chance or possibility the action will reduce the area of occupancy of an important population	**No.** The Proposed Action will retain core subterranean habitat through retention of the alluvial aquifers and connectivity of these aquifers. Given that potential disturbance to habitat via groundwater drawdown will be temporary and represents only a small proportion of habitat available in the broader Robe Valley it is unlikely that the Proposed Action will significantly reduce the area of occupancy of the Blind Cave Eel population.
Is there a real chance or possibility the action will fragment an existing important population into two or more populations	**No.** Proposed surface infrastructure will not prevent passage of individuals.
Is there a real chance or possibility the action will adversely affect habitat critical to the survival of the species	**No.** The Proposed Action will retain core subterranean habitat through retention of the alluvial aquifers and connectivity of these aquifers. Given that potential disturbance to habitat via groundwater drawdown will be temporary and represents only a small proportion of habitat available in the broader Robe Valley it is unlikely that the Proposed Action will adversely affect habitat critical to the survival of the species.

Significant impact criteria	Comment
Is there a real chance or possibility the action will disrupt the breeding cycle of an important population	**No.** The Proposed Action will retain breeding habitat through retention of the subterranean alluvial aquifer habitat.
Is there a real chance or possibility the action will modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline	**No.** The Proposed Action will retain core subterranean habitat through retention of the alluvial aquifers and connectivity of these aquifers. Impacts to groundwater levels are modelled to be minor along the Robe River and localised to a 9km section of Jimmawurrada Creek. The habitat will continue to be seasonally connected following rainfall events. Any disturbance to habitat would be temporary and would represent only a small proportion of the habitat available in the broader Robe Valley.
Is there a real chance or possibility the action will result in invasive species that are harmful to the vulnerable species becoming established in the vulnerable species' habitat	**No.** The Proposed Action manages surface and groundwater from the same connected catchments and aquifers. As the Blind Cave Eel habitat is subterranean, and the environment subject to significant natural flooding events which would support broad catchment connectivity, it is unlikely that the Proposed Action could result in the introduction of invasive species.
Is there a real chance or possibility the action will introduce disease that may cause the species to decline	**No.**
Is there a real chance or possibility the action will interfere substantially with the recovery of the species	**No.**

3.1 (e) Listed migratory species

Description

An EPBC Act Protected Matters search (21 November 2016, Attachment 4) identified nine Listed Migratory Species as potentially occurring within the Development Envelope and surrounds. Four additional species that potentially occur in the Development Envelope (Astron 2016a) are listed in Table 18 with their likelihood of occurrence in the Development Envelope.

Table 18: Likelihood of occurrence of Listed Migratory Species in the Development Envelope

Species	Likelihood of occurrence
Rainbow Bee-eater *Merops ornatus*	**Confirmed** Recorded from all habitats in the Proposal Area including loamy/stony plains, riverine, drainage lines, low hills and slopes, and breakaways
Eastern Great Egret *Ardea modesta*	**Confirmed** Recorded from riverine habitat within the Development Envelope
Cattle Egret *Ardea ibis*	**Moderate** May occur along watercourses in the Development Envelope
Oriental Pratincole *Glareola maldivarum*	**Moderate** May occur along watercourses in the Development Envelope
Common Sandpiper *Actitis hypoleucos*	**Moderate** May occur along watercourses in the Development Envelope during periods of flood

Species	Likelihood of occurrence
Wood Sandpiper *Tringa glareola*	**Moderate** May occur along watercourses in the Development Envelope during periods of flood
Common Greenshank *Tringa nebularia*	**Moderate** May occur along watercourses in the Development Envelope during periods of flood
Fork-tailed Swift *Apus pacificus*	**Moderate** Has the potential to overfly the Development Envelope
Eastern Osprey *Pandion cristatus*	**Low** May occur along watercourses in the Development Envelope during periods of flood
Barn Swallow *Hirundo rustica*	**Low** No regional records and no preferred habitat in the Development Envelope.
Oriental Plover *Charadrius veredus*	**Low** No regional records within 50 km of the Development Envelope but the species may occur intermittently in plains habitat in the Development Envelope
Curlew Sandpiper *Calidris ferruginea*	**Low** No regional records within 50 km of the Proposal Area and no preferred habitat present in the Proposal Area
Eastern Curlew, Far Eastern Curlew *Numenius madagascariensis*	**Low** No regional records within 50 km of the Proposal Area and no preferred habitat present in the Proposal Area
Grey Wagtail *Motacilla cinerea*	**Low** No regional records within 50 km of the Development Envelope and no preferred habitat present in the Development Envelope
Yellow Wagtail *Motacilla flava*	**Low** No regional records within 50 km of the Development Envelope and no preferred habitat present in the Development Envelope

Nature and extent of likely impact

The Proposed Action is not expected to have any significant impacts on the species listed in Table 18 for the following reasons:

- The Loamy/Stony Plain and Riverine habitats potentially used by the migratory species extend well beyond the Development Envelope; only a small proportion of available habitat is located within the Development Envelope.
- All of the species have extensive distributions across Western Australia (i.e. are not spatially restricted).
- The presence of the species in the Development Envelope is expected to be transitory only.
- All of the species are mobile, with the capacity to avoid mining disturbances such as vegetation clearing activities.
- Despite extensive fauna surveys conducted in and near the Development Envelope over a 20 year period, significant populations of these species have not been recorded in the locality.

3.1 (f) Commonwealth marine area

Not applicable

3.1 (g) Commonwealth land

Not applicable

3.1 (h) The Great Barrier Reef Marine Park

Not applicable

3.1 (i) A water resource, in relation to coal seam gas development or large coal mining development

Not applicable

3.2 Nuclear actions, actions taken by the Commonwealth (or Commonwealth agency), actions taken in a Commonwealth marine area, actions taken on Commonwealth land, or actions taken in the Great Barrier Reef Marine Park

3.2 (a)	**Is the proposed action a nuclear action?**	✓	No
3.2 (b)	**Is the proposed action to be taken by the Commonwealth or a Commonwealth agency?**	✓	No
3.2 (c)	**Is the proposed action to be taken in a Commonwealth marine area?**	✓	No
3.2 (d)	**Is the proposed action to be taken on Commonwealth land?**	✓	No
3.2 (e)	**Is the proposed action to be taken in the Great Barrier Reef Marine Park?**	✓	No

3.3 Description of the project area and affected area for the proposed action

3.3 (a) Flora and fauna

Flora

The Development Envelope is located in the Pilbara bioregion as defined by the Interim Biogeographic Regionalisation for Australia (IBRA) (DSEWPaC 2013). The Development Envelope is located within the Hamersley sub-region (refer Attachment 9).

Numerous flora and vegetation surveys have been undertaken across the Development Envelope and surrounds since the early 1990's.

There were 310 vascular flora species from 53 families and 150 genera recorded in the Development Envelope. The most represented families were Fabaceae, Poaceae and Malvaceae. No Threatened flora were recorded during the survey or are expected to occur. Three State-listed Priority flora were identified:

- *Indigofera* sp. Bungaroo Creek (S. van Leeuwen 4301) P3,
- *Triodia* sp. Robe River (M.E. Trudgen et al. MET 12367) P3; and
- *Rhynchosia bungarensis* P4.

These Priority flora are also represented in the surrounding landforms and vegetation, outside the Development Envelope. *Rhynchosia bungarensis* has been recorded from National Parks and/or Nature Reserves in protected habitat. *Triodia* sp. Robe River (M.E. Trudgen *et al*. MET 12367) has been recorded by Rio Tinto over a range of approximately 125 km extending south-east and 25 km north-west from Mesa H (Rio Tinto 2016) and floristic composition was found to be typical of the Hamersley and Roebourne sub-regions.

During the more recent two phase seasonal survey effort (2015-2016 (Astron 2016b)) across the Development Envelope, 38 vegetation associations were described, none of which represent a Threatened Ecological Community (TEC). All but three vegetation associations recorded are well represented beyond the Development Envelope and do not support assemblages of species that are unique, on restricted landforms, or of high conservation significance:

- Priority 3 Priority Ecological Community (PEC) '*Triodia sp. Robe River assemblages of mesas of the West Pilbara'*. Vegetation representing this PEC accounted for 14.6 ha (0.3%) within the Development Envelope.
- Vegetation association (ChAsppGOrGsppPlSsTeTw) contained all three of the recorded Priority flora species. This vegetation was associated with drainage lines comprising approximately 135 ha (3%) of the Development Envelope. Similar vegetation has been recorded from other regional surveys.
- Riparian vegetation association containing MaEcCv, represents approximately 174 ha (3%) of the Development Envelope, and is considered a groundwater dependent ecosystem as it is characterised by the obligate phreatophyte *Melaleuca argentea*. MaEcCv was mapped on the fringes of permanent and semi-permanent water pools both in and outside the Development Envelope and the main flow channels of the Robe River, and as such supported a number of species that were unique to this habitat.

The families and genera recorded in the Riverine and Drainage lines are typical of what would be expected in riparian vegetation of major drainage lines in the Pilbara. No Threatened taxa were recorded. There were 23 weed species recorded within the riparian habitats. None of the weed species recorded is listed as a declared pest for the Shire of Ashburton or a Weed of National Significance.

Vegetation condition ranged from 'very poor' to 'excellent' with approximately 67% of the Development Envelope classified as being in 'excellent' condition. The area is also subject to a history of pastoral activity with cattle grazing evident on the plains, floodplains and drainage lines.

Fauna

Astron undertook a multi-seasonal terrestrial fauna survey in 2015 and 2016 including systematic, targeted, and opportunistic sampling for terrestrial vertebrate fauna and potential short-range endemic (SRE) invertebrates. Seven broad fauna habitat types were recorded in the Development Envelope:

- Riverine;
- Drainage Line; Gorge;
- Breakaway;
- Rocky Hills;
- Low Hills and Slopes; and
- Loamy/Stony Plain.

The Gorge, Riverine and Breakaway habitats in the Development Envelope are considered important for fauna due to the microhabitats they provide such as caves and water pools. The Gorges and Breakaway habitats represent an important site of refuge due to their location close to the Robe River and as habitat for conservation significant fauna.

There were 169 vertebrate fauna species recorded within the Development Envelope including: two amphibian species: 55 reptile species: 85 bird species; and 27 mammal species (including four introduced species). The faunal assemblage recorded is considered typical of the Hamersley Range subregion extending from near Pannawonica to Mt Brockman.

Eight conservation significant fauna species have been recorded in the Development Envelope: Pilbara Olive Python (VU; S3) (*Liasis olivaceus barroni*); Northern Quoll (EN; S2) (*Dasyurus*

hallucatus); Pilbara Leaf-nosed Bat (VU; S3) (*Rhinonicteris aurantia*); Ghost Bat (VU; S3) (*Macroderma gigas*); Rainbow Bee-eater (Mi; S5) (*Merops ornatus*); Eastern Great Egret (Mi; S5) (*Ardea modesta*); Lined Soil-crevice Skink (P4) (*Notoscincus butleri*); and Western Pebble-mound Mouse (P4) (*Pseudomys chapmani*). These are listed in Table 19.

The Development Envelope was systematically trapped for vertebrates for a total of 3,493 trap nights across eight sites including targeted searching. Forty person hours were spent conducting avifauna surveys and 30 person hours were spent spotlighting. Motion-sensor cameras were deployed for 247 camera trap-nights and SM2 Bat detectors were deployed for 27 recording-nights. In addition, Rio Tinto personnel deployed SM2 Bat detectors for 61 recording nights in and near the Development Envelope.

Four of the eight recorded conservation significant species are classified under the EPBC Act as MNES species: the Pilbara Olive Python; Northern Quoll; Ghost Bat; and Pilbara Leaf-nosed Bat.

The following recordings were made of these species:

- A single juvenile Pilbara Olive Python and two Pilbara Olive Python scats were recorded within the Riverine and the Breakaway habitat type within the Development Envelope. All records were outside the indicative clearing footprint of the Proposed Action.

- The Northern Quoll was recorded 27 times comprising: six capture records; 19 remote camera location records; and from two scats within the Breakaway, Riverine and Gorge habitat types in and immediately outside the Development Envelope. All records were outside the indicative clearing footprint of the Proposed Action.

- The Ghost Bat was recorded twice through scat collections and acoustic recordings. Eleven caves were identified within the Development Envelope during the surveys during detailed assessments undertaken by Bat Call WA (2017a), including two potential diurnal roost caves and nine nocturnal roost shelters based on their size, complexity and the presence of Ghost Bats and /or scats. All records and caves were outside the indicative clearing footprint of the Proposed Action.

- The two diurnal caves were assessed as being maternity cave candidates although no evidence of intensive Ghost Bat use for this purpose was found during the survey.

- The Pilbara Leaf-nosed Bat was recorded at eight of the 14 SM2 bat detector locations, all at low activity levels apart from one location (BAT 14) located outside the Development Envelope which recorded 257 calls. Further data and analysis of the BAT 14 sites confirmed that the Pilbara Leaf-nosed Bats originated from a known roost site approximately 10 kms south of the Development Envelope.

Table 19: Conservation listed fauna species recorded in the Development Envelope*

Common name (*Scientific name*)	Status	
	EPBC Act	In Western Australia
Northern Quoll (*Dasyurus hallucatus*)	Endangered	Schedule 2
Ghost Bat (*Macroderma gigas*)	Vulnerable	Schedule 3
Pilbara Leaf-nosed Bat (*Rhinonicteris aurantia*)	Vulnerable	Schedule 3
Pilbara Olive Python (*Liasis olivaceus barroni*)	Vulnerable	Schedule 3
Rainbow Bee-eater (*Merops ornatus*)	Migratory	Schedule 5
Eastern Great Egret (*Ardea modesta*)	Migratory	Schedule 5
Lined Soil-crevice Skink (*Notoscincus butleri*)	-	Priority 4
Western Pebble-mound Mouse (*Pseudomys chapmani*)	-	Priority 4

The Blind Cave Eel (Vulnerable) was also recorded approximately 1.1 km outside of the Development Envelope*, but within the area of modelled groundwater drawdown impact.

3.3 (b) Hydrology, including water flows

The Hamersley sub-region experiences an arid to tropical climate characterised by hot summers, warm winters, high potential evaporation and intermittent intense rainfall, often associated with cyclones and thunderstorms. The region experiences climatic extremes where severe droughts and major floods can follow each other in close succession.

The Robe River is the major river system in the region and covers a linear distance in excess of 190 km. The majority of the Development Envelope lies within the Robe River catchment which has a catchment area of approximately 7,500 km^2. Major watercourses occurring within the catchment include the Robe River and the Jimmawurrada, Bungaroo and Mungarathoona Creek's. The major water courses generally flow from the southeast to the northwest through high relief areas of the Hamersley Ranges on to the more gently sloping areas of the coastal plain before discharging into the ocean approximately 150 km south of Dampier. For the majority of its course, the Robe River is ephemeral with a wide, shallow flood plain. During the dry season water is often restricted to a series of permanent pools that are maintained by sub-surface flow (Bowman *et al*. 1991).

The eastern part of the Development Envelope lies within the Jimmawurrada Creek catchment which has a catchment area of approximately 400 km^2. Jimmawurrada is an ephemeral creek containing numerous braided dry creek beds subject to flooding during the wet season and converges into the Robe River immediately to the east of Mesa J and the Development Envelope.

3.3 (c) Soil and vegetation characteristics

The Development Envelope is located in the Hamersley IBRA sub-region, the characteristics of which are described in Table 20 (Environment Australia 2000).

Soils of the Development Envelope are typically shallow and of poor quality; the river landform is characterised by sand, gravel, pebbles and stones. The surrounding drainage zones are red shallow loams (Van Vreeswyk *et al*. 2004).

Table 20: Description of the Hamersley IBRA sub-region

Sub-region	Description
Hamersley	Mountainous area of Proterozoic sedimentary ranges and plateaux with Mulga low woodland over bunch grasses on fine textured soils and Snappy Gum over *Triodia brizoides* on skeletal sandy soils of the ranges.

Van Vreeswyk *et al*. (2004) classified and mapped the land systems of the Pilbara region according to similarities in landform, soil, vegetation, geology and geomorphology. The Development Envelope intersects six land systems as described in Table 21. The Development Envelope incorporates low plateaux and mesas associated with the Robe Land System, and the Robe River itself as a component of the River Land System. The surrounding plains supporting spinifex are predominantly associated with the Boolgeeda Land System.

Table 21: Land systems in the Development Envelope

Land system	Land system description
Boolgeeda	Stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands and mulga shrublands.
McKay	Hills, ridges, plateaux remnants and breakaways of meta sedimentary and sedimentary rocks supporting hard spinifex grasslands.
Newman	Rugged jaspilite plateaux, ridges and mountains with hard spinifex.
River	Seasonally active flood plains and major river channels supporting grassy eucalypt woodlands, tussock grasslands and soft spinifex grasslands.
Robe	Low plateaux, mesas and buttes of limonite supporting soft spinifex and occasionally hard spinifex grasslands.
Urandy	Stony plains, alluvial plains and drainage lines supporting shrubby soft spinifex grasslands

3.3 (d) Outstanding natural features

The Development Envelope does not include any areas with outstanding natural features.

3.3 (e) Remnant native vegetation

The Development Envelope consists almost entirely of native vegetation, much of which has a history of pastoral land use. Apart from the adjacent active mining area (Mesa J and Mesa K), only a small proportion of the area has been cleared in association with mining exploration activities (i.e. tracks, drill pads, temporary workforce camps).

3.3 (f) Gradient (or depth range if action is to be taken in a marine area)

The Proposed Action will occur on a mesa landform and the surrounding plains. The plains in the Development Envelope occur at an elevation of approximately 122 mAHD, with the top of the mesa rising to a maximum elevation of approximately 55 m above the plain (177 mAHD). The mesa escarpments have variable gradients ranging from approximately 5º to 25º.

3.3 (g) Current state of the environment

The Development Envelope and surrounds has been subject to pastoral land use activities for over a century and iron ore mining since 1992 when productive mining commenced at Mesa J. Beyond the Development Envelope, iron ore mining has been undertaken in the Robe Valley in the Deepdale Area since the late 1960s.

The majority of the vegetation in the Development Envelope has been assessed as in Excellent or Very Good condition. Exceptions include areas cleared for the adjacent mine operations, infrastructure, vehicle tracks, rail line and drill pads as well as areas with high weed infestations and areas that have been heavily grazed or trampled by cattle.

3.3 (h) Commonwealth Heritage Places or other places recognised as having heritage values

The Development Envelope does not include Commonwealth Heritage Places or other places recognised as having heritage values.

3.3 (i) Indigenous heritage values

The Proposal lies within the Kuruma Marthudunera (K&M) Native Title Claim (WCD2016/006). The Proponent has a Participation Agreement and Indigenous Land Use Agreement with the K&M that includes an established consultation framework and ongoing engagement on processes such as: land access; tenure acquisition; heritage surveys and environmental management relating to the Proponent's operations.

All of the archaeological survey work and the majority of the ethnographic survey work has been completed for the Proposal. Heritage sites of high significance in the vicinity of the Development Envelope are ethnographic sites (including mythological locations, named pools and places of importance due to current use); the Robe River, and the mesa profiles which are used as landmarks within the landscape. The Proposal has been specifically designed to avoid significant impact and to protect key identified heritage sites in consultation with the K&M. Disturbance to less significant heritage sites will be avoided where practicable. Where these less significant heritage sites cannot be avoided, it is anticipated that potential impacts will be managed through the processes contained within the Participation Agreement and under the *Aboriginal Heritage Act 1972* (WA).

3.3 (j) Other important or unique values of the environment

The Development Envelope does not have other known important or unique environmental values.

3.3 (k) Tenure of the action area (e.g. freehold, leasehold)

The Robe Valley mining operations, including this Proposed Action, are predominantly located within the State Agreement Mineral Lease ML248SA granted pursuant to the *Iron Ore (Robe River) Agreement Act 1964* (WA). ML248SA is appropriate tenure for mining and mining related infrastructure.

The main co-existing Land Administration Act 1997 (WA) (LAA) tenure in the Development Envelope includes the Yarraloola Pastoral Station (Lease N49500) and the Yalleen Pastoral Station (Lease N49492). These pastoral leases are held by entities associated with members of the RRIA.

Existing tenure in and near the Development Envelope is shown in Attachment 2. The Proposal pits, dumps and the majority of infrastructure are located within ML248SA (section 104 and a portion of section 103). A powerline to the east of Mesa J in the eastern part of the Development Envelope will require grant of new tenure under the *Mining Act 1978*.

3.3 (l) Existing uses of area of proposed action

The Proposal is located in the Shire of Ashburton, approximately 16 km south west of the township of Pannawonica. Existing land uses in the Development Envelope include: pastoral activities (Yarraloola and Yalleen Stations); mineral exploration; mining activities; and cultural / recreational activities (predominantly by Traditional Owners) such as camping, fishing and hunting. The mesa landform / profiles of the Robe Valley are also used by Traditional Owners as landmarks when travelling though the countryside (refer Attachment 2).

3.3 (m) Any proposed uses of area of proposed action

It is anticipated that the Yarraloola and Yalleen pastoral leases will continue to support pastoral activities both during mining activities and post-mining.

The Proponent will prepare a Mine Closure Plan (MCP) for the entire Mesa J Hub Operation (which includes the Proposed Action) in accordance with the Western Australian *Guidelines for Preparing Mine Closure Plans* (Department of Mines and Petroleum and Environmental Protection Authority 2015). The MCP will be regularly updated over the life of the project in consultation with relevant government agencies. Closure activities will also conform to the global Rio Tinto Closure Standard.

4. Environmental outcomes

Based upon project design and biological assessment (Astron 2016a) - Attachment 5 and Bat Call WA (2017a & b) – Attachment 11 & 12), the Proposed Action is not anticipated to have any significant impacts upon MNES. Specifically, the Proposed Action includes the following environmental outcomes:

- Clearing of up to 2,200 ha in the Development Envelope of 4,930 ha. The majority of clearing will be on the top of the mesa and the surrounding plains. These areas do not represent core habitat for the MNES which may be impacted by the Proposed Action. All MNES records to date have been sampled outside the indicative Proposed Action clearing footprint.
- Retention of approximately 95% of the escarpments and associated gullies to ensure retention of core habitat for MNES to avoid impact by the Proposed Action.
- Continued retention of the escarpments, except for areas required to provide vehicle access to the mesa.
- Retention of the attributes of the diurnal (with potential to be maternity) Ghost Bat roost caves and associated roost complexes:
    - A mining exclusion zone of 40 m between the back of each diurnal / potential maternal roost cave and the proposed mine pit.
    - A mining exclusion zone of 50 m from the entry to each cave that is part of a roost complex (i.e. the caves in the same gullies as the diurnal / potential maternal roost caves) to the proposed mine pit.
- Retention of all recorded nocturnal Ghost Bat roosts.
- Ongoing availability of foraging habitat for the Northern Quoll, Ghost Bat, Pilbara Leaf-nosed Bat and Pilbara Olive Python both inside and outside the Development Envelope.
- No impact to the Pilbara Leaf-nosed Bat roost located approximately 10 km away to the south.
- Limited impact to core Pilbara Olive Python habitat along the Robe River and Jimmawurrada Creek from road access and groundwater drawdown. Potential extension of habitat in areas of surplus water discharge.
- Localised impact to the Blind Cave Eel habitat from groundwater drawdown.

5. Measures to avoid or reduce impacts

5.1 Northern Quoll

Potential impacts

Northern Quoll individuals may be impacted by:

- Minor reduction in denning habitat where cuts are made through the escarpments to allow access to the mesas.
- Minor clearing or modification of foraging habitat, including habitat associated with the Robe River (<5 ha) and indirect impact to Jimmawurrada Creek.
- Noise and vibration from mining activities.
- Increased risk of vehicle strike on roads.
- Increased predation from feral predators.

Management strategies

Strategies for avoiding and reducing impacts to the Northern Quoll include:

- **Designing the Proposed Action to minimise the proposed footprint.**
- **Designing the Proposed Action to avoid areas of core habitat:**
    - retain mesa escarpments; and
    - limited / minimal disturbance to the Robe River and Jimmawurrada Creek – minimal clearing within the Robe River (facilities in the Robe River limited to low impact crossing points); avoidance of direct disturbance to associated pools; and avoidance of clearing within Jimmawurrada Creek.
- **Delineating disturbance footprint and adhering to disturbance boundaries** to minimise disturbance and to avoid inadvertent disturbance to areas of significance.
- **Maintaining appropriate speed limits** for light vehicles by ensuring all roads are sign-posted and vehicle speeds are monitored.
- **Implementing programs for education of the workforce** with respect to fauna protection and management, specifically in relation to the Northern Quoll.
- **Implementing feral animal control.**

Anticipated residual impacts

The Proposed Action is not expected to result in significant impacts to the Northern Quoll as approximately 95% of Northern Quoll core habitat (mesa escarpments, particularly areas with deep gullies that are associated with drainage lines and water courses) within the Development Envelope will be retained. The Proposed Action is not expected to result in a significant impact to Northern Quoll foraging habitat as only a small proportion of available foraging habitat in the development envelope will be disturbed.

5.2 Ghost Bat

Potential impacts

Ghost Bat individuals may be impacted by:

- Minor loss of nocturnal roosts through cuts in the escarpments to allow vehicle access to the mesa.

- Minor clearing or modification of foraging habitat, including habitat associated with the Robe River and Jimmawurrada Creek.
- Dust, noise and vibration from mining activities.

Management strategies

Strategies for avoiding and reducing impacts to the Ghost Bat include:

- **Designing the Proposed Action to minimise the proposed footprint.**
- **Designing the Proposed Action to avoid areas of core habitat:**
    - retain escarpments at Mesa H;
    - establish mining exclusion zones around diurnal roosts and their associated cave complexes;
    - design the haul roads to avoid diurnal roosts and their associated cave complexes; and
    - limited / minimal disturbance to the Robe River and Jimmawurrada Creek – minimal clearing within the Robe River (facilities in the Robe River limited to low impact crossing points); avoidance of direct disturbance to associated pools; and avoidance of clearing within Jimmawurrada Creek.
- **Delineating disturbance footprint and adhering to disturbance boundaries** to minimise disturbance and to avoid inadvertent disturbance to areas of significance.
- **Ensuring barbed-wire fences are not installed** unless there is a statutory requirement to do so. Where barbed-wire is necessary, ensuring reflectors are installed to deter bats.
- **Controlling dust.**
- **Implementing programs for education** of the workforce with respect to fauna protection and management, specifically in relation to the Ghost Bat.

Anticipated residual impacts

The Proposed Action is not expected to result in significant impacts to the Ghost Bat as diurnal roosts will be retained with adequate buffer zones to protect the integrity of the caves. Most nocturnal roosts will also be retained. Nor is the Proposed Action expected to result in a significant impact to Ghost Bat foraging habitat given that any changes to foraging habitat associated with the Robe River would be temporary and would represent only a small proportion of the foraging habitat available in the Robe Valley.

5.3 Pilbara Leaf-nosed Bat

Potential impacts

Pilbara Leaf-nosed Bat individuals may be impacted by:

- Minor clearing or modification of foraging habitat, including habitat associated with the Robe River and Jimmawurrada Creek.
- Dust, noise, vibration and light from the mining operation.
- Increased risk of vehicle strike on roads.

Management strategies

- **Designing the Proposed Action to minimise the proposed footprint.**
- **Designing the Proposed Action to limit direct disturbance and limit indirect disturbance associated with water to the primary foraging areas**, the Robe River and Jimmawurrada Creek.

- **Delineating disturbance footprint and adhering to disturbance boundaries** to minimise disturbance and to avoid inadvertent disturbance to areas of significance.
- **Maintaining appropriate speed limits for light vehicles** by ensuring all roads are sign-posted and vehicle speeds are monitored.
- **Implementing programs for education** of the workforce with respect to fauna protection and management, specifically in relation to the Pilbara Leaf-nosed Bat.

Anticipated residual impacts

The Proposed Action is not expected to result in significant impacts to the Pilbara Leaf-nosed Bat given that the nearest roost is located well outside (>10 km south) of the Development Envelope.

5.4 Pilbara Olive Python

Potential impacts

Pilbara Olive Python individuals may be impacted by:

- Minor clearing or modification of habitat, including habitat associated with the Robe River and Jimmawurrada Creek.
- Minor reduction in lower quality habitat where cuts are made through the escarpments to allow access to the mesa.
- Potential extension of habitat in the Robe River via surplus water discharge.
- Noise and vibration from the mining operation.
- Increased risk of vehicle strike on roads.
- Increased predation from feral predators.

Management strategies

- **Designing the Proposed Action to minimise the proposed footprint.**
- **Designing the Proposed Action to avoid areas of core habitat:**
    - retain escarpments at Mesa H;
    - limited / minimal disturbance to the Robe River and Jimmawurrada Creek – minimal clearing within the Robe River (facilities in the Robe River limited to low impact crossing points); avoidance of direct disturbance to associated pools; and avoidance of clearing within Jimmawurrada Creek; and
    - maintaining pools in the Robe River via supplementary water supply should monitoring indicate significant pool level changes resulting from groundwater drawdown.
- **Delineating disturbance footprint and adhering to disturbance boundaries** to minimise disturbance and to avoid inadvertent disturbance to areas of significance.
- **Maintaining appropriate speed limits** for light vehicles by ensuring all roads are sign-posted and vehicle speeds are monitored.
- **Implementing programs for education of the workforce** with respect to fauna protection and management, specifically in relation to the Pilbara Olive Python.
- **Implementing feral animal control.**

Anticipated residual impacts

The Proposed Action is not expected to result in significant impacts to the Pilbara Olive Python as the mesa escarpment will be retained and any impact to foraging habitat along the Robe River

would be minor or temporary, with pools in the Robe River being maintained, and would represent only a small proportion of the foraging habitat available in the Robe Valley.

5.5 Blind Cave Eel

Potential impacts

Blind cave eel individuals may be impacted by:

- Modification of habitat through:
    - reduction of habitat via groundwater drawdown, including habitat associated with the Robe River and Jimmawurrada Creek alluvial aquifers; and
    - potential extension of habitat in the Robe River via surplus water discharge.
- Localised reduction in habitat quality from pollutants and sedimentation being transported into the surface water and groundwater systems.

Management strategies

- **Designing the Proposed Action to minimise the proposed footprint.**
- **Designing the Proposed Action to avoid direct removal of core habitat:**
    - direct physical disturbance to the Robe River and Jimmawurrada Creek will be limited to vehicle crossing points and no direct physical disturbance to the pools; and
    - creekline flood flows and flow paths will be maintained which will support retention of habitat connectivity.
- **Maintaining areas of viable habitat:**
    - limiting area of habitat subject to groundwater drawdown;
    - managing surface water discharge quality by managing erosion and sedimentation;
    - maintain groundwater and surface water quality by managing contaminants (e.g. Hydrocarbon spills);
    - maintaining alluvial habitat and connectivity; and
    - implementing a precautionary mitigation option such as supplementary water supply to alluvial ecosystems via controlled discharge to minimise localised impacts of groundwater drawdown should monitoring indicate significant groundwater level changes.
- **Delineating disturbance footprint and adhering to disturbance boundaries** to minimise disturbance and to avoid inadvertent disturbance to areas of significance.
- **Implementing programs for education of the workforce** with respect to fauna protection and management, specifically in relation to the Blind Cave Eel.

Anticipated residual impacts

The Proposed Action is not expected to result in significant impacts to the Blind Cave Eel as potential habitat impacts along the Robe River and Jimmawurrada Creek would be temporary and localised – with subterranean habitat substrate and connectivity retained, and thus the impacts are constrained to only a small proportion of the habitat available in the broader Robe Valley.

6. Conclusion on the likelihood of significant impacts

6.1 Do you THINK your Proposed Action is a Controlled Action?

No. Refer to Section 6.2.

6.2 Proposed action IS NOT a controlled action.

As detailed in Section 3.1, based on extensive flora/vegetation and fauna surveys in and near the Development Envelope:

- The Northern Quoll has been recorded in the Development Envelope as well as numerous times throughout the broader Robe Valley and occur outside the indicative Proposed Action clearing footprint.
- The Ghost Bat and Ghost Bat roosts have been recorded in the Development Envelope as well as numerous times throughout the Robe Valley. No confirmed maternal roots have been located in the Development Envelope and all known roosts are located outside the indicative clearing footprint of the Proposed Action.
- The Pilbara Leaf-nosed Bat has been recorded foraging in the Development Envelope as well as numerous times throughout the broader Robe Valley. Based on acoustic records, the nearest Pilbara Leaf-nosed Bat roost is estimated to be approximately 10 km south of Mesa H, well outside the Development Envelope.
- The Pilbara Olive Python has been recorded in the Development Envelope as well as numerous times throughout the broader Robe Valley and were located outside the indicative clearing footprint of the Proposed Action.
- Nine migratory bird species (refer Table 18) have been recorded or are likely to occur in the Development Envelope as well as more broadly in the Robe Valley.
- The Blind Cave Eel has been recorded in the groundwater approximately 1.1 km outside the Development Envelope, but within the modelled groundwater drawdown cone of depression. Another record exists 5km from the Development Envelope, outside the predicted impact area. The same species has also been recorded from 11 localities in the subterranean waters of Cape Range.

The potential impacts of the Proposed Action on MNES have been assessed against:

- The general significance test required under the EPBC Act, whether there is ‘a real chance or possibility’ of an impact that is ‘important, notable or of consequence, having regard to its context or intensity’ (Department of the Environment 2013).
- The criteria specified by Department of the Environment (2013) regarding significant adverse impacts to Listed Threatened Species.

Based on the assessment of the Proposed Action against the above criteria, the Proposed Action is **not** considered to be a controlled action as:

- The Proposed Action will protect and avoid mining of the Mesa H escarpments which contain denning habitat for the Northern Quoll. The Proposed Action will disturb only a small proportion of the available primary foraging habitat for the Northern Quoll in the vicinity of the Development Envelope.
- The Proposed Action will retain the diurnal Ghost Bat roosts and associated roost complexes with buffer zones between the proposed mine pits and the caves. The availability of diurnal roosts is believed to be a key factor in the persistence of the Ghost Bat in the Pilbara. The Proposed Action avoids disturbance to the diurnal Ghost Bat roosts (mining, habitat removal and roads). Any impact to Ghost Bat foraging habitat would be temporary and limited to a very small proportion of the available foraging habitat along the Robe River.

- The Proposed Action will not impact on any Pilbara Leaf-nosed Bat roosts as the nearest roost is estimated to be approximately 10 km south from Mesa H, outside the Development Envelope. The availability of suitable roosts is key to the persistence of the Pilbara Leaf-nosed Bat.
- The Proposed Action will retain the Mesa H escarpments which potentially contains breeding habitat for the Pilbara Olive Python. The Proposed Action will disturb only a small proportion of the available foraging habitat for the Pilbara Olive Python in the vicinity of the Development Envelope and the disturbance will be temporary.
- The Proposed Action will impact only a small proportion of the available Plains and Riverine habitats used by migratory bird species in the Robe Valley. The presence of the migratory species in the Development Envelope is expected to be transitory only and all of the migratory species likely to occur in the Development Envelope have extensive distributions across Western Australia.
- The Proposed Action will potentially impact on a 9 km portion of the Blind Cave Eel habitat from groundwater drawdown and minor surface clearing for road access. However, the functioning of the creekline alluvial aquifer systems, which are understood to form the core habitat for the Blind Cave Eel, will be retained and seasonal rainfall will ensure that the aquifer is periodically recharged to retain habitat connectivity.

7 Environmental record of the person proposing to take the action

		Yes	No
7.1	**Does the party taking the action have a satisfactory record of responsible environmental management?**	✓	
	Rio Tinto's iron ore business has over 50 years of experience in mining iron ore successfully and responsibly in the Pilbara region of Western Australia. With a network of 15 mines (including joint ventures), four port facilities, a 1,700 km rail network and related infrastructure, the group produces more than 300 million tonnes of iron ore annually. Rio Tinto has developed and refined environmental management policies, systems and procedures over decades of operational mining experience in the Pilbara region. These are successfully applied at the group's numerous existing Pilbara iron ore mine sites. The key components of Rio Tinto's environmental management approach that are applicable to the Proposed Action include: • Rio Tinto's Iron Ore Health, Safety, Environment, Communities and Quality Policy (HSECQ Policy). The HSECQ Policy is the guiding document for environmental management and provides context and direction for continuous improvement. • Rio Tinto's Environmental Management System (EMS) - The EMS is a continuous improvement model that covers key elements including systematic assessment of environmental risk and legal requirements and the development of objectives and targets for improvement, as well as systems for training, operational control, communication, emergency response, corrective actions, audits and review. • a Construction Environmental Management Plan (CEMP) will be prepared to address environmental factors potentially subject to impacts arising from construction activities. For each factor, the CEMP will identify potential impacts, management controls, monitoring, reporting and contingency actions. This will include clear identification of roles and responsibilities associated with the implementation of the CEMP. • an Environmental Management Plan (EMP) will be prepared and implemented for the operational phase of the project. The EMP will be interfaced with the EMS, and address all relevant environmental aspects of the project. No proceedings have been taken against the Proponent, or known to be in the process of being taken against the Proponent, under the EPBC Act.		
7.2	**Provide details of any proceedings under a Commonwealth, State or Territory law for the protection of the environment or the conservation and sustainable use of natural resources against:** **a) the person proposing to take the action, or** b) **if a permit has been applied for in relation to the action - the person making the application.**		✓
7.3	**If the person taking the action is a corporation, please provide details of the corporation's environmental policy and planning framework and if and how the framework applies to the action.**	✓	
	The Rio Tinto Iron Ore HSECQ Policy is the guiding document for environmental management and provides context and direction for continuous improvement. Rio Tinto's iron ore mines in the Pilbara region operate under an EMS which is a continuous improvement model covering systematic assessment of environmental risk and legal requirements and the development of objectives and targets for improvement; as well as systems for training, operational control, communication, emergency response, corrective actions, audits and review. The Proposed Action will be undertaken in accordance with both the HSECQ Policy and the EMS.		

7.4	**Has the party taking the action previously referred an action under the EPBC Act, or been responsible for undertaking an action referred under the EPBC Act?** Yes, Robe River Mining Co. Pty. Limited has previously referred three other iron ore mining projects in the Pilbara under the EPBC Act: • Mesa A/Warramboo Iron Ore Project (2006/2698) • Bungaroo Iron Ore Trial Mining Operation (2006/2771) • Extension of Mesa A Warramboo Iron Ore Project (2016/7843)	✓

8.2 Reliability and date of information

All information sources discussed in Section 3 are included in the reference list. The key survey reports for the Development Envelope (Astron 2016a, Astron 2016b, Bat Call WA 2017a) are included as Attachments. These surveys were undertaken by suitably qualified ecologists with extensive experience in surveys of this type in the Pilbara region. Each survey report includes a discussion of survey limitations and uncertainties. The Proponent considers that the information presented has a high level of reliability and that limitations associated with the information have been explicitly appraised in the survey report.

REFERRAL CHECKLIST

HAVE YOU:	
✓	Completed all required sections of the referral form?
✓	Included accurate coordinates (to allow the location of the proposed action to be mapped)?
✓	Provided a map showing the location and approximate boundaries of the project area for the proposed action?
✓	Provided a map/plan showing the location of the action in relation to any matters of NES?
✓	Provided a digital file (preferably ArcGIS shapefile, refer to guidelines at Attachment A) delineating the boundaries of the referral area?
❑	Provided complete contact details and signed the form?
❑	Provided copies of any documents referenced in the referral form?
❑	Ensured that all attachments are less than three megabytes (3mb)?
❑	Sent the referral to the Department (electronic and hard copy preferred)

WESTERN AUSTRALIA

MINISTER FOR THE ENVIRONMENT

STATEMENT THAT A PROPOSAL MAY BE IMPLEMENTED (PURSUANT TO THE PROVISIONS OF THE ENVIRONMENTAL PROTECTION ACT 1986)

MESA J IRON ORE DEVELOPMENT, PANNAWONICA (590)

ROBE RIVER IRON ASSOCIATES

This proposal may be implemented subject to the following conditions:

1 Proponent Commitments

In implementing the proposal, the proponent shall fulfil the commitments (which are not inconsistent with the conditions or procedures contained in this statement) made in the proponent's Consultative Environmental Review (a copy of the commitments is attached).

2 Implementation

Subject to these conditions, the manner of detailed implementation of the proposal shall conform in substance with that set out in any designs, specifications, plans or other technical material submitted by the proponent to the Environmental Protection Authority with the proposal. Where, in the course of that detailed implementation, the proponent seeks to change those designs, specifications, plans or other technical material in any way that the Minister for the Environment determines on the advice of the Environmental Protection Authority, is not substantial, those changes may be effected.

3 Environmentally Significant Areas

The Robe River - Jimmawurrada Creek environment, its vegetation, water levels and water quality, and particularly the permanent pools of the Robe River, are to be protected from unacceptable direct and indirect impacts by this project during the life of the project, recognising the requirements of mining and ore transport. This includes but is not necessarily limited to the following requirements:

1. Mining and other activities associated with the project shall be excluded from those areas of the Mesa J escarpment along the Robe River as delineated on the sketch plan of September 1991 prepared by the proponent and attached to this Statement; and

2. The alignment of the rail route from Mesa K to Mesa J shall utilise the Jimmawurrada Creek escarpment and not the creek bed, and accordingly shall be rail alignment option 2 as identified by the proponent in Addendum "A" to the Consultative Environmental Review.

4 Drainage Management

The Robe River - Jimmawurrada Creek system needs to be protected from pollution and unacceptable sedimentation, recognising the requirements of mining and ore transport.

Published on

15 JAN 1992

18th FLOOR, ALLENDALE SQUARE, 77 ST GEORGE'S TERRACE, PERTH, W.A. 6000 TELEPHONE 325 9422 FAX. 325 5621

4-1 Prior to construction at the site, the proponent shall prepare a Drainage Management Programme, to protect the Robe River - Jimmawurrada Creek system from the deleterious impacts of sedimentation and pollution from the project, to the satisfaction of the Minister for the Environment on advice of the Environmental Protection Authority, the Department of Conservation and Land Management and the Water Authority of Western Australia. The plan is to include but is not necessarily limited to:

1. a monitoring programme to detect impacts;
2. procedures for protecting the ecology of the system;
3. procedures for reporting on the programme; and
4. a commitment to ameliorate environmental impacts to the satisfaction of the Environmental Protection Authority if impacts are detected which are deemed unacceptable by the Environmental Protection Authority.

4-2 Subsequent to condition 4-1, the proponent shall implement the approved Drainage Management Programme to the satisfaction of the Environmental Protection Authority on advice of the Water Authority of Western Australia and the Department of Conservation and Land Management.

5 Dewatering Management

The permanent pools and vegetation of the Robe River - Jimmawurrada Creek system are to be protected from unacceptable environmental impacts, recognising the requirements of mining and ore transport.

5-1 Prior to the commencement of dewatering, the proponent shall prepare a Dewatering Management Programme, to protect the Robe River - Jimmawurrada Creek system, to the satisfaction of the Environmental Protection Authority on advice of the Department of Conservation and Land Management and the Water Authority of Western Australia. The plan is to include but is not necessarily limited to:

1. a monitoring programme to detect impacts;
2. procedures for protecting the ecology and water quality of the permanent pools and associated vegetation;
3. procedures for reporting on the programme; and
4. a commitment to ameliorate environmental impacts to the satisfaction of the Environmental Protection Authority if impacts are detected which are deemed unacceptable by the Environmental Protection Authority.

5-2 Subsequent to condition 5-1, the proponent shall implement the approved Environmental Management Programme to the satisfaction of the Environmental Protection Authority on advice of the Water Authority of Western Australia and the Department of Conservation and Land Management.

6 Rehabilitation

Rehabilitation is an integral part of the project and requires management throughout the life of the project.

6-1 Within 12 months of the date of this statement, the proponent shall prepare a Rehabilitation Management Programme to the satisfaction of the Environmental Protection Authority on advice of the Department of Mines and the Department of Conservation and Land Management. The programme shall include but not necessarily be limited to:

1. proposals for rehabilitation of the project area; and
2. a monitoring programme to determine success of the rehabilitation.

6-2 The initial programme shall be submitted to the Environmental Protection Authority, with subsequent programmes for the project to be updated annually in conjunction with reporting requirements under the Iron Ore (Robe River) Agreement Act.

6-3 At least twelve months prior to decommissioning, the proponent shall prepare a plan for decommissioning and rehabilitating the site, to the satisfaction of the Environmental Protection Authority on advice of the Department of Mines and the Department of Conservation and Land Management.

6-4 Subsequent to conditions 6-1 and 6-3, the proponent shall implement the approved programmes for rehabilitating and decommissioning the site, to the satisfaction of the Environmental Protection Authority on advice of the Department of Mines and the Department of Conservation and Land Management.

7 Environmental Management Programme

A comprehensive management programme for the project should be prepared to integrate the various components referred to in conditions 4, 5 and 6 above. This will allow reporting for the various aspects of the project to be done in one document.

7-1 Prior to construction, the proponent shall prepare an interim report outlining the key components of a comprehensive environmental management programme to the satisfaction of the Minister for the Environment on advice of the Environmental Protection Authority. The programme shall include but not necessarily be limited to:

1. drainage;
2. rehabilitation; and
3. dewatering.

7-2 Subsequent to condition 7-1 and prior to the commencement of mining, the proponent shall prepare a comprehensive environmental management programme to the satisfaction of the Minister for the Environment on advice of the Environmental Protection Authority. Whilst initial reporting would be to the Environmental Protection Authority, future reporting could be done under the Iron Ore (Robe River) Agreement Act. The programme shall include but not necessarily be limited to:

1. the plan for drainage management required by condition 4-1;
2. the plan for rehabilitation required by condition 6-1; and
3. a status report on the plan for dewatering management as per condition 5-1.

8 Proponent

Prior to any transfer of ownership, control or management of the project being effected which would give rise to the need for the replacement of the proponent, the Minister for the Environment shall be advised of the name and details of the transferee and invited to nominate a replacement proponent.

If the Minister nominates a replacement proponent, a copy of this statement endorsed with an undertaking by the replacement proponent to carry out the project in accordance with the conditions and procedures set out in the statement shall be

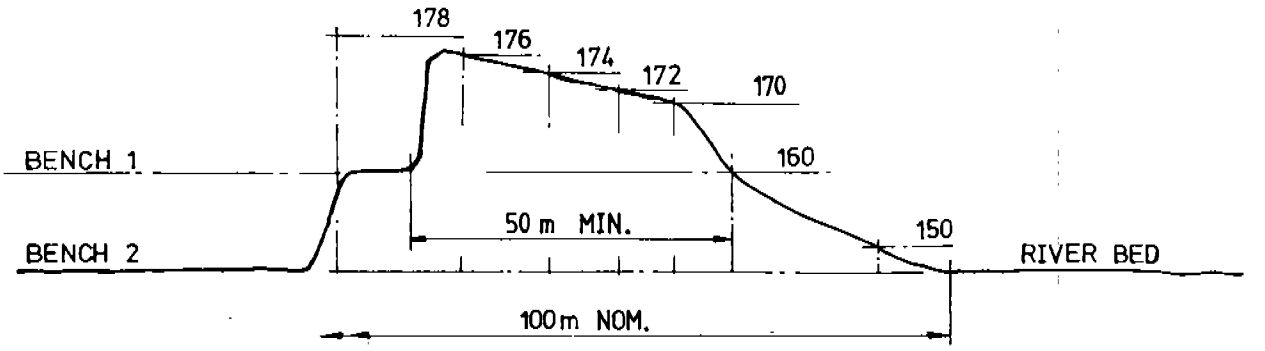
delivered to the Minister and thereupon the former proponent shall be released from the conditions of this statement to the extent of its interest transferred.

9 Time limit on approval

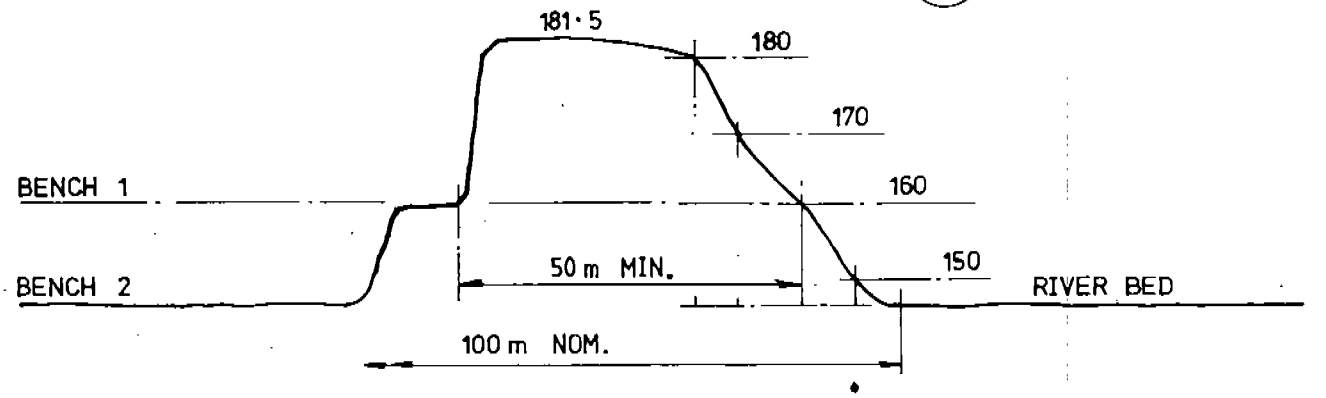
If the proponent has not substantially commenced the project within five years of the date of this statement, then the approval to implement the proposal as granted in this statement shall lapse and be void. The Minister for the Environment shall determine any question as to whether the project has been substantially commenced. Any application to extend the period of five years referred to in this condition shall be made before the expiration of that period, to the Minister for the Environment by way of a request for a change in the condition under Section 46 of the Environmental Protection Act. (On expiration of the five year period, further consideration of the proposal can only occur following a new referral to the Environmental Protection Authority).

Bob Pearce, MLA
MINISTER FOR THE ENVIRONMENT

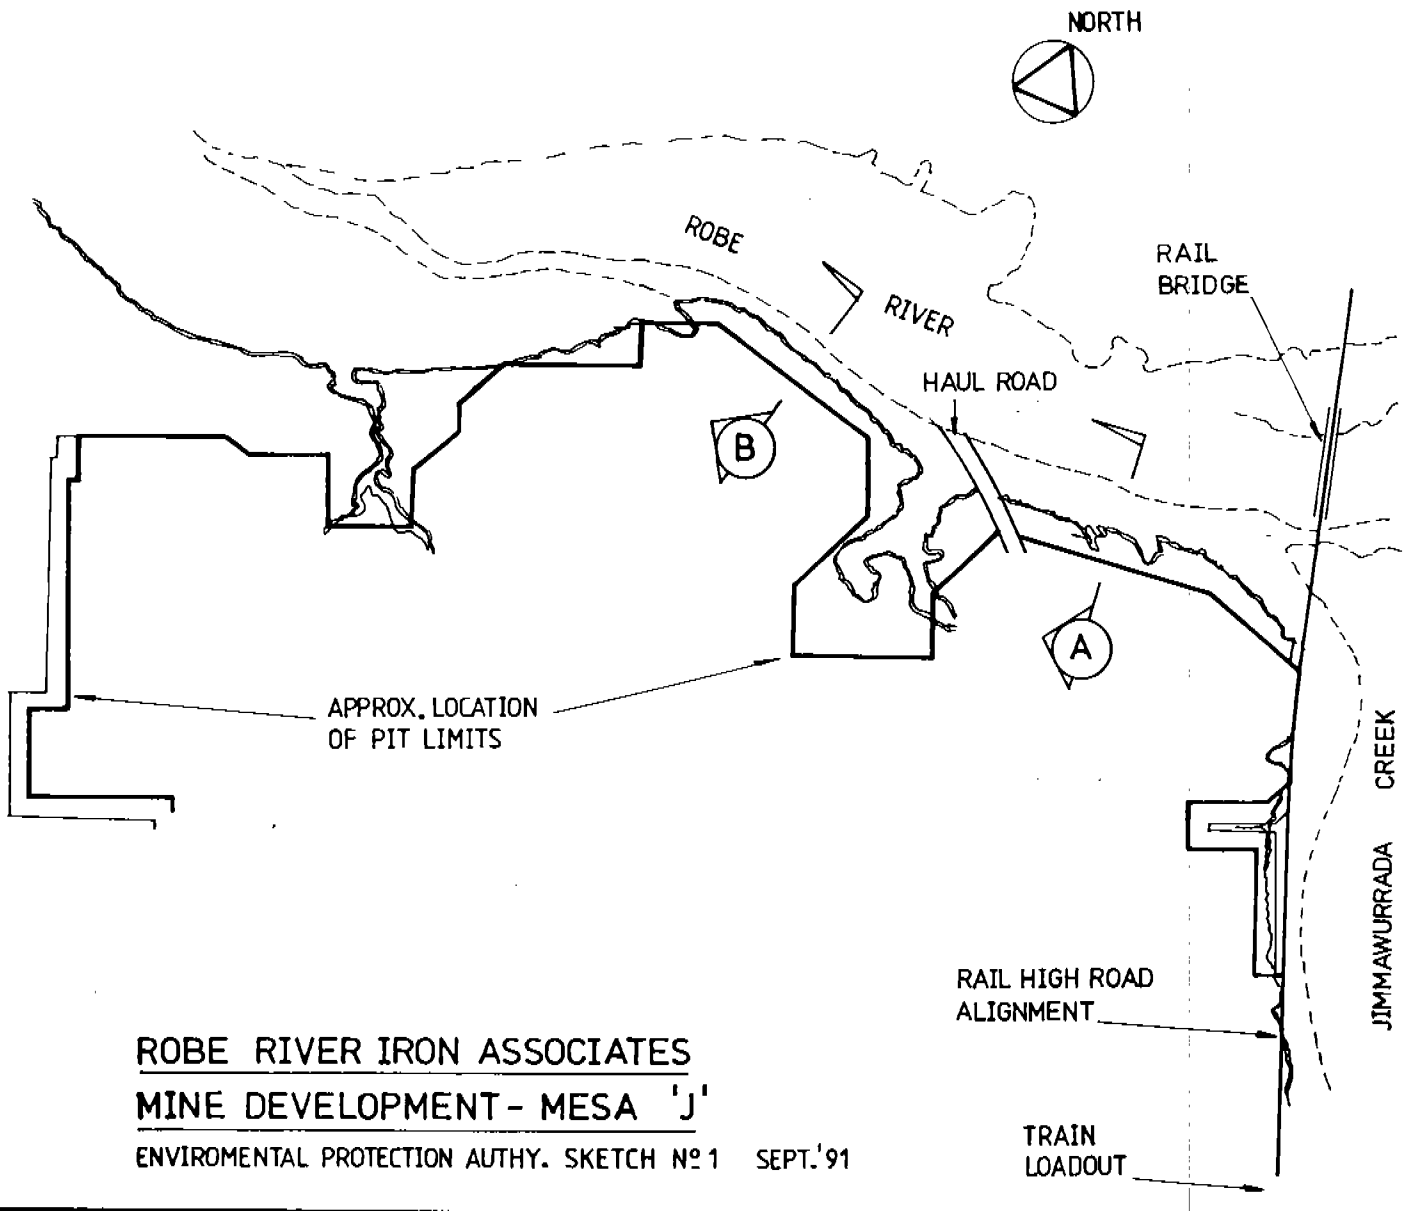
14 JAN 1997



NOMINAL LEVELS THROUGH SECTION (A)



NOMINAL LEVELS THROUGH SECTION (B)



ROBE RIVER IRON ASSOCIATES

MINE DEVELOPMENT - MESA 'J'

ENVIROMENTAL PROTECTION AUTHY. SKETCH Nº 1 SEPT.'91

PROPONENT'S COMMITMENTS (CONSOLIDATED)

MESA J IRON ORE DEVELOPMENT, PANNAWONICA (590)

The proponent has made the following environmental commitments:

1. The proponent will develop and implement environmental monitoring and management programmes for the mining operation and associated activities in the course of project implementation.

2. The proponent will assign environmental monitoring and management responsibilities to appropriate personnel for the duration of the project.

3. The proponent will develop and implement an environmental awareness programme for all construction and operational workforce at the implementation phase of the project, and will continue it during ensuing years.

4. The proponent will minimise as far as practicable, recognising the requirements of mining and ore transfer, direct and indirect alteration of the physical environment for the duration of the project.

5. The proponent will control and monitor and manage noise, occupational and ambient dust, erosion, stormwater discharge, and sewage disposal for the duration of the project.

6. The proponent will implement landform stabilization and revegetation programs in the project area for the duration.

7. The proponent will monitor and manage dewatering of the mining area, and discharge of excess water to adjacent watercourses.

8. The proponent will take appropriate steps to protect, monitor and manage hydrology and vegetation within the adjacent riverine environment.

9. The proponent will monitor and manage any scour or siltation in the Robe River and Jimmawurrada Creek adjacent to the project, and will implement remedial works if deemed necessary by expert opinion.

10. The proponent will minimise, as far as practical, disturbance to culturally significant sites for the duration of the project.

11. At the completion of the project, the proponent will prepare the site for abandonment in accordance with the requirements of the Mines Department and in recognition of the requirements of the Iron Ore (Robe River) Agreement Act, 1964, including, as applicable:

1. Re-establishment of pre-existing drainage patterns as far as can be practicably achieved;
2. The initiation of stabilisation and revegetation activities to stabilise structures and communities; and
3. The mining plan will be modified to incorporate the return of as much waste rock to the mined out pit as can be practically achieved during the life of the project.

Attachment to Statement 208

Change to description of Proposal

Proposal: Mesa J Iron Ore Development, Pannawonica

Proponent: Pilbara Iron (on behalf of Robe River Mining Co Pty Ltd)

Change: Installation of Fibre Optic Cable for railway communications system

Features of currently approved Proposal:

Element	Quantities/Description
Railway communications system	Single standard gauge railway line with a voice and data radio communications system.
Vegetation disturbance from railway communications construction	Unspecified in original approval.

Features of approved change to Proposal:

Element	Quantities/Description
Railway communications system	Single standard gauge railway line with a voice and data radio communications system with a Fibre Optic Cable from the 5 kilometre peg near Cape Lambert to the 71 kilometre peg near Western Creek.
Vegetation disturbance from railway communications construction	Unspecified plus 11 hectares permanent and 48 hectares temporary.

Approved: 6 March, 2007

Attachment 2 to Statement 208

Change to Proposal

Proposal: Mesa J Iron Ore Development, Pannawonica

Proponent: Robe River Iron Associates

Change: Installation of Fibre Optic Cable for railway communications system from the Cape Lambert administration offices to the 5 kilometre peg and from the 71 kilometre peg to the Mesa J mine operations at Pannawonica (known as "the Deepdale Fibre Optic Cable").

Features of previously approved Proposal:

Element	Quantities/Description
Railway communications system	Single standard gauge railway line with a voice and data radio communications system.
Vegetation disturbance from railway communications construction	Unspecified in original approval.

Features of changed Proposal:

Element	Quantities/Description
Railway communications system	Single standard gauge railway line with a voice and data radio communications system with a Fibre Optic Cable from the Cape Lambert administration offices to the 5 kilometre peg, and from the 71 kilometre peg to the Mesa J mine operations at Pannawonica (a total of approximately 130 kilometres).
Vegetation disturbance from railway communications construction	Unspecified plus 0.3 hectares permanent disturbance for construction of three 'communication shelters', and 68 hectares temporary disturbance.

Approved under delegation from the Minister for the Environment:

EPA Chairman

Summary

This Mesa H and J Environmental Management Plan (Mesa J Hub EMP) is submitted by Rio Tinto on behalf of Robe River Mining Co. Pty. Limited (the Proponent) in accordance with Ministerial Statement xxxx (MS xxxx).

Summary Table 1 below presents the environmental criteria to measure achievement of the environmental outcomes that must be met through implementation of this EMP.

Summary Table 1: Environmental criteria to measure achievement of environmental outcomes and objectives

Proposal title		Mesa H (Revision to Mesa J Iron Ore Development)
Proponent		Robe River Mining Co. Pty. Ltd.
Ministerial Statement		MS xxxx
Purpose of this EMP		This EMP fulfils the requirements of the Mesa H (Revision to Mesa J Iron Ore Development) Environmental Scoping Document and Conditions x – x of MS xxxx.
Mesa J and Mesa H **Inland Waters; Vegetation; and Aquatic Fauna** - abstraction of groundwater; surface water discharge; riparian vegetation and groundwater dependent ecosystems of the Robe River and Jimmawurrada Creek. **EPA Objective:** *To protect flora and vegetation so that biological diversity and ecological integrity are maintained* *To maintain the hydrological regimes and quality of groundwater and surface water so that environmental values are protected.*		
Outcome Based Provisions	**Condition environmental outcome**	The Proponent shall ensure there is no irreversible impact to the semi-permanent and permanent pools of the Robe River, aquatic fauna of the Robe River pools, and health of riparian vegetation communities of the Robe River and Jimmawurrada Creek as a result of groundwater abstraction and discharge for the Revised Proposal (Figure 1-3). The Proponent shall ensure that groundwater abstraction and surplus dewater discharge does not cause long term impacts to the Aboriginal heritage values linked to the physical and/or biological surroundings of the Robe River.

	Trigger criteria	1. The mean vegetation index for the riparian upper canopy (*E. victrix, E. camaldulensis* and *M. argentea*) of Zones 1 & 2 of Jimmawurrada Creek and the Robe River declines by ≥ 2 standard deviations from baseline. 2. A statistically significant decline from baseline ($p<0.05$) in the number and/or cover of native perennial species of Zones 1 & 2 of Jimmawurrada Creek and the Robe River. 3. Detection of new introduced species at a potential impact site, previously not detected within the Development Envelope. 4. Decline of >0.5m between paired Alluvial Aquifer bores in the Robe River near targeted pools. 5. Yeera Bluff (Gnieroora) Pool drops below 2m depth. 6. Water quality in pools exceeds rolling quarterly median measured against the operational guideline SSTV equivalent of 95%ile value of baseline or the ANZECC/ARMCANZ (2000) default TV for toxicants for protection of 95% of species, whichever is higher (except for pH).
	Threshold criteria	1. The mean vegetation index for the riparian upper canopy (*E. victrix, E. camaldulensis* and *M. argentea*) of Zones 1 & 2 of Jimmawurrada Creek and the Robe River declines by ≥ 2 standard deviations from baseline over two consecutive monitoring events. 2. A statistically significant decline from baseline ($p<0.05$) in the number and/or cover of native perennial species over two consecutive monitoring events of Zones 1 & 2 of Jimmawurrada Creek and the Robe River. 3. Detection of new introduced species rated high or very high management priority (by the Department of Biodiversity, Conservation and Attractions) at a potential impact site, previously not detected within the Development Envelope and a significant increase in cover or abundance over successive monitoring events. 4. Decline of ≥1 m between paired Alluvial Aquifer bores in the Robe River near targeted pools. 5. Yeera Bluff (Gnieroora) Pool drops below 1m depth. 6. Three (3) or less species of fish recorded during a sampling event.
Mesa H **Terrestrial fauna – Ghost Bat (*Macroderma gigas*)** **EPA Objective:** *To protect terrestrial fauna so that biological diversity and ecological integrity are maintained.*		
Outcome Based Provisions	**Condition environmental outcome**	The Proponent shall ensure there is no irreversible impact, as a result of the Mesa H Project, to Breakaways and Gullies habitat retained in the escarpments of the Mesa H Mining Exclusion Zone (MEZ), other than exiting and authorised disturbance.
	Trigger criteria	1. Vibration levels exceed 50mm/s peak particle velocity at the potential diurnal/maternal Ghost Bat roost caves. 2. Disturbance, other than approved clearing, within 50m of the recorded back of the potential diurnal/maternal Ghost Bat roost caves.
	Threshold criteria	1. Significant damage to diurnal/maternal Ghost Bat roost caves as shown in Figure 1-4. 2. Disturbance, other than approved than approved clearing, within 40m of the recorded back of the potential diurnal/maternal Ghost Bat roost caves.

Management Based Provisions	**Condition environmental objective**	The Proponent shall improve knowledge of the Ghost Bat population and utilisation of high value habitat in the Robe Valley in order to assist in maintaining biological diversity and ecological integrity.
	Management targets	1. Estimate the local population of Ghost Bats in the central part of the Robe Valley. 2. Indicate how Ghost Bats use caves within the central part of the Robe Valley (e.g. diurnal versus maternal), including the degree of utilisation of caves by pregnant females.
Mesa H **Terrestrial fauna – Northern Quoll (*Dasyurus hallucatus*)** **EPA Objective:** *To protect terrestrial fauna so that biological diversity and ecological integrity are maintained.*		
Outcome based Provisions	**Condition environmental outcome**	The Proponent shall ensure there is no irreversible impact, as a result of the Mesa H Project, to Breakaways and Gullies habitat retained in the escarpments of the Mesa H MEZ (Figure 1-4) other than existing and authorised disturbance.
	Trigger criteria	1. Disturbance of ≥ 5% of potential Northern Quoll denning habitat on the retained escarpment (MEZ) of Mesa H.
	Threshold criteria	1. Disturbance of > 10% of potential denning Northern Quoll habitat on the retained escarpment (MEZ) of Mesa H.
Mesa H **Subterranean Fauna – Troglofauna** **EPA Objective:** *To protect subterranean fauna so that biological diversity and ecological integrity are maintained.*		
Outcome Based Provisions	**Condition environmental outcome**	The Proponent shall ensure there is no irreversible impact, as a result of the Mesa H Project, to the troglofauna habitat retained within the Mesa H MEZ (Figure 1-5).
	Trigger criteria	1. Operational error **during mining** resulting in removal of greater than 0.01% by volume annually of the MEZ at Mesa H.
	Threshold criteria	1. Net loss of the MEZ at Mesa H, at the **completion of mining**.
Management Based Provisions	**Condition environmental objective**	The Proponent shall protect the biological diversity and ecological integrity of the troglofauna assemblages of Mesa H by minimising impacts as far as practicable
	Management targets	1. Total clearing of native vegetation across the surface of the Mesa H MEZ is less than 30% of the MEZ surface area. 2. Troglofauna specimen capture rate is not below the baseline minimum for three (3) consecutive sampling events at Mesa H.
Mesa H and Mesa J **Subterranean Fauna – Stygofauna** **EPA Objective:** *To protect subterranean fauna so that biological diversity and ecological integrity are maintained.*		

Outcome Based Provisions	**Condition environmental outcome**	The Proponent shall ensure there is no irreversible impact, as a result of the Revised Proposal's water management activities, to stygofauna habitat within the CID aquifers and stygofauna / Blind Cave Eel habitat within the alluvial aquifer habitats of Jimmawurrada Creek and the Robe River shown in Figure 1-6.
	Trigger criteria	1. Groundwater levels drop three (3) m below predicted water table heights in the Jimmawurrada Creek alluvial aquifer. 2. Diversity of stygofauna Orders collected during annual survey events reduced to three (3) or less.
	Threshold criteria	1. Alluvial aquifer bores in the margins of Jimmawurrada are dry for two (2) consecutive years. 2. Absence of Blind Cave Eel recorded for two (2) consecutive annual sampling events. 3. Absence of stygofauna specimens for two (2) consecutive annual sampling events.
Management Based Provisions	**Condition environmental objective**	The Proponent shall protect the biological diversity and ecological integrity of the stygofauna assemblages within the CID and Alluvial aquifer habitats shown in Figure 1-6 by minimising impacts as far as practicable.
	Management target	5. Understand the distribution and ecology of key stygofauna taxa within the Robe Valley area.

Corporate endorsement

I hereby certify that to the best of my knowledge, the provisions within this Mesa H and J Environmental Management Plan are true and correct and address the legal requirements of MS xxxx.

1. CONTEXT, SCOPE AND RATIONALE

1.1 Mesa H and J Project (Mesa J Hub)

Robe River Mining Co. Pty. Limited (the Proponent) manages and operates the Robe Valley mining operations, which includes iron ore mines at Mesa J and H as approved by MS XXXX under Part IV of the *Environmental Protection Act 1986* (EP Act). Mesa H is an extension of the existing Mesa J operation and for the purposes of this Environmental Management Plan (EMP) both are referred to as the Mesa J Hub.

The Mesa J Hub is located approximately 16 km south west of Pannawonica in the Pilbara region of Western Australia (Figure 1-1) and consists of the following:

- Mine Pits:
  - Mesa J – open cut above and below water table pit; and
  - Mesa H - new open cut above and below water table pits.
- Ore processing supported by existing processing facilities at Mesa J, but may require other processing facilities, including, but not limited to waste fines storage facilities.
- Mineral waste management including backfilling, ex-pit waste dumps, low grade ore dumps, topsoil and sub-soil stockpiles.
- Infrastructure including but not limited to the following:
  - Dewatering and surplus water management infrastructure such as bores, pipelines, and discharge outlets, for use in processing, on-site use and controlled discharge to the Robe River and tributaries.
  - Surface water management infrastructure, including surface water diversion drains, levees and culverts.
  - Linear infrastructure, including heavy vehicle and light vehicle access roads, upgrades to existing vehicle access roads, pipelines and power (including sub-stations) and communications distribution networks.
  - Support facilities, including the workshops, power supply infrastructure, hydrocarbon storage, laydown areas, offices and waste water treatment plants.
  - Water supply utilising groundwater abstracted for dewatering, surface water that reports to pits, an expansion to the existing Mesa J borefield (Southern Cutback Borefield).

The Mesa J Hub Development Envelope and the conceptual layout for the Mesa H Project is shown in Figure 1-2.

This EMP will supersede the existing Mesa J Operation Environmental Management Plan (December 2012, RTIO-HSE-0162720).

This EMP has been developed in accordance with the EPA's *Instructions on how to prepare Environmental Protection Act 1986 Part IV Environmental Management Plans.*

1.2 Key Environmental Factors

Management of the following key aspects of the Mesa J Hub are incorporated in this EMP:

- **Inland Waters; Flora and Vegetation; and Aquatic Fauna** - abstraction of groundwater; surface water discharge; riparian vegetation and groundwater dependent ecosystems of the Robe River and Jimmawurrada Creek.
- **Terrestrial fauna** – conservation significant fauna species (Ghost Bat and Northern Quoll).
- **Subterranean fauna** – troglofauna and stygofauna.

Inland Waters

Pools and Aquatic fauna

The Robe River is predominantly an ephemeral river which carries a significant base-flow in its alluvial bed, which maintains permanent and semi-permanent pools, a number of which are contained within the Development Envelope. These pools are maintained by groundwater in the absence of surface water inputs, with a range in seasonal groundwater variability of up to 3m, as recorded in alluvial bores within the Study Area. These pools along the Robe River support “River Pool Ecosystem” type GDEs. These ecosystems are an important component of the river ecosystem, supporting a diverse range of aquatic fauna and specialised flora, and rely on consistent surface expressions of groundwater. The fringing vegetation surrounding the pools generally support a high diversity of flora species and the pools themselves were found to have elevated to high macrophyte (including sedges) and ephemeral taxa diversity

Groundwater abstraction for pit dewatering will result in localised groundwater drawdown in CID aquifers that may have some connectivity to the Robe River alluvial aquifer. Modelling indicates the potential for a reduction in water levels in the Robe River alluvial aquifer and the Robe River semi-permanent and permanent pools may be up to 1m. This is not anticipated to change the permanent or semi-permanent nature of any of the pools, but shallow pools (<1m) have the potential to dry out as a result.

Riparian Vegetation

Riparian ecosystems occur along the Robe River and along and Jimmawurrada Creek, supporting woodlands comprising silver cadjeput (*Melaleuca argentea*) and eucalypt species (*Eucalyptus camaldulensis, E. victrix*).

The riparian vegetation of Jimmawurrada Creek predominantly comprises facultative phreatophytic species (i.e. species that utilise groundwater for a portion of their water requirements, but can also satisfy their water requirements through stored soil water reserves). Riparian vegetation of the Robe River differs from Jimmawurrada Creek due to the dominance of obligate phreatophytic species, which are considered groundwater dependent.

The Mesa J Hub operations require groundwater abstraction to facilitate mining of the CID ore located below the water table, which has the potential to lower groundwater levels in the adjacent sections of the Robe River. Additional groundwater abstraction for water supply (predominantly for wet ore processing) is sourced from the Southern Cutback Borefield. The additional abstraction will result in further lowering of the groundwater table around the borefield. Combined with the cumulative effects of the Coastal water Supply Project and mine pit dewatering, the drawdown cone of depression is modelled to extend below Jimmawurrada Creek and further lower the water table between 1 – 9 m below a 12 km section of Jimmawurrada Creek.

This may reduce the availability of water to GDV occurring within the Development Envelope and adjacent sections of Jimmawurrada Creek immediately upstream of the Development Envelope, potentially resulting in health decline of these riparian communities and in some cases death of obligate phreatophytes.

All abstracted water is planned to be used on site for operational requirements however during wet season or significant rainfall events when storage capacity is exceeded, surplus water will be periodically discharged. Discharge of surplus water will be via a number of existing Mesa J discharge outlets into Jimmawurrada Creek and / or West Creek, and may intermittently result in a surface water expression extending up to 8 km from the discharge outlet(s) depending on seasonal water availability and processing plant water demand. Given the intermittent nature of discharge and discharge continuing within the existing Mesa J operational discharge footprint, no additional significant impact to riparian communities are expected.

Discharge directly into the Robe River is not proposed unless required as a mitigation strategy for maintaining the pools.

Terrestrial fauna

The most important habitat types for the Ghost Bat and Northern Quoll within the Development Envelope includes Gorge and Breakaway habitat for their cave forming characteristics providing potential shelter and foraging habitat and Riverine and Drainage Line habitats for foraging and dispersal.

Potential impacts of the Project on the Ghost Bat and the Northern Quoll are loss or fragmentation of habitat, including breeding, foraging and dispersal habitat, due to clearing; indirect disturbance to critical habitat (potential diurnal/maternal Ghost Bat roosts) via blast vibrations; and indirect impacts to foraging habitat in the Major River/Creek habitat due to groundwater drawdown and surplus water discharge.

Subterranean Fauna – troglofauna and stygofauna

The target ore body in the Mine Development Envelope comprises Robe Pisolite which is considered to be high prospectivity habitat for troglofauna and stygofauna. Most species of obligate troglofauna are considered to be Short Range Endemic (SRE) with many species believed to be endemic to individual mesas in the Robe Valley. Stygofauna are also commonly considered to be SRE's however species' distribution is linked to aquifer extent. Mine pit excavation to be conducted as part of the Project will result in direct loss of troglofauna and stygofauna habitat and a loss of individuals, which in turn has the potential to result in changes to community assemblages. Groundwater abstraction for mine pit dewatering and water supply will also result in direct loss of stygofauna habitat, loss of individuals and potential changes in community assemblages. Clearing of vegetation may lead to a reduction in organic inputs into the subterranean environment which may reduce the quality of troglofauna and stygofauna habitat.

1.3 Condition Requirements

The proposed EMP condition and the associated proposed environmental objectives for the Mesa J Hub are detailed below in Table 1-1.

Table 1-1 Proponent proposed conditions for the Mesa J Hub

Condition		Section in EMP
5	**Condition Environmental Management Plans**	
5-1	The proponent shall prepare and submit a Condition Environmental Management Plan to the satisfaction of the CEO. This plan shall demonstrate that the environmental outcomes specified in in condition 6-1, condition 7-1, condition 8-1, and condition 9-1 will be met.	
5-2	The Condition Environmental Management Plan shall: (1) specify the environmental outcomes to be achieved, as specified in condition 5-1;	Table 2-1 to Table 2-5

	Condition	Section in EMP
	(2) specify trigger criteria that must provide an early warning that the threshold criteria may not be met; (3) specify threshold criteria to demonstrate compliance with the environmental outcomes specified in condition 5-1. Exceedance of the threshold criteria represents non-compliance with these conditions; (4) specify monitoring to determine if trigger criteria and threshold criteria are exceeded; (5) specify trigger level actions to be implemented in the event that trigger criteria have been exceeded; (6) specify threshold contingency actions to be implemented in the event that threshold criteria are exceeded; and (7) provide the format and timing for the reporting of monitoring results against trigger criteria and threshold criteria to demonstrate that condition 5-1 has been met over the reporting period in the Compliance Assessment Report required by condition 3-6. For management based provisions, the Condition Environmental Management Plan shall: (8) specify the environmental objectives to be achieved, as specified in condition 5-1; (9) specify management actions to meet the environmental objective; (10) specify management targets; (11) specify monitoring to determine if management targets are being met (12) provide the format and timing for the reporting of monitoring results against management targets to demonstrate that condition 5-1 has been met over the reporting period in the Compliance Assessment Report required by condition 3-6.	
5-3	After receiving notice in writing from the CEO that the Condition Environmental Management Plan satisfies the requirements of condition 5-2 the proponent shall: (1) implement the Condition Environmental Management Plan, or any subsequent approved versions; and (2) continue to implement the Condition Environmental Management Plan until the CEO has confirmed by notice in writing that the proponent has demonstrated the objectives specified in condition 5-1 have been met.	N/A

	Condition	Section in EMP
5-4	In the event that the monitoring indicates an exceedance of the threshold criteria specified in the Condition Environmental Management Plans, the proponent shall: (1) report the exceedance in writing to the CEO within seven (7) days of the exceedance being identified; (2) implement the threshold level contingency actions specified in the Condition Environmental Management Plans within 24 hours and continue implementation of those actions until the CEO has confirmed by notice in writing that it has been demonstrated that the threshold criteria are being met and the implementation of the threshold contingency actions is no longer required; (3) investigate to determine the cause of the threshold criteria being exceeded; (4) investigate to provide information for the CEO to determine potential environmental harm that occurred due to the threshold criteria being exceeded; and (5) provide a report to the CEO within twenty one (21) days of the exceedance being reported as required by condition 5-6(1). The report shall include: a. details of threshold contingency actions implemented; b. the effectiveness of the threshold contingency actions implemented, against the threshold criteria; c. the findings of the investigations required by condition 5-5(3) and 5-5(4); d. measures to prevent the threshold criteria being exceeded in the future; e. measures to prevent, control or abate the environmental harm which may have occurred; and f. justification of the threshold remaining, or being adjusted based on better understanding, demonstrating that outcomes would continue to be met.	Table 2-1 to Table 2-5
5-5	The proponent: (1) may review and revise the Condition Environmental Management Plan, or (2) shall review and revise the Condition Environmental Management Plan as and when directed by the CEO.	N/A
5-6	The proponent shall implement the latest revision of the Condition Environmental Management Plan, which the CEO has confirmed by notice in writing, satisfies the requirements of condition 5-1 and condition 5-2.	

	Condition	Section in EMP
6	**Mesa H and J Inland Waters** **Dewatering of groundwater and groundwater dependent ecosystems of the Robe River and Jimmawurrada Creek; surface discharge of surplus water and riparian vegetation of the Robe River and Jimmawurrada Creek.**	
6-1	The proponent shall manage the implementation of the Proposal to meet the following environmental outcomes: (1) No irreversible impact, as a result of the proponent's water abstraction, to the health of groundwater dependent vegetation within the Robe River. (2) No irreversible impact, as a result of the proponent's water abstraction, to the health of riparian vegetation communities within Jimmawurrada Creek. (3) No irreversible impact, as a result of the Proponent's discharge of surplus water, to the health of riparian vegetation communities of Jimmawurrada Creek and the Robe River. (4) No irreversible impact, as a result of the Proponent's drawdown and discharge, to the pool ecosystems of the Robe River.	Table 2-1
7	**Mesa H Terrestrial Fauna** **Conservation significant fauna species; Ghost Bat (*Macroderma gigas*) and Northern Quoll (*Dasyurus hallucatus*)**	
7-1	The proponent shall manage the implementation of the Proposal to meet the following environmental outcome: (1) No irreversible impact, as a result of the proponent's activities, to Breakaways and Gullies habitat retained in the escarpments of Mesa H.	Table 2-2 Table 2-3
7-2	The proponent shall manage the implementation of the Proposal to meet the following environmental objective: (1) The proponent shall improve knowledge of the Ghost Bat population and utilisation of high value habitat in the Robe Valley in order to assist in maintaining biological diversity and ecological integrity.	Table 2-3
8	**Mesa H Subterranean fauna – Troglofauna**	
8-1	The proponent shall manage the implementation of the Proposal to meet the following environmental outcome: (1) No irreversible impact, as a result of the proponent's activities, to the troglofauna habitat retained within the Mesa H MEZ.	Table 2-4
8-2	The proponent shall manage the implementation of the Proposal to meet the following environmental objective: (1) The Proponent shall protect the biological diversity and ecological integrity of the troglofauna assemblages of Mesa H by minimising impacts as far as practicable.	Table 2-4
9	**Mesa H and Mesa J Subterranean fauna – Stygofauna**	
9-1	The proponent shall manage the implementation of the Proposal to meet the following environmental outcome: (1) No irreversible impact, as a result of the proponent's water management activities to the stygofauna habitat within the CID aquifer and stygofauna and Blind Cave Eel habitat within the alluvial aquifer habitat of Jimmawurrada Creek and the Robe River.	Table 2-5
9-2	The proponent shall manage the implementation of the Proposal to meet the following environmental objective:	Table 2-5

Condition			Section in EMP
	(1)	The Proponent shall protect the biological diversity and ecological integrity of the stygofauna assemblages within the Robe River and Jimmawurrada Creek alluvial aquifer habitats by minimising impacts as far as practicable.	

1.4 Rationale and Approach

This EMP addresses environmental factors (and relevant environmental outcomes and objectives) which were determined by the Department of Water and Environmental Regulation – EPA Services (EPA Services) as being relevant to the management of groundwater abstraction, surface water discharge, conservation significant vegetation communities and fauna species associated with the Mesa J Hub.

This EMP identifies:

- The environmental criteria that the Proponent will use to monitor performance of the management measures to ensure environmental objectives are met.
- The management actions that will be implemented in response to monitoring results.

Results of baseline surveys, monitoring and a number of assumptions and uncertainties inform the management approach for meeting the environmental outcomes and objectives stated in conditions 6, 7, 8 and 9 of MS xxxx.

The identified trigger criteria, threshold criteria, management targets and response actions are aligned with the overall management approach.

Monitoring data is used to evaluate compliance with the trigger and threshold criteria to achieve the environmental outcomes and management targets are used to assess whether the management actions are effective in meeting the environmental objectives.

1.4.1 Survey and Study Findings

a) Inland Waters – Pools and Aquatic Fauna

Permanent and semi-permanent pools exist along the Robe River due to the significant subsurface flow in the coarse channel gravels of the Robe River alluvial aquifer. There is potentially a strong hydraulic correlation between the Robe River alluvium and the underlying aquifer, the direction of interaction changes seasonally in response to stream flow events and evapotranspiration. Streamflow events also recharge groundwater, causing the groundwater level to rise, creating large and continuous pools. After a period of no flow, the hydraulic gradient between the groundwater and the pools reverse and groundwater discharges into the pools. Ephemeral pools eventually become disconnected from intermittent pools and as surface water evaporates, these pools reduce in size or disappear.

Drought conditions and declining groundwater levels result in shallower pool depths and semi-permanent pools becoming disconnected from the groundwater. Permanent pools have long-term connectivity to the groundwater and are expected to be maintained by natural groundwater discharge during drought periods.

The history of isolation of river systems of the Pilbara results in a low biodiversity of freshwater fish being recorded from the Pilbara (12 species) (Allen *et al*. 2002 cited in Streamtec 2017). A total of ten species have been recorded in the Robe River during aquatic surveys since 1991 (Streamtec 2017).

The baseline aquatic survey in 2016 (WRM 2017) recorded a total of 3,515 fish in the Development Envelope including seven true freshwater taxa. There was no significant difference in abundance of fish upstream and downstream of the Jimmawurrada-Robe confluence; however, there was a significant difference in mean species richness between upstream and downstream, with significantly higher richness downstream of the Jimmawurrada-Robe confluence, adjacent to the Mesa J Hub.

b) Inland Waters - Riparian Vegetation

Robe River

The Robe River is an ephemeral river with significant base-flow in its alluvial aquifer, which maintains permanent and semi-permanent pools; a number of which are within the Development Envelope. These pools are maintained by groundwater in the absence of surface water inputs, with a range in seasonal groundwater levels of up to 3m, as recorded in alluvial bores. As groundwater levels drop during prolonged dry periods, the semi-permanent pools may dry out.

Key features of the vegetation associated with the Robe River in the Development Envelope (as summarised by Astron 2018) include:

- No Threatened or Priority Ecological Communities (TECs/PECs) and no Threatened flora; however does contain Priority flora (primarily *Rhynchosia bungarensis* P4).
- Permanent and semi-permanent pools - these pools generally support high species diversity. Vegetation surrounding these pools is typically dominated by dense *Melaleuca argentea* and *Eucalyptus camaldulensis* subsp. *refulgens* over sedge, grass and herbaceous species.
- Pools and main channels support Groundwater Dependant Ecosystems including groundwater dependant vegetation dominated by *M. argentea.*
- Vegetation condition varies from 'Very Poor' to 'Excellent' in the Robe River and its tributaries. Poorer condition is generally as a result of weed proliferation, grazing and trampling. **Cenchrus* species (spp.) (Buffel and Birdwood Grasses) are a common component of the vegetation in some areas.

Jimmawurrada Creek

Jimmawurrada Creek is an ephemeral system with negligible base-flow, and possesses stretches of riparian vegetation which has been modified by changes to drainage lines; drawdown associated with the Mesa J Project, the Southern Cutback Borefield and the Coastal Water Supply; and mine dewatering discharge through existing licensed outlets.

Key features of the vegetation associated with Jimmawurrada Creek in the Development Envelope and within the extent of the modelled groundwater drawdown include:

- No TECs or PECs and no Threatened flora.
- No permanent and semi-permanent pools.
- Vegetation is dominated by *Eucalyptus camaldulensis* subsp. *refulgens* and *E. victrix*
- Vegetation condition varies from 'Very Poor' to 'Excellent' with poorer condition generally as a result of weed proliferation, grazing and trampling. **Cenchrus* species (Buffel and Birdwood Grasses) are a common component of the vegetation in some areas.

Refined Riparian Mapping

Given the local and sub-regional significance of the riparian zone vegetation, a refined riparian mapping program was undertaken across both the Robe River and Jimmawurrada Creek (Rio Tinto 2017a, 2017b) in order to attribute an impact 'risk rating' to each vegetation association. This involved an interpretation of the degree of sensitivity (or vulnerability) of each community to hydrological change and the risk that "measurable" impact/change to a community could result from significant hydrological changes.

Within the Development Envelope, Astron (2016a) mapped two riparian communities which they identified as potential GDE's: MaEcCv (representing the obligate phreatophytic (OPV) or generally "high risk" type communities mapped by Rio Tinto (2017a); and EcEvAtrApyPlTw) (representing the

facultative phreatophytic (FPV) or generally “moderate risk” type communities mapped by Rio Tinto (2017a)).

Vegetation association MaEcCv was considered a GDE due to the dominant species being *Melaleuca argentea* (an obligate phreatophyte) and *E. camaldulensis var. refulgens* (a facultative phreatophyte). *M. argentea* and *E. camaldulensis* var. *refulgens*, and therefore the vegetation in which they predominate, is highly likely to be sensitive to changes in groundwater depth and availability. These two vegetation associations are typical of riparian vegetation that occurs along minor and major channels within the River Land System in the Pilbara.

The two riparian vegetation units identified by Astron (2016a, 2016b) as GDE’s equate to ten ‘refined’ units mapped by Rio Tinto (2017a, 2017b), only three of which are considered to contain obligate phreatophytes (Table 1-2). The differentiation by Rio Tinto (2017a, 2017b) is a result of differences in canopy structure, the dominance or co-dominance of *E. camaldulensis* versus *E. victrix*, and differences in mesic understorey composition observed through detailed field mapping (Rio Tinto 2017a, 2017b).

The three key vegetation associations identified by Rio Tinto (2017a, 2017b) as representing GDE communities and dominated by obligate phreatophytes comprise: C1AA (a&b); C1A; and C1B. The C1AA (a&b) and C1A communities possess relatively mature OPV, while the C1B community comprises relatively immature OPV. The mature community was generally uniform in its presence and spatial extent in the environment, indicating more consistent groundwater access, whereas the immature community is likely to be more transient in nature, have less consistent groundwater access and likely to have established in response to dewatering discharge. The C1AA communities have a canopy dominated by *Melaleuca argentea,* which generally form an open forest overstorey, whereas C1A and C1B communities had an overstory only co-dominated by *Melaleuca argentea (*and *Eucalyptus* spp.*)*.

Table 1-2: Significant riparian vegetation units in the Development Envelope

Astron (2016a, 2016b) vegetation association	Equivalent (or associated) Rio Tinto (2017a, 2017b) units*	Broad Rio Tinto (2017) GDE classification type	Rio Tinto (2017) Residual Significance
MaEcCv	**C1AA (a&b), C1A, C1B**	OPV-A, B and C (vegetation at least co-dominated by the obligate phreatophyte *Melaleuca argentea* of varying age structure)	High to Moderate (locally and sub-regionally significant)
EcEvAtrApyPITw	**C2AA**, C2AACr, C2A, C2B, C2A-B, C2B-B, C3A	FPV-A and FPV-B (vegetation at least co-dominated by the facultative phreatophyte *Eucalyptus camaldulensis*)	Moderate to Minor (locally restricted but common regionally to common locally and regionally)

*Bold and underlined units indicate significant vegetation

Of the Rio Tinto (2017a) refined riparian vegetation units, only the *Melaleuca argentea* dominated and co-dominated communities (C1AA(a&b), C1A, and C1B) are considered locally and sub-regionally significant as potential GDE’s (Rio Tinto 2017a, 2017b). Unit C2AA (*Eucalyptus camaldulensis* open forest) is considered to be locally and potentially sub-regionally significant and similar to Astron’s (2016a) EcEvAtrApyPITw community.

Unit C2A (*Eucalyptus camaldulensis* woodland-open forest) mapped on Jimmawurrada Creek is broadly similar to the significant C2AA community but the conservation significance was reduced based on it being restricted to creek landforms, possessing lower species diversity, having reduced condition due to grazing pressure and alteration of the community from discharge. The remaining units are typically found in mesic riparian environments and are widely represented in creek and river systems in the Pilbara (Rio Tinto 2017a).

Based on the refined riparian mapping and likely sensitivity of the riparian vegetation units to changes in groundwater levels, combined with predicted extent and depth of groundwater drawdown, a number of impact 'Zones' have been defined along Jimmawurrada Creek and the Robe River as provided in

Table 1-3 and shown in Figure 1-3.

Table 1-3: Riparian vegetation Zones in the Development Envelope and extent of modelled groundwater drawdown

Zone	Max water table depth - (bgl)		Magnitude of Drawdown	Mitigating factors	Presence/Absence of OPV or FPV in the Riparian Zone
Jimmawurrada Creek					
JIM 1	*<7		*1-4	Discharge and Robe River alluvial aquifer; large scale influence. Surface water flows; moderate to large scale influence (due to creek attenuation by range).	Some OPV present, although FPV broadly dominant. Potential baseline OPV restricted to low flow channels skirting the west bank within this zone. The remainder of OPV in this zone appears to have established post mining. Single riparian corridor present.
JIM 2	A	*7-11	*4-8	Discharge; large scale Influence. Robe River alluvial aquifer; moderate to large scale influence. Surface water flows; moderate to large scale influence (due to creek attenuation by the range).	Some pre and post-mining (augmented) OPV present, however creek broadly dominated by FPV. OPV generally restricted to a strip surrounding the low flow channel skirting the west boundary of the creek. Single riparian corridor present.
	B			Discharge; low to negligible influence. Surface water flows; moderate scale influence.	OPV absent. Creek dominated by FPV. Single riparian corridor present in the west, dual corridors (Channel splits to Bungaroo and Jimmawurrada Creeks) in the eastern end of polygon.
JIM 3	A	*11-14	*8-10	Discharge; minor to moderate scale influence. Surface water flows; moderate to large scale influence.	Some post-mining (augmented) OPV present, however creek broadly dominated by FPV. OPV generally restricted to a thin strip surrounding the low flow channel skirting the west boundary of the creek. Single riparian corridor present in the north, dual corridors in the southern 1/3 of polygon.
	B		*4-8	Discharge; low to negligible scale influence. Surface water flows; moderate scale influence.	No OPV present; area dominated by FPV. Dual riparian corridor present in two sections, with a central section where a single corridor is present.
Robe River					
RR-1A	Zone A*: Low flow and secondary	~1.5-3m	~<0.5m	Discharge; minor to moderate scale influence. Surface water flows and subsurface base-flow; large scale influence.	OPV represents the dominant riparian vegetation present. FPV is also common and relatively widespread.

Zone	Max water table depth - (bgl)		Magnitude of Drawdown	Mitigating factors	Presence/Absence of OPV or FPV in the Riparian Zone
	channel Zones.				
RR-1B	Zone B*: Outer/flanking, and generally more elevated cobbled bed zones – includes minor channels.	~3 - 5.5m	<0.5m	Discharge; minor scale influence. Surface water flows and subsurface base-flow; large to moderate scale influence.	FPV represents the dominant riparian vegetation present. OPV is also common throughout.
RR-2A	Zone A*: Low flow and secondary channel Zones.	2 - 3.5m	*<1m	Discharge; minor to moderate scale influence. Surface water flows and subsurface base-flow; large scale influence.	OPV represents the dominant riparian vegetation present. FPV is also common and relatively widespread.

Geospatial Information and Mapping

c) Terrestrial fauna – Ghost Bats

Roost sites used permanently by Ghost Bats are generally deep natural caves with a relatively stable temperature of 23-28^{o}C and humidity above 50%. Individuals require a range of cave sites and move between roosts seasonally or according to weather conditions. The most significant habitats in the Development Envelope for the species are the Breakaways and Gullies (including the mesa escarpments) and the Major River/Creek habitat (Figure 1-4); these areas represent potential roosting and foraging habitat. Habitat loss through impact or disturbance to roost sites, specifically caves that play a role in breeding activities (maternal roosts), and nearby areas is seen as a key risk to this species conservation status.

Previous assessments of caves in the Mesa H Survey Area and Development Envelope (Astron 2014; Bat Call 2017a) have collectively identified two diurnal roosts (with maternity roost potential) and ten nocturnal feeding roosts (two were part of the one system) (Astron 2017a) Figure 1-4.

An assessment of the conservation value of caves associated with Ghost Bats at Mesa H indicated that Ghost Bat presence at the mesa is intermittent, with the mesa being used for nocturnal foraging and occasional diurnal roosting (Bat Call 2017a). The Ghost Bats at Mesa H likely originate from Buckland Hills to the south, Yeera Bluff (Gnieroora) between Mesa's G and H or the Three Peak hills to the north-west (Bat Call 2017a).

d) Terrestrial fauna - Northern Quoll

In the Pilbara, the Northern Quoll favours rocky gorges, breakaways and hills, usually of high relief and often along drainage lines for denning purposes. Adjacent plains and vegetated areas provide habitat suitable for foraging and dispersal of young (Van Dyck and Strahan 2008), but are considered to be of less importance for the species' conservation (DSEWPaC 2011). The rocky facades of the mesa landforms are important sources of shelter, food and moisture for species of conservation significance.

The Northern Quoll was recorded in the Development Envelope, with the majority of records occurring in Breakaway habitat with some in Riverine and Gorge habitat types; however, the species is also likely to utilise Rocky Hills habitat (Astron 2017a). Historical surveys have also recorded the Northern Quoll from scat records within the Rocky Hills habitat type immediately south of the Development Envelope and within Riverine and Breakaway habitats within the Development Envelope (Astron 2015 and Biota 2011). All previous records of this species in the Development Area were from sites consistent with the preferred habitat for this species.

The most important habitat types for the Northern Quoll likely includes the Gorge and Breakaway habitat (Figure 1-4), which contain rocky environments of high relief that are particularly important for Northern Quolls as they provide potential denning sites for breeding and shelter and diverse microhabitats for foraging (Astron 2017a). The Riverine and Rocky Hills habitats, especially adjacent to Gorge and Breakaway habits provide microhabitats for (e.g. crevices and cracks) for foraging (Astron 2017a).

e) Subterranean fauna - Troglofauna

Troglofauna were first recorded at Mesa A in 2003 as by-catch of stygofauna sampling. Since 2003 numerous troglofauna surveys and assessments have been undertaken across the Robe Valley. The combined coverage of these surveys provides a considerable knowledge base of the troglofauna present in the Mesa H and J Development Envelope.

One of the key characteristics of geological units known to provide habitat for troglofauna relates to the physical features, particularly the presence of fractures and cavities sufficient in size to accommodate troglofauna. Throughout the Pilbara, a range of geological formations contain the necessary physical characteristics that have been shown to provide habitat for troglofauna. In the Development Envelope the Robe Pisolite is considered to be the geological unit that provides primary habitat for troglofauna as it contains the necessary cavities to accommodate troglofauna. The clay pockets and lenses within the Robe Pisolite may also contribute to the suitability of the habitat for troglofauna as the retention of water in, or on top of, certain clay types may assist in maintaining high humidity levels in the subterranean environment. Troglofauna habitat is shown in Figure 1-5.

Compilation of all troglofauna sampling to date has recorded 34 troglofauna species from the Development Envelope and all are considered potential SRE species.

Two Priority 1 PECs relevant to troglofauna are present in the Development Envelope:

- *Subterranean invertebrate communities of mesas in the Robe Valley region*; and
- *Subterranean invertebrate community of pisolitic hills in the Pilbara*

No troglofauna of conservation significance (i.e. those listed as Priority, Schedule or Vulnerable at State or Federal levels) were recorded in the Development Envelope.

f) Subterranean fauna - Stygofauna

Compilation of all stygofauna sampling to date has recorded:

- 46 stygofauna species have been recorded in and around the Development Envelope.
- 16 key species are recorded from within the Mesa J Hub potential drawdown impact area, including:
    - 9 widespread species;
    - 7 potential SRE species, including a number of listed threatened species:
        - *Nedsia hurlberti* – Schedule 3;
        - *Nedsia sculptilis* – Schedule 3; and
        - Blind Cave Eel, *Ophisternon candidum* – Vulnerable; Schedule 3;
- One Priority 1 PEC (*Stygofaunal Community of the Bungaroo Aquifer)* overlaps with the Development Envelope.

Stygofauna habitat and the modelled extent of groundwater drawdown is shown in Figure 1-6.

1.4.2 Key Assumptions and Uncertainties

The key limitations relating to the information used for this EMP include:

- Limited hydrogeological data on the Jimmawurrada Alluvial Aquifer and Robe River Alluvial Aquifer, to better inform the hydraulic connectivity between the CID and alluvial aquifers and hence possible impacts to pools and vegetation.
- Limited understanding of the response of riparian vegetation to cumulative stressors e.g. dewatering, water abstraction, climate variability.
- Inherent difficulty in interpolating local groundwater table elevation from limited groundwater data available in the Robe River and Jimmawurrada Creek to predict the groundwater dependence of riparian vegetation.
- Limited regional population studies for Ghost Bat and Northern Quoll, to provide an understanding of the long-term natural population variability and movements of these species.
- Limited data on the sensitivity of the Ghost Bat and Northern Quoll to noise and vibration.
- Inherent limitations in troglofauna and stygofauna sampling methodology that limit predictive ability of habitat modelling. Limitations include limited access to the subterranean environment (via drill holes only); modification of potential habitat through establishment of drill holes; trapping and scraping methodology may not be appropriate for some species depending on species preferences and mobility; sampling bias towards orebodies; difficulty in determining the specific geological strata that specimens originate from therefore limiting predictive ability of habitat modelling.
- Lack of taxonomic framework and specialist expertise to identify and determine conservation significance of many groups of subterranean fauna.
- Limited knowledge of troglofauna and stygofauna distribution patterns, ecological requirements and resilience.

The key assumptions relating to this EMP are:

- The hydrogeological modelling of groundwater abstraction from the CID aquifers provide accurate estimates of the extent and depth of groundwater drawdown, however may not capture the full range of climatic variables experienced in an arid environment (which may vary on a decadal-scale). The hydrogeological models will be updated as additional data become available hence revisions to the proposed management of pools, phreatophytic vegetation and stygofauna may be required.
- Facultative phreatophytic vegetation along Jimmawurrada Creek may be utilising groundwater to varying degrees despite the current depth to water table potentially being close to the limit of accessibility in some areas for facultative phreatophytic species, thus there is potential for impacts from abstraction of groundwater to the Jimmawurrada Creek Alluvial Aquifer.
- Baseline data collected for riparian vegetation, fish, the Ghost Bat, the Northern Quoll and subterranean fauna provide representative species inventories and reflect sampling over variable seasonal conditions, however may not necessarily capture the full range of climatic variables experienced in an arid environment (which may vary on a decadal-scale).
- Baseline surveys provide complete representative species inventories and reflect sampling over variable seasonal conditions.
- Tolerance of conservation significant fauna species to some level of noise, vibration and light emissions without any significant impact to their normal behaviours or survival.

- The effectiveness of blast management measures to prevent disturbance to the mesa façades. The Proponent has a strong record of maintaining landform stability, as demonstrated at Mesa A and J, with no record of mesa façade collapse or failure.

1.4.3 Management Approach

A risk-based approach has been taken through the Environmental Impact Assessment processes to identify the key environmental values that may be impacted by the Mesa J Hub and warrant additional management. Regional data, baseline survey data and, where available, ongoing monitoring data have been used to assess the potential impacts of the Mesa J Hub on environmental values.

The key environmental values that have been identified as warranting additional management are:

- riparian vegetation associated with the Robe River and Jimmawurrada Creek;
- semi-permanent and permanent pools and aquatic fauna;
- conservation significant fauna - Ghost Bat and Northern Quoll; and
- subterranean fauna - troglofauna and stygofauna.

This EMP adopts a combination of an outcome-based approach and a management-based approach.

- For parts of the environment that can be objectively measured and monitored an outcome-based approach is adopted with establishment of trigger and threshold criteria and associated contingency actions if the environmental criteria are not met. Trigger criteria are set at a conservative level to ensure management actions are implemented well in advance of the environmental outcome being compromised. Thus, trigger criteria are set at a level below the threshold criteria to signal the need to focus and investigate and where applicable, mitigate the impact.
- For parts of the environment that are not amenable to objective measurement, a management-based approach is adopted with a management objective that relates to the EPA's environmental objective for the relevant environmental factor, management actions to meet the environmental objective and management targets to assess the effectiveness of the management actions.

This EMP also describes the monitoring that will be undertaken to measure performance against the environmental outcomes and to assess the effectiveness of management actions in meeting management-based objectives. The monitoring to be undertaken as part of this EMP has been designed to build upon and improve on existing monitoring programs conducted as part of the Mesa J Project and build upon data from baseline surveys.

Key to the overall environmental management approach for the Mesa J Hub is avoidance of direct disturbance to key environmental values such as pools and riparian vegetation of the Robe River and Jimmawurrada Creek. Specific to the Mesa H Project is avoidance of direct disturbance to potential diurnal/maternal Ghost Bat roosts and denning habitat of the Northern Quoll. Where avoidance is not practicable, the management approach is to minimise disturbance to key environmental values, particularly habitats, such as troglofauna and stygofauna habitat and the mesa escarpments as detailed in this EMP.

1.4.4 Rationale for choice of provisions

Environmental criteria have been developed based on consideration of:

- Threatening processes and risks associated with each environmental factor;
- The current state of knowledge for each environmental value;
- The availability of suitable monitoring methods; and
- Relevance to the condition environmental outcomes sought for each environmental factor.

The specific trigger and threshold criteria and actions defined in Table 2-1 to Table 2-5 have been chosen as they provide a basis for detecting and avoiding or otherwise managing potential impacts, such that the condition environmental outcomes stated in conditions 6, 7, 8 and 9 of MS xxxx can be achieved.

Trigger criteria are set at a conservative level to ensure management actions are implemented well in advance of the environmental objective being compromised. Exceedance of a trigger criterion will, therefore, not be treated as a non-compliance. There is potential for the threshold criteria for vegetation to be exceeded due to natural variability; this must be accounted for in the management response. Exceedance of a threshold criterion will be treated as a potential non-compliance against the environmental objective if the exceedance is attributable to the Mesa J Hub.

The tables of EMP provisions (Table 2-6 to Table 2-10) contain environmental outcomes that include 'no irreversible impact'. For the purpose of this EMP, an irreversible impact is defined as, 'an impact resulting in a permanent loss of environmental value(s); or where intensive, and/or un-proven management intervention, potentially over a long timeframe, would be required to restore the environmental value(s)'.

The tables of EMP provisions (Table 2-6 to Table 2-10) include monitoring to measure performance against the environmental outcome and to determine whether trigger or threshold levels have been exceeded. Table 2-7, Table 2-8, Table 2-9 and Table 2-10 also include supporting monitoring that will be undertaken. Supporting monitoring is not directly required as a measure of performance but will be used to provide context, to assess the impact on the environmental value and to investigate possible causes should the trigger or threshold criteria be exceeded

The rationale for selection of provisions for each environmental value is discussed below.

a) Inland waters

Two environmental outcomes have been adopted for riparian vegetation, semi-permanent and permanent pools and aquatic fauna for different aspects of the Mesa J Hub:

- Ensure there is no irreversible impact to the semi-permanent and permanent Pools (water quality / integrity) and aquatic fauna of the Robe River pools and health of riparian vegetation communities of the Robe River and Jimmawurrada Creek as a result of groundwater abstraction and discharge for the Mesa J Hub.
- Ensure that groundwater abstraction and surplus dewater discharge, does not cause long term impacts to the Aboriginal heritage values linked to the physical and/or biological surroundings of the Robe River or Jimmawurrada Creek.

Riparian Vegetation

The outcomes for riparian vegetation were selected as it is acknowledged that the Mesa J Hub may have an impact on riparian vegetation communities, particularly in Jimmawurrada Creek 'Zone 3' (Table 1-3), however potential impacts are not expected to be permanent as they will be limited in spatial extent and/or will occur over a limited time period and changes are considered unlikely to be so great that they result in permanent changes in the composition of riparian vegetation.

The selected trigger and threshold criteria are based on standard deviations in foliage cover of phreatophytic overstorey riparian tree species from the baseline period mean as measured by mean vegetation index. Mean vegetation index is a readily measurable indicator of the health of riparian vegetation for which reference sites can be established and regular monitoring undertaken. Measurement of mean vegetation index is also consistent with other riparian vegetation monitoring programs. The approach taken is analogous to the 'control chart' method (Morrison 2008) that has been applied to a wide range of environmental impact studies and monitoring programs. In line with this, a trigger criterion of ≥ 2 standard deviations from baseline mean vegetation index has been selected for the following reasons:

- Decline from a baseline mean in number of standard deviations aligns with commonly accepted convention for establishing trigger criteria to detect potential environmental impacts.
- Quantifying decline in number of standard deviations from the baseline mean takes into account the natural variability observed in the system. This is preferable to using a set value or percentage decline which does not take natural variability into account.
- In a normally distributed dataset, 2 standard deviations from the mean encompasses 95% of the observed values, that is, there is a 5% chance of measuring a value either higher or lower than 2 standard deviations from the mean prior to any disturbance being imposed. This is aligned with the convention of using a statistical significance level of p=0.05.

A threshold criterion of ≥ 2 standard deviations from baseline mean vegetation index over a period of two consecutive monitoring events has been selected. Mean vegetation index is a readily measurable indicator of the health of riparian vegetation and comparison with standard deviation from baseline values is consistent with other riparian vegetation monitoring programs conducted by the Proponent in the Pilbara region. Rainfall and streamflow can fluctuate, both seasonally and across multiple years, influencing the condition of phreatophytic vegetation. As such two years has been selected as a suitable timeframe to assess whether the condition of upper canopy vegetation is under threat of long term impacts from the Mesa J Hub, and to differentiate natural variation of the canopy from the potential impacts of groundwater abstraction and surplus water discharge. Following the completion of collection and analysis of baseline data, the trigger and threshold criteria will be reviewed and adjusted if deemed appropriate.

Trigger and threshold criteria for detection of new introduced species in the riparian zone of the Robe River were selected as an indicator of potential impacts from discharge of surplus water. Introduced species can be monitored regularly, have a baseline, and measurement of these parameters is consistent with other flora and vegetation monitoring programs.

Semi-permanent and permanent pools and aquatic fauna

The outcome for semi-permanent and permanent pools was selected based on the high cultural and environmental value of Robe River Pools.

The selected triggers and threshold criteria for semi-permanent and permanent pools of the Robe River are groundwater levels adjacent to select pools, pool depth, water quality and aquatic fauna (fish).

Installation of paired alluvial aquifer bores in the Robe River near targeted pools is proposed to monitor groundwater levels and hence potential impact to water levels in pools. Bores will be placed (subject to approvals) on the north and south side of the river. The south edge of the river receives water from the Mesa H CID / basement aquifers that has a northern groundwater flow direction, whilst the northern edge receives groundwater from the aquifer to the north that has a southern flow direction. The drawdown from Mesa H operations are likely to be observed earlier in the south edge of the river channel rather than in the north, hence if the predicted maximum drawdown (~0.5m) is observed in the proximal monitoring bores and not in the distal bores would be a clear indication the drawdown is higher than expected.

Trigger and threshold criteria have also been developed for Yeera Bluff (Gnieroora) Pool. A depth trigger of 2m and threshold of 1m was selected on the basis that is appears that it is a permanent pool. It is likely that if this pool is dry, others will be too and key environmental values will be compromised Surface water is directly associated with maintaining the cultural and aesthetic values.

A trigger criterion was developed for water quality in pools exceeding the rolling quarterly median measured against the operational guideline site specific trigger value (SSTV) equivalent to the 95th percentile value of baseline or the ANZECC/ARMCANZ (2000) default trigger value for toxicants for protection of 95% of species, whichever is higher (except for pH).

An additional threshold criteria for semi-permanent and permanent pools of the Robe River is fish species richness. A threshold criterion of three or less species of fish recorded in Robe River Pools was selected on the basis of approximately 27 years of sampling of Robe River pools (Streamtec 2017, WRM 2017). The total number of species recorded is 11 species with a range in species richness of 4 to 11 in any sampling event. To date, species richness has been highly correlated with pool depth and volume and hence climate. A threshold has been developed of three (or less) species recorded across all sampling sites indicating that pool levels may have dropped beyond the range of natural variability.

b) Terrestrial Fauna

Ghost Bat

Outcome-based and management-based provisions have been adopted for the Ghost Bat on the basis that objective measurement and reporting is possible for some parts of the environment and some of the potential impacts but not for others.

The environmental outcome adopted for the Ghost Bat is:

- No irreversible impact as a result of the Project to retained escarpments of Mesa H which are high value habitat for the Ghost Bat.

No irreversible impact to the retained escarpments is defined as not resulting in 'significant damage'. Significant damage is considered to be damage that negatively impacts the structural integrity and microclimate of the cave such that future Ghost Bat use of the site is prevented.

This outcome has been selected as the escarpments of Mesa H represent potential roosting and foraging habitat. Habitat loss through disturbance to roost caves, specifically caves that play a role in breeding activities (maternal roosts) and nearby areas is seen as a key risk to this species conservation status. The Mesa H Project has been designed to retain the mesa escarpment, except where cuts are required to access the top of the mesa, and to avoid direct disturbance to diurnal/potential maternal roosts and known nocturnal roosts on Mesa H particularly those associated with or in close proximity to the diurnal / potential maternal roosts.

Vibration levels and direct disturbance near the potential diurnal/maternal roosts have been selected as triggers as both can be directly targeted to the highest value habitat, are readily measurable, can be monitored regularly and are consistent with other Ghost Bat monitoring programs. Ensuring the vibration levels at the potential diurnal/maternal roosts remain below a peak particle velocity determined for each cave reduces the risk that vibrations compromise the structural integrity of the roosts.

Temperature and humidity monitoring of the two diurnal/potential maternal caves on Mesa H (MH16-34 and AC4) have been selected on the basis of ensuring that the roost cave is viable for Ghost Bats not only from a physical perspective, but also from a cave microclimate perspective. The approach is readily measurable and will enable verification that blasting and mine pit development within adjacent pits does not inadvertently open up new cavities or openings at the back of the potential diurnal/maternal roost caves which may change the cave microclimate.

The management objective adopted for the Ghost Bat is:

- Improve knowledge of the Ghost Bat population and utilisation of high value habitat in the Robe Valley in order to assist in maintaining biological diversity and ecological integrity.

This management objective has been selected as it relates to the EPA objective for Terrestrial Fauna and is specific to the Project. One of the limitations noted during the Environmental Impact Assessment is the lack of long-term data that would provide an estimate of natural Ghost Bat population variability and an indication of how the Ghost Bat utilises caves within the central part of the Robe Valley. The proposed management action to undertake a five-year study of Ghost Bat

utilisation of high value habitat in the Robe Valley has been selected to start to address this limitation.

Northern Quoll

Northern Quoll population numbers fluctuate on both annual and inter-annual cycles. This variability is driven by both the reproductive biology of individuals (males usually die-off after one year) and longer-term cycles in response to regional stochastic processes such as rainfall, fire and related changes of prey populations (How et al. 2009). This natural variability makes threshold criteria based on population dynamics inappropriate for compliance at this stage. Protection of high value habitat for the Northern Quoll is, therefore, the most appropriate strategy to protect this conservation significant fauna within the Development Envelope.

The environmental outcome adopted for the Northern Quoll is:

- No irreversible impact as a result of the Project to Breakaways and Gullies habitat retained in the escarpment of Mesa H.

This outcome has been selected as the escarpment of Mesa H contains high value denning and foraging habit. The Mesa H Project has been designed to retain the mesa escarpment, except where cuts are required to access the top of the mesa, and to avoid the highest value sections of mesa escarpment (Astron 2017a).

A trigger and threshold have been developed for direct disturbance to the breakaway and gullies habitat of the retained escarpment. Direct disturbance to these breakaway and gorge habitats in the retained escarpment is readily measurable and can be monitored regularly. Ensuring direct disturbance to the breakaway and gullies habitat of the mesa escarpment is minimised reduces the risk that Northern Quoll denning habitat is disturbed or degraded.

Note that the proposed triggers and thresholds relate to the Northern Quoll habitat within the *retained* sections of the escarpments (MEZs) which already account for the approved disturbance (escarpment cuts and waste dump). i.e. the triggers and thresholds are impacts over and above the proposed / approved impacts to the MEZ.

c) Subterranean Fauna

Outcome-based and management-based provisions have been adopted for subterranean fauna on the basis that objective measurement and reporting is possible for some parts of the environment but not for others.

Subterranean fauna surveys in general have low capture rates per survey effort meaning the abundance and diversity of specimens recorded during surveys are highly variable (Halse and Pearson 2014). These sampling artefacts mean that threshold criteria based on abundance or diversity would be inappropriate at this stage. Protection of high value habitat for subterranean fauna is, therefore, considered the most appropriate strategy to protect subterranean fauna so that biological diversity and ecological integrity are maintained. The following environmental outcomes have been adopted:

- Troglofauna: The Proponent shall ensure there is no irreversible impact as a result of the Project to the troglofauna habitat retained within the Mesa H MEZ.
- Stygofauna: The Proponent shall ensure there is no irreversible impact, as a result of the Proponents water management activities, to stygofauna habitat within the CID aquifer and stygofauna and Blind Cave Eel habitat within the alluvial aquifer habitat of Jimmawurrada Creek and the Robe River shown in Figure 1-6.

Mesa H comprises iron-rich Robe Pisolite which is considered to be the geological unit that provides primary habitat for troglofauna. As the Robe Pisolite is also the target ore body, a key part of the Mesa H Project design is to ensure retention of a significant volume of Robe Pisolite habitat in the

form of a MEZ. The environmental outcome has been selected to reflect this key part of the Mesa H Project design.

Trigger and threshold criteria have been developed to limit the direct removal, through operational error, of troglofauna habitat to be retained in the MEZ. Blasting and excavation carried out as part of the mining process have a degree of operational error associated with them. The trigger and threshold criteria, while recognising the practical limits to operational precision, have been structured to ensure that significant volumes of troglofauna habitat are not lost from the MEZ over the life of the mine. Volume excavated is readily measurable and is part of the causal relationship between mining and impacts on troglofauna.

The amount, quality and distribution of stygofauna habitat within the Development Envelope may be influenced by dewatering as well as pit excavation. The below water table extent of the Robe Pisolite, alluvium and Wittenoom aquifer are considered to be the geological units that provide primary habitat for stygofauna. Trigger and threshold criteria have been developed around the amount and quality of water drawdown at key locations in the CID and alluvial aquifer habitat of Jimmawurrada Creek and the Robe River. The ongoing persistence of connected stygofauna habitat in the Development Envelope was a key consideration when defining these criteria and thus doubles as trigger and threshold criteria for stygofauna and Blind Cave Eel habitat. Trigger and threshold values criteria also been developed around the ongoing persistence of a diverse stygofauna community, including the Blind Cave Eel, within the available stygofauna habitat.

The management objectives adopted for subterranean fauna are:

- Troglofauna: The Proponent shall protect the biological diversity and ecological integrity of the troglofauna assemblage at Mesa H by minimising impacts as far as practicable.
- Stygofauna: The Proponent shall protect the biological diversity and ecological integrity of the stygofauna assemblages within the CID and Alluvial aquifer habitats shown in Figure 1-6 by minimising impacts as far as practicable.

These management objectives have been selected as they relate to the EPA objective for Subterranean Fauna and are specific to a key part of the Mesa H Project. Six management targets (three for troglofauna and three for stygofauna) have been selected to assess whether the management actions are effective in meeting the environmental objective. Management targets relate to:

- clearing of native vegetation in the MEZs to limit the potential for degradation of retained troglofauna habitat as a result of diminished organic nutrient inputs;
- troglofauna specimen capture rate to assess whether the Mesa H Project has an impact on troglofauna utilization of retained habitat in the MEZs; and
- further research to understand the distribution of key stygofauna species and allow refinement of the proposed outcome and management based provisions.

Management actions and targets have been selected to address potential impacts of the Mesa H Project as well as to build upon existing data.

2. EMP PROVISIONS

This section of the EMP identifies the legal provisions that the Proponent will implement to ensure that the environmental outcomes of conditions 6, 7, 8 and 9 are met during implementation of the Mesa J Hub.

Outcome and management based provisions are provided in Section 2.1. Monitoring and reporting are detailed in Section 2.4 and Section 2.5 respectively.

Table 2-6 to Table 2-10 detail for all provisions within this EMP.

2.1 Outcome and Management Based Provisions

The following outcome based provisions are included in this EMP:

Mesa H and J: Inland waters, Vegetation and Aquatic Fauna

- No irreversible impact, as a result of the proponent's water abstraction, to groundwater dependent vegetation within the Robe River.
- No irreversible impact, as a result of the proponent's water abstraction, to riparian vegetation communities within Jimmawurrada Creek.
- No irreversible impact, as a result of the Proponent's discharge of surplus water, to the health of riparian vegetation of Jimmawurrada Creek and the Robe River.
- No irreversible impact, as a result of the Proponent's drawdown and discharge, to the pool ecosystems of the Robe River.

Mesa H: Terrestrial Fauna – Ghost Bat and Northern Quoll

- No irreversible impact, as a result of the proponent's activities, to Breakaways and Gullies habitat (and associated Ghost bat Roosts) retained in the escarpments of Mesa H.

Mesa H: Subterranean Fauna – Troglofauna and Stygofauna

- No irreversible impact, as a result of the proponent's activities, to the troglofauna habitat retained within the Mesa H MEZ.
- No irreversible impact, as a result of the proponent's water management activities, to stygofauna habitat within the CID aquifer and stygofauna and Blind Cave Eel habitat within the alluvial aquifer habitat of Jimmawurrada Creek and the Robe River.

The following management based provisions are included in this EMP:

Mesa H: Terrestrial Fauna – Ghost Bat

- The Proponent shall improve knowledge of the Ghost Bat population and utilisation of high value habitat in the Robe Valley in order to assist in maintaining biological diversity and ecological integrity.

Mesa H: Subterranean Fauna – Troglofauna and Stygofauna

- The Proponent shall protect the biological diversity and ecological integrity of the troglofauna assemblages of Mesa H by minimising impacts as far as practicable.
- The Proponent shall protect the biological diversity and ecological integrity of the stygofauna assemblages within the CID and Alluvial aquifer habitat by minimising impacts as far as practicable.

2.2 Performance Indicators (environmental criteria)

2.2.1 Trigger level criteria

Trigger criteria measures are set at a conservative level to ensure management actions are implemented well in advance of the environmental objective being compromised. Thus, trigger criteria are set at a level below the threshold criteria to signal the need to focus and investigate and where applicable, mitigate the impact further or increase the level of protection or rehabilitation.

Mesa H and J: Inland waters, Vegetation and Aquatic Fauna

1. The mean vegetation index for riparian overstorey taxa (E. victrix, E. camaldulensis and M. argentea) of Zones 1 & 2 of Jimmawurrada Creek and the Robe River changes by ≥ 2 standard deviations.
2. A statistically significant decline from baseline ($p<0.05$) in the number and/or cover of native perennial species of Zones 1 & 2 of Jimmawurrada Creek and the Robe River.
3. Detection of new introduced species at a potential impact site, previously not detected within the Development Envelope.
4. Decline of >0.5m between paired Alluvial Aquifer bores in the Robe River near targeted pools.
5. Yeera Bluff (Gnieroora) Pool drops below 2m depth.
6. Water quality in pools exceeds rolling quarterly median measured against the operational guideline SSTV equivalent of 95%ile value of baseline or the ANZECC/ARMCANZ (2000) default TV for toxicants for protection of 95% of species, whichever is higher (except for pH).

Mesa H: Terrestrial Fauna – Ghost Bat

1. Vibration levels exceed 50mm/s peak particle velocity at the potential diurnal/maternal Ghost Bat roost caves.
2. Disturbance, other than approved clearing, within 50m of the recorded back of the potential diurnal/maternal Ghost Bat roost caves.

Mesa H: Terrestrial Fauna – Northern Quoll

1. Disturbance of >5% of potential Northern Quoll denning habitat on the retained escarpment of Mesa H.

Mesa H: Subterranean Fauna – Troglofauna

1. Operational error during mining resulting in removal of greater than 0.01% by volume annually of the MEZ at Mesa H.

Mesa H: Subterranean Fauna – Stygofauna

1. Groundwater levels drop three (3) m below predicted water table heights in the Jimmawurrada Creek alluvial aquifer.
2. Diversity of stygofauna Orders collected during annual survey events reduced to three (3) or less.

2.2.2 Threshold level criteria

Mesa H and J: Inland waters, Vegetation and Aquatic Fauna

3. The mean vegetation index for the riparian upper canopy (*E. victrix, E. camaldulensis* and *M. argentea*) of Zones 1 & 2 of Jimmawurrada Creek and the Robe River declines by ≥ 2 standard deviations from baseline over two consecutive monitoring events.

4. A statistically significant decline from baseline ($p<0.05$) in the number and/or cover of native perennial species over two consecutive monitoring events.
5. Detection of new introduced species rated high or very high management priority (by the Department of Biodiversity, Conservation and Attractions) at a potential impact site, previously not detected within the Development Envelope and a significant increase in cover or abundance over successive monitoring events.
6. Decline of ≥1 m between paired Alluvial Aquifer bores in the Robe River near targeted pools.
7. Yeera Bluff (Gnieroora) Pool drops below 1m depth.
8. Three (3) or less species of fish recorded during a sampling event.

Mesa H: Terrestrial Fauna – Ghost Bat

1. Significant damage to diurnal/maternal Ghost Bat roost caves.
2. Disturbance, other than approved than approved clearing, within 40m of the recorded back of the potential diurnal/maternal Ghost Bat roost caves.

Mesa H: Terrestrial Fauna – Northern Quoll

1. Disturbance of >10% of potential Northern Quoll denning habitat on the retained escarpment of Mesa H.

Mesa H: Subterranean Fauna – Troglofauna

1. Net loss of the MEZ at Mesa H, at the completion of mining.

Mesa H: Subterranean Fauna – Stygofauna

1. Alluvial aquifer in Jimmawurrada is dry for two (2) consecutive years.
2. Absence of Blind Cave Eel recorded for two (2) consecutive annual sampling events.
3. Absence of stygofauna specimens for two (2) consecutive annual sampling events.

2.2.3 Management Targets

Mesa H: Terrestrial Fauna – Ghost Bat

1. Estimate the local population of Ghost Bats in the central part of the Robe Valley.
2. Indicate how Ghost Bats use caves within the central part of the Robe Valley (e.g. diurnal versus maternal), including the degree of utilisation of caves by pregnant females.

Mesa H: Subterranean Fauna – Troglofauna

1. Total clearing of native vegetation across the surface of the MEZ is less than 30% of the MEZ surface area.
2. Troglofauna specimen capture rate is not below the baseline minimum for three (3) consecutive sampling events at Mesa H.

Mesa H: Subterranean Fauna – Stygofauna

1. Understand the distribution and ecology of key stygofauna taxa within the Robe Valley area.

2.3 Response Actions

The Proponent has developed a number of trigger level actions that would be implemented if the associated trigger criterion signals the need to increase mitigation or protection (Table 2-6 to Table 2-10). These trigger level actions will be implemented by the Proponent to mitigate and manage impacts so they once again will meet trigger and safeguard the threshold criteria.

The Proponent has developed a number of threshold contingency actions that would be implemented if the associated threshold criterion signals that the environmental outcome is exceeded (Table 2-6 to Table 2-10). The threshold contingency actions will be implemented to manage aspects of the proposal and achieve the condition environmental outcome and manage the impact to below threshold and trigger criteria again and hence bring the Proponent back into compliance.

2.4 Monitoring

Monitoring will be undertaken to measure performance against the environmental outcomes and to assess the effectiveness of management actions in meeting management-based objectives. Monitoring will inform, through the environmental criteria, when trigger or threshold contingency actions will be implemented.

2.4.1 Inland Waters

The Proponent will monitor the health of riparian vegetation of the Robe River and Jimmawurrada Creek both within the potential groundwater drawdown and surplus water discharge impact zones and at reference sites.

The effects of groundwater drawdown on facultative and obligate phreatophytes are dependent upon both the baseline groundwater level and the rate of groundwater drawdown. For example, trees accessing shallow groundwater may be more sensitive to groundwater drawdown than trees growing above a groundwater table at greater depth. While it is inherently difficult to interpolate local groundwater table elevation from limited data and hence predict groundwater dependence of local phreatophytes, monitoring the cover of the upper canopy provides an indicator of stress either due to groundwater drawdown or due to surplus water discharge. The health of phreatophytic species along the Robe River and Jimmawurrada Creek will, therefore, be monitored utilizing remote sensing with supporting field-based surveys. Due to the difficulty of distinguishing phreatophytic riparian trees using remote sensing, the phreatophytic assemblages of the Robe River and Jimmawurrada Creek will be treated as a functional group 'riparian overstorey' for trigger and threshold criteria.

The Proponent will monitor the health of obligate and facultative vegetation of the Robe River and Jimmawurrada Creek using remote sensing to ensure there are no significant changes to health beyond natural variation. Annual remote sensing will provide an indication of vegetation condition over the riparian zones. The foliage cover of the upper canopy will be assessed as a time series, to compare against both baseline conditions and also alongside correlative parameters including rainfall, water levels and fire. The large coverage of canopy captured in remote sensing will accommodate assessment of potential relationships between dewatering and vegetation condition across the entire riparian zone, overcoming some of the limitations of field-based assessment. The monitoring to be undertaken is summarised in Table 2-1.

Baseline data from potential impact and reference sites will be collected prior to operations commencing to quantify natural variation in foliage cover (and health). The mean of all measurements made during the baseline period will be calculated for each reach (or system). Changes over time at these reaches (or zones) will be compared back to the baseline and to reference sites to assess any potential impacts from the Project.

A decline in vegetation index of ≥ 2 standard deviations from the baseline for upper canopy vegetation has been selected as the trigger (trigger criterion 1) to prompt causal investigation and if necessary, remedial actions. Applying criteria to the results of one image with no temporal replication does not adequately accommodate investigation into causation, and comparison with vegetation health at reference sites, and hence is not appropriate as a pass/fail compliance measure. However, a shift of ≥ 2 standard deviations from a sample of adequate size (through spatial coverage) does warrant investigation, including time series assessment of vegetation condition in conjunction with correlative environmental parameters and monitoring results from reference sites. The outcomes of investigation will inform the proponent whether dewatering

operations pose a risk of irreversible impact to the riparian vegetation of the Robe River and Jimmawurrada Creek.

A decline in vegetation index of ≥ 2 standard deviations from the baseline for upper canopy vegetation over a period of two consecutive sampling events has been selected as the threshold criterion (threshold criterion 1) for the Robe River and Zones 1 and 2 in Jimmawurrada Creek. In the absence of data to support that obligate and facultative phreatophytic species can recover or re-establish following periods of stress, a decline of ≥ 2 standard deviations from baseline has been selected as a pass/fail criterion. In the event this criterion is exceeded, the Proponent will conduct additional assessments of the impacted riparian vegetation, and liaise with the EPA Services on both the appropriateness of a decline of ≥ 2 standard deviations as a compliance threshold, and also the remedial actions required to prevent the impacts becoming irreversible.

The species richness and cover of both native and introduced species will be recorded during field-based, post-wet season, annual monitoring surveys in selected transects established during baseline surveys. Monitoring of the understorey vegetation will provide data about the structure, cover and health of both native and introduced species to assist in investigation of any trends that may occur as a result of changed hydrological regime and measured against management criteria. Trends in the presence of native species will be analysed in parallel with the presence of introduced species, to detect any threats which introduced species may pose to native vegetation. The presence of introduced species will be monitored in isolation as an early warning indicator, though the threshold criterion take into account the balance of all species, to ensure that the potential increased productivity as a result discharge is not misinterpreted as a negative impact to the health of riparian vegetation.

Due to the difficulty in establishing reference pool levels due to differences in pool morphology, depth and overstorey cover (which impacts evaporations rates), paired bores (on the north/south sides of the Robe River) once installed will be monitored continuously via data loggers and downloaded quarterly. The paired bores on either side of the Robe River will enable early detection of changes to water table levels in the Robe River proximal to the Mesa J Project when mine pit dewatering commences, relative to its paired alluvial bore on the other side of the Robe River. This is considered the most accurate way to determine a mine dewatering related change to water table levels in the pools as compared to natural seasonal pool water table fluctuations.

Pool depth at Yeera Bluff will be determined by bathymetry measurements, field morphology measurements or remotely via drone. Water quality will be sampled quarterly in five (5) key pools in the Robe River to determine adherence to the SSTV or ANZECC/ARMCANZ values.

Fish species richness will be recorded during biannual surveys of selected Robe River pools through direct observation. Water levels and quality will be assessed through the use of paired bores, bathymetry and direct sampling (of fish and water).

Table 2-1: Monitoring required to evaluate performance against the environmental outcomes for hydrological processes and riparian vegetation

Monitoring action	Location	Frequency and timing	Data collection method and analysis	Responsible
Capture and analysis of remote sensing images (criterion 1)	Selected potential impact sites and reference sites established during baseline monitoring	Annual during operational mine life[1]	Remote sensing images Calculation of vegetation index and analysis of changes to vegetation index	Operations Environment team
Annual field survey (criterion 2)	Selected transects established during baseline monitoring	Annual during operational mine life Post wet season	Understorey riparian taxa: condition, cover and health Introduced species: number and locations	Operations Environment team
Paired Alluvial Aquifer bores[2] in the Robe River near targeted pools (criterion 3).	3 sets of paired bores, on the Mesa H side of the Robe River, paired with a bore on the opposite side of the River	Quarterly downloads (of daily data)	Bore data loggers Automated triggers in database	Mesa H and J Hydrogeology team
Yeera Bluff (Gnieroora) Pool depth (criterion 4)	Yeera Bluff (Gnieroora) Pool	Biannual	Bathymetry measurements Field morphology monitoring of impact and reference pools or remote assessment via drone	Mesa H and J Hydrogeology team Operations Environment Team
Water quality (criterion 5)	5 Key pools on the Robe River; Japanese, Yeera Bluff (Gnieroora), Medawandy, Yarramudda, Martangkuna	Quarterly	Monitoring of impact and reference pools	Operations Environment team
Monitoring of aquatic fauna (fish) (criterion 6)	13 pools on the Robe River; Mussel Pool – Yeera Bluff (Gnieroora) Pool (established in 1991)	Bi-annual	Fish – direct observation at selected pools	Operations Environment team

[1] Locations may not always be available due to accessibility, weather conditions, safety considerations etc.

[2] Alluvial Bore locations subject to approval from the Kuruma Marthadunera People.

2.4.2 Terrestrial fauna (Ghost Bat)

Protection of high value habitat for the Ghost Bat is the most appropriate strategy to protect this conservation significant fauna within the Development Envelope. High value habitat for the Ghost Bat includes the escarpment and cave structures associated with mesa formations in the Robe Valley. Trigger and threshold criteria have been applied to potential diurnal/maternal roosts, as diurnal/maternal roosts are recognised as geographically restricted and ecologically critical. These trigger and threshold criteria have been designed to ensure no 'significant damage' to critical Ghost Bat roosts, where 'significant damage' is defined as 'damage that negatively impacts the structural integrity and microclimate of the cave such that future Ghost Bat use of the site is prevented'.

Baseline monitoring of the two potential diurnal/maternal caves on Mesa H (MH16-34 and AC4), MH16-34 will continue to be undertaken prior to commencement of mining. Additional data from longer term monitoring of these caves may indicate that a different status, and potentially a different level of management, may be appropriate for these caves; this may require revision of the EMP.

Vibration levels will be measured at the potential diurnal/maternal Ghost Bat roost caves at Mesa H for all blasts within 300 m of the potential diurnal/maternal roosts. Ensuring the vibration levels at the potential diurnal/maternal roosts remain below a peak particle velocity determined for each cave reduces the risk that vibrations compromise the structural integrity of the roosts. Annual land clearing reconciliation using GIS disturbance layers will also be undertaken to monitor disturbance close to the potential diurnal/maternal roost caves. Annual assessment of Ghost Bat roost utilisation across the broader Robe Valley will also be completed as supporting monitoring to provide context to any potential impacts from blasting or ground disturbance in the vicinity of the potential diurnal/maternal roosts.

Temperature and humidity of the two potential diurnal/maternal caves on Mesa H (MH16-34 and AC4) will be monitored on a continuous basis, and calibrated with ambient temperature and humidity. The approach is to support the above described monitoring actions to verify that blasting and mine pit development within adjacent pits does not inadvertently open up new cavities or openings at the back of the potential diurnal/maternal roost caves which may change the cave microclimate.

The Proponent has identified that there is a lack of regional population studies for the Ghost Bat to assist in understanding the long-term natural population variability and movements of this species. The EMP includes a management objective to improve knowledge of the Ghost Bat population and utilisation of high value habitat in the Robe Valley. The associated monitoring includes bi-annual collection of scats from Ghost Bat roost caves across the broader Robe Valley where safety and heritage considerations allow. Analysis of scat samples will include genetic and hormone analysis to provide information on utilisation of caves by individuals including pregnant females.

Table 2-2 summarises the monitoring required to measure performance against the environmental outcome and to assess the effectiveness of management actions in meeting the management-based objective.

Table 2-2: Monitoring required to evaluate performance against the environmental outcome and to assess the effectiveness of management actions for the Ghost Bat

Monitoring action	Location	Frequency and timing	Data collection method and analysis	Responsible
Vibration levels (criterion 1)	Caves MH16-34 and AC4 (Figure 1-4)	For all blasts within 300m of caves MH16-34 and AC4	Modelling of peak particle velocity prior to blast. Vibration monitoring of actual peak particle velocity. Analysis of modelled versus actual peak particle velocity.	Drill and Blast team

Land clearing reconciliation (criterion 2)	Caves MH16-34 and associated cave complexes, and AC4 (Figure 1-4)	Annual during operational mine life	GIS avoidance and disturbance layers. Internal approvals request process.	Operations Environment team
Temperature and Humidity	Caves MH16-34 and AC4 (Figure 1-4)	Ongoing (continuous) during operational mine life	Temperature and humidity logging and data analysis correlated against ambient temperature; and timing of mine pit development / blasting data in adjacent pits.	Operations Environment team
Scat collection and analysis (management target)	Caves across the broader Robe Valley*	Bi-annual for 5 years	Scat collection from Ghost Bat roost caves. Genetic and hormone analysis.	Operations Environment team

* Access subject to safety and heritage assessments of caves

2.4.3 Terrestrial fauna (Northern Quoll)

Protection of high value habitat for the Northern Quoll is the most appropriate strategy to protect this conservation significant fauna within the Mine Development Envelope. High value habitat for the Northern Quoll in the Robe Valley includes the Breakaways and Gullies habitat contained within the mesa escarpments which provides denning habitat. Trigger and threshold criteria for disturbance to Northern Quoll denning habitat on the retained escarpments of Mesa H will be applied.

An annual field survey of Northern Quoll will be undertaken as supporting monitoring.

Offset actions, including Northern Quoll monitoring, are currently being undertaken on parts of Yarraloola Station as part of the approved Yandicoogina Threatened Species Offset Plan (TSOP). Yarraloola Pastoral Station underlies and surrounds the Development Envelope. Camera monitoring and trap monitoring protocols for the annual field survey will be based on the protocols established as part of the TSOP so that data from the two programs are comparable. Forty cameras will be utilised at eight mesas across the Robe Valley (nominally Mesa A, Mesa B, Mesa C, Mesa F, Mesa G, Mesa H, Mesa 2402D and Mesa 2403E).

Four trap sites will be established within the Robe Valley and designed in two categories ‘impact’ or ‘reference’ sites. Impact sites will be located at Mesa B (TSOP Site Q) and Mesa H (TSOP Site L) and reference sites will be located at Mesa G (TSOP Site K) and Mesa F (TSOP Site B). Each site will consist of 20 cage traps spaced at 50 m intervals and will be set up, where possible, in preferred habitat for this species in the Robe Valley. The preferred habitat is seen as the rocky escarpments abutting a major drainage system (i.e. Robe River), however additional habitats including the Plains habitat will be included in the monitoring design to enable a full picture of extent of habitat utilisation to be understood.

Table 2-3 summarises the monitoring required to measure performance against the environmental outcome and the supporting field monitoring that will be undertaken.

Table 2-3: Monitoring required to evaluate performance against the environmental outcome for the Northern Quoll

Monitoring action	Location	Frequency and timing	Data collection method and analysis	Responsible
Land clearing reconciliation (criterion 1)	Escarpment of Mesa H	Annual during the operational mine life	GIS avoidance and disturbance layers. Internal approvals request process.	Operations Environment team
Annual field survey (supporting monitoring)	Escarpments of mesas across the broader Robe Valley and other targeted habitats (e.g. Plains) 40 camera monitoring sites spread over Mesa A, Mesa B, Mesa C, Mesa F, Mesa G, Mesa H, Mesa 2402D and Mesa 2403E 4 trap monitoring sites located at Mesa B, Mesa H, Mesa G and Mesa F	Annual (May–September) during operational mine life	Camera monitoring Trapping	Operations Environment team

2.4.4 Subterranean fauna (troglofauna)

Protection of high value habitat for troglofauna is the most appropriate strategy to protect troglofauna so that biological diversity and ecological integrity are maintained. High value habitat in the Development Envelope includes the CID comprising Mesa H. The Proponent will ensure that at least 50% by volume of pre-mining troglofauna habitat will be retained through delineation of a MEZ.

Monitoring of the retained volume of troglofauna habitat in the MEZ will require regular on-ground surveying of the actual pit shell for comparison with the planned pit shell.

A biennial field survey for troglofauna specimens will also be conducted (Table 2-4). This will be the primary source of monitoring data with which to evaluate progress against management targets. As a minimum, the survey will include trapping and scraping from 25 drill holes in the Mesa H MEZ. Previously sampled sites will be used wherever possible to ensure results from each survey are readily comparable. All specimens will be identified to species level and aligned with existing taxa/specimens where possible. Molecular identification will be used where morphological identification is not possible or is less efficient. All specimens with troglomorphic characteristics will be included in the analysis and reporting as 'potentially troglobitic' until shown otherwise.

Following biennial sampling, troglofauna capture rate will be calculated as the number of troglobitic specimens collected per 100 trapping sites, per survey. Appendix 1 shows baseline values for capture rates at Mesa H. Capture rate has naturally high variability with survey timing, location and rainfall potentially influencing the capture rate. Specimens collected via scraping will be excluded from capture rate calculations to ensure pre-mining data are comparable with data collected during mining.

Table 2-4: Monitoring required to evaluate performance against the environmental outcome and to assess the effectiveness of management actions for troglofauna

Monitoring action	Location	Frequency and timing	Data collection method and analysis	Responsible
Pit shell reconciliation (criterion 1)	Mine pits at Mesa H	Annual during operational mine life	High accuracy differential GPS. 3-dimensional coordinates of the mine pit shell in the area of active mining. Reconcile actual and planned 3-dimensional pit shell.	Mine Planning team
Land clearing reconciliation (management target)	MEZ at Mesas H	Annual during operation mine life	GIS avoidance and disturbance layers. Internal approvals request process.	Operations Environment team
Troglofauna field survey (management target)	Minimum 25 sites	Biennial during operational mine life Post- wet season	Trapping and scraping. Morphological and molecular species level identifications. Analysis to evaluate capture rate trends	Operations Environment team

2.4.5 Subterranean fauna (stygofauna)

Protection of high value habitat for stygofauna is the most appropriate strategy to protect stygofauna so that biological diversity and ecological integrity are maintained. High value habitat in the Mine Development Envelope includes the alluvial aquifer, and the CID aquifer (BWT Robe Pisolite).

Monitoring of the retained stygofauna habitat will be completed by monthly monitoring of groundwater levels in groundwater bores (Table 2-5). These bores will intercept the alluvial aquifer of the Robe River and Jimmawurrada Creek and be strategically located to assess cumulative impacts from mine dewatering. Trigger and threshold criteria have been chosen on the modelled extent of drawdown in relation to the thickness of the alluvial aquifer.

An annual field survey for stygofauna specimens will also be conducted. Previously sampled sites will be used wherever possible to ensure results from each survey are readily comparable. Reference sites will also be sampled to provide context to the results. All specimens will be identified to species level and aligned with existing taxa/specimens where possible. Molecular identification will be used where morphological identification is not possible or is less efficient. All specimens with stygobitic characteristics will be included in the analysis and reporting as 'potentially stygobitic' until shown otherwise. Results will also be compared with those from monitoring conducted for the Bungaroo CWP to improve understanding of the regional context of the stygofauna community at Mesa H.

Following annual sampling, the number of stygobitic Orders collected will be calculated as a measure of diversity. Order level comparison has been chosen as species level identifications are not always possible. Surveys where three or less Orders are collected will be considered a breach of trigger criteria and stimulate management intervention.

Environmental DNA (eDNA) survey will be conducted annually in the dewatering impact footprint to detect the persistence of the Blind Cave Eel. Representative reference sites from the wider Robe Valley will be included to provide regional context and further understanding of the distribution and ecology of the species. An inability to detect the Blind Cave Eel in the dewatering impact footprint for two consecutive years - via either eDNA or direct collection - is regarded as a breach of threshold

criteria. Monitoring for eels using eDNA has been piloted by industry leading researchers during the environmental approvals process and shows great potential for efficient and effective detection (Biota 2018).

Further research focussing on understanding the distribution and ecology of stygofauna will be supported. Key subjects are the Blind Cave Eel, *Nedsia sculptilis* and *Nedsia hurlberti*, as well as the PEC entitled '*Stygofaunal Community of the Bungaroo Aquifer*'. Currently, Rio Tinto is proposing to support an Australian Research Council Linkage project entitled 'Transforming assessment of subterranean ecosystems using environmental DNA'. This project aims to develop eDNA methods for more effective and efficient monitoring of stygobitic communities and, if successful, could be incorporated into this EMP through adaptive management.

Table 2-5: Monitoring required to evaluate performance against the environmental outcome and to assess the effectiveness of management actions for stygofauna

Monitoring action	Location	Frequency and timing	Data collection method and analysis	Responsible
Groundwater levels (criterion 1)	Strategically located bores intercepting the alluvial aquifer.	Monthly	Groundwater monitoring Bore network (as per the Groundwater Operating Strategy (GWOS)).	Hydrogeologists
Stygofauna field survey (criterion 2)	• Minimum 25 sites within the dewatering extent. • Minimum 10 reference sites within the wider Robe Valley.	Annually	Haul net sampling Morphological and molecular species identifications Comparison with Bungaroo CWP results. Calculate number of stygobitic Orders present.	Operations Environment team
Blind Cave Eel eDNA field survey (criterion 3)	• Minimum five sites within the dewatering extent. • Minimum 10 reference sites within the wider Robe Valley.	Annually	eDNA water sample methods and analysis as per Biota (2018).	Operations Environment team

Table 2-6: EMP Provisions – Inland Waters and Flora and Vegetation

Outcome based provisions – Inland Waters and Flora and Vegetation			
EPA objectives: - To maintain the hydrological regimes of groundwater and surface water so that environmental values are protected. - To protect flora and vegetation so that biological diversity and ecological integrity are maintained. **Outcomes relating to Condition xx:** - No irreversible[3] impacts to the semi-permanent and permanent Pools (water quality / integrity) and aquatic fauna of the Robe River and health of riparian[4] vegetation of the Robe River and Jimmawurrada Creek as a result of groundwater abstraction and discharge for the Project. **Key environmental values:** Groundwater Dependant Ecosystems: Semi-permanent and Permanent Pools (water quality / integrity) and aquatic fauna of the Robe River and riparian[5] vegetation of the Robe River and Jimmawurrada Creek. **Key impacts and risks:** Potential adverse impacts to the semi-permanent and permanent Pools (water quality / integrity) and aquatic fauna of the Robe River and health of riparian[6] vegetation of the Robe River and Jimmawurrada Creek as a result of groundwater abstraction and discharge for the Mesa J Hub.			
Environmental criteria	**Response actions**	**Monitoring**	**Reporting**
Trigger criterion: 1. The mean vegetation index for riparian overstorey[7] taxa (*E. victrix, E. camaldulensis and M. argentea*) of Zones 1 & 2[8] of Jimmawurrada Creek and the Robe River declines by ≥ 2 standard deviations from baseline.	• Review discharge regime, frequency, extent and timing in relation to predicted impacts on riparian vegetation. • Review supporting water quality data for surplus discharge (conducted under the Groundwater Operating Strategy) and supporting field-based overstorey and understorey vegetation monitoring data at selected sites • Review local/regional reference data. • Increase frequency and/or extent of on-ground assessments as appropriate.	• Capture and analysis of remote sensing images within selected[9], established monitoring areas, as appropriate[10]. • Annual condition, cover and health of riparian vegetation (understorey) within selected established monitoring areas.	The environmental outcome will be reported against the trigger criteria for each calendar year by 30 April in the ACAR for MS xxxx. If the trigger criterion was exceeded during the reporting period, the ACAR will discuss potential reasons for exceedance of the trigger criterion and include a description of the effectiveness of trigger level actions.

[3] Where 'irreversible impact' is defined as, 'an impact resulting in a permanent loss of environmental value(s); or where intensive, and/or un-proven management intervention, potentially over a long timeframe, would be required to restore the environmental value(s)'.

[4] See Section b) for more information regarding composition of riparian vegetation within the Robe River and Jimmawurrada Creek systems.

[5] See Section b) for more information regarding composition of riparian vegetation within the Robe River and Jimmawurrada Creek systems.

[6] See Section b) for more information regarding composition of riparian vegetation within the Robe River and Jimmawurrada Creek systems.

[7] Due to the difficulty in distinguishing *E. victrix* and *E. camaldulensis* (reliance on seed capsules that are not always present), the overstorey riparian vegetation will be represented as a functional group for the trigger and threshold criteria. Should any exceedance occur around these species specific on-ground investigations may be appropriate.

[8] Impacts are predicted in Zone 3 of Jimmawurrada creek which may exceed this trigger periodically during initial dewatering and later in the mine life (estimated to be 2030)

[9] The Proponent will determine "selected" transects from the established transects based on factors such as trigger and threshold outcome from H2 survey, discharge and/or dewatering extent and volume.

[10] Locations may not always be available due to accessibility, weather conditions, safety considerations etc.

2. A statistically significant decline from baseline ($p<0.05$) in the number and/or cover of native perennial species	• Review contingency actions/strategy, including potential modification to surplus water management and discharge regime. • Implement remedial or management actions as appropriate. • Consult with DWER if investigation indicates threshold criterion is likely to be exceeded.		
3. Detection of a new introduced species at a potential impact site, previously not detected within the Development Envelope			
4. Decline of >0.5m between paired Alluvial Aquifer bores[11] in the Robe River near targeted pools.	• Review dewatering regime, in relation to predicted drawdown. • Review local/regional reference data. • Increase frequency and/or extent of on-ground assessments as appropriate. • Review contingency actions/strategy, including potential modification to drawdown management and discharge regime. • Implement remedial or management actions as appropriate. • Consult with DWER if investigation indicates threshold criterion is likely to be exceeded.	• Monitoring bores (subject to installation approval). • Quarterly download of daily data.	
5. Yeera Bluff (Gnieroora) Pool drops below 2 m depth[12].	• Review dewatering regime, in relation to predicted drawdown. • Review local/regional reference data. • Increase frequency and/or extent of on-ground assessments as appropriate. • Review contingency actions/strategy, including potential modification to surplus water management and discharge regime.	• Pool morphology and bathymetry via Biannual (post wet and dry) monitoring. • Direct visualization or remote assessment via drone.	The environmental outcome will be reported against the trigger criteria for each calendar year by 30 April in the ACAR for MS xxxx. If the trigger criterion was exceeded during the reporting period, the ACAR will discuss potential reasons for exceedance of the trigger criterion and include a description of the effectiveness of trigger level actions

[11] Alluvial Bore locations subject to approval from the Kurama Marthadunera People.

[12] Except where a cyclonic event changes pool morphology

	• Implement remedial or management actions as appropriate. • Consult with DWER if investigation indicates threshold criterion is likely to be exceeded. • Compare to alluvial bore water depths to ascertain if mining and / or climatic related.		
6. Exceedance of rolling quarterly median measured against the operational guideline SSTV equivalent of 95%ile value of baseline or the ANZECC/ARMCANZ (2000) default TV for toxicants for protection of 95% of species, whichever is higher (except for pH).	• Review discharge regime, frequency, extent and timing in relation to predicted impacts on water quality. • Review local/regional reference data. • Increase frequency and/or extent of on-ground assessments as appropriate. • Review contingency actions/strategy, including potential modification to surplus water management and discharge regime. • Implement remedial or management actions as appropriate.	Quarterly pool water sampling	The environmental outcome will be reported against the trigger criteria for each calendar year by 30 April in the ACAR for MS xxxx. If the trigger criterion was exceeded during the reporting period, the ACAR will discuss potential reasons for exceedance of the trigger criterion and include a description of the effectiveness of trigger level actions
Threshold criterion: 1. The mean vegetation index for riparian vegetation overstorey[13] taxa (*E. victrix, E. camaldulensis and M. argentea*) of Zones 1 & 2[14] of Jimmawurrada Creek and the Robe River changes by ≥ 2 standard deviations from baseline values over two (2) consecutive sampling events.	As for trigger level actions with the addition of: • If exceedance of threshold criterion is considered likely to be attributable to the Project, submit a report including proposed contingency actions to the DWER. • Implement contingency action/s as agreed with the DWER. • Monitor to ensure contingency actions are successful and review procedures, if appropriate.	As for trigger level monitoring with the addition of monitoring of the effectiveness of contingency actions	• Notify the DWER within 7 days of the non-compliance being known and provide a report within 21 days of the non-compliance being known. • The environmental outcome will be reported against the threshold criterion for each calendar year in the ACAR. • If the threshold criterion was exceeded during the reporting period, the ACAR will include a description of the effectiveness of threshold contingency action/s that have been implemented to manage the potential impact. • Submit a report within 12 months after notification to the DWER of the non-compliance detailing the:

[13] Due to the difficulty in distinguishing *E. victrix* and *E. camaldulensis* (reliance on seed capsules that are not always present), the overstorey riparian vegetation will be represented as a functional group for the trigger and threshold criteria. Should any exceedance occur around these species specific on-ground investigations may be appropriate.

[14] Impacts are predicted in Zone 3 of Jimmawurrada creek which may exceed this trigger periodically during initial dewatering and later in the mine life (estimated to be 2030)

2. A statistically significant decline from baseline (P<0.05) in the number and/or cover of native perennial species over two successive monitoring events			o effectiveness of contingency actions o analysis of trends of riparian tree health o schedule for ongoing reporting.
3. Detection of new introduced species rated high or very high management priority (by DBCA) at a potential impact site, previously not detected within the Development Envelope and a significant cover or abundance over successive monitoring events.			
4. Yeera Bluff (Gnieroora) Pool drops below 1m depth[15]	As for trigger level actions with the addition of: • If exceedance of threshold criterion is considered likely to be attributable to the Project, submit a report including proposed contingency actions to the DWER. • Implement contingency action/s including either: o Cease dewatering below the 120 mRL in Pit 7 of Mesa H. o Option for supplementary water direct to Yeera Bluff Pool o Or actions as agreed with the DWER. • Monitor to ensure contingency actions are successful and review procedures, if appropriate.	As for trigger level monitoring with the addition of monitoring of the effectiveness of contingency actions.	• Notify the DWER within 7 days of the non-compliance being known and provide a report within 21 days of the non-compliance being known. • The environmental outcome will be reported against the threshold criterion for each calendar year in the ACAR. • If the threshold criterion was exceeded during the reporting period, the ACAR will include a description of the effectiveness of threshold contingency action/s that have been implemented to manage the potential impact.

[15] Except where a cyclonic event changes pool morphology

5. Three (3) or less species of fish recorded in Robe River Pools.	• If exceedance of threshold criterion is considered likely to be attributable to the Project, submit a report including proposed contingency actions to the DWER. • Implement contingency action/s as agreed with the DWER. • Monitor to ensure contingency actions are successful and review procedures, if appropriate.	Bi-annual (pre and post wet) survey of semi-permanent and permanent pools	• Submit a report within 12 months after notification to the DWER of the non-compliance detailing the: o effectiveness of contingency actions. o schedule for ongoing reporting.

Environmental criteria	Response actions	Monitoring	Reporting
Supporting[16] riparian and aquatic fauna monitoring parameters for the trigger and threshold criteria			
Riparian overstorey taxa (*E. victrix, E. camaldulensis*)	N/A	• Annual post-wet season survey in selected[17], established transects, as appropriate[18]	N/A
Riparian understorey taxa (native and introduced)	N/A		
Aquatic ecosystems	N/A	• Continue biophysical/ecological survey established in 1991: aquatic fauna (macroinvertebrates and fish), channel/pool morphology, riparian/bank condition, weeds, water flows and water quality.	

[16] Parameters collected during annual surveys will assist in the interpretation of trigger and threshold criteria should an exceedance or trend be noted.

[17] The Proponent will determine "selected" transects from the established transects based on factors such as trigger and threshold outcome from H2 survey, discharge and/ or dewatering extent and volume.

[18] Locations may not always be available due to accessibility, weather conditions, safety concerns etc.

Table 2-7: EMP Provisions – Terrestrial Fauna (Ghost Bat)

Terrestrial fauna – Ghost Bat			
EPA objectives: To protect terrestrial fauna so that biological diversity and ecological integrity are maintained **Key environmental values:** Conservation significant fauna species – Ghost Bat **Key impacts and risks:** Potential loss or degradation of high value (roosting) habitat as a result of implementation of the Project			
Outcome-based provisions			
Outcome: No irreversible[19] impact, as a result of the Project, to Breakaways and Gullies habitat retained in the escarpments of Mesas H			
Environmental criteria	**Response Actions**	**Monitoring**	**Reporting**
Trigger criterion: 1. Vibration levels exceed 50 mm/s peak particle velocity at the potential diurnal/maternal Ghost Bat roost caves as shown in Figure 1-4.	• Complete in-field inspection of the area. • Review blast vibration predictions and blast vibration monitoring data. • Update vibration model if appropriate. • Review supporting Ghost Bat monitoring data.	Blast vibration monitoring for all blasts within 300 m of the potential diurnal/maternal Ghost Bat roosts. Temperature and humidity monitoring in Diurnal Roost caves.	• The environmental outcome will be reported against the trigger criteria for each calendar year by 30 April in the ACAR for MS xxxx. • If the trigger criterion was exceeded during the reporting period, the ACAR will discuss potential reasons for exceedance of the trigger criterion and include a description of the effectiveness of trigger level actions in controlling vibration levels at the potential diurnal/maternal Ghost Bat roost caves.
Threshold criterion: 1. Significant damage[20] to diurnal/maternal Ghost Bat roost caves.	As for trigger level actions with the addition of: • Conduct geotechnical assessment of the site to assess structural stability of the roost. • Review temperature and humidity monitoring data to determine if the roost cave microclimate has been compromised. Remediate any noticeable new cave openings exposed pit-side. • If structural stability of the roost is considered to be compromised as a result of the Project, submit a report including proposed contingency actions to the DWER. • Implement contingency action/s as agreed with the DWER.	As for trigger level monitoring with the addition of monitoring of the effectiveness of contingency actions	• Notify the DWER within 7 days of the non-compliance being known and provide a report within 21 days of the non-compliance being known. • The environmental outcome will be reported against the threshold criterion for each calendar year in the ACAR. • If the threshold criterion was exceeded during the reporting period, the ACAR will include a description of the effectiveness of threshold contingency action/s that have been implemented to manage the potential impact. • Submit a report within 12 months after notification to the DWER of the non-compliance detailing the: o effectiveness of contingency actions o schedule for ongoing reporting.

[19] Where 'irreversible impact' is defined as, 'an impact resulting in a permanent loss of environmental value(s); or where intensive, and/or un-proven management intervention, potentially over a long timeframe, would be required to restore the environmental value(s)'.

[20] Where 'significant damage' is defined as, 'damage that negatively impacts the structural integrity and microclimate of the cave such that future Ghost Bat use of the site is prevented'.

	• Monitor to ensure contingency actions are successful and review procedures, if appropriate.		
Environmental criteria	**Response Actions**	**Monitoring**	**Reporting**
Trigger criterion: 2. Disturbance, other than approved clearing, within 50 m of the recorded back of the potential diurnal/maternal Ghost Bat roost caves	• Complete in-field inspection of the area. • Review site specific observations; clearing extent; blast vibration predictions / blast vibration monitoring levels; and other natural factors (i.e. seasonal rainfall data etc.) to determine if disturbance is attributable to implementation of the Project. • Review supporting Ghost Bat monitoring data • Investigate potential remediation strategies (such as review of land clearing procedure or modified blast management strategy).	Annual land clearing reconciliation against potential diurnal/maternal Ghost Bat roost caves.	• The environmental outcome will be reported against the trigger criteria for each calendar year by 30 April in the ACAR for MS xxxx. • If the trigger criterion was exceeded during the reporting period, the ACAR will discuss potential reasons for exceedance of the trigger criterion and include a description of the effectiveness of trigger level actions in managing disturbance near the potential diurnal/maternal Ghost Bat roost caves.
Threshold criterion: 2. Disturbance, other than approved clearing, within 40 m of the recorded back of the potential diurnal/maternal Ghost Bat roost caves	As for trigger level actions with the addition of: • Conduct geotechnical assessment of the site to assess structural stability of the roost. • If exceedance of threshold criterion is considered likely to be attributable to the Project, submit a report including proposed contingency actions to the DWER. • Implement contingency action/s as agreed with the DWER. • Monitor to ensure contingency actions are successful and review procedures, if appropriate.	As for trigger level monitoring with the addition of monitoring of the effectiveness of contingency actions.	• Notify the DWER within 7 days of the non-compliance being known and provide a report within 21 days of the non-compliance being known. • The environmental outcome will be reported against the threshold criterion for each calendar year in the ACAR. • If the threshold criterion was exceeded during the reporting period, the ACAR will include a description of the effectiveness of threshold contingency action/s that have been implemented to manage the potential impact. • Submit a report within 12 months after notification to the DWER of the non-compliance detailing the: o effectiveness of contingency actions

			o schedule for ongoing reporting.
Supporting[21] Ghost Bat monitoring parameters for the trigger and threshold criteria			
Ghost Bat monitoring	N/A	• Annual assessment of evidence of Ghost Bat use in potential diurnal/ maternal roost caves in the broader Robe Valley	N/A

[21] Parameters collected during annual surveys will assist in the interpretation of trigger and threshold criteria should an exceedance or trend be noted.

Management-based provisions			
Management objective: Improve knowledge of the Ghost Bat population and utilisation of high value habitat in the Robe Valley in order to assist in maintaining biological diversity and ecological integrity			
Management Actions	**Management Targets**	**Monitoring**	**Reporting**
Undertake a five year study of Ghost Bat utilisation of high value habitat.	• Estimate[22] the local population of Ghost Bats in the central part of the Robe Valley. • Indicate how Ghost Bats use caves within the central part of the Robe Valley (e.g. diurnal versus maternal), including the degree of utilisation of caves by pregnant females[23].	Bi-annual collection and analysis (genetic and hormone) of scat samples from across the broader Robe Valley[24].	• The environmental outcome will be reported against the management target for each calendar year by 30 April in the ACAR for MS xxxx. • If a management target was not met during the reporting period, the annual report will include discussion of the effectiveness of the management actions and whether revision of the management actions is required.

[22] Preliminary estimate of the local population based on the data collected during the five year study period

[23] Preliminary indication of utilisation based on the data collected during the five year study period

[24] Access subject to safety and heritage assessments of caves

Table 2-8: EMP Provisions – Terrestrial Fauna (Northern Quoll)

Terrestrial fauna – Northern Quoll			
EPA objectives: To protect terrestrial fauna so that biological diversity and ecological integrity are maintained **Key environmental values:** Conservation significant fauna species – Northern Quoll **Key impacts and risks:** Potential loss or degradation of high value (denning) habitat as a result of implementation of the Project			
Outcome-based provisions			
Outcome: No irreversible[25] impact, as a result of the Project, to Breakaways and Gullies habitat retained in the escarpments of Mesas H			
Environmental criteria	**Response Actions**	**Monitoring**	**Reporting**
Trigger criterion: 1. Disturbance of ≥ 5% of potential Northern Quoll denning habitat on the retained escarpments[26] (MEZs) of Mesa H	• Complete in-field inspection of the area. • Review site specific observations such as clearing extent and natural factors (e.g. seasonal rainfall data) to determine if disturbance is attributable to implementation of the Project. • Review supporting Northern Quoll monitoring data. • Review local/regional reference data. • Increase frequency and/or extent of on-ground assessments as appropriate. • Investigate potential remediation strategies, including rehabilitation.	Annual land clearing reconciliation against escarpments of Mesas H.	The environmental outcome will be reported against the trigger criteria for each calendar year by 30 April in the ACAR for MS xxxx If the trigger criterion was exceeded during the reporting period, the ACAR will discuss potential reasons for exceedance of the trigger criterion and include a description of the effectiveness of trigger level actions in managing disturbance of the mesa escarpments.

[25] Where 'irreversible impact' is defined as, 'an impact resulting in a permanent loss of environmental value(s); or where intensive, and/or un-proven management intervention, potentially over a long timeframe, would be required to restore the environmental value(s)'.

[26] Where disturbance of 'retained escarpments" is disturbance over and above existing or approved disturbance

Environmental criteria	Response Actions	Monitoring	Reporting
Threshold criterion: 1. Disturbance of >10% of potential denning Northern Quoll habitat on the retained escarpments (MEZs) of Mesa H.	As for trigger level actions with the addition of: • If exceedance of threshold criterion is considered likely to be attributable to the Project, submit a report including proposed contingency actions to the DWER. • Implement contingency action/s as agreed with the DWER. • Monitor to ensure contingency actions are successful and review procedures, if appropriate.	As for trigger level monitoring with the addition of monitoring of the effectiveness of contingency actions.	• Notify the DWER within 7 days of the non-compliance being known and provide a report within 21 days of the non-compliance being known. • The environmental outcome will be reported against the threshold criterion for each calendar year in the ACAR. • If the threshold criterion was exceeded during the reporting period, the ACAR will include a description of the effectiveness of threshold contingency action/s that have been implemented to manage the potential impact. • Submit a report within 12 months after notification to the DWER of the non-compliance detailing the: o effectiveness of contingency actions o schedule for ongoing reporting.
Supporting[27] Northern Quoll monitoring parameters for the trigger and threshold criteria			
Northern Quoll monitoring	N/A	Annual field survey of Northern Quoll	N/A

[27] Parameters collected during annual surveys will assist in the interpretation of trigger and threshold criteria should an exceedance or trend be noted.

Table 2-9: EMP Provisions – Subterranean Fauna (Troglofauna)

Subterranean fauna – troglofauna			
EPA objectives: To protect subterranean fauna so that biological diversity and ecological integrity are maintained **Key environmental values:** Subterranean fauna - troglofauna **Key impacts and risks:** Loss of habitat from mining as a result of implementation of the Project			
Outcome-based provisions			
Outcome: No irreversible impact, as a result of the Project, to the troglofauna habitat retained within the Mesa H MEZ			
Environmental criteria	**Response Actions**	**Monitoring actions**	**Reporting**
Trigger criterion: 1. Operational error during mining resulting in removal of greater than 0.01% by volume annually per mesa of the MEZ at Mesas H.	• Review 3-dimensional pit shell and adjust to ensure no predicted net loss of the MEZ per individual mesa (i.e. amend mine plan to ensure retention of the same volume of habitat as approved under MS xxxx; or backfill; or attempt habitat recreation). • Assess the adequacy of work practices and propose changes if necessary to prevent future deviations from the planned 3-dimensional pit shell.	Annual pit shell reconciliation for mine pits at Mesa H	• The environmental outcome will be reported against the trigger criteria for each calendar year by 30 April in the ACAR for MS xxxx • If the trigger criterion was exceeded during the reporting period, the environmental outcome will be reported against the trigger criteria for each calendar year by 30 April in the ACAR for MS xxxx. • If trigger criterion was exceeded during the reporting period, the ACAR will discuss potential reasons for exceedance of the trigger criterion and include a description of the effectiveness of trigger level actions to prevent removal of the MEZ.
Threshold criterion: 1. Net loss of the MEZ at Mesa H at the completion of mining.	As for trigger level actions with the addition of: • If exceedance of threshold criterion is considered likely to be attributable to the Project, submit a report including proposed contingency actions (e.g. backfill; attempt habitat recreation) to the DWER. • Implement contingency action/s as agreed with the DWER. • Monitor to ensure contingency actions are successful and review procedures, if appropriate.	Monitor the effectiveness of contingency actions	• Notify the DWER within 7 days of the non-compliance being known and provide a report within 21 days of the non-compliance being known. • The environmental outcome will be reported against the threshold criterion for each calendar year in the ACAR. • If the threshold criterion was exceeded during the reporting period, the ACAR will include a description of the adequacy of threshold contingency action/s that have been implemented to manage the potential impact. • Submit a report within 12 months after notification to the DWER of the non-compliance detailing the: o adequacy of contingency actions to re-instate the appropriate amount of lost habitat o schedule for ongoing monitoring and reporting.

Management-based provisions			
Management objective: To minimize impacts as far as practicable to protect the biological diversity and ecological integrity of the troglofauna assemblages of Mesa H			
Management actions	**Management targets**	**Monitoring**	**Reporting**
• Maintain MEZ (significant troglofauna habitat). • Minimise ground disturbance and potential for degradation in the retained MEZ habitat.	• Maintain MEZ (significant troglofauna habitat). • Total clearing of native vegetation across the surface of the MEZ is less than 30% of the MEZ surface area. • Troglofauna specimen capture rate is not below the baseline minimum for three consecutive sampling events for Mesa H.	• Annual land clearing reconciliation against escarpments of Mesa H. • Biennial troglofauna field survey.	• The environmental outcome will be reported against the management target for each calendar year by 30 April in the ACAR for MS xxxx. • If a management target was not met during the reporting period, the annual report will include discussion of the effectiveness of the management actions and whether revision of the management actions is required.
Supporting[28] Troglofauna monitoring parameters for the trigger and threshold criteria			
Troglofauna monitoring	N/A	Daily weather and climatic data	N/A

[28] Parameters collected during annual surveys will assist in the interpretation of trigger and threshold criteria should an exceedance or trend be noted.

Table 2-10: EMP Provisions – Subterranean Fauna (Stygofauna)

Subterranean fauna – stygofauna			
EPA objectives: To protect subterranean fauna so that biological diversity and ecological integrity are maintained **Key environmental values:** Subterranean fauna – stygofauna community and Blind Cave Eel **Key impacts and risks:** Loss of habitat from mining (groundwater management) as a result of implementation of the Project			
Outcome-based provisions			
Outcome: No irreversible impact, as a result of the Proponents water management activities, to the stygofauna habitat within the CID aquifer and stygofauna and Blind Cave Eel habitat within the alluvial aquifer habitat of Jimmawurrada Creek and the Robe River shown in Figure 1-6.			
Environmental criteria	**Response Actions**	**Monitoring actions**	**Reporting**
Trigger criterion: 1. Groundwater levels drop three (3) m below predicted water table heights in the Jimmawurrada Creek alluvial aquifer. 2. Diversity of stygofauna Orders collected during annual survey events reduced to 3 or less.	• Review site specific observations such as clearing extent and natural factors (e.g. seasonal rainfall data) to determine if exceedance is attributable to implementation of the Project. • Review trends in alluvial groundwater levels • Review stygofauna monitoring data. • Review local/regional reference data. • Increase frequency and/or extent of monitoring as appropriate. • Investigate potential remediation strategies.	• Monthly monitoring of groundwater levels in alluvial aquifer bores. • Annual stygofauna field survey.	• The environmental outcome will be reported against the trigger criteria for each calendar year by 30 April in the ACAR for MS xxxx • If the trigger criterion was exceeded during the reporting period, the environmental outcome will be reported against the trigger criteria for each calendar year by 30 April in the ACAR for MS xxxx. • If trigger criterion was exceeded during the reporting period, the ACAR will discuss potential reasons for exceedance of the trigger criterion and include a description of the effectiveness of trigger level actions to prevent loss of habitat.
Threshold criterion: 1. Alluvial aquifer is dry for 2 consecutive years. 2. Absence of Blind Cave Eel recorded for two consecutive annual sampling events. 3. Absence of stygofauna specimens for two consecutive sampling events.	As for trigger level actions with the addition of: • If exceedance of threshold criterion is considered likely to be attributable to the Project, submit a report including proposed contingency actions (e.g. backfill; attempt habitat recreation) to the DWER. • Implement contingency action/s as agreed with the DWER. • Monitor to ensure contingency actions are successful and review procedures, if appropriate.	• Monthly monitoring of groundwater in alluvial aquifer bores. • Annual eDNA field survey targeting the Blind Cave Eel. • Annual stygofauna field survey.	• Notify the DWER within 7 days of the non-compliance being known and provide a report within 21 days of the non-compliance being known. • The environmental outcome will be reported against the threshold criterion for each calendar year in the ACAR. • If the threshold criterion was exceeded during the reporting period, the ACAR will include a description of the adequacy of threshold contingency action/s that have been implemented to manage the potential impact. • Submit a report within 12 months after notification to the DWER of the non-compliance detailing the: o adequacy of contingency actions to re-instate the appropriate amount of lost habitat o schedule for ongoing monitoring and reporting.

Management-based provisions			
Management objective: The Proponent shall protect the biological diversity and ecological integrity of the stygofauna assemblages within the CID and Alluvial aquifer habitat shown in Figure 1-6 by minimizing impacts as far as practicable.			
Management actions	**Management targets**	**Monitoring**	**Reporting**
• Continue to improve understanding of stygofauna distribution and ecology by supporting research. (e.g. ARC Linkage Project currently entitled 'Transforming assessment of subterranean ecosystems using environmental DNA'). • Retain significant connected stygofauna habitat.	Understand the distribution and ecology of key stygofauna taxa within the Robe Valley area.	• Annual stygofauna field survey results. • Annual eDNA field survey targeting the Blind Cave Eel.	• The environmental outcome will be reported against the management target for each calendar year by 30 April in the ACAR for MS xxxx. • If a management target was not met during the reporting period, the annual report will include discussion of the effectiveness of the management actions and whether revision of the management actions is required.

Supporting[29] Stygofauna monitoring parameters for the trigger and threshold criteria			
Meteorological monitoring	N/A	Daily weather and climatic data.	N/A
Water quality	N/A	Water quality parameters in alluvial aquifer bores.	

[29] Parameters collected during annual surveys will assist in the interpretation of trigger and threshold criteria should an exceedance or trend be noted.

2.5 Reporting

The management outcomes will be reported against the management target (Table 2-11) for each calendar year in the Annual Compliance Assessment Report (ACAR) for the Mesa J Hub against MS xxxx.

The annual report will also include a summary of the analysis of monitoring data to facilitate adaptive management.

In the event that trigger and threshold criteria are exceeded during the reporting period or management targets are not met, the annual report will include a description of the effectiveness of any management contingency actions that have been implemented to manage the impact. A stand-alone report will also be produced for the DWER within 21 days of any exceedance of the threshold criteria. A follow up report detailing the adequacy of the response actions will also be submitted to the DWER within 12 months of the initial notification.

Table 2-11: Mesa J Hub Environmental Management Plan Reporting Table

Key environmental factors: Inland waters, vegetation and aquatic fauna; terrestrial fauna (Ghost Bat and Northern Quoll); subterranean fauna (troglofauna and stygofauna).	
Condition environmental outcome, trigger and threshold criteria as per MS xxxx	**Reporting period** **1 January - 31 December**
Trigger criteria:	**Status report:** Environmental outcome achieved Environmental outcome not achieved
Inland waters, vegetation and aquatic fauna 1) The mean vegetation index for riparian overstorey[30] taxa (*E. victrix, E. camaldulensis and M. argentea*) of Zones 1 & 2[31] of Jimmawurrada Creek and the Robe River changes by ≥ 2 standard deviations. 2) A statistically significant decline from baseline ($p<0.05$) in the number and/or cover of native perennial species of Zones 1 & 2 of Jimmawurrada Creek 3) Detection of new introduced species at a potential impact site, not previously detected within the Development Envelope. [surplus water discharge] 4) Decline of >0.5m between paired Alluvial Aquifer bores[32] in the Robe River near targeted pools. 5) Yeera Bluff (Gnieroora) Pool drops below 2m depth. 6) Water quality in pools exceeds rolling quarterly median measured against the operational guideline SSTV equivalent of 95%ile value of baseline or the ANZECC/ARMCANZ (2000) default TV for toxicants for protection of 95% of species, whichever is higher (except for pH).	
Ghost bat 1) Vibration levels exceed 50mm/s peak particle velocity at the potential diurnal/maternal Ghost Bat roost caves. 2) Disturbance, other than approved clearing, within 50m of the recorded back of the potential diurnal/maternal Ghost Bat roost caves.	
Northern Quoll 1) Disturbance of >5% of potential Northern Quoll denning habitat on the retained escarpment of Mesa H.	

[30] Due to the difficulty in distinguishing E. *victrix* and *E. camaldulensis* (reliance on seed capsules that are not always present), the overstorey riparian vegetation will be represented as a functional group for the trigger and threshold criteria. Should any exceedance occur around these species specific on-ground investigations may be appropriate.

[31] Impacts are predicted in Zone 3 of Jimmawurrada creek which may exceed this trigger periodically during initial dewatering and later in the mine life (estimated to be 2030)

[32] Alluvial Bore locations subject to approval from the Kurama Marthadunera People.

Key environmental factors: Inland waters, vegetation and aquatic fauna; terrestrial fauna (Ghost Bat and Northern Quoll); subterranean fauna (troglofauna and stygofauna).	
Condition environmental outcome, trigger and threshold criteria as per MS xxxx	**Reporting period** **1 January - 31 December**
Troglofauna 1) Operational error during mining resulting in removal of greater than 0.01% by volume annually of the MEZ at Mesa H.	
Stygofauna 1) Groundwater levels drop three (3) m below predicted water table heights in the Jimmawurrada Creek alluvial aquifer. 2) Diversity of stygofauna Orders collected during annual survey events reduced to three (3) or less	
Threshold criteria:	**Status report:** Environmental outcome achieved Environmental outcome not achieved
Inland waters, vegetation and aquatic fauna 1) The mean vegetation index for riparian vegetation overstorey (upper canopy) taxa (E. victrix, E. camaldulensis and M. argentea) of Zones 1 & 2 of Jimmawurrada Creek and the Robe River declines by ≥ 2 standard deviations from baseline values over two consecutive sampling events. 2) Statistically significant decline from baseline ($p<0.05$) in the number and/ or cover of native perennial species of Zones 1 & 2 of Jimmawurrada Creek and the Robe River. 3) Statistically significant decline from baseline ($p<0.05$) in the number and/or cover of native perennial species over two successive monitoring events. 4) Decline of ≥1 m between paired Alluvial Aquifer bores in the Robe River near targeted pools. 5) Yeera Bluff (Gnieroora) Pool drops below 1m depth[33]. 6) Three (3) or less species of fish recorded across all sampled Robe River Pools.	
Ghost bat 1) Significant damage to diurnal/maternal Ghost Bat roost caves. 2) Disturbance, other than approved clearing, within 40m of the recorded back of the potential diurnal/maternal Ghost Bat roost caves.	
Northern Quoll 1) Disturbance of >10% of potential denning Northern Quoll habitat on the retained escarpment of Mesa H.	

[33] Except where a cyclonic event changes pool morphology

Key environmental factors: Inland waters, vegetation and aquatic fauna; terrestrial fauna (Ghost Bat and Northern Quoll); subterranean fauna (troglofauna and stygofauna).	
Condition environmental outcome, trigger and threshold criteria as per MS xxxx	**Reporting period** **1 January - 31 December**
Troglofauna 1) Net loss of the MEZ at Mesa H, at the completion of mining.	
Stygofauna 1) Alluvial aquifer in Jimmawurrada is dry for two (2) consecutive years. 2) Absence of Blind Cave Eel recorded for two (2) consecutive annual sampling events. 3) Absence of stygofauna specimens for two (2) consecutive annual sampling events.	
Management-based targets:	**Status report:** Environmental target achieved Environmental target not achieved
Ghost bat 1) Estimate the local population of Ghost Bats in the central part of the Robe Valley. 2) Indicate how Ghost Bats use caves within the central part of the Robe Valley (e.g. diurnal versus maternal), including the degree of utilisation of caves by pregnant females.	
Troglofauna 1) Total clearing of native vegetation across the surface of the MEZ is less than 30% of the MEZ surface area. 2) Troglofauna specimen capture rate is not below the baseline minimum for three (3) consecutive sampling events at Mesa H.	
Stygofauna 1) Understand the distribution and ecology of key stygofauna taxa within the Robe Valley area.	

3. ADAPTIVE MANAGEMENT AND REVIEW OF THIS EMP

The Proponent will implement adaptive management to learn from the implementation of mitigation measures, monitoring and evaluation against trigger and threshold criteria, to more effectively meet the conditioned environmental outcome.

The following approach will apply:

- Monitoring data will be systematically evaluated and compared to baseline and reference site data on a regular basis in a process of adaptive management to verify whether riparian vegetation responses to the impact are the same or similar to predictions.
- The effectiveness and relevance of trigger level and threshold contingency actions will be evaluated on an annual basis to determine if any changes to management actions are required.
- The effectiveness and relevance of management actions will be evaluated on an annual basis to determine is any changes are required.

4. STAKEHOLDER CONSULTATION

Consultation specific to this EMP will be undertaken during the Environmental Impact Assessment process for the Mesa H Proposal. Consultation will be documented and any concerns will be addressed prior to finalisation of the EMP. Stakeholder consultation will include the Department of Biodiversity, Conservation and Attractions - Park and Wildlife Service and the Department of Water and Environmental Regulation – EPA Services and Compliance and Reporting (Water).

6. APPENDIX

Appendix 1: Baseline Troglofauna 'hit rate' for Mesa H

Change in specimen capture rate over time for troglofauna recorded from the Mesa H landform.

Collection rate has been converted to a rate per 100 trapped holes. Data tracks changes over eight sampling events spanning 12 years including pre mining initiation. The variation in collection rate is naturally large (17 to 228.6). Larger collection rates are more likely influenced by rainfall prior to sampling rather than mining, however the required timing and size of the rainfall event is still uncertain from the current data. All troglobitic but indeterminate specimens are included in these calculations for completeness. Specimens collected via scraping have been omitted; this collection method was only employed in recent sampling events and is thus will not be comparable pre and post mining. Weather information was taken from Pannawonica BOM Station.

Mesa H	**Pre-mining**

EXECUTIVE SUMMARY

Overview

The Mesa J Hub deposits include Mesa J, Mesa K and Mesa H, and are located in the Pilbara region of Western Australia, approximately 16km from Pannawonica in the Shire of Ashburton. The deposits are located within the traditional lands of the Kuruma Marthudunera people and the area is managed by Robe River Mining Co Pty Limited, which is a member of the Rio Tinto Group.

The Mesa K mine commenced operations in 1988 and Mesa J in 1992, and comprise open cut operations utilising conventional drill-and-blast and load and haul mining methods. Ore is crushed on-site before being transported via rail to Cape Lambert for shipping. This closure plan incorporates the current Mesa J and K operation and has been extended to include the adjacent Mesa H deposit.

The currently approved Mesa J and Mesa K mines have an operational life of 13 years with completion of mining scheduled for 2029. The proposed development of Mesa H will incorporate mining until 2037. Mineral waste generated by mining will be placed in a small number of external dumps as well as progressively backfilled into pit voids as they become available. The site is expected to encounter some highly erodible materials which will be used for pit backfill or placed in external waste dumps with appropriate final parameters and/or capping with competent waste. The site has been assessed as having a low geochemical risk and is not expected to encounter acid or metalliferous drainage during mining or post closure.

Scope

This document, titled ‘Mesa J Hub Closure Plan July 2018’, represents the updated closure plan for the Mesa J and K operations and proposed Mesa H operations and supersedes previous closure plans. It is applicable to mine developments and all associated infrastructure at Mesa J Hub iron ore deposits within the following leases:

- ML248SA Section 103 (Part)
- ML248SA Section 104

The scope of the plan has been aligned to existing tenure boundaries, which may differ from the footprint approved or referred under Part IV of the *Environmental Protection Act 1986.*

Post-mining land use

Post-mining land use options in the Pilbara are generally limited due to the remote location. The proposed final land use assumes that the site will be rehabilitated to create a safe, stable and non-polluting landscape revegetated with native species, to maximise environmental and cultural heritage outcomes and ensure the site does not adversely impact on the current surrounding land use.

Due to the nature of the mining activity undertaken, the final landform will include large voids and waste dumps, and will therefore be unlikely to support pastoral activities in the immediate disturbed areas. However, it is recognized that surrounding areas are likely to remain subject to pastoral activity. For the purpose of this closure plan, it is assumed that the post closure landform will be shaped and rehabilitated to support ongoing pastoral activity and to ensure that the visual amenity and associated heritage and ecological values will be retained in the post closure landform. The final land use will be determined prior to closure during final planning phases and in consultation with relevant stakeholders.

Closure objectives

The following objectives have been developed in relation to the closure strategy contained within this closure plan:

- Public safety hazards have been managed.
- Contaminated sites are appropriately managed in accordance with the Contaminated Sites Act 2003 (WA).
- Final landform is stable and considers ecological and hydrological issues.
- Vegetation on rehabilitated land is self-sustaining and compatible with the final land use.
- Infrastructure has been appropriately managed.
- Robe River permanent pools function similar to the pre-mining state.

Indicative completion criteria have been proposed for each of these objectives; however these have not been the subject of consultation with stakeholders at this point, which is considered acceptable given the long timeframe for mining operations for this site.

Anticipated closure outcome

At closure all below water table pits (with the exception of pit 15 at Mesa J) will be backfilled to suppress the formation of pit lakes. Above water table pits will be backfilled opportunistically with waste. Several pits in the Mesa J mining area will be backfilled with waste fines and capped with inert waste rock. Mining exclusion zones will remain undisturbed as agreed. External waste dumps will be reprofiled to meet final design parameters. Disturbed surfaces will be rehabilitated including pit floors (excluding pit faces). Abandonment bunding or other appropriate means of access restriction will be placed around pits as described within the plan. Disturbed landform features will be rehabilitated with appropriate native species.

CLOSURE PLAN CHECKLIST

The following table provides cross reference to the requirements of the Department of Mines and Petroleum / Environmental Protection Authority *Guidelines for preparing mine closure plans* (2015).

	Mine Closure Plan (MCP) Checklist	Y/N/NA	Page No.	Comments	Change from previous version (Y/N)	Page No.	Comments
1	Has the Checklist been endorsed by a senior representative within the operating company?						
Public Availability							
2	Are you aware that from 2015 all MCPs will be made publically available?	Y	NA				
3	Is there any information in this MCP that should not be publicly available?	Y	Appendix C				
4	If "Yes" to Q3, has confidential information been submitted in a separate document / section?	Y	Appendix C				
Cover page, table of contents							
5	Does the MCP cover page include: Project Title, Company Name, Contact Details (including telephone numbers and email address) Document ID and version number, Date of submission (needs to match the date of this checklist)	Y					
Scope and purpose							
6	State why the MCP is submitted (e.g. as part of a Mining Proposal, a reviewed MCP or to fulfil other legal requirement)	Y	1				
Project overview							
7	Does the project summary include land ownership details, location of the project, comprehensive site plans and background information on the history and status of the project?	Y	3-47				

	Mine Closure Plan (MCP) Checklist	Y/N/NA	Page No.	Comments	Change from previous version (Y/N)	Page No.	Comments
Legal obligations and commitments							
8	Does the MCP include a consolidated summary or register of closure obligations and commitments been included?	Y	Appendix A				
Stakeholder engagement							
9	Have all stakeholders involved in closure been identified?	Y	12				
10	Does the MCP included a summary or register of historic stakeholder engagement been provided, with details on who has been consulted and the outcomes?	Y	Appendix B				
11	Does the MCP include a stakeholder consultation strategy to be implemented in the future?	Y	12				
Post mining land use(s) and closure objectives							
12	Does the MCP include agreed post-mining land use, closure objectives and conceptual landform design diagram?	Y	13, 13 and Appendix F	Preliminary final land use options, closure objectives and final landform design is presented in the plan. These will continue to be refined during operations and agreed with relevant parties prior to closure.			
13	Does the MCP identify all potential (or pre-existing) environmental legacies which may restrict the post mining land use (including contaminated sites)?	NA		There are no contaminated sites associated with the operation.			
14	Has any soil or groundwater contamination that occurred, or is suspected to have occurred, during the operation of the mine, been reported to DER as required under the Contaminated Sites Act 2003?	NA		There are no known or suspected contaminated sites associated with the operation.			

	Mine Closure Plan (MCP) Checklist	Y/N/NA	Page No.	Comments	Change from previous version (Y/N)	Page No.	Comments
Development of completion criteria							
15	Does the MCP include an appropriate set of specific completion criteria and closure performance indicators?	Y		14			
Collection and analysis of closure data							
16	Does the MCP include baseline data (including pre-mining studies and environmental data)	Y	18 and Appendix C				
17	Has materials characterisation been carried out consistent with applicable standards and guidelines (e.g. GARD Guide)?	Y	24				
18	Does the MCP identify applicable closure learnings from benchmarking against other comparable mine sites?	Y	Appendix C				
19	Does the MCP identify all key issues impacting mine closure objectives and outcomes (including potential contamination impacts)?	Y	49				
20	Does the MCP include information relevant to mine closure for each domain or feature?	Y	59				
Identification and management of closure issues							
21	Does the MCP include a gap analysis / risk assessment to determine if further information is required in relation to closure of each domain or feature?	Y	48 and Appendix D				
22	Does the MCP include the process, methodology and has the rationale been provided to justify identification and management of the issues?	Y	48 and Appendix D				

	Mine Closure Plan (MCP) Checklist	Y/N/NA	Page No.	Comments	Change from previous version (Y/N)	Page No.	Comments
Closure Implementation							
23	Does the MCP include a summary of closure implementation strategies and activities for the proposed operations or for the whole site?	Y	59				
24	Does the MCP include a closure work program for each domain or feature?	Y	59	To be developed prior to closure			
25	Does the MCP contain site layout plans to clearly show each type of disturbance as defined in Schedule 1 of the MRF Regulations?	Y	62	Mine layout is included in the plan and discussed in detail; however it is not categorised according to MRF regulations.			
26	Does the MCP contain a schedule of research and trial activities?	Y	Appendix E				
27	Does the MCP contain a schedule of progressive rehabilitation activities?	N		Indicative closure schedule provided. Opportunities for rehabilitation assessed annually			
28	Does the MCP include details of how unexpected closure and care and maintenance will be handled?	Y	66				
29	Does the MCP contain a schedule of decommissioning activities?	N		To be developed prior to closure			
30	Does the MCP contain a schedule of closure performance monitoring and maintenance activities?	Y	67				
Closure monitoring and maintenance							
31	Does the MCP contain a framework, including methodology, quality control and remedial strategy for closure performance monitoring including post-closure monitoring and maintenance?	N		To be developed prior to closure			

	Mine Closure Plan (MCP) Checklist	Y/N/NA	Page No.	Comments	Change from previous version (Y/N)	Page No.	Comments
Financial provisioning for closure							
32	Does the MCP include costing methodology, assumptions and financial provision to resource closure implementation and monitoring?	Y	68				
33	Does the MCP include a process for regular review of the financial provision?	Y	68				
Management of information and data							
34	Does the MCP contain a description of management strategies including systems and processes for the retention of mine records?	Y	69				

Corporate endorsement:

I hereby certify that to the best of my knowledge, the information within this Mine Closure Plan is true and correct and addresses the relevant requirements of the *Guidelines for Preparing Mine Closure Plans* approved by the Director General of Mines and Petroleum.

SCOPE AND PURPOSE

1. Purpose

Planning for closure of a site is a critical business process that demonstrates Rio Tinto's commitment to sustainable development. This closure plan follows the format and content requirements for mine closure plans as recommended in the Department of Mines and Petroleum (DMP) / Environmental Protection Authority (EPA) *Guidelines for preparing mine closure plans* (2015).

This closure plan has been developed to achieve the following goals:

- to reflect the current knowledge and requirements for closure of Mesa H, Mesa J and Mesa K mines (collective known from here as the Mesa J Hub) and identify the future requirements to continue to progress towards a planned and managed closure of the site;
- to inform the development of closure provisions;
- to meet the internal requirements of the Rio Tinto Closure Standard (2015) mandated for all Rio Tinto businesses;
- for submission to the Department of State Development, to satisfy a request from that Department; and
- to support the environmental approval of the Mesa H Deposit.

2. Scope

This plan covers the current mining operations at Mesa J and K deposits, and the proposed development of the Mesa H deposit. The plan is applicable to areas and mine development features within the following leases[1],

- ML248SA Section 103 (Part);
- ML248SA Section 104.

The plan excludes the following:

- The Pannawonica town and associated access roads
- The mainline rail and associated infrastructure
- Previously developed deposits at Eastern Deepdale and Middle Robe
- The Coastal Water Project (a water supply borefield feeding into the public water system)
- Other undeveloped deposits in the Robe Valley.

The plan will refer to the areas described above as the 'Mesa J Hub' throughout this document.

This closure plan supersedes all previous closure, decommissioning and rehabilitation plans for the Mesa J Hub.

The Robe JV hold mineral leases pursuant to the RR Agreement Act over multiple undeveloped deposits in the Robe Valley. Development of several of these deposits will potentially require continued utilisation of the Mesa J Hub infrastructure after completion of mining at the Mesa J, K and H deposits. These future developments are excluded from the scope of this current Mesa J Hub closure plan, but will be included in future closure plan updates with improved certainty of the specifics of these developments.

[1] Note that the scope of the closure plan has been aligned to tenure boundaries, which may differ from the footprint approved or referred under Part IV of the *Environmental Protection Act 1986*.

2.1 Closure Planning Process

Closure planning is an iterative process that commences during the planning phase of the mine development and is regularly updated and refined during the operational phase (Figure 1). Closure plans are updated to account for changes resulting from:

- amendments to the mine plan;
- improvements of the site closure knowledge base (e.g. through daily activities, technical studies and research actions, progressive rehabilitation);
- new or amended regulation;
- changes to surrounding land uses; and
- evolving stakeholder expectations.

Reviews brings specialists together to discuss current performance, proposed mine changes and opportunities to improve closure outcomes. At the end of the review, improvement actions are assigned and the closure plan is updated.

A key output of closure planning is the development of a closure cost estimate. Closure provisions are subsequently integrated into our business planning processes to ensure funds will be available to close the site effectively.

The detail of each closure plan increases as the knowledge base develops. When the site approaches scheduled closure, studies will be completed to define how infrastructure, decontamination, rehabilitation, the workforce and communications will be managed throughout the mine closure period (and beyond). Stakeholder engagement continues and endorsement of completion criteria is conducted at this time.

In the final closure plan, location specific management plans are provided for each closure domain. These detailed plans cover the physical closure, dismantling and subsequent rehabilitation implementation requirements. The supporting technical reports that have been used to predict the post-closure outcomes are appended to the final closure plan.

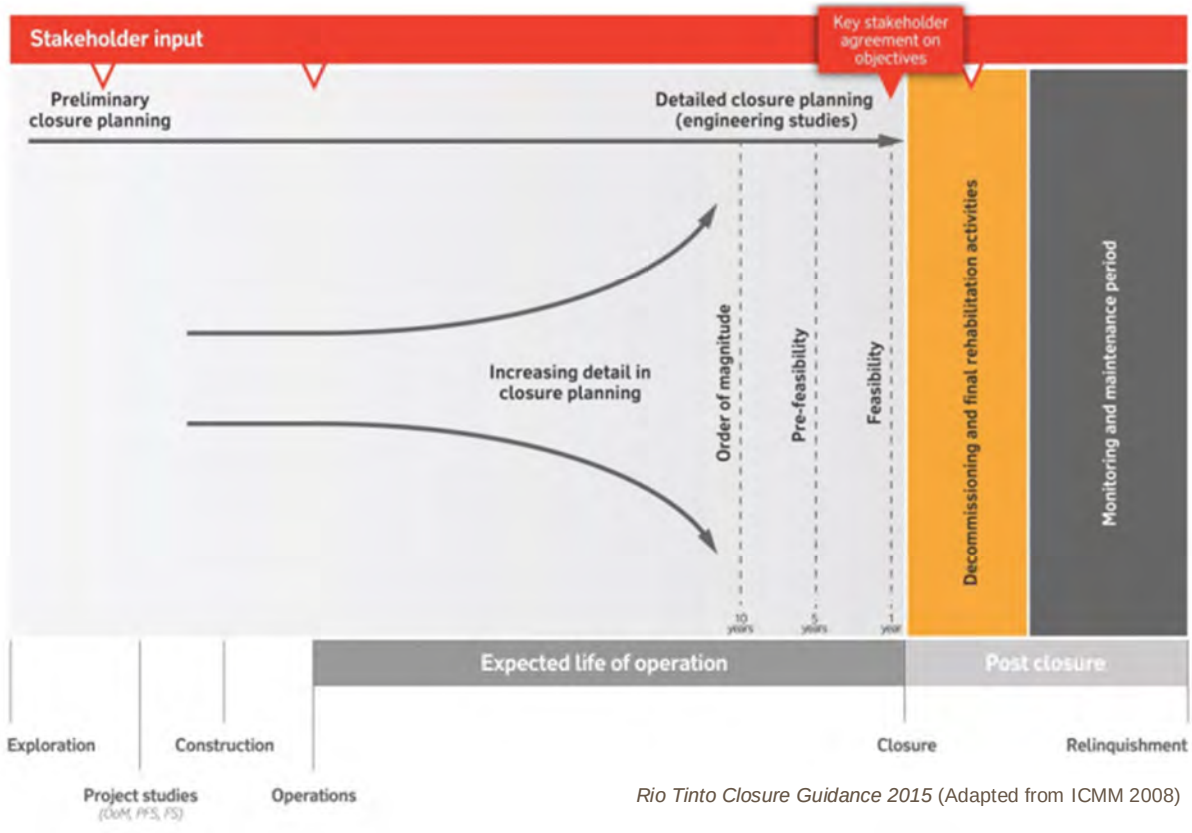

Figure 1: Progression of closure planning

PROJECT OVERVIEW

3. Description of the operation

3.1 Location

The Mesa J Hub includes Mesa H, Mesa J and Mesa K deposits, and is located in the Pilbara region of Western Australia, approximately 100km east of Onslow and 14km southwest of the township of Pannawonica (Figure 2, Figure 3).The area falls within the local authority of the Shire of Ashburton. Tenure associated with current and proposed mining activities is shown in Figure 4, and listed above in Section 2. The mine is located within the traditional lands of the Kuruma Marthudunera (K&M) people (Figure 5). The nearest Aboriginal community is a small settlement known as "The Block" located three kilometres north of Mesa H, which is not permanently occupied.

The Mesa J Hub is overlain by pastoral leases as shown in Figure 4. The eastern operations of Mesa J and K fall within the Yalleen Station (N049492) lease and the western side of Mesa J and H fall within the Yarraloola Station (N049500) lease. Both Yalleen and Yarraloola Stations are owned by Robe River Iron Associates, which is majority owned by Rio Tinto. Both stations are currently sub-leased, with Yalleen managed by Williambury Station Pty Ltd and Yarraloola managed by Cardoo Holdings.

The site is located in proximity to various sensitive environmental and cultural heritage receptors. The ephemeral Robe River is located immediately north of Mesa J and H and south of Mesa K, with permanent and semi-permanent pools occurring in proximity to the deposits. The Robe River and associated pools, together with the mesa landform, have significant cultural value for the local indigenous people. The Robe River and pools, and the breakaway landform on the mesa perimeter, also have value for local biodiversity. There are two Priority Ecological Communities (PEC's) associated with troglofauna communities in mesa landforms of the Robe Valley, comprising 'Subterranean invertebrate communities of mesas in the Robe Valley region' and 'Subterranean invertebrate community of pisolitic hills in the Pilbara'.

The Mesa J Hub is operated under a Joint Venture (JV) agreement of which Rio Tinto owns the majority share. The allocations are as follows;

- Rio Tinto (53%)
- Mitsui Iron Ore Development Pty Ltd (33%)
- Pannawonica Iron Associates (10.5%); and,
- Cape Lambert Iron Associates (3.5%).

3.2 Mine Operations

The Mining operations currently managed by the Robe JV have been active in the Robe Valley for over 40 years at multiple locations, facilitated by the *RR Agreement Act 1964* (Agreement Act). Robe JV deposits within the scope of this closure plan comprise the following:

- Mesa J deposit, which commenced mining in 1992.
- Mesa K deposit 1.5 km north-east of Mesa J, that commenced mining in 1988,
- Mesa H deposit, immediately west of Mesa J, which is proposed for development from 2019.

At Mesa J and K, iron ore is mined using conventional open cut mining methods of drilling and blasting, and load and haul. Waste rock is hauled to designated waste dumps or to back fill unused pits, with a priority to store in unused pits. Only a limited number of external dumps are proposed. Ore is hauled to the processing plants at Mesa J, with product transported to Cape Lambert via rail. Mining of the Mesa H deposit will follow a similar method with ore hauled to the Mesa J plants for processing. Minor expansion of the Mesa J plant facilities will occur.

The Mesa J, K and H deposits have a current combined operational life of 20 years with completion of mining scheduled for 2037. The current mine development schedule is outlined in Table 1 below. The mine schedules and plans are subject to regular review to ensure optimised performance of the operations and are therefore subject to change over time. The key landforms associated with the mine are shown in Table 2 below, and the proposed construction and rehabilitation design criteria for these landforms are included in Appendix F. The proposed mine layout is shown in Figure 6.

Table 1: Indicative mining schedule

Deposit	Pit	Commencement	Completion	Description	Regulatory Status

IDENTIFICATION OF CLOSURE OBLIGATIONS AND COMMITMENTS

4. Legal obligations

A closure obligations register is presented as Appendix A. It contains details of legal obligations from the following instruments:

- *Iron Ore (Robe River) Agreement Act 1964*;
- Ministerial Statement 208 (Mesa J Iron Ore Development);
- Ministerial Statement 776 (Mesa K Remnant Mining Project);
- relevant Native Vegetation Clearing Permits (NCVP); and
- mineral leases issued under the *Mining Act 1978* pursuant to approval under the *Iron Ore (Robe River) Agreement Act 1964*.

The register also identifies legislation, standards and guidelines that may not apply to Mesa J Hub specifically, but that may be relevant to closure of mine sites generally.

STAKEHOLDER ENGAGEMENT

5. Stakeholder engagement

5.1 Engagement process

Stakeholder engagement is a key part of mine closure planning as it ensures that the expectations of stakeholders are understood by the mine operator and these can be considered and managed during the planning and implementation phase of closure. Rio Tinto has established processes for consultation with stakeholders, these are imbedded in both the Rio Tinto *Mine closure standard* (2015) and *Community and social performance standard* (2015). These standards are aligned with principles from the Australian and New Zealand Minerals and Energy Council and the Minerals Council of Australia (ANZMEC/MCA, 2000). Consultation commences at appropriate times during the early stages of exploration planning and will continue until the final relinquishment of the site.

As part of this process all likely impacted stakeholders are identified and recorded in a register. This register is used to ensure relevant and timely communications are held with stakeholders across a broad range of topics relevant to the mining operations, including closure, and is regularly reviewed and updated to maintain currency. Regular consultation is conducted with a wide range of stakeholders via a variety of forums, for example various State and Local Government agency briefing meetings and Traditional Owner consultation forums established under Indigenous Land Use Agreements. Discussions regarding closure and related activities are included in these meetings as appropriate. The level of closure specific content and detail will increase as closure approaches (see Figure 1).

A communications register specifically for closure of Mesa J Hub is maintained and a copy as at the time of writing is included in Appendix B. This register is used to ensure stakeholder feedback is tracked and monitored to ensure that appropriate actions are taken to address these issues in a timely manner.

POST-MINING LAND USE AND CLOSURE OBJECTIVES

6. Post-mining land use

6.1 Historical land use

The Pilbara is classified as an Extensive Land Use Zone. The lands surrounding the mine are the traditional lands recognised as belonging to the Kuruma and Marthudunera (K&M) people. Since European settlement land uses in the region have included cattle grazing, exploration and mining and conservation reserves. Prior to the commencement of this mine the immediate area was primarily used for pastoral purposes.

6.2 Proposed post-mining land use

Options for post-mining land use in this region are considered limited. However it is recognised that there is an increasing focus on seeking options for diversification of land use and options which are currently unidentified or not considered viable may eventually be implemented.

The proposed final land use assumes that the site will be rehabilitated to create a safe, stable and non-polluting landscape revegetated with native species, to maximise environmental and cultural heritage outcomes and ensure the site does not adversely impact on the current surrounding land use.

Due to the nature of the mining activity undertaken, the final landform will include large voids and waste dumps, and will therefore be unlikely to adequately support pastoral activities in the immediate disturbed areas. However, it is recognized that surrounding areas are likely to remain subject to pastoral activity, and the Mesa J Hub closure needs to be undertaken in such a manner that minimizes land use impacts.

Visual representation of the site at completion of mining, and after completion of proposed rehabilitation activities are included in Figure 28 to Figure 32.

7. Closure objectives

7.1 Rio Tinto vision for closure in the Pilbara

Closure objectives have been developed with consideration of Rio Tinto's general vision for closure, which is to:

- Relinquish its mining leases to the Western Australian State Government.
- Preserve, protect and manage the cultural heritage values of the area in cooperation with the Traditional Owners and other stakeholders.
- Develop and implement strategies for closure which consider the implications on local communities.
- Achieve completion criteria which have been developed with stakeholders and agreed with WA Government.
- Develop landforms that are safe and stable and compatible with the surrounding environment and post-mining land use.
- Achieve environmental outcomes that are compatible with the surrounding environment.
- Implement a workforce strategy which addresses the impacts of closure on employees and contractors.
- Achieve successful closure in a cost effective manner.

7.2 Mesa J Hub closure objectives

The site specific closure objectives that are proposed for the Mesa J Hub are shown in Table 3, along with the proposed criteria for how these objectives will be assessed and measured (completion criteria).

Due to the early stage of closure these objectives require further consultation with key stakeholders and are likely to evolve in future versions of this plan as knowledge of closure issues progresses and detailed closure discussions commence.

8. Completion criteria

Completion criteria are defined as the indicators used to determine whether closure objectives have been met. They are used to measure the success of closure implementation against objectives, and to facilitate relinquishment of mining tenure.

The completion criteria, as detailed in Table 3, have been developed in consideration of the predicted closure outcomes. Measurement processes and the associated supporting data (evidence and / or metrics), that could be used to evaluate the success of closure at Mesa J Hub are also described in Table 3.

The completion criteria are subject to ongoing review and update, informed by the outcome from studies, monitoring and ongoing stakeholder consultation. Given the number of years until scheduled closure the completion criteria contained in this plan should be considered indicative only. As the site approaches scheduled closure the completion criteria will continue to be refined.

Table 3: Indicative completion criteria

Objective	Indicative completion criteria	Verification process/method	Evidence
Public safety hazards have been managed.	1) Safety and health risks have been identified. 2) Measures to mitigate the identified public safety (and fauna where appropriate) and human health hazards have been agreed with key stakeholders and have been implemented. 3) Transfer of any residual liabilities is agreed with stakeholders.	1) Risk assessment conducted and mitigation actions implemented. 2) Relevant stakeholders have been engaged on risk mitigation measures to be employed. 3) Independent audit(s)/review to confirm that hazard mitigation measures have been implemented. 4) Process for transfer of residual liabilities is documented.	1) Risk assessment report. 2) Audit report to confirm effectiveness of controls. 3) Records of stakeholder engagement. 4) Liability transfer agreement/s.
Contamination risks have been appropriately managed.	1) Requirements under the Contaminated Sites Act 2003 (WA) have been met for the identification, recording, management, remediation and transfer of any contaminated sites as appropriate.	1) The site has been appropriately assessed for the presence of suspected or known contaminated sites. 2) Suspected or known contaminated sites have been appropriately reported under the Contaminated Sites Act 2003. 3) Appropriate management measures to address contamination have been implemented. 4) Process for transfer of residual liabilities is documented.	1) Contaminated sites investigation report/s. 2) Reports submitted to the Department of Environment Regulation (if required). 3) Liability transfer agreement/s. (if required).

Objective	Indicative completion criteria	Verification process/method	Evidence
Final landform[4] is stable and considers ecological and hydrological factors.	1) There are no erosion features present that compromise landform integrity, and if present, erosion features are stable. 2) The final landform was designed and constructed with consideration given to its stability during intense rainfall and large flood events. 3) Final landforms are outside predicted zones of instability of pits. 4) Mining exclusion zones remains as per approval. 5) Ground water levels and quality are trending towards acceptable ranges to support stygofauna and ground water dependant ecosystems (outside mining areas). 6) Backfill of the final landform (with the exception of Pit 15) has been undertaken to prevent formation of pit lakes and facilitate ground water recovery. 7) Operational drainage structures have been constructed or modified to consider local surface water regimes post closure.	1) Rehabilitation monitoring program including quantitative evaluation of behaviour of rills and gullies (if required) over time. 2) Analysis of aerial imagery to provide qualitative analysis of landform stability. 3) Post-closure landform review to confirm that risks have been appropriately managed. 4) Survey of exclusion zones.	1) Rehabilitation monitoring results. 2) Post closure landform evaluation report. 3) Façade assessment. 4) Survey data assessment. 5) Ground water monitoring report 6) Drainage design report
Vegetation on rehabilitated land is self-sustaining and compatible with the final land use.	1) Seed used in rehabilitation works is of local provenance[5]. 2) Native plants within rehabilitated areas are observed to flower and/or fruit. 3) Recruitment of native perennial plants is observed. 4) Species richness[6] of native perennial plants within rehabilitated areas is not less than reference sites. 5) Any weed species recorded within rehabilitation areas are present within the local area. 6) Erosion from landforms does not threaten surrounding significant natural ecosystems (Robe River Pools).	1) Rehabilitation monitoring/site inspections. 2) Analysis of historical monitoring data.	1) Rehabilitation monitoring reports. 2) Ecological monitoring reports.

[4] 'Landform' includes all post mining constructed features: waste dumps, waste fines storage facilities, abandonment bunds and pits.

[5] Note: Some seed used in rehabilitation predates accurate recording of collection area. Note 2: Local is defined as Pilbara IBRA

[6] Richness is defined as the number of different species in the defined area.

Objective	Indicative completion criteria	Verification process/method	Evidence
Infrastructure appropriately managed.	1) Legal agreement to transfer residual liability completed (if required). 2) Where transfer of liability is not established, infrastructure has been decommissioned and removed.	1) Appropriate agreements and transfer processes in place and communicated for any infrastructure remaining post closure.	1) Agreements in place with party assuming liability for infrastructure. 2) Close out report 3) Visual inspection
Robe river pools (in proximity to Mesa J Hub) function similar to the pre-mining state.	1) Water quality in Robe River pools is comparable to natural local ecosystems. 2) Ecological function of the pools is comparable to natural local ecosystems incorporating climate changes.	1) Surface and groundwater quality monitoring. 2) Environmental and Ecological monitoring.	1) Water quality reports. 2) Ecological monitoring reports.

COLLECTION AND ANALYSIS OF CLOSURE DATA

The closure knowledge base (Appendix C) is a collection of baseline studies, models and interpretations, which are used to inform the closure planning process presented in this closure plan. The knowledge may be specific to the site or generally applicable to the Pilbara region; and includes information on the performance of closure-related trials completed at other Pilbara mining operations (when appropriate). At this stage of the closure plan development, only summaries of these reports are provided and the relevant information is summarised in this section. The relevant knowledge base reports will be included in the final closure plan.

9. Climate

The closest official Bureau of Meteorology weather recording station is at Pannawonica (station 005069), which is approximately 15km to the northeast of the Mesa J Hub. Climatic information has been captured from this site since 1971. In addition, Rio Tinto maintains an automatic weather station at Mesa J itself. Information in this closure plan is sourced from both stations.

9.1 Climate and significant weather events

The climate in the area can be characterised as arid tropical with two distinct seasons, hot wet summers and cooler dry winters. Mean daily maxima temperatures range from 41°C in summer to 27°C in winter (Figure 7).

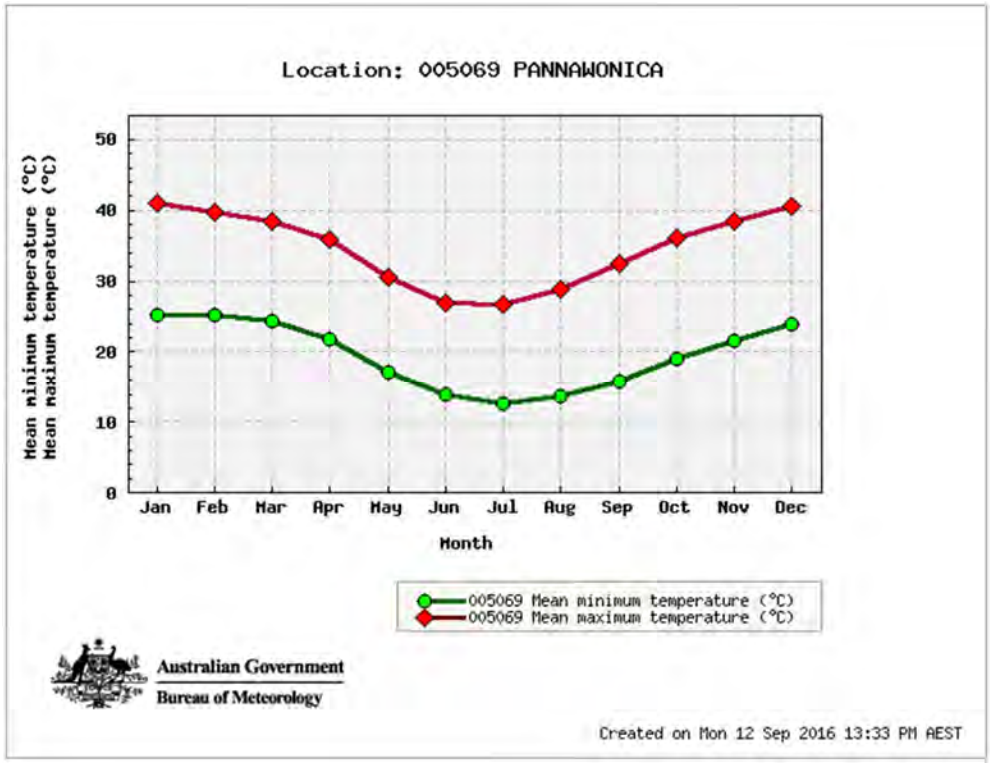

Figure 7: Mean monthly temperatures, Pannawonica 1971-2015.

The north/north-western coastline of Australia has experienced more tropical cyclones than anywhere else on mainland Australia. Most tropical cyclones are observed during the late summer, occurring between November and April. Tropical cyclones can produce damaging wind gusts in excess of 150 km per hour, with heavy rains resulting in regional flooding. Seven tropical cyclones are expected off the coast of the Pilbara each year, with three expected to make landfall.

Precipitation is driven by summer cyclonic activity, with the months of August, September and October have the lowest average rainfall, and January February and March the highest average rainfall (Figure 8). Annual rainfall is also highly variable, (Figure 9). Evaporation rates in the region greatly exceed rainfall, which is typical for similar climate conditions around Australia. Annual average pan evaporation rate is 3200-3600 mm/year (Figure 10).

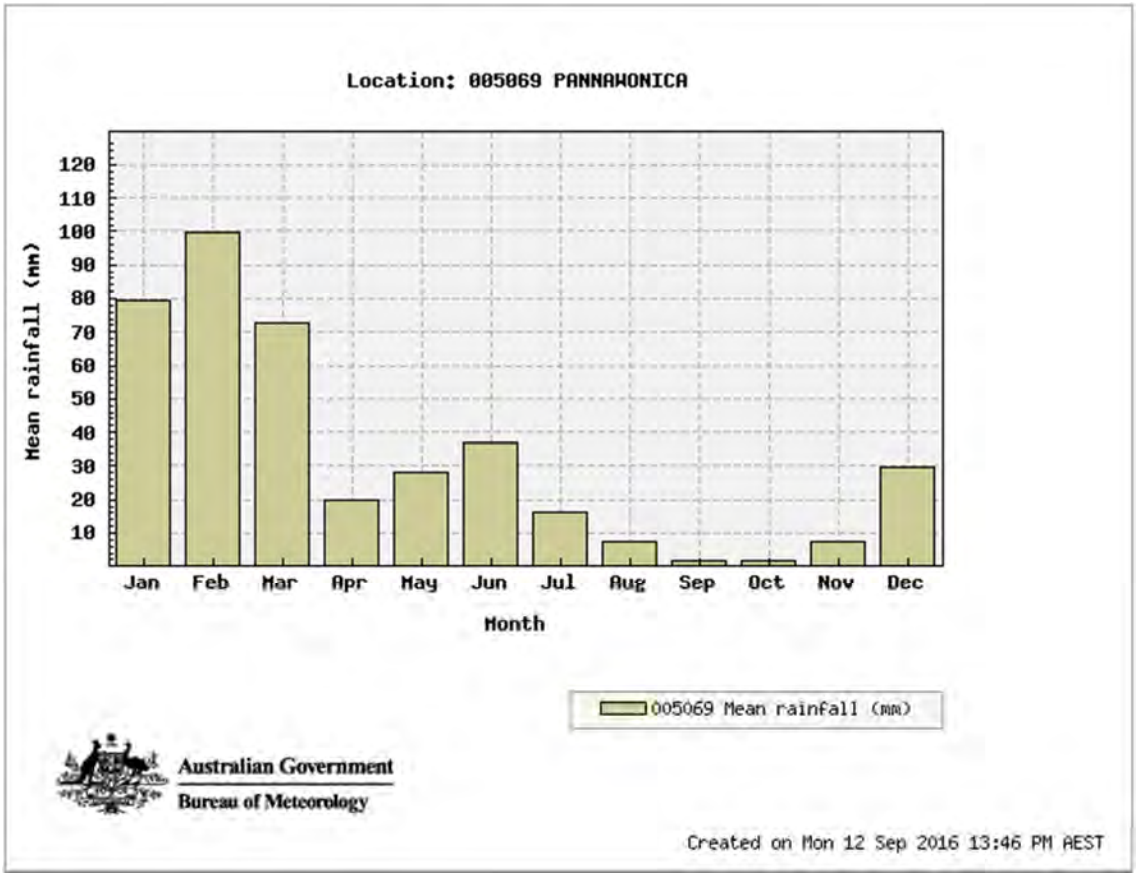

Figure 8: Mean monthly rainfall (1971 to 2015) at Pannawonica

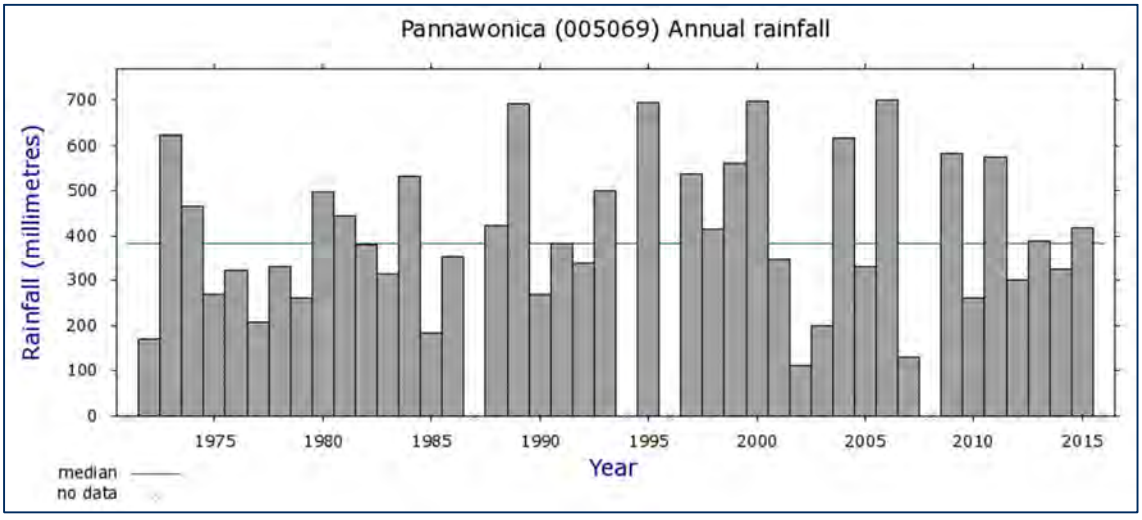

Figure 9: Historical annual rainfall (1971 to 2015) at Pannawonica

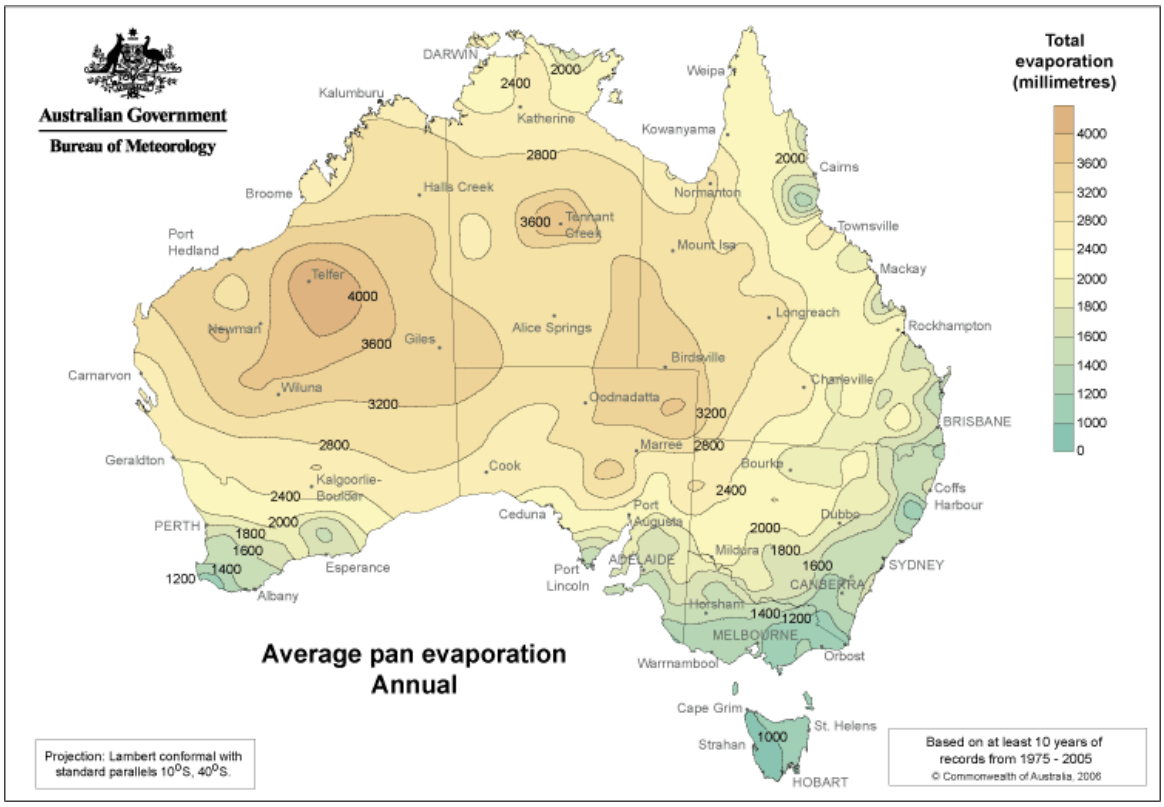

Figure 10: Average annual pan evaporation rates across Australia

9.2 Climate and landform stability

The heavy, intense rainfall experienced in the Pilbara makes rainfall the key climatic factor that influences surface stability in built landforms. Rainfall erosivity (measured in mega joule millimetre per hectare per hour per year - MJ.mm/ha/hr/yr) is the term used to describe the erosive force of rain. For Pilbara sites, long-term annual erosivity values range from ~1,000-1,600 MJ.mm/ha/hr/yr. Rainfall in the Pilbara is typically more erosive than Perth's rainfall, even though it only receives on average half the rainfall that Perth receives on an annual basis. For comparison, average annual erosivity values for Perth are ~1000 MJ.mm/ha/hr/yr from an average of 780 mm of rain a year.

Rainfall erosivity is highly variable for each rainfall event. Studies of Pilbara rainfall concluded that at Tom Price, for example, erosivity for the period 1998 to 2009 ranged from 212 – 6,349 MJ.mm/ha/hr/yr. A review of data in the Paraburdoo area indicates that the most erosive year recorded was 2007, where 421mm fell during February, with only a further 283mm during the rest of that year. This singular rain period embodied 11,994 MJ.mm/ha/hr/yr of erosive force, or 89% of the entire erosivity of rain for that year. Given the pattern of intense and infrequent rainfall events in the Pilbara, it can be expected that only a few events every year (~1-3 events) will generate the majority of runoff and erosion of that occurs each year.

The studies showed a rapid decline in erosion or sediment yield occurs when annual rain decreases below about 300mm per year due to a corresponding decline in rainfall volumes and rainfall erosivity. However, when annual rainfall increases above ~300mm, vegetation growth increases and becomes increasingly effective in controlling soil erosion. Hence, there is a point of maximum erosion potential at an annual rainfall value of ~200-400 mm such that surface (vegetation) cover is low due to lack of rain and ineffective for controlling erosion, yet rainfall erosivity is sufficiently high to cause erosion, as observed in the Pilbara. Outcomes from these studies have informed development of the *Rio Tinto Iron Ore (WA) Landform Design Guidelines* for achieving stable waste dumps.

9.3 Climate and vegetation growth

Water is generally the limiting factor for plant growth in the Pilbara's arid environment. As a consequence of the hot temperatures, high evaporative demand and infrequent and irregular rainfall, much of the vegetation displays xeromorphic adaptations (plant structural adaptations for survival in dry conditions). These adaptations include the ability to regulate water loss from leaves, extract water from very dry soils and match reproductive strategies with wetter periods. Many species are ephemeral and persist in soil seed banks in between wetter periods.

The adaptive capacity of Pilbara species implies a degree of resilience to changes to hydrological regimes. However, the impacts to Pilbara vegetation as a consequence of climate change are not clear. Changes in vegetation density and water use will alter the amount of runoff that occurs after a rainfall event, which in turn will alter creek flows and groundwater recharge.

Some initial studies within the wider Pilbara are underway to understand how the presence and absence of water affects vegetation growth within riparian corridors. The outcomes from these studies and other evolving research on climate change will be monitored and integrated into future closure studies to inform assumptions on climate influences and impacts.

9.4 Climate change

The understanding of how climate will change in the future in the Pilbara is guided by the outcomes of climate modelling, commissioned privately by Rio Tinto and other Australian government agencies. The main climate drivers for the Pilbara are the El Niño Southern Oscillation (ENSO) and Indian Ocean Dipole (IOD) ocean currents. However, these ocean currents are not well represented in most global climate models, and as a result climate predictions for the northwest of Western Australia vary significantly. Consequently the impact of climate change, the change in water availability and influence on ecosystems, in the Pilbara is still unclear.

The ENSO and IOD ocean currents are currently being researched by CSIRO. At the same time, modelling is being progressively improved by various Australian Government agencies to expand our understanding of the climate drivers in the southern hemisphere, to understand the associated impacts on water availability and to predict changes to existing ecosystems.

From the modelling completed to date, our understanding of Pilbara climate change suggests the region will experience the following climate trends:

- A shift in the historical tropical cyclone season, with an earlier start and potentially later finish.
  - For the period 2051 to 2099, compared to present day, tropical cyclone frequency could decrease by half, and the duration of a given tropical cyclone by 0.6 days on average. Projections also suggest that tropical cyclones could increase in size and intensity
- Continuation of the highly variable multi-decadal scale rainfall trends.
  - Projected rainfall reductions range from 1 to 24 percent for mid-century, and 9 to 24 percent for the end of the century
- A significant warming trend, influencing maximum temperatures, with the largest changes during the January to March period.
  - On average, maximum temperatures are expected to increase by 2.1 to 3.2 ˚C by mid-century and by a total range of 3.8 to 4.6 ˚C by the end of the century. For minimum temperatures the corresponding averaged increases are 1.9 to 2.4 ˚C (mid-century) and 4.1 to 4.6 ˚C (end of the century).

These changes, if realised as modelled, are likely to make successful rehabilitation in the Pilbara more challenging. Current landform designs are conservative, providing contingency for increased erosion factors, however lower average rainfall will impact ability to establish vegetative cover.

10. Land

10.1 Biogeographic overview

The Mesa J Hub lies within the Pilbara Craton, a bioregion defined by the Interim Biogeographic Regionalisation for Australia (IBRA). The Pilbara bioregion is divided into four subregions: Chichester, Fortescue Plains, Hamersley and Roebourne Plains. The study area is located in the Hamersley subregion which is described as a “Mountainous area of Proterozoic sedimentary ranges and plateaux with Mulga low woodland over bunch grasses on fine textured soils and Snappy Gum over *Triodia brizoides* on skeletal sandy soils of the ranges”.

10.2 Geological setting

Mesa H, Mesa J and Mesa K are three of a group of pisolitic goethite-hematite iron deposits of Tertiary age which have formed in ancestral drainage channels (palaeochannels) of the Robe River (commonly known as a Channel Iron Deposits (CID), in the western Pilbara region of WA. This group is known as the Lower Robe (or Deepdale) group and comprises a series of mesas formed by the erosion of the surrounding landscape which has exposed the more competent CID paleochannel, thus creating and inverted topography. Subsequent erosion has dissected the outcropping CID paleochannel creating isolated mesa formations.

The Mesa J deposit consists of up to 50 metres thickness of CID (the Robe Pisolite), overlying basement rocks of Proterozoic age. The CID outcrops along the Robe River, and underlies Quaternary sediments elsewhere in the region. The CID at Mesa J occupies an area of approximately 3 x 3.5 km on the south-western side of the Robe River - Jimmawurrada Creek confluence.

The geology of Mesa K is homogenous on a large scale. The dominant geological formation is of dehydrated CID. On a smaller scale the geology varies with the amount of clay pods, rock fractures, alluvium sediment and hardcap.

The Mesa H deposit covers approximately 6.5 x 3 km of CID, at up to 80 m in thickness. It is dissected through the middle and bound to the east by incised drainage channels. The mineralised sequence outcrops as a low mesa-form hill in the north, rising up to 20 m above plain level (176 mRL) and bounded in the north west by the current Robe River. To the south the pisolite sequence is concealed by recent, unconsolidated fluvial gravel, clay, and localised calcrete. The Buckland Hills form the southern boundary along a north-westerly strike and rises up to 266 mRL.

Stratigraphy is shown in Figure 11, Figure 12 and Figure 13. The key formations comprise:

- Alluvial Cover.
- Surficial Unit: Surficial deposits comprise nodules of massive, dark brown goethite surrounded by yellow clay. Where goethite nodules occur at topographic highs they are commonly silicified and contain minor crystalline carbonate. These calcite-dolomite-bearing deposits are essentially calcrete. Alluvial deposits associated with Jimmawurrada Creek mainly comprise coarse ‘shingle’ with red clay. Elsewhere, bedded red to grey clay dominates. Sandy alluvium appears to be rare.
- Hardcap Tertiary Pisolite (HTP): Which is the weathered and lateritised zone predominantly at the top of the Robe Pisolite. This zone ranges from 5m to 10m in thickness, and contains secondary soils, silica and alumina. The transition between the HTP and the underlying TP/TPH is gradational and visually difficult to identify. Hardcap Tertiary Pisolite often contains clay horizons.
- The upper ore zone: Tertiary Pisolite (TP) forms the main ore zone in the Mesa J and Mesa K deposits, but is less prominent at Mesa H, where it has undergone more weathering and is transitional to HTP. It has a pisolitic texture and is cemented together by a goethitic matrix. Internal zones of poorer quality material exist in the form of clay (TPC) or as hydrated/denatured pisolite (TPH/TPD), but these are infrequent.
    - Limonite zone: A limonite-rich zone is present at Mesa J in the vicinity of the water table and limonite persists below the water table. It appears to be coarser grained and the rocks show evidence of abundant secondary processes. Clay bodies are also far more irregularly distributed.
    - Clay Zone: A thick clay rich Tertiary Pisolite unit (TPC) is present extensively throughout Mesa H and extending in to the very southernmost portion of Mesa J. This unit marks the base of the upper ore zone and can be up to 20m in thickness.
- The lower Tertiary Pisolite zone: The Mixed/Massive Sub-Grade Pisolite (TPM), Found in the southern half of Mesa J, underlying the TP, and at Mesa H in a deep north westerly trending channel below the TPC zone. It is characterised by a limonitic, denatured/massive appearance and clay is common throughout. This zone has been subjected to a palaeo-water table, which has resulted in a significant hydration effect in comparison to the upper TP/TPH.
- The deepest parts of the CID are characterised by an enriched/denatured pisolite zone (TPD). It occurs at Mesa J in the south of the deposit and at Mesa H in the deep north westerly trending channel. It is a discreet, semi continuous unit of enriched pisolite that ranges in thickness from 2 m to 10 m. Geologically the unit consists of predominantly goethitic minerals with a minor hematitic component. Goethite, ochreous goethite and clay are most common.
- Basal Pisolite: The Basal Unit (TPB) is dominated by clay and reworked channel deposits, which may include conglomerate coarse pisolites. The Basal Unit also contains laterite, both as reworked remnants of a laterite profile developed on basement rocks, and as the products of extensive in situ lateritisation.
- Basement rock: Basement rocks comprises a number of rock types: Marra Mamba Iron Formation, Jeerinah Formation, duricrust and reworked pisolite and clay. The Marra Mamba Iron Formation and Jeerinah Formation are to be considered the basement and the duricrust, reworked pisolites and clay should be considered a basal unit of the Robe Pisolite sequence.

The Mesa deposits comprise a combination of low, medium and high erodibility wastes. Further discussion on the management of waste materials is contained in section 18.2. Table 4, Table 5 and Table 6 below illustrates the anticipated waste volumes for each deposit.

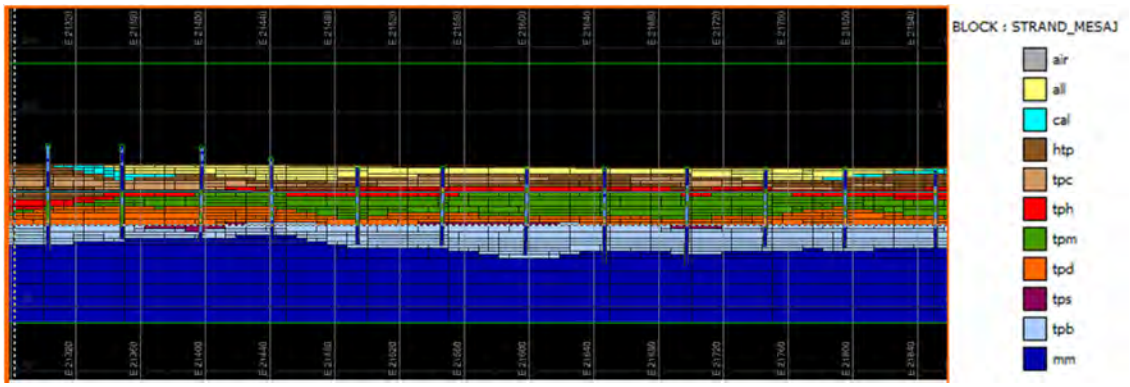

Figure 11: Mesa J stratigraphy

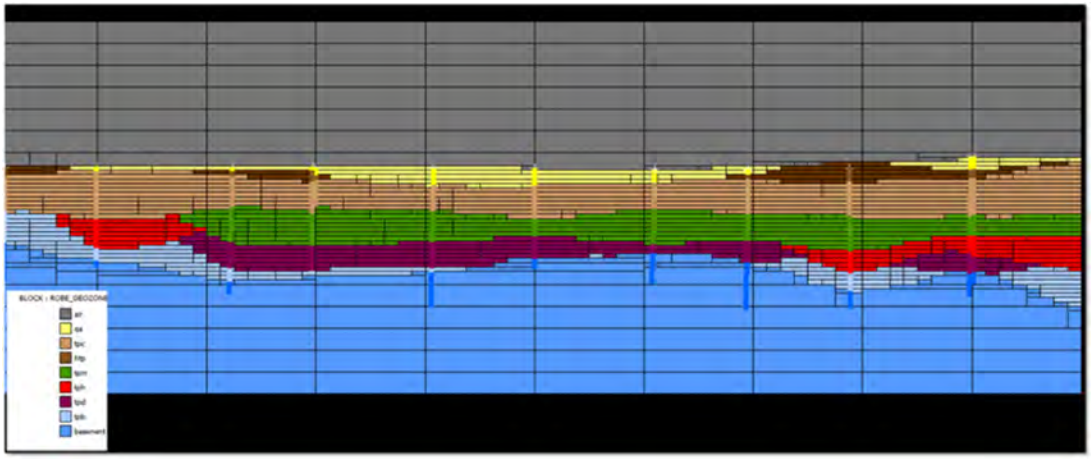

Figure 12: Mesa H stratigraphy (key as above, Figure 11)

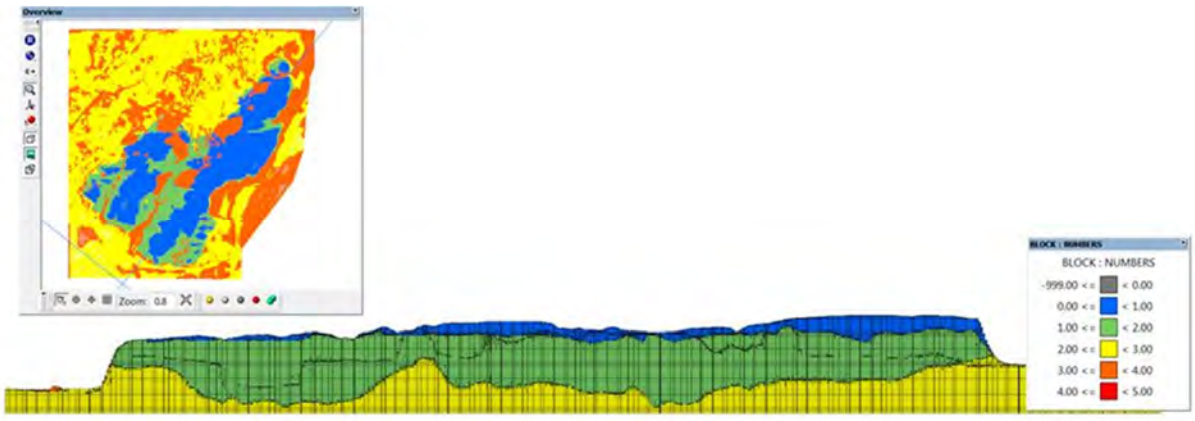

Figure 13: Mesa K stratigraphy, where blue represents weathered zone (HTP), green represents the main ore zone (TP) and yellow represents undifferentiated basement.

10.3 Mineral waste characteristics and inventory

Developing a comprehensive understanding of the types and volumes of materials that will remain at the completion of mining at Mesa J Hub is critical for the effective design, construction and rehabilitation of the mining landforms. Rio Tinto has well-developed processes for the collection and analysis of this data that are implemented from early exploration works and continues through the life of the mine. Long term material behaviour can also be predicted through characterisation of representative waste types and correlation to similar waste materials present at other sites.

Table 4 to Table 6 below provides a summary of the volumes of key material types at the Mesa J Hub. This information is used to inform the landform design and management strategies during operations and closure. Volumes are based on current mining models and will be subject to change. Further detail on these materials are provided in subsequent sections.

Table 4: Materials summary – Mesa H

Material	Volume (m^3)	Comments
Total waste material expected	123,330,000	
Material with potential AMD risk (PAF)	0	
Material with significant fibre risks	0	
Inert mineral waste - low erodibility		
Hydrated (HTP)	9,467,500	
Inert mineral waste- medium erodibility	0	
Inert mineral waste - high erodibility

Rock	42,500	
Others	2,500.00	

10.3.1 Physical characteristics

The key physical property of the waste material that is applicable to the closure design is how susceptible the material is to erosion. Materials are assessed and classified in one of three levels of erodibility; low, medium or high. Materials which are classified as low erodibility, for example, are competent hard rock that is suitable for placement on the outer surface of waste landforms to provide long term protection against erosion. Potential waste types across the Mesa J Hub have been assessed using a combination of site-specific geophysical test work and extrapolation from equivalent material similar sites. Table 4 to Table 6 above lists the material types and volumes for the various erosion classifications. The erosion classification of individual landforms is included in Appendix F.

10.3.2 Geochemical characteristic

Rio Tinto has undertaken an extensive program of geochemical testing over several years to understand the potential for acidification and/or metalliferous drainage to occur as a result of exposing various waste rock types common to mining operations in the Pilbara. The geochemical characterisation process aims to assess sulfur content as an indicator of acid generation potential, and to undertake static (acid base accounting) and, if appropriate, kinetic testing of materials. This information is applied to the geological block model and subsequent mining model, to ensure materials posing potential geochemical risks are identified prior to mining and managed appropriately. This work is in accordance with the *Rio Tinto Iron Ore (WA) Mineral Waste Management Plan for Undeveloped Resources and Studies* and the *Spontaneous Combustion and Acid Rock Drainage (SCARD) Management Plan*.

The most significant geochemical risk posed by mining iron ore deposits in the Pilbara is associated with the sulfide mineral pyrite (FeS_2), which can form sulfuric acid when exposed to oxygen and water. The Mount McRae Shale (MCS), most commonly associated with pyrite and acid and metalliferous drainage in the Pilbara, is not expected to be exposed during mining at Mesa H, Mesa J and Mesa K based on the current proposed pit shells for each deposit; mining is confined to CID materials.

A review of the geochemical risk assessment for each deposit was undertaken in 2015/16 which assessed the sites to be a low risk for acid and/or metalliferous mine drainage (AMD). A further review of Mesa H in 2017 utilising new drilling data supported the Mesa H assessment as low risk. Based on the proposed final pit shells for each deposit it is not anticipated that any moderate or high risk material types will be exposed.

Table 7: Assessed Geochemical risk in the Mesa J Hub mining areas

Mining Area	Geochemical Risk
Mesa H	Low
Mesa J	Low
Mesa K	Low

In terms of potential for metalliferous drainage, minor and trace elements that were enriched compared to average crustal abundances were Fe, As, Sn, Co, Cr, Cu, Mn, Pb, Se, Te, V, Zr and Zn. However, whilst concentrations of some trace elements were elevated these elements are unlikely to mobilise into ground water.

10.3.3 Fibrous minerals

Fibrous minerals present a health hazard if fibres of a (defined) respirable size become airborne and are inhaled. The most common mineral associated with fibrous minerals encountered within the iron formations present in the Robe Valley area is riebeckite. Riebeckite is usually found in fresh (unweathered) BIF. The asbestiform variety of riebeckite is crocidolite, or blue asbestos. The presence of riebeckite does not necessarily pose a fibrous mineral risk but it is a precursor mineral to crocidolite, therefore, there exists a likelihood of encountering crocidolite.

If present, crocidolite seams would primarily occur within the unmineralised Marra Mamba Iron Formation that underlies the CID at Mesa H and Mesa J. In addition, crocidolite may also occur in BIF clasts found within overlying alluvium cover or within the tertiary basal pisolite horizon (i.e. TPB).

Crocidolite has not been intersected in any drillholes within the Mesa H, Mesa J and Mesa K mining or project areas (based on historical drillhole information up to October 2016). However, the underlying basement formation, which includes the Marra Mamba Iron Formation, as well as the TPB horizon in the Mesa H area, is considered to pose a potential fibre risk if exposed in the footwall. However the current mining sequence does not intersect this material.

The *Rio Tinto Iron Ore (WA) Fibrous Minerals Management Plan* describes guidelines for the management of fibrous minerals encountered during mine production, however, based on current drilling and mine planning information, which indicates that basal or basement lithologies can generally be avoided during operations, potentially hazardous or designated hazardous areas are not expected within the life of mine or upon closure in these areas.

10.4 Local soils

Topsoil is recognised as an important factor is achieving high quality rehabilitation results. Characterisation of soils provides an indication of soil properties and their potential impacts on vegetation establishment, growth and landform stability; although it is important to recognise that they are expected to be altered as a result of mining processes. Appropriate characterisation can also help ensure soils with adverse properties are avoided in landform design.

The physical and chemical properties of Robe Valley topsoil are provided in Table 8. Soil properties are within the range typical of that found elsewhere in the Pilbara. It is generally classified as sandy clay loam to medium clay with a coarse material fraction value of up to 81.7%. It is neutral pH, non-saline and non-sodic (below exchangeable sodium percentage of <6%). Both organic carbon and nutrient levels vary according to landscape position: they are typically very low in the higher portions of the landscape, but are present in slightly higher levels in low-lying areas and drainage lines. Robe Valley soils possess low hydraulic conductivity indicating that they could be naturally susceptible to increased surface run off, less water availability to plants and surface erosion. Overall Robe Valley topsoil is consistent with Pilbara soil parameters.

Subsoil has physical properties suitable for plant growth and generally has chemical properties amenable to plant growth, although it does lack the nutrient content, organic matter and soil seed bank of topsoil.

Table 8: Comparison between Robe Valley soils and typical Pilbara soil parameters[7]

Properties		Pilbara Soils	Robe Valley Topsoil
Physical Properties	Soil texture (<2mm soil fraction)	Sand – Clay Loam	Sandy clay loam – Medium heavy clay
	Coarse material content (%)	0 - 93	0.0 – 81.7
	Aggregate stability (Emerson Class[1])	2 - 6	2 – 5
	Soil Strength (Modules of Rupture (kPa))	0 - 267	13.9 – 112.4
	Plant available water holding capacity	-	Low
	Hydraulic conductivity (Ksat(mm/h))	-	0.5 – 1.6
Chemical Properties	Soil pH	5.3 – 9.5	6.0 – 8.6
	Salinity (dS/m)	0.007 – 0.233	0.012 – 0.080
	Organic Carbon (%)	0.07 – 3.74	0.14 – 1.69
	Macro-nutrient status	-	Low
	Micro-nutrient status	-	Low
	Effective Cation Exchange Capacity (meq/100g)	1.9 – 16.8	3.6 – 17.68
	Exchangeable Sodium Percentage (%)	0.21 – 6.39	1.39 – 5.90
	Total metal concentrations	Low	Low

10.5 Soil inventory

Topsoil is often a limited resource in the Pilbara with topsoil recovery often being restricted due to the nature and terrain of the landscape. The goal of soil management is to maximise the collection of topsoil and subsoil, and to store it to maximise its viability and productivity to ensure there is sufficient soil for subsequent use in rehabilitation.

Where practical, a minimum of 200mm of topsoil and 600mm of subsoil is collected when new areas are disturbed. Mesa K currently has a shortfall of material, as the existing stockpiles were moved to Mesa J. As a result, the soil balance for these sites should be considered collectively. It is anticipated that sufficient soil volumes will be available to meet rehabilitation requirements for the deposits.

Table 9 to Table 11 provide the current and projected soil inventory for the Mesa J Hub. Mesa H disturbance is limited to exploration activities, and although some areas have been disturbed the topsoil remains available for collection from the future pit areas.

Table 9: Predicted LOM soil balances for Mesa H

Material	Current volume (m^3)	Predicted total volume LOM (m^3)	Predicted volume required for rehabilitation (m^3)
Topsoil	0	1,764,720	1764,720
Subsoil	0		
Total	0	1,764,720	1,764,720

Table 10: Predicted LOM soil balances for Mesa J

Material	Current volume (m^3)	Predicted total volume LOM (m^3)	Predicted volume required for rehabilitation (m^3)
Topsoil	600,000	3,390,043	2,977,500
Subsoil	2,782,657		
Total	3,382,657	3,390,043	2,977,500

[7] Note that the typical ranges above apply to topsoil and may not be representative of subsoil properties.

Table 11: Predicted LOM soil balances for Mesa K

Material	Current volume (m^3)	Predicted total volume LOM (m^3)	Predicted volume required for rehabilitation (m^3)
Topsoil	0	5,060	254,060
Subsoil	0		
Total	0	5,060	254,060

Whilst it is predicted that Mesa J Hub will have sufficient soil resources to complete rehabilitation works, each project is assessed to determine the type and amount of soil used. This could include an assessment of:

- current soil inventory;
- landform and rehab type;
- potential for trials;
- distance to soil stockpiles; or
- potential upcoming rehabilitation.

10.6 Alternative growth media

Whilst rehabilitation areas have proven to generally perform better with topsoil application, absence of topsoil does not necessarily mean that rehabilitation will fail, or that completion criteria will not be achieved. Trials have been conducted on waste dump rehabilitation without topsoil application (e.g. S Dump and T Dump at Mesa J, see Section 13.1). The trials were performing strongly against most success indicators, however these waste dumps have been re-disturbed due to additional ore being located under the waste dumps.

In 2009, Rio Tinto commissioned a study into the use of waste fines storage facility material as an alternative rehabilitation growth medium, using Mesa J TSF1 materials. A more extensive study in 2010 investigated additional types of mine waste materials. The studies reviewed soil, waste fines and mineral waste characteristics from select Pilbara mining operations, to identify material combinations that may be suitable as a topsoil substitute or supplement in cases where topsoil volumes may be insufficient for rehabilitation requirements. In these cases, topsoil would be applied to high impact and visibility areas such as waste landforms first and lower impact areas such as laydown areas may receive alternative growth media.

The studies showed plant-available nutrients held within the waste materials, although variable and characteristically low, were comparable to natural soils in the region. The majority of the waste materials had macro and micro nutrient concentrations within the range or above the levels measured in benchmark Pilbara topsoil and rehabilitated soils. The pH and phosphorus buffering index of most waste materials were also comparable to that of the benchmark topsoil materials.

In general, Pilbara mineral wastes were non-saline and non-sodic, with no sample presenting above the 15% threshold for exchangeable sodium percentage (ESP), the indicator of high sodicity. The soil structure of waste materials were relatively stable, with only slight or no dispersion upon re-moulding, indicating a structure that is not easily degraded, and is not prone to hard setting. However, estimated plant available water content of the waste materials ranged from 3% to 25%.

Four material classes were analysed from Mesa J and Mesa K, including surficial waste, alluvial waste, weathered waste and waste fines storage material. All material classes were assessed as suitable waste materials for use as a surface growth medium, from both a physical and chemical perspective. A further study in 2015 tested additional waste fines storage material samples from Mesa J, finding them also suitable.

In summary, alternative growth media options are available for consideration in the Mesa J Hub rehabilitation, should a shortfall of available topsoil and subsoil be encountered. Options for utilising the alternative growth media will be considered as the site comes closer to closure. Opportunities to utilise the growth media in field trials will be considered as part of progressive rehabilitation planning.

11. Water

11.1 Surface water

The Mesa J and K mines are located immediately downstream of the confluence of Robe River and Jimmawurrada Creek (Figure 14).

The Robe River is the major river system in the region and covers a linear distance of approximately 260 km, with a catchment area of approximately 7,500 km^2. The Robe River catchment generally drains east to west through the high relief areas of the Hamersley Ranges onto the more gently sloping areas in the coastal plain before discharging into the Indian Ocean. Surface flows are intermittent, typically once per year after significant and intense rainfall. The river has significant underflow in its alluvial bed which maintains a number of permanent pools in the river channel.

Mesa K is located at the top of a local sub-catchment and there are no tributaries that originate in or cross the project area. Two historic waste dumps are situated close to the Robe River, which show limited impacts from past flood events. Existing regional 1 in 100 annual exceedance probability (AEP) – previously referred to as a 1 in 100 year average recurrence interval (ARI) – flood modelling for Mesa K suggests that these dumps are located outside 1 in 100 AEP floodplain of the Robe River (Figure 15), however this will be re-assessed as part of the planned hydrological modelling of the final landforms for Mesa J Hub.

Surface water management at Mesa J operations currently employs a “sump and pump” and “diversion” strategy. The southern cutback pits at Mesa J, including Pit 11, Pit 12, Pit 14, Pit 7 and Pit 6, are exposed to surface water flows from the surrounding catchment, with dumps protecting a majority of the southern cutback, and the remaining runoff flowing into Pit 11 South. Levees and waste dumps to the south and east protect Mesa J from local flooding of the Jimmawurrada Creek. A diversion drain also exists on the western side of Mesa J to direct flows from the adjacent small western catchment, as well as breakout flows from a larger southern catchment, around Pit 11 North and into the natural drainage line to the west of Mesa J.

Although Mesa H deposit is located outside the 1in 100 AEP floodplain of the Robe River, flood protection will be required during operations to manage the runoff from a 24 km^2 local catchment that currently discharges directly over the south-eastern extent of the Mesa H deposit and floods Pit 11 at Mesa J (Figure 15). Diversion drains have been designed, with the preferred design option to divert the local catchment westwards into the central watercourse that bisects Mesa H.

At closure it is expected that any diversion structures that were used to control surface water flows during operations at Mesa J Hub would undergo a slow and inevitable collapse, resulting in runoff from the local catchments draining into the backfilled pit voids. With the exception of the waste dump proposed to the south of Mesa J, all waste dumps at Mesa H and Mesa J are located outside of the current 1 in 100 AEP floodplain (Figure 15). The long-term, post-closure stability of the dump proposed to the south of Mesa J could potentially be compromised if water were to permanently pool against the dump, depending on the waste type. A large portion of these flows can be diverted and the requirement for these diversion structures to meet closure objectives will be further assessed as part of the planned hydrological modelling of the final landforms for Mesa J Hub.

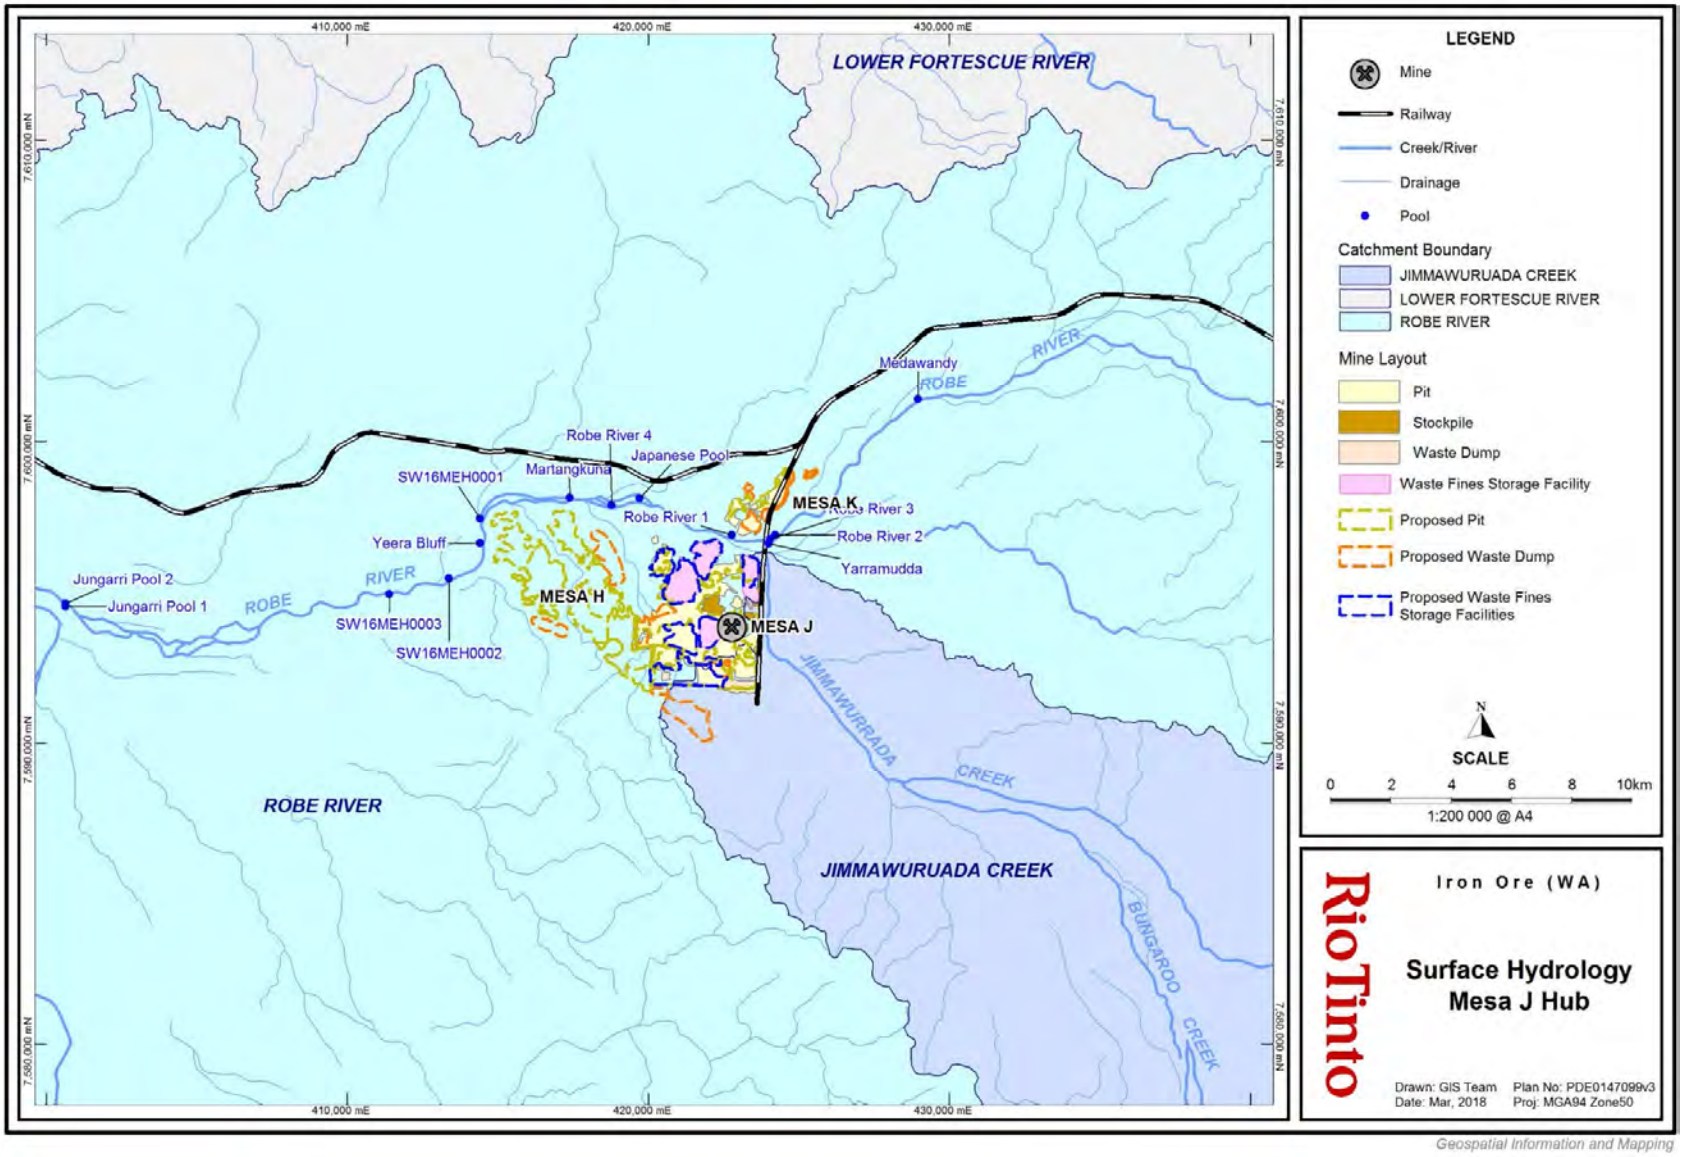

Figure 14: Surface hydrology surrounding Mesa J Hub

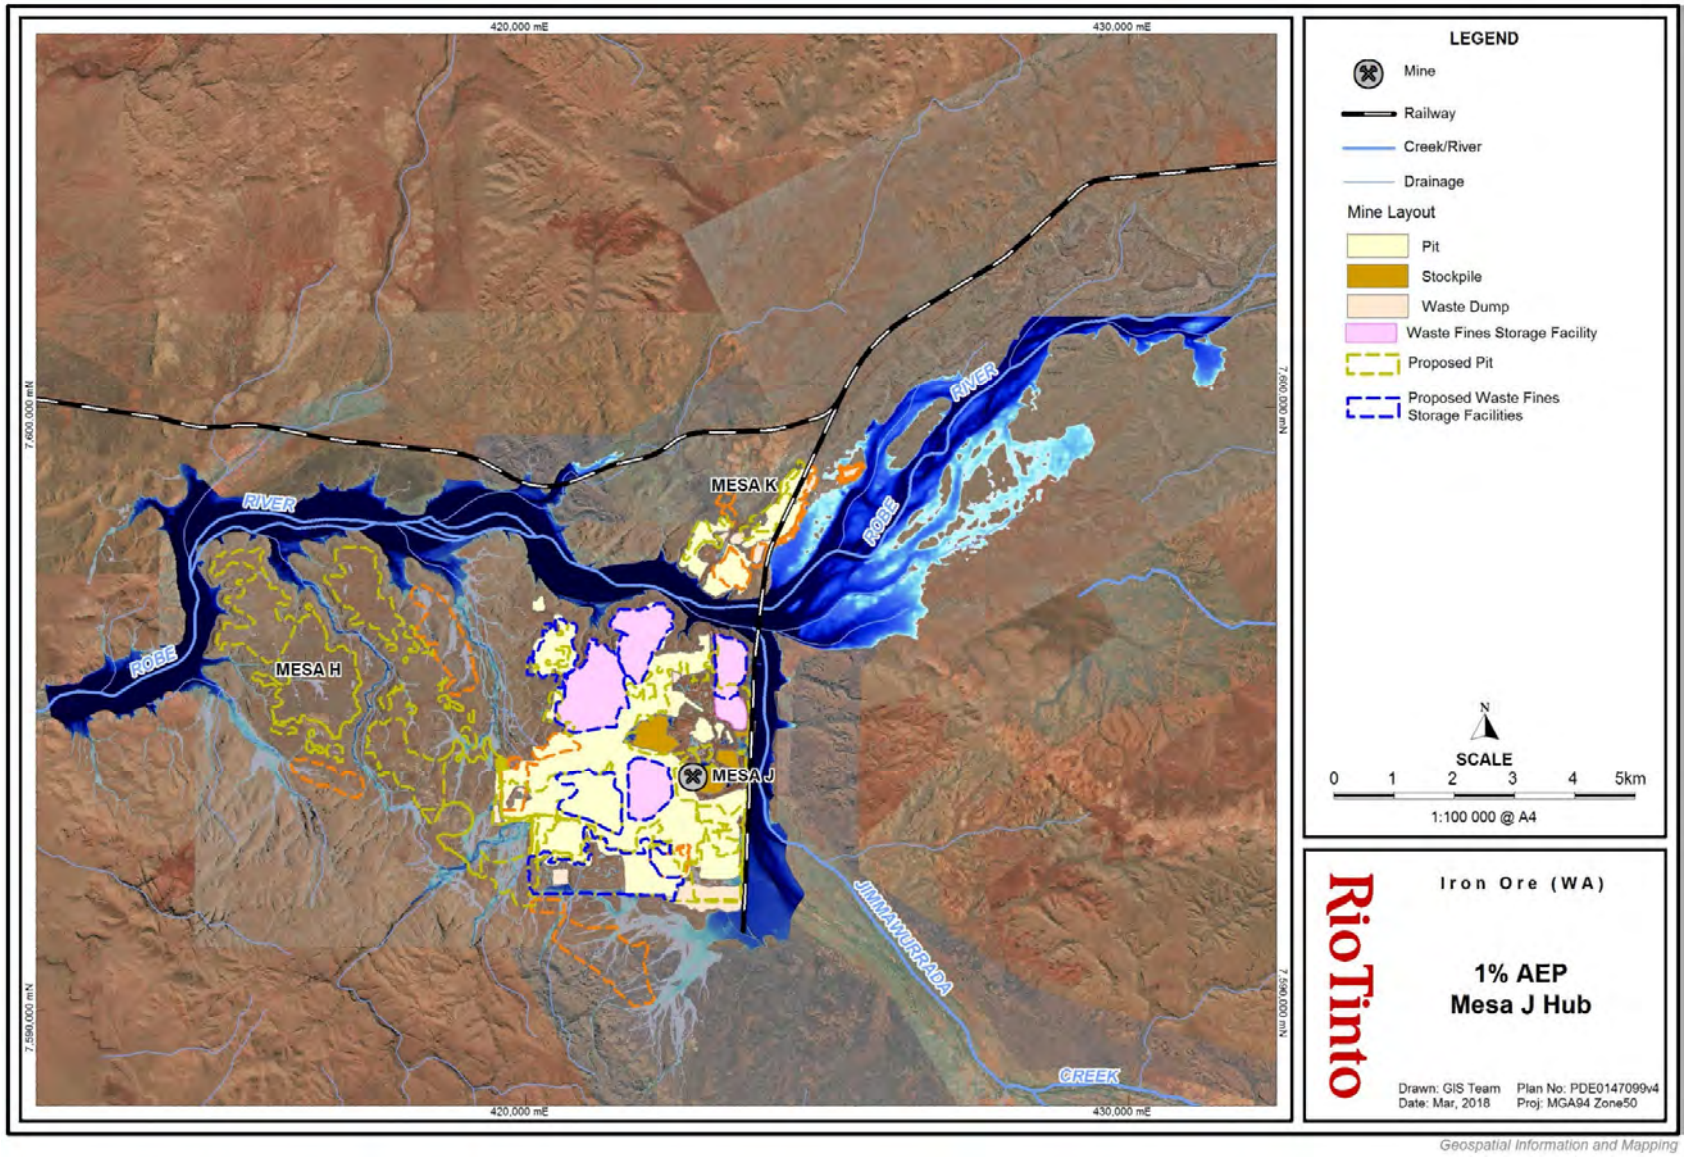

Figure 15: Mesa J Hub 1% AEP Flood Extent

11.2 Groundwater

Dewatering via in-pit sumping has occurred at Mesa J since 1995. Approximately 34% of the Mesa H scheduling inventory occurs below the pre-mining water table (water table prior to Mesa J's operation), however due to the passive dewatering of Mesa H caused by the dewatering of Mesa J, only ~13% of the scheduling inventory is below the present-day water table.

The existing Mesa J Hub borefield (Southern Cutback borefield) is situated in the southern part of Mesa J mine site and is used in conjunction with dewatering volume reuse to supply water for the wet plant. To enable the ongoing operation of a wet plant to process ore extracted at Mesa J and Mesa H, water demand is estimated to be between broadly 4 and 9 GL/year.

The Mesa J Hub is situated downstream from the confluence of the Robe River and Jimmawurrada Creek. The local catchment is defined by three major aquifers: the weathered basement aquifer, overlaid by the CID aquifer, and the alluvium aquifer which occurs along the Robe River.

A major alluvial aquifer underlies the lower Robe River. It consist of gravels beds with a saturated thickness of up to 20-25 m adjacent the river; gradually reducing in thickness laterally from the river and downstream, locally creating surface expressions of groundwater as pools. Based on available data and pumping test results, the highly permeable Robe River alluvium is conceptually in partial hydraulic connection with the underlying aquifers. The localised alluvium/colluvium overburden found on top of the mesas occurs above the water table and is unsaturated.

The mineralised section of the CID forms a semi-confined aquifer of variable permeability due to the juxtaposition of solution cavities and CID (highly permeable) and horizontal lenses of clay and clay alteration near fractures (low permeability). Groundwater in the ore body tends to flow from the southeast in the Bungaroo Valley aquifer under the Jimmawurrada Creek catchment (Figure 14), to the north and northwest towards the Robe River.

Beneath the Robe Pisolite is the confined basement aquifer consisting of the Wittenoom and Marra Mamba Iron Formations. The basement units are intruded by several dolerite dykes and bounded by fault structures formed during three major deformation events.

Long term water quality monitoring indicates that groundwater and surface water is predominantly fresh across the Mesa J Hub. The chemistry of the Robe River pools is primarily influenced by significant rainfall, stream flow events and evapotranspiration.

Salinity levels recorded in permanent pools are generally considered fresh (<2000 µS/cm) with some seasonal variation identified by short duration changes in chloride concentration associated with rainfall events and pool evaporation cycles. The pH values are within the typical range for Pilbara inland waters, slightly alkaline (7.4 - 8.2). The only proposed pit lake in the post closure landform will be located in the Mesa J Pit 15 area, which is planned to be used as a water storage dam. Further investigation is required to determine the risk, extent, quality and management of this pit lake. If required, mitigation actions will be implemented, potentially including backfilling.

Recharge to local aquifers currently occurs as a result of multiple inputs; rainfall and cyclonic event recharge, seepage leakage from the existing waste fines storage facilities and water reservoir, Robe River and Jimmawurrada Creek recharge through stream-flow events, and operational surplus discharge into the Jimmawurrada Creek and the west creek located between Mesa H and J.

Based on the water balance for the area, groundwater recovery is expected to begin after groundwater abstraction activities cease. Recovery will be to the pre-mining water table level and recovery timeframes are currently estimated in the order of ~60 years post mine closure within the pit areas. Recovery of Robe River pools and Jimmawurrada Creek is expected to predominantly happen within the first or second major rainfall events, historically between 5 and 10 years.

Predicted groundwater recovery levels and the modelled time to recovery are listed in Table 12[8].

Table 12: Predicted groundwater level and approximate time to recovery.

Deposit	Pre-mining level (mAHD)	Estimated maximum drawdown level (mAHD)	Recovery level (mAHD)	Time (years)
Mesa H	120-144	110 (34m drawdown)	120-144	60
Mesa J	142-155	110 (45m drawdown)	142-155	60
Mesa K	144-146	No change – AWT mining	N/A	N/A

11.3 Robe River Pools

Permanent and semi-permanent pools exist along the Robe River due to the significant subsurface flow in the alluvium. The number and permanency of pools are controlled by rainfall and groundwater levels. When a rainfall event occurs, the underlying aquifer is recharged causing the water table to rise and replenish the pools. During a dry period the water table will lower resulting in shallower pools or disconnection from groundwater. The Robe River pools remain as the only surface water source during dry periods, and therefore are an important refuge for aquatic ecosystems in the region. Permanent and deep pools are the most stable and consequently have the greatest diversity and stability of species. These pools also have significant value for the local Traditional Owners.

Environmental and hydrological monitoring occurs at various pools and stream locations along the Robe River in the vicinity of the Mesa J Hub, including Medawandy, Yarramudda, Martangkuna, Yeera Bluff, Japanese Pool, four stream locations near Mesa J and three stream locations near Mesa H (Figure 14). This long-term monitoring of the Robe River includes an integrated assessment of ecological parameters including freshwater fauna (i.e. macroinvertebrates and fish), channel/pool morphology, riparian/bank condition and water quality, utilising an upstream/downstream approach. Over 25 years of monitoring to date indicates any detectable changes to the ecology of the Robe River pools has been influenced by climate, and could not be attributed to mining operations. Work is ongoing to improve knowledge and predict groundwater level and quality changes that may occur in the future.

12. Biodiversity

12.1 Terrestrial fauna habitat

There are 16 terrestrial habitat types identified at the Mesa J Hub. These habitats are broadly grouped into six main habitat types, including breakaways & gullies, mesa plateaus, rocky ranges, plains, water-courses and ‘disturbed’ (Figure 16). Characteristics of these habitat types are provided in Table 13.

Breakaways & gullies have been recognised as high value habitat for species of conservation significance, such as Pilbara Olive Python, Northern Quoll, Pilbara Leaf-nosed Bat and Ghost Bat. The Water-courses habitat is recognised as high value habitat as it supports a greater diversity and abundance of fauna than other habitats, provide foraging habitat and provide potential dispersal routes for conservation significant fauna.

[8] Recovery levels are based on the continuation of current climate conditions.

Table 13: Description of pre-mining habitats identified at Mesa J Hub

Landform	Habitat	Basic description
Breakaways & Gullies	Breakaways	• Eucalyptus leucophloia over mixed Acacia tumida var. pilbarensis and Acacia bivenosa shrubland over Triodia wiseana hummock grassland. • Breakaway or ridge line, falling away to steep scree slope. Stony compact soils, low levels of leaf litter, sparse open vegetation; small caves and crevices.
Breakaways & Gullies	Gullies	• Scattered Eucalypts over Acacia shrubland over hummock or tussock grassland. • Deep often rocky gorges, sometimes with semi-permanent or permanent pools. Rocky structures providing large opportunities of refuge and foraging for a wide suite of vertebrate fauna species; numerous rock ledges, crevices and caves. Some semipermanent water pools.
Mesa Plateaus	Mesa Plateaus	• Scattered Eucalyptus leucophloia over mixed Acacia ancistrocarpa, Acacia bivenosa, Acacia maitlandii, shrubland over Triodia wiseana hummock grassland. • Elevated flat hill top on stony soils.
Plains	Grassland Plains	• Corymbia hamersleyana woodland over Acacia ancistrocarpa shrubland over Triodia wiseana grassland. • Broad flat low lying plains to undulating plain on soft loamy soils.
Plains	Loamy Plains	• Scattered to open Corymbia hamersleyana woodland over mixed Acacia ancistrocarpa, A. inaequilatera, A. bivenosa, A. colei var. ileocarpa, Grevillea pyramidalis subsp. leucadendron shrubland over Triodia wiseana or T. epactia hummock grassland or *Cenchrus ciliaris and *C. setiger grassland. • Low-lying undulating loamy to stony plain within Bungaroo valley floor.
Plains	Stony Plains	• Mixed Acacia shrubland over Triodia Hummock grassland. • Low-lying undulating Stony plain. Stony compact soils, low levels of leaf litter, sparse open vegetation.
Plains	Stony Shrubland Plain	• Trees (usually Corymbia hamersleyana) are few and shrubs are generally openly scattered. Dominant shrub species include Acacia inaequilatera, A. orthocarpa, A. ancistrocarpa and A. atkinsiana. • Relatively flat, stony plains covered by shrublands over spinifex hummock grasses with scattered emergent trees. The substrate comprises firm, red-brown fine clay-sand under loose pebbles and stones. Wood and leaf litter is sparse to moderate, and is generally concentrated under shrubs and trees.
Plains	Undulating Plains	• Corymbia spp. scattered low trees over Acacia spp. tall open shrubland to open shrubland over Triodia epactia, T. wiseana hummock grassland. • This landform comprised the stony undulating plains and wetter plains that were dominated by a clayey substrate.
Rocky Ranges	Hill Tops	• Scattered Eucalypts over sparse Acacia shrubland over hummock or tussock grassland. • Stony hills on high ranges with dissected valleys and gullies. Stony compact soils, low levels of leaf litter, sparse open vegetation, small overhangs.
Rocky Ranges	Low Hills	• Corymbia hamersleyana scattered low trees over mixed Acacia shrubland over Triodia hummock grassland. • Low rolling stony hills and valleys. Stony compact soils, low levels of leaf litter, sparse open vegetation.

Landform	Habitat	Basic description
Rocky Ranges	Stony Hills and Rises	• Scattered Corymbia hamersleyana over mixed Acacia inaequilatera, Acacia pyrifolia var. pyrifolia shrubland over Triodia wiseana hummock grassland. • Low stony hills and slopes with dissected valleys and drainage on stony soils.
Water-courses	Drainage Line	• Scattered Eucalyptus camaldulensis and E. victrix over mixed Acacia shrubland over mixed herbs and grasses. • Broad valley or drainage line. Range from soft sandy soils with surface cobbles and pebbles, diversity of microhabitats leaves logs and twigs to rocky structures with ephemeral drainage lines sometimes containing small semipermanent water pools.
Water-courses	Minor Creekline	• Corymbia hamersleyana low open woodland over Acacia spp. tall shrubland to shrubland over Triodia wiseana, T. epactia hummock grassland. • Permanent or semi-permanent water is not expected to occur within the creeks or flowlines; they are only likely to flow during significant rainfall events and thus do not represent true riverine landforms.
Water-courses	Riverine	• Melaleuca argentea and Eucalyptus camaldulensis over mixed Acacia colei var. colei, Acacia trachycarpa, Acacia tumida var. pilbarensis shrubland over mixed herbs. • Part of the Robe River riparian zone containing a diverse vegetation and with semipermanent or permanent pools. Dense diverse vegetation with significant level of leaf litter providing large opportunities of refuge and foraging for a wide suite of vertebrate fauna species; permanent pools of water.
Disturbed	Disturbed	• Cleared - Disturbed habitat within mining area, mainly attributed to exploration activities. • Little value as fauna habitat.

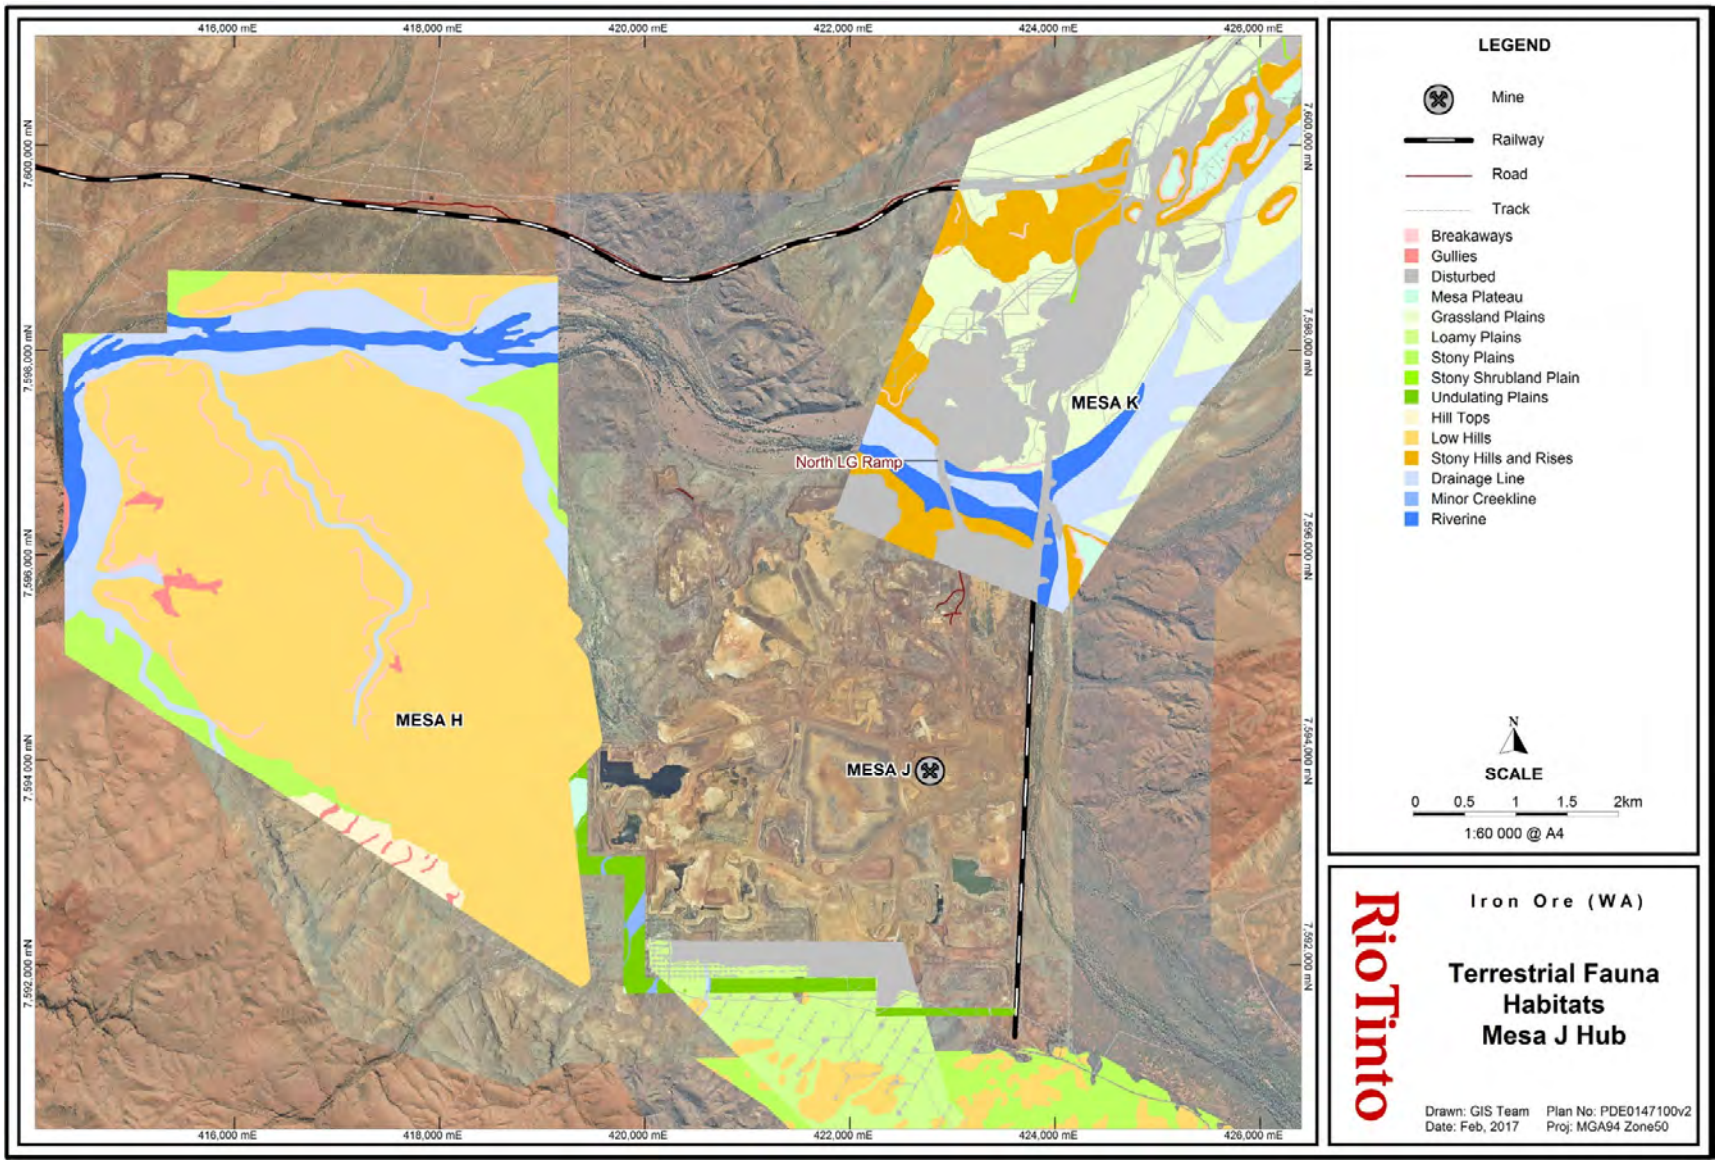

Figure 16: Terrestrial fauna habitats of Mesa J Hub

12.2 Fauna habitat

Re-introduction of fauna is not considered as part of this closure plan. Instead, natural migration of fauna species into rehabilitated land is encouraged by creating habitats with similar composition to pre-mining communities in appropriate locations and with consideration of the post-closure soil and landforms design.

Habitat elements that are considered as part of the closure landform design include:

- vegetation known to provide preferred food or shelter preference;
- retaining and replacing woody debris;
- rapid generation and retention of leaf litter using small-scale topography (e.g. furrows created from ripping);
- introducing or leaving rocky features such as oversized waste burden or scree slopes;
- creating greater depths of friable soil (or suitable mineral wastes) for burrowing fauna;
- preserving connectivity with unmined areas, and maintaining the quality of these habitats; and
- managing feral predators and herbivores across both reference and rehabilitated areas.

Species associated with plains, drainage line or disturbed habitats have the potential to benefit from the rehabilitation of mine, as a consequence of returned or expanded habitat post-closure.

12.3 Conservation significant fauna

Eight species of conservation significance have been recorded or evidence found of their presence within the Mesa J Hub mining area.

A summary of the species, conservation status and habitat is presented in Table 14.

Table 14: Species of conservation significance and associated habitats at Mesa J Hub

Fauna species	Conservation status WA	EPBC Act status	Habitat occurrence
Dasyurus hallucatus (Northern Quoll)	Schedule 2	Endangered	Breakaways & Gullies Rocky Ranges Water-courses
Liasis olivaceus barroni (Pilbara Olive Python)	Schedule 3	Vulnerable	Breakaways & Gullies
Macroderma gigas (Ghost Bat)	Schedule 3	Vulnerable	Breakaways & Gullies Water-courses
Rhinonicteris aurantia (Pilbara) (Pilbara Leaf-nosed Bat)	Schedule 3	Vulnerable	Breakaways & Gullies Water-courses
Merops ornatus (Rainbow Bee-Eater)	Schedule 5		Breakaways & Gullies Water-courses Plains
Ardea modesta (Eastern Great Egret)	Schedule 5		Water-courses
Pseudomys chapmani (Western pebble-mound mouse)	Priority 4		Rocky Ranges
Notoscincus butleri (Lined soil-crevice skink)	Priority 4		Plains

12.4 Feral animals

Feral carnivores (e.g. cats, dogs, foxes) can create locally increased predation pressure on native fauna as well as increase competition with native species for resources such as space (territory), water and food. Feral herbivores (e.g. cattle, camels, donkeys) can also have a significant impact in Rangeland areas, such as the Pilbara. In dry times, grazing pressure reduces the abundance of palatable native species, impacting biodiversity and can create conditions that encourage weeds to grow. Foot traffic impacts the soil conditions, and in combination with over grazing, can encourage erosion. Foot traffic has also been the cause of damage to cultural landmarks and Aboriginal sites. Overgrazing and damaged soils has a flow-on effect to native fauna species that rely on this vegetation for food and shelter. Should management of feral animals be required at closure, a management plan will be developed. Feral animal control is an operational requirement, however it is not expected to be required post closure.

12.5 Conservation significant flora

Table 15 describes the Priority flora that have been identified in or near the Mesa J Hub. No Declared Rare or Threatened flora have been recorded in or near the Mesa J Hub area, nor are any expected to occur.

Table 15: Conservation significant flora identified in or near the Mesa J Hub.

Flora taxon	Conservation status WA	Habitat comments
Triodia sp. Robe River (M.E. Trudgen et al. MET 12367)	Priority 3	Ironstone substrates, sometimes with a clay loam content, most commonly on the crests of mesas (particularly around the rocky margins) and sometimes in in flowlines dissecting these areas.
Indigofera sp. Bungaroo Creek (S. van Leeuwen 4301)	Priority 3	Drainage lines, creeks in hills or plains. Brown silty loam.
Rhynchosia bungarensis	Priority 4	Pebbly coarse sand and amongst boulders on the banks of flowlines.

12.6 Invasive flora

Flora and vegetation surveys have recorded 24 introduced species (Table 16), with 20 species on the Department of Parks and Wildlife Impacts and Invasiveness Ratings list for the Pilbara.

Table 16: Weed species recorded at Mesa J Hub

Scientific Name	Common Name	Ecological Impact	Invasiveness
**Aerva javanica*	Kapok Bush	High	Rapid
**Argemone ochroleuca*	Mexican Poppy	Unknown	Rapid
**Bidens bipinnata*	Bipinnate Beggartick	Unknown	Rapid
**Cenchrus ciliaris*	Buffel grass	High	Rapid
**Cenchrus setiger*	Birdwood Grass	High	Rapid
**Chloris barbata*	Purpletop Chloris	High	Rapid
**Citrullus colocynthis*	Colocynth	Unknown	Moderate
**Cucumis melo*	Ulcardo Melon	Unknown	Moderate
**Cynodon dactylon*	Couch	High	Rapid
**Datura leichhardtii*	Native Thornapple	Unknown	Unknown
**Echinochloa colona*	Awnless Barnyard Grass	High	Rapid

Scientific Name	Common Name	Ecological Impact	Invasiveness
**Euphorbia hirta*	Asthma Plant	Low	Slow
**Flaveria trinervia*	Speedy Weed	-	-
**Lactuca serriola*	Prickly Lettuce	-	-
**Malvastrum americanum*	Spiked Malvastrum	High	Rapid
**Melochia pyramidata*		-	-
**Ocimum basilicum*	Basil	-	-
**Passiflora foetida*	Stinking Passion Flower	High	Rapid
**Phoenix dactylifera*	Date Palm	High	Rapid
**Rumex vesicarius*	Ruby Dock	High	Rapid
**Setaria verticillata*	Whorled Pigeon Grass	High	Rapid
**Solanum nigrum*	Black Berry Nightshade	Low	Rapid
**Sonchus oleraceus*	Common Sowthistle	Low	Rapid
**Tribulus terrestris*	Caltrop	Unknown	Moderate
**Vachellia farnesiana*	Mimosa Bush	High	Rapid

12.7 Priority and/or Threatened Ecological Communities

No Threatened Ecological Communities have been recorded in or near the Mesa J Hub area. Three Priority Ecological Communities (PEC) occur within the Mesa J Hub area as described in Table 17. However, vegetation which is considered analogous to the Priority 3 PEC '*Triodia sp. Robe River assemblages of mesas of the West Pilbara'* has been mapped at Mesa H.

Table 17: Priority and/or threatened ecological communities in or near the Mesa J Hub area

Community Name	Conservation status WA	Description	Location in respect to Mesa J Hub
Subterranean invertebrate communities of mesas in the Robe Valley region	Priority 1	A series of isolated mesas occur in the Robe Valley in the Pilbara Region. The mesas are remnants of old valley infill deposits of the palaeo Robe River. The troglobitic faunal communities occur in an extremely specialised habitat and appear to require the particular structure and hydrogeology associated with mesas to provide a suitable humid habitat. Short range endemism is common in the fauna. The habitat is the humidified pisolitic strata.	Central and northern sections of Mesa J and all of Mesa K
Subterranean invertebrate community of pisolitic hills in the Pilbara	Priority 1	A series of isolated low undulating hills occur in the Pilbara region. The troglofauna are being identified as having very short range distributions.	Southwestern potion of Mesa J and all of Mesa H
Stygofaunal community of the Bungaroo Aquifer	Priority 1	A unique assemblage of aquatic subterranean fauna including eels, snails and other stygofauna.	South-eastern corner of Mesa J, extending south

13. Progressive rehabilitation

Regular reviews of the mine plan are used to identify disturbed areas of the site where mining activity has been completed. These areas are then reviewed for potential to undertake progressive rehabilitation works. Lessons learnt during these activities and from subsequent monitoring campaigns are used to inform and update our standard management practices and provide input into suitability of final closure criteria for the site.

To date, approximately 310ha of rehabilitation has been completed at the Mesa J and Mesa K operations. Approximately 105ha of previously rehabilitated areas have been re-disturbed to facilitate ongoing mining activities, with 205ha remaining. Table 18 and Figure 17 provide an overview of the main areas of progressive rehabilitation undertaken at Mesa J and Mesa K to date.

Table 18: Progressive rehabilitation details

Site	Location	Category	Area rehabilitated (ha, approximate)	Year of Rehabilitation (estimated)
Mesa J	Calcium Dump	Waste Dump	6.57 Disturbed	1996
Mesa J	A Dump	Waste Dump	10.77 Disturbed	2004
Mesa J	North West Dump	Waste Dump	7.08 Partially disturbed 5.40 remaining	2002-2004
Mesa J	North East Dump	Waste Dump	4.86 Disturbed	2002
Mesa J	S Waste Dump	Waste Dump	31.10 Planned to be reclaimed	2004-2008
Mesa J	T Waste Dump	Waste Dump	28.70 Planned to be reclaimed	2004-2008
Mesa J	Pit 10	Pit Floor	13.26	2014
Mesa J	TSF1	Waste Fines Storage Facility	44.87	2014
Mesa J	CLBB	Rail (Construction)	1.62	2014
Mesa K	K Pit	Pit Floor	142.00 Partially disturbed 62.22 remaining	1994-1996
Mesa K	West WD	Waste Dump	3.87	1996
Mesa K	Haul Rd	Haul Road	11.23	1997
Mesa K	Gravel Pit	Pit Floor	4.48	2013

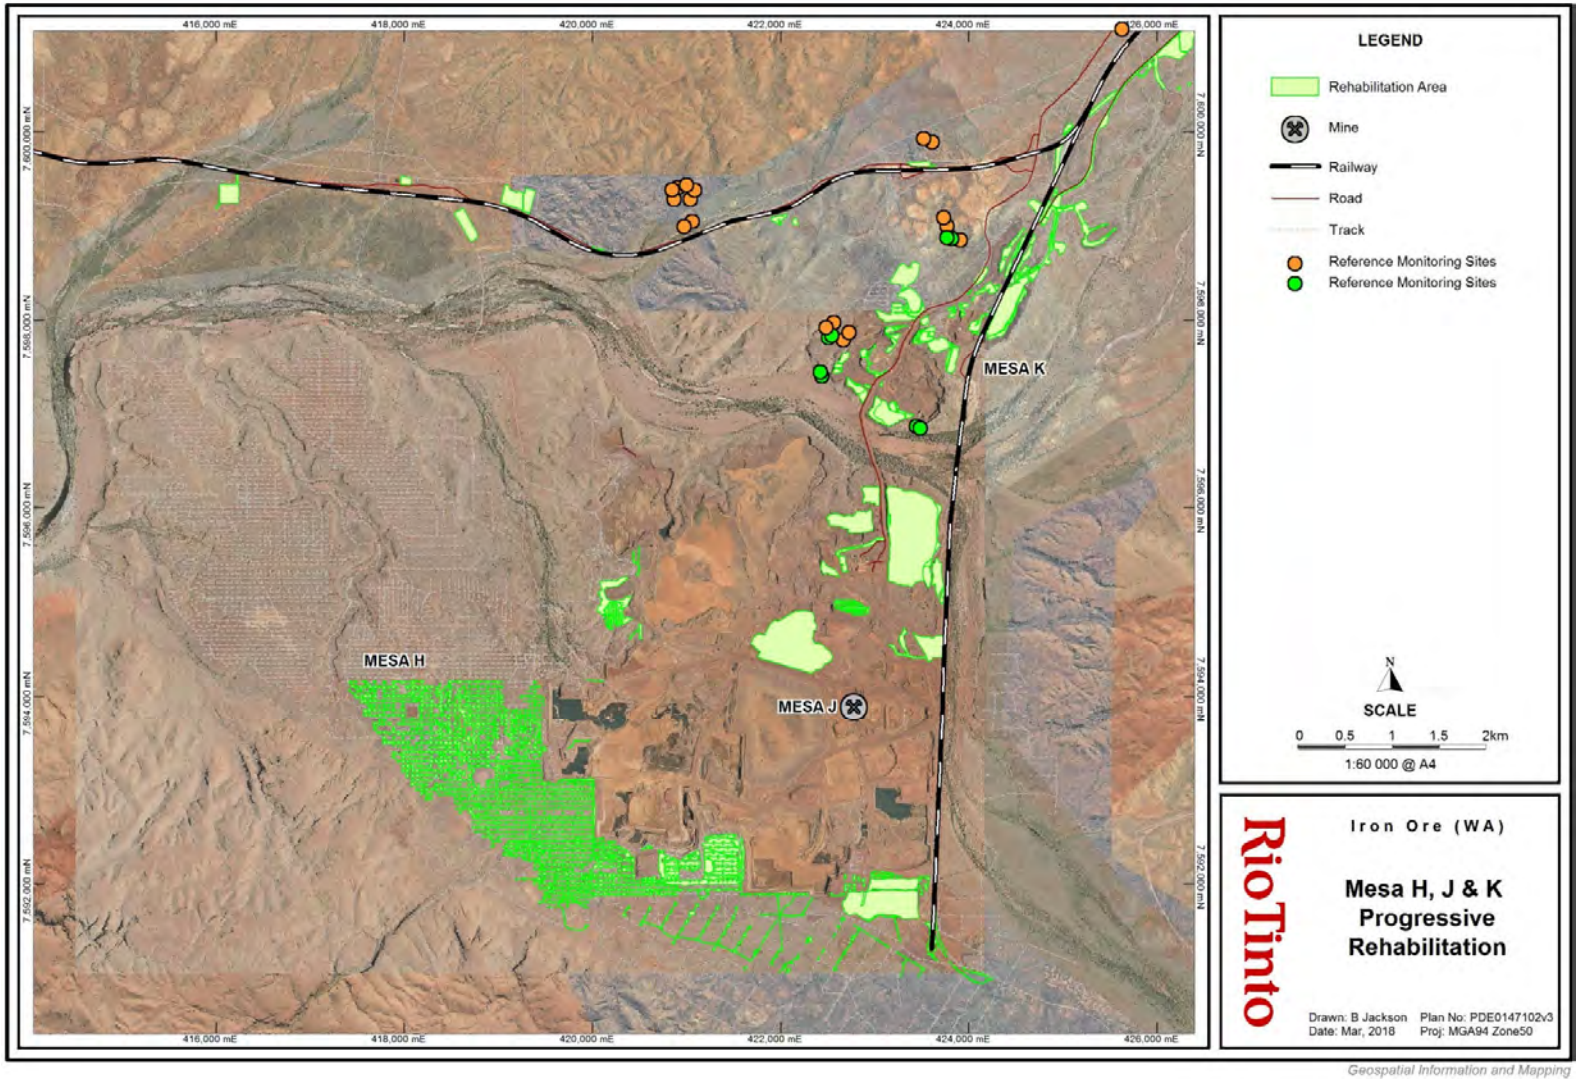

Figure 17: Progressive rehabilitation areas at Mesa J and Mesa K

13.1 Seed provenance and selection

Locally collected seed is needed to assist in revegetation and the creation of a self-sustaining ecosystem. Over time the viability of seeds in stockpiled topsoil decreases, and thus the quality of the topsoil deteriorates. In addition, the topsoil that was salvaged prior to disturbance may not contain seeds of all the target species of its new location / habitat.

Seed mixes for rehabilitation are of local provenance where possible. Specific seed mixes are selected to provide a range of species appropriate to the desired habitat, taking into consideration landscape position and slope. In areas where erosion risks are identified, seed mixes may be modified to include or increase the portion of species that provide rapid cover.

Rio Tinto purchases seeds from commercial seed suppliers, with emphasis on ensuring that there are appropriate local provenance seeds available for rehabilitation of each of its sites. Seeds are stored in purpose-built, climate controlled storage facilities to maximise long term viability.

The inclusion of rare and threatened species in rehabilitation programmes is limited by:

- habitat preference (preference for drainage lines, gullies, calcretes or other habitat not suitable or similar to those likely to be present in the rehabilitation landscapes);
- abundance – very few populations or small populations from which to source seed;
- difficult taxonomy / unresolved taxonomy issues and thus status of species highly uncertain;
- growth form – e.g. short lived annual species with preference for growth under woodland canopies;
- seed production – some species do not regularly produce seed;
- propagation methods – some species are not able to germinate from seed and cuttings are required which is not a suitable method for broad scale application in an arid environment;
- availability of seed at the time when rehabilitation occurs; and/or
- seed dormancy.

Given these issues, the main focus of rehabilitation programs is to restore vegetation complexes that include the more common species present in the particular habitat type, and to achieve a diverse range of strata. Seed mixes may include species of conservation significance if they are available, but presence of these species in rehabilitation areas is more likely to result from natural recruitment from surrounding areas.

13.2 Pits

The majority of Mesa K Pits were rehabilitated between 1994 and 1996. Some topsoil was spread on the area, followed by shallow ripping and seeding. Monitoring locations were installed in 1999, at 25 different locations around the pit. A suite of sites were monitored on six occasions, the most recent of which was in 2013. The rehabilitation was compared to local undisturbed reference sites. Vegetation is well established, reflecting the maturity of the rehabilitation.

Mesa J Pit 10 was rehabilitated in 2014. The pit was ripped and seeded, with topsoil only spread on the northern area of Pit 10. Monitoring locations were installed in 2014 on both the top-soiled and non-top-soiled areas of Pit 10. Development of the rehabilitation was monitored in 2014 and 2015 (Figure 18). The rehabilitation is compared to local undisturbed reference sites. Pit 10 North has good vegetation establishment with a range of native vegetation species. Pit 10 South has limited native perennial vegetation establishment, due to both the young age of the rehabilitation and the lack of topsoil. Over time, it is expected to perform similarly well to Mesa K Pit rehabilitation (Figure 19), with differences attributed to topsoil, particularly at Pit 10 South. Buffel Grass and Birdwood Grass are present at Pit 10 North and Ruby Dock at Pit 10 South. Weeds in rehabilitation are managed under the company's *Weed Management Strategy* which has control measures such as periodic spraying and equipment hygiene procedures.

The Gravel Pit at Mesa K was rehabilitated in 2013 by reshaping, ripping, and seeding. Good regrowth had occurred on the area prior to rehabilitation, so the soil and vegetation were collected and respread during rehabilitation. Monitoring locations were installed in 2014, one on the upper area and one on the lower area. These were monitored in 2014 and 2015. The rehabilitation was compared to local undisturbed reference sites. Vegetation is establishing well, with vegetation parameters comparable to the reference sites (Figure 20).

13.3 Waste dumps and waste fines storage facilities

Mesa K West waste dump and a haul road were rehabilitated in 1996 and 1997 respectively. Both locations had topsoil spread on the area. Monitoring locations were installed in 2013; two at the Waste Dump and one at the Haul Road. These were monitored in 2013. The rehabilitation was compared to local undisturbed reference sites. Vegetation is well established at both rehabilitation areas, reflecting the maturity of the rehabilitation; however density and cover are slightly lower than reference sites.

The S and T Waste Dumps at Mesa J were rehabilitated between 2004 and 2008 by reshaping, ripping, and seeding the dump slopes and tops. S Dump received topsoil, whilst T Dump received subsoil. Monitoring locations were installed in 2008, including both sloped and flat areas. Development of the rehabilitation was monitored on five occasions, the most recent of which was in 2015. The rehabilitation is compared to local undisturbed reference sites. At S Dump, vegetation cover and density had been increasing since completion, with an upper storey developing since 2010. The flat areas on top of the dump had plant density and cover plateauing in 2015, indicating the rehabilitation had completely established. T Dump also increased vegetation cover and density in the early stages, and plateaued around 2010. S Dump had higher cover and density than the compared reference sites, while T Dump had lower values (Figure 21). Minor erosion occurred on the sloped sides of both dumps; however monitoring data demonstrates it was not active and had stabilized. Buffel Grass was present at S Dump and Ruby Dock at T Dump; both are sparse and not outcompeting native vegetation. Weeds in rehabilitation are managed under the company's weed management strategy which has control measures such as periodic spraying and equipment hygiene procedures.

Mesa J Waste Fines Storage Facility 1 (TSF1) was rehabilitated in 2014 as a trial of WFSF closure without the use of a capping layer. TSF1 was ripped and seeded, taking care to avoid large trees established in the area. Topsoil was not spread on TSF1, as growth media studies supported the surface material being suitable for vegetation growth. Monitoring locations were installed in 2014 on the upper and low-lying (periodic inundation) areas of TSF1. Development of the rehabilitation was monitored in 2014 and 2015. The rehabilitation is compared to local undisturbed reference sites. Vegetation establishment has been variable across TSF1 (Figure 22); however vegetation metrics have mostly increased since 2014. Minor subsidence has been noted, although is expected to stabilize as vegetation establishes and waste fines settle. Birdwood Grass is present in the low-lying areas and Buffel Grass in the upper areas. Ruby Dock is present across TSF1; however in general, introduced species are declining in density. Weeds in rehabilitation are managed under the company's weed management strategy which has control measures such as periodic spraying and equipment hygiene procedures.

13.4 Low impact disturbance areas, roads and borrow pits

The construction areas along the rail line at Mesa J were rehabilitated in 2014. Topsoil was respread and the areas were shallow ripped; no seeding occurred due to the direct return of fresh topsoil. Three monitoring locations were installed and monitored in 2015; two next to the rail line and one along the access road. The rehabilitation was compared to local undisturbed reference sites. Vegetation establishment along the access road was comparable to reference sites, even at a young age, with no weeds present. Good results are attributed to the lack of disturbance and traffic surrounding the area. Vegetation establishment along the rail line is beginning to occur, however vegetation parameters are low, reflecting the young age of the rehabilitation. Buffel Grass, Birdwood Grass, Ruby Dock, Kapok and Pie Melon are present in these areas; Birdwood Grass, Spiked Malvastrum and Mimosa Bush were also present in nearby reference sites. Weeds in rehabilitation are managed under the company's *Weed Management Strategy* which has control measures such as periodic spraying and equipment hygiene procedures.

14. Contaminated sites

Rio Tinto maintains registers for potentially contaminating activities and known or suspected contaminated sites which have been formally reported under s11 of the *Contaminated Sites Act 2003* (WA). The registers are informed by regular review of operations and where required preliminary site investigations to assess contaminants associated with such activities and assess their risk of harm to human health, the environment and environmental values. Potentially contaminating activities and land uses as described in the guideline '*Assessment and management of contaminated sites'* (DER, 2014), that may be associated with mining activities onsite include, but not limited to:

- Airport facilities;
- Automotive repair workshops (light and heavy machinery);
- Substations and transformers;
- Fertiliser and explosives storage;
- Landfill sites;
- Mineral processing, mining, screening and crushing facilities;
- Rail transport corridors;
- Hydrocarbon storage, handling and dispensing facilities;
- Sewage waste water treatment plants and irrigation areas; and
- Disturbance of potentially acid forming materials during the course of mining.

All potentially contaminating activities and land uses identified on the site register are managed as part of the ongoing mining operation. Prior to closure as part of the decommissioning process, a contaminated site assessment will be undertaken. Based on this assessment, specific plans will be developed to remediate or manage contaminants, where required, to support the final land use.

15. Cultural heritage

Rio Tinto recognises and respects the significance of Australia's cultural heritage, and in particular the cultural heritage of Aboriginal people who have traditional ownership of, and/or cultural connections to, the land on which it operates. Extensive archaeological and ethnographic surveys have been undertaken in the Mesa J Hub area, and these surveys help to inform the heritage values of the area. Rio Tinto takes all reasonable and practicable measures to prevent harm to cultural heritage sites, this includes during works associated with rehabilitation and closure. Where this is not possible, steps are taken to minimise or mitigate impacts and ensure required statutory approvals are obtained. Closure works consider issues such as post closure access requirements to culturally significant sites and appropriate return of any materials salvaged during mining operations.

15.1 Relevant Aboriginal groups

The Mesa J Hub lies within the traditional country of the Kuruma Marthudunera (K&M) people. The K&M currently have a large native title claim area over the Robe Valley, which includes the Mesa J Hub, and K&M also possess a native title determination (Part A) over a large area east of the claim into the western Hamersley ranges, which abuts the native title claim.

The extent of Kuruma Marthudunera country in relation to Mesa J Hub is shown on Figure 5. A Claim Wide Participation Agreement (CWPA) was signed by Rio Tinto and K&M in 2011, and an Indigenous Land Use Agreement (ILUA) registered in 2013. A Cultural Heritage Management Plan is scheduled to be completed in 2017, and is due for review every 5 years.

15.2 Ethnographic and archaeological values

Heritage surveys (in alignment with the Heritage Protocol within the CWPA) with nominated Kuruma Marthudunera representatives and external consultants have identified archaeological and ethnographic sites and made recommendations on the significance and management of each site. Sites of significance within the Mesa J Hub area include:

- 3 Law Grounds (Thalartna, Yarramarda and Buggumadda);
- Old Deepdale Homestead;
- 3 important ethnographic (thalu/increase) sites (Jirti Thalu, Parkunyji and Yunta);
- one large rockhole at Mesa J with high ethnographic significance (Mesa J Rockhole);
- one permanent waterhole in the Robe River with high ethnographic significance (Yeera Bluff);
- numerous named (ethnographic) waterholes spread along the Robe River. Some permanent, some semi-permanent;
- a burial site north of Mesa H on the terrace between the mesa escarpment and the Robe River;

- the Robe River is viewed by K&M as a whole system, which includes its general health and waterholes, vegetation and fauna;
- the existing Mesa Façades are used as navigational landmarks; and
- multiple archaeological sites (including several gender restricted sites).

In some cases where disturbance is unavoidable, artefacts and cultural material may be disturbed and removed under Section 18 consent of the *Aboriginal Heritage Act* 1972 and placed into storage to facilitate mining activity. A number of such sites at the Mesa J Hub have either been cleared or nominated to be cleared under these provisions, with material stored in the Mesa J Keeping Place located at the Mesa J minesite In some circumstances, when objects or artefacts have been salvaged from a site, the K&M people have expressed the desire to repatriate the artefacts to the land from which they were removed post closure and rehabilitation. The particular circumstances where this may be required is captured in the Cultural Heritage Management Plan (CHMP) for the Mesa J Hub area

16. Regional Community

The town of Pannawonica is 16 kilometres north-west of the mine. Pannawonica was established in 1970 specifically to support the adjacent mines, and is one of a limited few closed towns remaining in the Pilbara whereby all facilities are owned by a mining company, in this case Rio Tinto, and are maintained and operated on its behalf. It has a resident population of over 700 people.

Approximately 350 people work at the Mesa J and K operation. Employees either reside permanently in the town of Pannawonica or reside in the town on a fly-in, fly-out (FIFO) roster. The FIFO workforce utilise the Karratha airport and travel to Pannawonica via the North West Highway. The town falls within the Yarraloola pastoral lease.

There are no permanent Aboriginal communities in close proximity to the Mesa J Hub. The nearest Aboriginal community is a small settlement known as “The Block” which is located 3km north of Mesa H. The Block is seasonally occupied by some families from the K&M and contains limited permanent infrastructure. There is potential for the occupation of the community to increase over time.

IDENTIFICATION AND MANAGEMENT OF CLOSURE ISSUES

17. Risk evaluation process

A closure risk assessment was completed to identify and assess closure issues for Mesa H, J and K. The risk assessment is included in Appendix D. The assessment was completed by an internal panel of multi-disciplinary subject matter experts with the aim of:

- identifying hazards, aspects and opportunities that could influence the successful closure of the site;
- evaluating the resulting risks to people, property and the environment; and
- defining the actions required to reduce the risk to below the risk acceptance threshold.

Risk was evaluated on the basis of the maximum reasonable outcome consequence and the likelihood of that consequence occurring. Risks were evaluated inclusive of current management and commitments, and represent current residual risk.

Issues are assessed against the following consequence criteria:

- **Costs:** economic impacts if the risk were to eventuate ranging from low to very high, determined as a percentage of the projected closure cost for the operation;
- **Health:** reversible health effects of little concern (very low) to multiple fatalities (very high);
- **Personal safety:** inconvenient first aid treatments (very low) to multiple fatalities (very high);
- **Environment:** reversible impact (very low) to widespread, long-term impacts (very high). These risks are separated into two categories – during decommissioning/active closure implementation or post closure.
- **Community trust:** mistrust amongst a small section of the wider community (very low) to widespread mistrust with key stakeholders (very high). Also includes potential heritage impacts ranging from reparable damage to a site of low cultural significance (very low) through to irreparable damage to a site of international cultural significance (very high); and
- **Compliance:** non-conformance to internal requirements (very low) to prosecution for breach of regulatory licence(s) (very high).

Risks are classified as follows:

- **Class I:** Risks that are below the risk acceptance threshold and do not require further active management.
- **Class II:** Risks that lie on the risk acceptance threshold and require active monitoring to ensure management remains adequate and fit-for-purpose.
- **Class III:** Risks that, based on the current level of knowledge, could exceed the risk acceptance threshold and require proactive management and / or resolution of knowledge gaps.
- **Class IV:** Risks that, based on the current level of knowledge, will exceed the risk acceptance threshold and need urgent and immediate action.

Actions are assigned to risks that exceeded the risk acceptance threshold and therefore require additional control measures to reduce the risk to an acceptable level. Actions are also assigned to address knowledge gaps where it is assessed that further information is required to better understand and/or adequately assess the risk presented by an issue. This would typically be the case in the early stages of closure where the detailed knowledge of the issues may be low. These actions are captured in Appendix E.

18. Management of key issues

The DMP/EPA *Guidelines for Preparing Mine Closure Plans* lists a number of rehabilitation and closure issues that may be relevant for mine sites. An evaluation of the relevance of each of these issues to the Mesa J Hub is presented in Table 19. The information in this table is intended to compliment that contained in the risk assessment presented as Appendix D.

Table 19: Relevance of potential closure and rehabilitation issues to Mesa J Hub

Issue	Evaluation of relevance to Mesa J Hub	Further discussion
Acid and metalliferous drainage	The geochemical evaluation has determined that the sites are a low AMD risk.	Not addressed further in this chapter.
Challenges associated with rehabilitation and revegetation	The Mesa J and K areas have had areas of successful rehabilitation undertaken in both waste dumps and pits. Progressive backfill of pits to meet closure commitments and other opportunistic rehabilitation will be undertaken during operations, however the majority of rehabilitation will be completed at closure. A significant proportion of Mesa J will be covered by in-pit waste fines storage facilities. Management of waste fines rehabilitation is discussed in Section 18.2.	Section 18.1 and 18.2
Dispersive, sodic and erosive materials	The sites have a proportion of material which is of high erodibility.	Section 18.3.
Radioactivity	Not a significant issue for this site	Not addressed further in this chapter.
Mine pit lakes	A small pit lake is proposed at the Mesa J reservoir, (pit 15) a small water storage area during operations.	Section 18.4
Geotechnical instability	The waste dumps planned to remain at closure are not within the zone of instability of any pit voids. To ensure long term stability of the Mesa façades, the pit design incorporates pit wall design parameters and minimum façade width based on geotechnical assessment	Section 18.5
Inadvertent public access	There is potential for public access to the area post closure. Options are being considered for each mining area to address the risk of inadvertent public access.	Section 18.6
Hazardous materials	Hazardous materials (e.g. hydrocarbons, ammonium nitrate) will be removed prior to or during decommissioning.	Not addressed further in this chapter.
Hazardous and unsafe facilities	All infrastructure will either be demolished during decommissioning, or handed to the State in accordance with State Agreement requirements.	Not addressed further in this chapter.
Contaminated sites	There are no reportable contaminated sites.	Not addressed further in this chapter.
Fibrous materials	The geological evaluation has determined that the sites are a low fibrous materials risk.	Not addressed further in this chapter.
Non-target metals and target metal residues in mine wastes	No chemical processing occurs at the site.	Not addressed further in this chapter.

Issue	Evaluation of relevance to Mesa J Hub	Further discussion
Adverse impacts on surface and groundwater quality	Surface and groundwater quality are not expected to be significantly impacted as a result of the closure strategy. Monitoring of the Robe River Pools occurs regularly to assess water quality.	Section 18.7
Design and management of surface water structures	Surface water diversions and flood protection features will be present. No major creek diversion is required.	Section 18.8.
Dust emissions	This is not considered to be a significant closure issue for the site due to its remote location and no specific sensitive receptors identified.	Not addressed further in this chapter.
Flora and fauna diversity/threatened species	Subterranean Fauna Priority Ecological Communities (PECs) intersect the mining footprint. Mining exclusion zones have been established to ensure sufficient troglofauna habitat will remain at closure. The Bungaroo community does not require management at this stage.	Section 18.9
Visual amenity	The results of a visual impact assessment have been considered during planning of waste dump locations and height.	Section 0
Heritage issues	Management of cultural heritage values is conducted through processes established under the Indigenous Land Use Agreement, and strategies incorporated into Cultural Heritage Management Plans (CHMP). The CHMP for the Mesa J Hub will be drafted in 2017 and reviewed annually.	Not addressed further in this chapter.
Alteration of the direction of groundwater flow	Alteration of groundwater flow direction is not expected in the long term.	Not addressed further in this chapter.
Alteration of the depth to water table of the local aquifer	Dewatering will suppress groundwater levels at the operation. Ongoing and adaptive management will occur in response to modelling and monitoring indicating an impact to the Robe River pools.	Section 18.7
Alteration of the hydrology and flow of surface waters	No major creek diversion are required. Landform design takes into account surface water impacts and changes to hydrology.	Section 18.8.

18.1 Challenges with progressive rehabilitation

Rio Tinto has formal processes for identifying areas which are no longer required for operational activity and are therefore available for rehabilitation. However, mine plans are dynamic and subject to continuous revision, and rehabilitation may need to be re-disturbed for mining or operational use. Progressive rehabilitation opportunities are reassessed regularly as part of the planning process.

A legacy area review workshops was conducted at Mesa J and K in early 2017. The workshops focus on all areas of the mine, particularly the older lesser known areas. The current mine plan for Mesa J incorporates progressive backfill of pits where practical as required by Ministerial Statement 208, and proposed mining for Mesa H also incorporates progressive backfill of pits. The majority of backfill is undertaken during operations, however some backfill may not be possible until the end of mine life due to mine sequencing. Some backfill areas require additional landform design which has been included as an action in the closure task list.

Rehabilitation is conducted in accordance with the *Rio Tinto Iron Ore Rehabilitation Handbook*, which is reviewed and updated periodically to reflect changes in industry standards, reflect new knowledge obtained through research and development, and to adopt learnings from ongoing rehabilitation projects. The Handbook addresses:

- soil resource management;
- rehabilitation techniques;
- local provenance species seeding practices;
- records and data management; and
- on-going monitoring.

Rehabilitation typically involves:

- removal of rubbish, redundant equipment and infrastructure, ensuring the area is not contaminated;
- reshaping and contouring land to blend with natural relief to manage drainage to ensure stability;
- ensuring that appropriate controls are in place to manage hazardous mineral wastes, including encapsulation of PAF and fibrous wastes (not applicable in the Mesa J Hub), and installation of store and release covers where required;
- installation of abandonment and drainage management bunds where required;
- application of soil to a depth of 200mm where practical to promote vegetation growth;
- deep rip to an appropriate depth prior to seeding;
- seeding to ensure a suitable vegetation cover and composition, generally using a mechanical seeder;
- recording rehabilitated areas on internal GIS databases; and
- inclusion within the rehabilitation monitoring program where appropriate.

Topsoil and subsoil is managed in accordance with the *Rio Tinto Iron Ore Soil Resource Management Work Practice* in order to ensure appropriate material is available for rehabilitation activities. Where practical, a minimum of 200mm of topsoil and up to 600mm of subsoil is collected whenever new ground is disturbed. Reconciliations of topsoil volumes are undertaken to confirm that sufficient material is available to spread across the rehabilitated area, assuming a spreading depth of 200mm. Locations for soil stockpiles have been identified and incorporated into the mine plan. Topsoil stockpiles are planned to be up to 2m tall to maintain viability, and will be used to rehabilitate areas cleared for mining and infrastructure, including pit voids.

18.1.1 Revegetation challenges

The use of topsoil in rehabilitation is generally linked to improved revegetation outcomes. The soil seed bank quality within the stockpiled soil is known to reduce over time. Given the long mine schedules in Iron Ore operations it is anticipated that the soil quality may be reduced. Field trials been undertaken in the business to gauge results of using reduced soil quality, no soil or alternative growth media. It is likely that the reduced viability of the seed bank is a key concern in achieving the range of key species desired in the rehabilitation in a cost effective process.

Supplementary seeding is commonly undertaken in rehabilitation of medium and high disturbance areas. The ability to meet seed requirement volumes for closure is captured as a risk in achieving successful revegetation. A long term seed procurement strategy requires development to ensure sufficient volumes of seed are available for use when required. Seed used in rehabilitation is local provenance where possible, and availability can be limited by seasonal variation and a lack of suitable collectors. Currently seed procurement is focused on meeting the requirements of progressive rehabilitation targets.

Actions have been included in the sites closure task register relating to improving rehabilitation and revegetation success.

18.2 Management of waste fines storage facilities

The Mesa J Hub will utilise the existing Mesa J wet plants for processing. All waste fines are proposed to be contained in in-pit Waste Fines Storage Facilities (WFSF). Waste fines are scheduled to be contained entirely within the Mesa J in-pit facilities. As WFSF's reach capacity they will be capped with a layer of waste rock, when safe to access with heavy equipment.

The final landform design of these areas assumes a minimum 2m capping layer of inert material will be placed over the facilities. The capping layer thickness may be increased to facilitate disposal of waste rock, and enable utilisation of the surface of the WFSF for operational purposes. Given the designs for the future WFSF are still conceptual, further work will be required to review the interaction between pit walls and the WFSF's. Updates to the landform will be included in closure plan updates.

A closure task has also been identified to assess the potential for seepage from WFSF into the aquifer and potential impact to groundwater quality and subterranean habitats.

Rehabilitation of the existing TSF1 has been completed. This area was rehabilitated without capping as a trial. It is anticipated that all other waste fines storage facilities may be capped to reduce the heights and expanse of waste dumps and meet the project commitment to backfill as much waste rock within the pit limits as possible.

18.3 Management of erodible mineral waste

18.3.1 Principles of waste dump design

Mineral waste dumps located on mine sites that are operated by Rio Tinto are designed and rehabilitated in accordance with internal Landform Design Guidelines, which provides guidance on:

- the objectives of waste dump design, which is to achieve dumps that are:
  - safe;
  - stable;
  - aesthetically compatible with the surrounding landscape;
  - vegetated;
  - non-polluting;
  - compatible with the agreed post-mining land use; and
  - progressively rehabilitated;
- appropriate locations for the siting of waste dumps;
- appropriate shapes and designs of waste dumps;
- appropriate surface treatments; and
- links to other relevant internal and external guidance material.

These Guidelines are updated on a regular basis to incorporate learnings from research, studies and rehabilitation implementation projects. The most significant update occurred in 2012 to provide design criteria for waste dumps based on the specific waste types present. This was the result of several years of materials testing and landform evolution modelling studies of wastes typically found in the Pilbara including those at the Mesa J Hub, with design recommendations based on the assumption that an average erosion rate of 5/ha/year (with a maximum of 10/ha/year) will be acceptable. Further studies have since been undertaken on additional waste types, and this resulted in further minor updates in 2014 and 2016.

It should be noted that erosion modelling is conducted on the conservative assumption that slopes are not vegetated. However, vegetation is expected to establish on all slopes, thereby further reducing the erosion potential.

18.3.2 Erosion risk

The Mesa H and Mesa J deposits have a proportion of higher erodibility waste materials, include Tertiary Pisolite Clay (TPC) and Alluvials. Waste disposal via in-pit backfill, and location of several waste dumps in-pit, reduces the erosion risk associated with these materials, as sedimentation would be contained in-pit. The main erosion risk is associated with ex-pit dumps. Erodibility testing and landform modelling of the alluvial materials has been completed and testing is currently underway for the TPC material. To ensure long term stability of waste dumps, design parameters are based on erodibility testing of specific material types, as documented in the *Rio Tinto Iron Ore Batter Selector Tool*. Waste dumps in the project area are generally limited to 40m height, to ensure long-term stability and to reduce visual impact.

The Mesa H external waste dumps have been designed to incorporate a capping layer of competent material on the external surface, to enable 20 degree batter angle and 20m lift height, and a reduction in dump footprint. A competent waste stockpile area has been included in the mine plan, separate to the waste dumps. The Hardcap or HTP geo zone as illustrated in Figure 12 comprises suitable low erodibility waste that will be utilised for capping.

The Mesa K waste dumps contain a large proportion of low erodibility hydrated waste, that present a low erosion risk. Generally the waste dumps have maximum 20 meter lift heights, 20 degree slopes and 10 meter wide berm, based on recommended parameters within the batter selector tool.

A portion of waste at Mesa J and H will be utilised to cap the waste fines facilities to a minimum thickness of 2m. The capping layer thickness may be increased to facilitate disposal of waste rock, and to enable utilisation of the surface of the WFSF for operational purposes. Mine planning to support this closure plan has assumed waste fines will receive a minimum 2m capping depth, if this increases there would be an associated reduction in the final waste dump configurations.

18.4 Management of pit lakes

The water management strategy for Mesa J requires a water reservoir to store water from various sources (including pit dewatering, and WFSF decant), that is used for operational purposes, primarily in the wet processing plants. A small pit lake is currently proposed at the Mesa J Pit 15 reservoir, which is planned as a water storage area from 2020. This may be subject to change over time dependant on changes to the waste and waste fines deposition strategy and designs. Water quality modelling is required to confirm an acceptable environmental outcome. The water quality is anticipated to remain acceptable in the long term with seasonal flushing events contributing to this. Should water modelling outcomes be unfavourable, mitigation actions to address the impact would be implemented, including potential backfilling.

Consideration will need to be given on the accessibility of this area in terms of cattle and other livestock. Further detailed design will be provided in future updates to the closure plan.

18.5 Management of pit void stability

As the Mesa landforms have landscape, visual, heritage and ecological value, it is important to ensure they remain stable in the long term. To ensure long term stability of the Mesa façades, the pit design incorporates pit wall design parameters and minimum required façade width based on geotechnical assessment. A mining exclusion zone (MEZ) protects the façade (Figure 26).

The predicted zones of instability from the pit floors are illustrated in Figure 23, Figure 24 and Figure 25. All permanent landforms such as external waste dumps will be located outside these zones. Abandonment bund locations are conceptual only at this stage, and require further refinement however they will be located outside the zones of instability. Actions to address void stability are included in the sites closure task register.

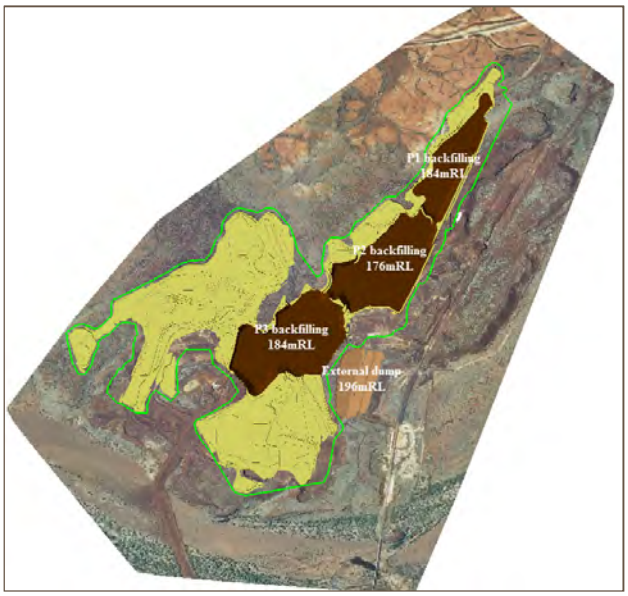

Figure 23: The Mesa K predicted zones of instability

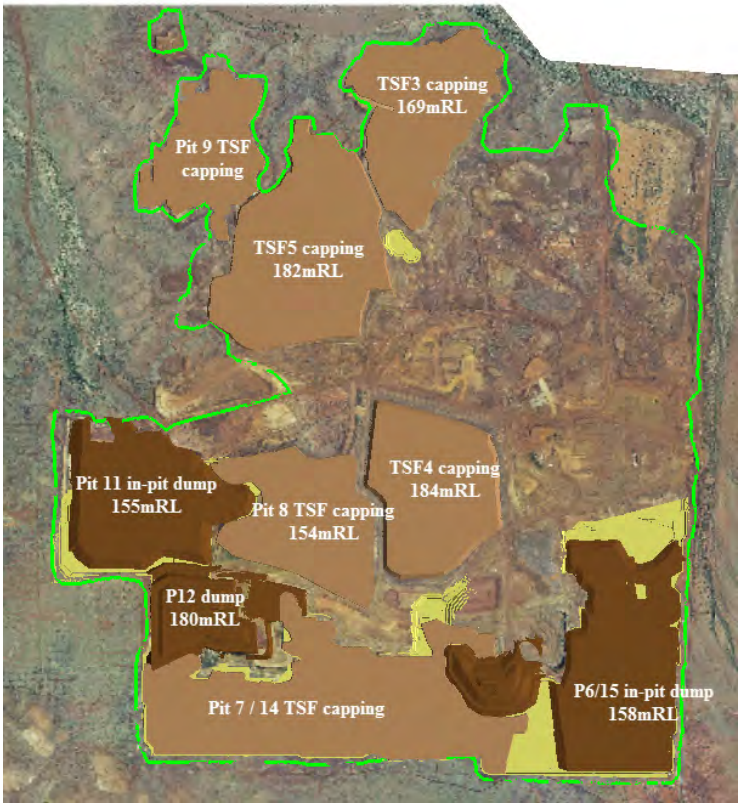

Figure 24: The Mesa J predicted zones of instability

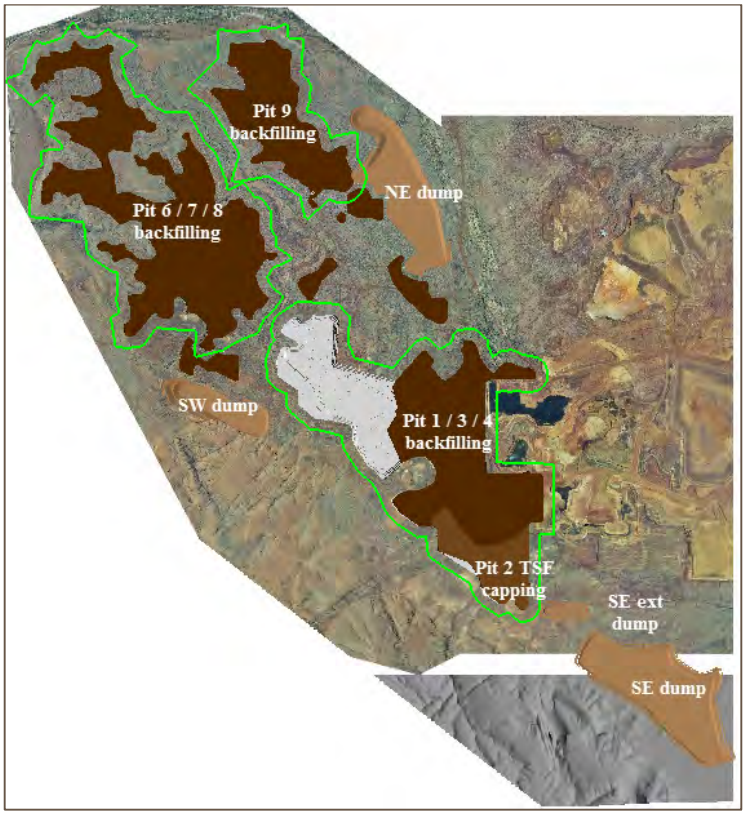

Figure 25: The Mesa H predicted zones of instability

18.6 Management of inadvertent public access

Inadvertent access to the site footprint post closure poses a safety risk due to the following circumstances:

- parts of the area are likely to be suitable to return to pastoral activities post closure;
- there will be pit voids not backfilled to the surface topography;
- there will be a pit lake at Mesa J; and
- access by Traditional Owners to significant heritage and ethnographic sites in the area.

This risk is considered to be reduced to an acceptable level and appropriately managed by the following:

- the area is remote from population centres;
- infrastructure will be decommissioned prior to relinquishment;
- the pits will be predominantly surrounded by the steep mesa façades, providing an effective barrier to inadvertent vehicle access;
- abandonment bunds will be established in areas where the mesa façade does not provide a barrier to inadvertent vehicle access to pits;
- tracks not required for post closure monitoring will be rehabilitated during closure implementation and prior to relinquishment all remaining tracks will be rehabilitated; and
- potential handover of ownership and maintenance requirements for post closure access by stakeholders such as pastoralists and Traditional owners.

18.6.1 Abandonment bunds

The Department of Mines and Petroleum (DMP) Abandonment Bund Guidelines require a 5 meter wide by 2 meter high abandonment bund be placed around a completed pit outside the zone of instability. The purpose of the guidelines is to reduce the likelihood of inadvertent access to the pit. Abandonment bund scenarios will be discussed for each mining area.

The mesa landform and mining method for Robe Valley deposits presents a relatively unique circumstance in regards to requirements for abandonments bunds. The retention of the breakaway landform around the edge of the mesa as a façade up to 20m in height, after mining out the central portion of the mesa, provides an effective barrier to inadvertent access to the pit. Where the façade does not provide an effective barrier to pit access, an abandonment bund is warranted. Consultation with the DMP has commenced on this, including members of the Environment and Safety Divisions.

The nearby Mesa A deposit at the Mesa A Hub provides a precedent of a pragmatic approach to abandonment bunds that is proposed to be adopted at the Mesa J Hub. Mesa A has a steep mesa face to the east, that gradually reduces in elevation to the west to the same height as the surrounding plain. An abandonment bund design for Mesa A was approved under an *Environmental Protection Act* Section 45C approval, and by the District Inspector DMP. Vehicle access to the pit was considered unlikely where the façade was retained at the western end of the mesa, due to the steep terrain. Therefore no abandonment bund is required where the mesa façade is retained. An abandonment bund was required around the flat eastern extent of the deposit, joining to the mesa façade to the west. The abandonment bund has been constructed and the majority of it is already in place. A bund to block vehicular access points onto the mesa is also required.

The majority of the Mesa H pit perimeter will be contained within a steep mesa façade, and no abandonment bund is currently proposed where this façade provides an effective barrier to vehicular access. The south east of the deposit is not bordered by a mesa landform, and will require an abandonment bund. The project will have a conceptual abandonment bund design completed at feasibility stage. During the approvals process for this area, mining exclusion zones may be amended, therefore a bund location design cannot be completed at this time.

Following initial consultation of the project with DMP officers, the company has a project proposed during 2017 to incorporate abandonment bund requirements for new pits and deposits into the required project outputs. Mesa H is likely to be one of the first sites to complete this process during 2017 and should enable a bund design that can be implemented during construction.

The Mesa J and K mining areas do not currently have abandonment bunds in place. An action in the closure task register for the site is to develop these designs with a view to include them in the next update to the closure plan. Specifics of Abandonment bund locations will be discussed with the DMP Environment and Safety Divisions as appropriate.

18.7 Management of dewatering impacts

Dewatering of below water table pits and abstraction at borefields creates a cone of depression in the water table which, depending on geological and hydraulic boundaries, can extend up to several kilometres beyond the area dewatered. This can reduce the amount of groundwater available for any groundwater dependent vegetation and local permanent pools, and therefore efforts are made to reduce the zone of this impact as much as practical.

At Jimmawurrada Creek, the cumulative drawdown along the creek during operations as a result of the Mesa J dewatering, abstraction from the Southern Cutback borefield and the adjacent Coastal Water Project is proposed to be reduced by the implementation of a thickener plant, which will reduce the water demand by approximately 35% and therefore reduce the overall time for the groundwater to recover.

Although poorer water quality may affect the riparian vegetation, terrestrial, subterranean and aquatic fauna around the permanent pools in the Robe River, groundwater abstraction from the CID and basement aquifers has been consistently of fresh quality with chloride concentrations lower than concentrations recorded in the down gradient pools; surplus water discharge monthly quality monitoring data also support this finding.

Semi-permanent and permanent pools exist along the Robe River and have high biodiversity and heritage value. As detailed in Section 11.2, Mesa H and Mesa J aquifers are a continuity of the same system, discharging to the Robe River alluvium aquifer to the north. Annual monitoring of Robe River pools and vegetation since 1993 has reported no measurable impact on the ecology of pools north of Mesa J due to mine-related dewatering. Supplemental discharge may potentially need to continue for a period of time after cessation of active mining at Mesa J Hub to support maintaining environmental and heritage values, this period is largerly dependent on climate. Once mining starts, the aquifer is further stressed and more data becomes avalibale the existing groundwater model will be continuously revised to assess the impacts of dewatering and determine appropriate mitigation requirements.

Groundwater is expected to recover to pre-mining water table levels once dewatering has ceased in the area. Modelling of ground water draw down and recovery timeframes will continue to be updated during the life of the project. Should any potential significant impact to the environmental or heritage values associated with the pools be predicted, mitigation strategies such as direct / optimised discharge to key pools, and avoiding mine pit dewatering below a 120m RL in pit 7 will be considered in consultation with stakeholders.

18.8 Management of surface water

Landforms need to consider the surrounding hydrology of the area, as landforms can have an impact in catchments both upstream and downstream of their location. Both situations need to be considered when conducting a hydrological study. Waste dumps and other landforms can act as a diversion or dam for upstream surface water, reducing flow to the downstream catchment. Likewise, these landforms can erode with surface water flow, destabilising the landform and impacting the downstream environment with sediment.

At the Mesa J Hub, waste dumps and other landforms are generally built outside the 1 in 100 AEP flood plain, consider material characterisation and often include surface water management structures such as diversions, bunds and surface water retention cells. There are, however, two historic waste dumps associated with Mesa K that are potentially constructed within the 1 in 100 AEP flood plain of the Robe River. Preliminary investigation shows that the waste dumps have survived a 1 in 20 to 1 in 50 AEP event in 2009 with minimal disturbance. Further hydrologic/hydraulic modelling and investigation will inform an appropriate closure strategy for these dumps.

Surface water diversions to the south of Mesa H and J pits are not intended to continue to function post-closure. Post-closure drainage will report to backfilled pits, which is likely to intercept 0.5% of the Robe River catchment area. Diversions may be deliberately breached at closure so that surface flows enhance recovery of the groundwater table; alternatively the diversions will likely be breached by large events post-closure that exceeds design criteria. Further assessment will be required to determine the optimal closure strategy for these diversions.

The impacts of the final landform design on surface drainage flows at a site level will require assessment prior to final closure planning

18.9 Management of threatened flora and fauna

As detailed in Section 12.7, there are two PEC's associated with troglofauna communities in mesa landforms of the Robe Valley. Impacts to troglofauna communities during mining of the Mesa J Hub are primarily managed via establishment of avoidance areas or mining exclusion zones. At Mesa K, several avoidance areas to preserve troglofauna habitat have been agreed with regulators as part of environmental assessment and approval. At Mesa J, MS 208 requires protection of the mesa façade adjacent to the Robe River north of the mine to protect heritage values, which will also protect significant fauna and troglofauna habitat. Mesa H pit designs have incorporated mining exclusion zones to protect heritage and biological values including retention of troglofauna habitat. The retention of the Mesa facades during operations will ensure that significant fauna and troglofauna habitat is retained in the final landform upon closure. Proposed mining exclusion zones are shown in Figure 26.

The Bungaroo stygofauna PEC community lies outside the scope of proposed mining operations, and any management of stygofauna will largely be completed during the operational phase.

18.10 Management of social surroundings

The mesa landforms have high cultural value to the K&M, particularly when viewed from within or near the Robe River. The facades also support important Matters of National Environmental Significance (MNES) species habitat and also serve to preserve intact troglofauna habitat. At Mesa J, MS 208 requires retention of the mesa façade adjacent to the Robe River north of the mine to protect environmental and heritage values. At Mesa H, the façades adjacent to the Robe River will also be retained to protect heritage values. Visual impact is a key consideration during waste dump design, generally waste dumps are similar height to the surrounding topography, with a focus on minimising the visual impact of any waste landforms when viewed from the Robe River.

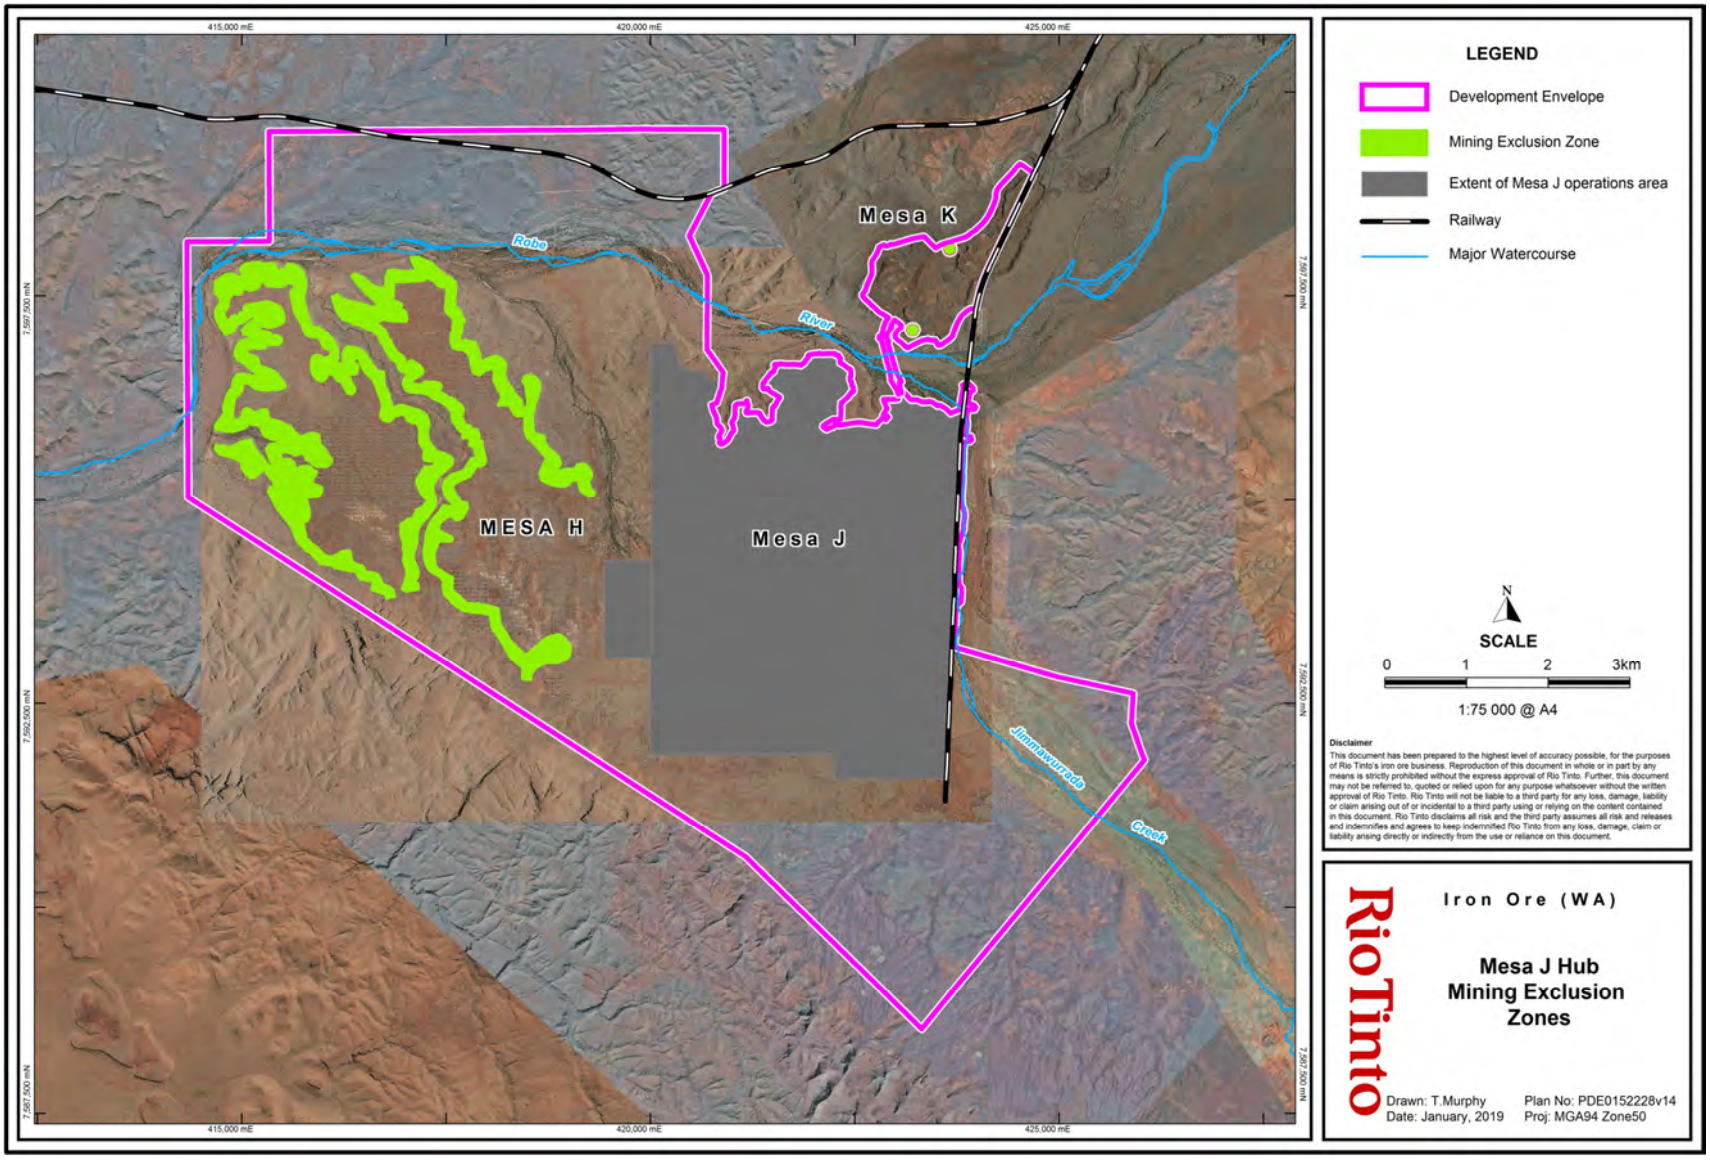

Figure 26: Mesa J Hub Mining Exclusion Zones

CLOSURE IMPLEMENTATION

Rio Tinto uses closure domains to group areas with common features, rehabilitation and decommissioning requirements at closure. Detailed closure strategies for the rehabilitation and decommissioning of individual closure domains, beyond those of current standard management practices, will be documented in the Mine Closure Plan to be prepared as the site approaches closure. The closure measures identified below consider the methods used to manage key risks as discussed in the previous section.

19. Closure Measures

Proposed closure measures for each of the closure domains are included in Table 20. The distribution of closure domains are illustrated in Figure 27. Designs and key criteria for all major landforms are included in Appendix F.

Table 20: Mesa J Hub general area implementation strategies by closure domain.

Domain class	Domains	Closure measures
Pits		
Above water table (AWT) pits	Mesa H Pit 9 Mesa J Pit 1 Mesa J Pit 2 Mesa J Pit 3 Mesa J Pit 4 Mesa J Pit 5 Mesa K Pit 1 Mesa K Pit 2 Mesa K Pit 3 Mesa K Pit 4 Mesa K Pit 5 Mesa K Pit 6	• Pits may be partially backfilled where possible to minimise the volume of waste in out of pit waste landforms. • Prior to final closure, appropriate evaluation and implementation of measures to restrict public access will be undertaken. • Rehabilitate final surface of pit floors in accordance with standard procedures (as per infrastructure areas) (Note. pit walls will remain).
Below water table pits (geochemical risk: low)	Mesa H Pit 1 Mesa H Pit 2 Mesa H Pit 3 Mesa H Pit 4 Mesa H Pit 5 Mesa H Pit 6 Mesa H Pit 7 Mesa H Pit 8 Mesa J Pit 6 Mesa J Pit 7 Mesa J Pit 8	• Undertake opportunistic backfill during operations and if required post-closure to prevent the formation of pit lakes in the final landform (excluding pit 15)[9]. • Rehabilitate final surface of pit floors in accordance with standard procedures (as per infrastructure areas) (Note. pit walls will remain). • Mesa J pit 15 will have an area partially left as a pit lake.

[9] Below water table pits (not differentiated in Figure 27 as each Pit is a section of the wider mining area) may not be backfilled uniformly across the entire surface. Sections of the pit may remain above water table during mining, and therefore not require backfill. All areas with a recovering water table at risk of forming a pit lake are backfilled (as indicated in orange)

Domain class	Domains	Closure measures
	Mesa J Pit 9	
	Mesa J Pit 10	
	Mesa J Pit 11	
	Mesa J Pit 12	
	Mesa J Pit 14	
	Mesa J Pit 15	
Waste dumps and stockpiles		
In-pit waste dumps (inert)	Mesa H Pit1 backfill Mesa H Pit2 backfill Mesa H Pit3 backfill Mesa H Pit4 backfill Mesa H Pit6/8 backfill Mesa H Pit9 backfill Mesa J Pit 11 inpit WD Mesa J P12 WD Mesa J P6 WD Mesa J P7/15 WD Mesa K Pit 1 backfill Mesa K Pit 2 backfill Mesa K Pit 3 backfill Mesa K Gravel Pit WD	• Reshaping outer slopes to appropriate angles/profiles based on design criteria suitable for waste type. • Rehabilitate final surface in accordance with standard procedures (as per infrastructure areas).
Free standing inert waste dumps	Mesa H NE Dump Mesa H SW Dump Mesa H SE Dump Mesa J Boondock WD Mesa K North WD Mesa K WD	• Where practicable, construct dumps in accordance with criteria outlined in Appendix F. • Reshaping outer slopes to appropriate angles/profiles based on design criteria suitable for waste type. • Application of subsoil/topsoil. • Rip and seed using appropriate native species.
Other domains		
Haul roads		• Push slopes at either side of the haul road to a maximum gradient of 20 degrees with berms at 10 metre intervals. • Install cross bunds where appropriate (at approximately 50m to intervals if the gradient of the reshaped road corridor is <10 degrees). • Rehabilitate final surface in accordance with standard procedures (as per inert waste dumps).
ROM pad	ROM pad	• Remove infrastructure. • Utilise earthen mound for pit backfill OR rehabilitate as a free standing inert waste dump.
Landfill	Landfill	• Cap landfill with a layer of inert material to a minimum thickness of 2 metres. • Rehabilitate final surface in accordance with standard procedures (as per infrastructure areas).

Domain class	Domains	Closure measures
Waste fines storage facility	Mesa J TSF 1 Mesa J TSF 3 Mesa J TSF 4 Mesa J TSF 5 Mesa J Pit7/14 TSF Mesa J Pit 8 TSF Mesa J Pit 9 TSF	• Cap waste fines storage facility with a layer of inert material to a minimum thickness of 2 metres. • Rehabilitate final surface in accordance with standard procedures (as per infrastructure areas). • TSF1 will remain uncapped.
Infrastructure areas	Plant Maintenance Buildings Roads Laydown Conveyors (etc.)	• Retain or remove infrastructure in accordance with State Agreement requirements. • Undertake contaminated sites evaluation and clean up if required. • Where infrastructure requires removal, remove all structures and footings that is above surface or within 1m of the final land surface. • Drain pipelines and remove hazardous materials (from pipelines and elsewhere across the site) in accordance with Controlled Waste Regulations. • Actively seek reuse and recycling opportunities for decommissioned infrastructure. • Dispose of inert materials are not retained, reused or recycled in an inert landfill area (may be a used pit area) and then cap with at least 2 metres of inert material. • Where linear infrastructure is removed, reinstate drainage lines where appropriate. • Rehabilitate final surface in accordance with standard procedures, which includes: o add a layer of topsoil where available and appropriate; o deep rip the surface where required to address compaction; o revegetate with an appropriate mix of native species.

20. Post-mining and post-closure landforms

The post mining landform is the landform that would be generated as a result of implementation of the mine plan assuming no progressive rehabilitation activities are conducted. A conceptual image of the post mining landform is shown in Figure 28 and Figure 30.

The post closure landform is the final expected landform at the completion of the closure measures outlined in Table 20 above. A conceptual image of this landform is shown in Figure 29, Figure 31 and Figure 32.

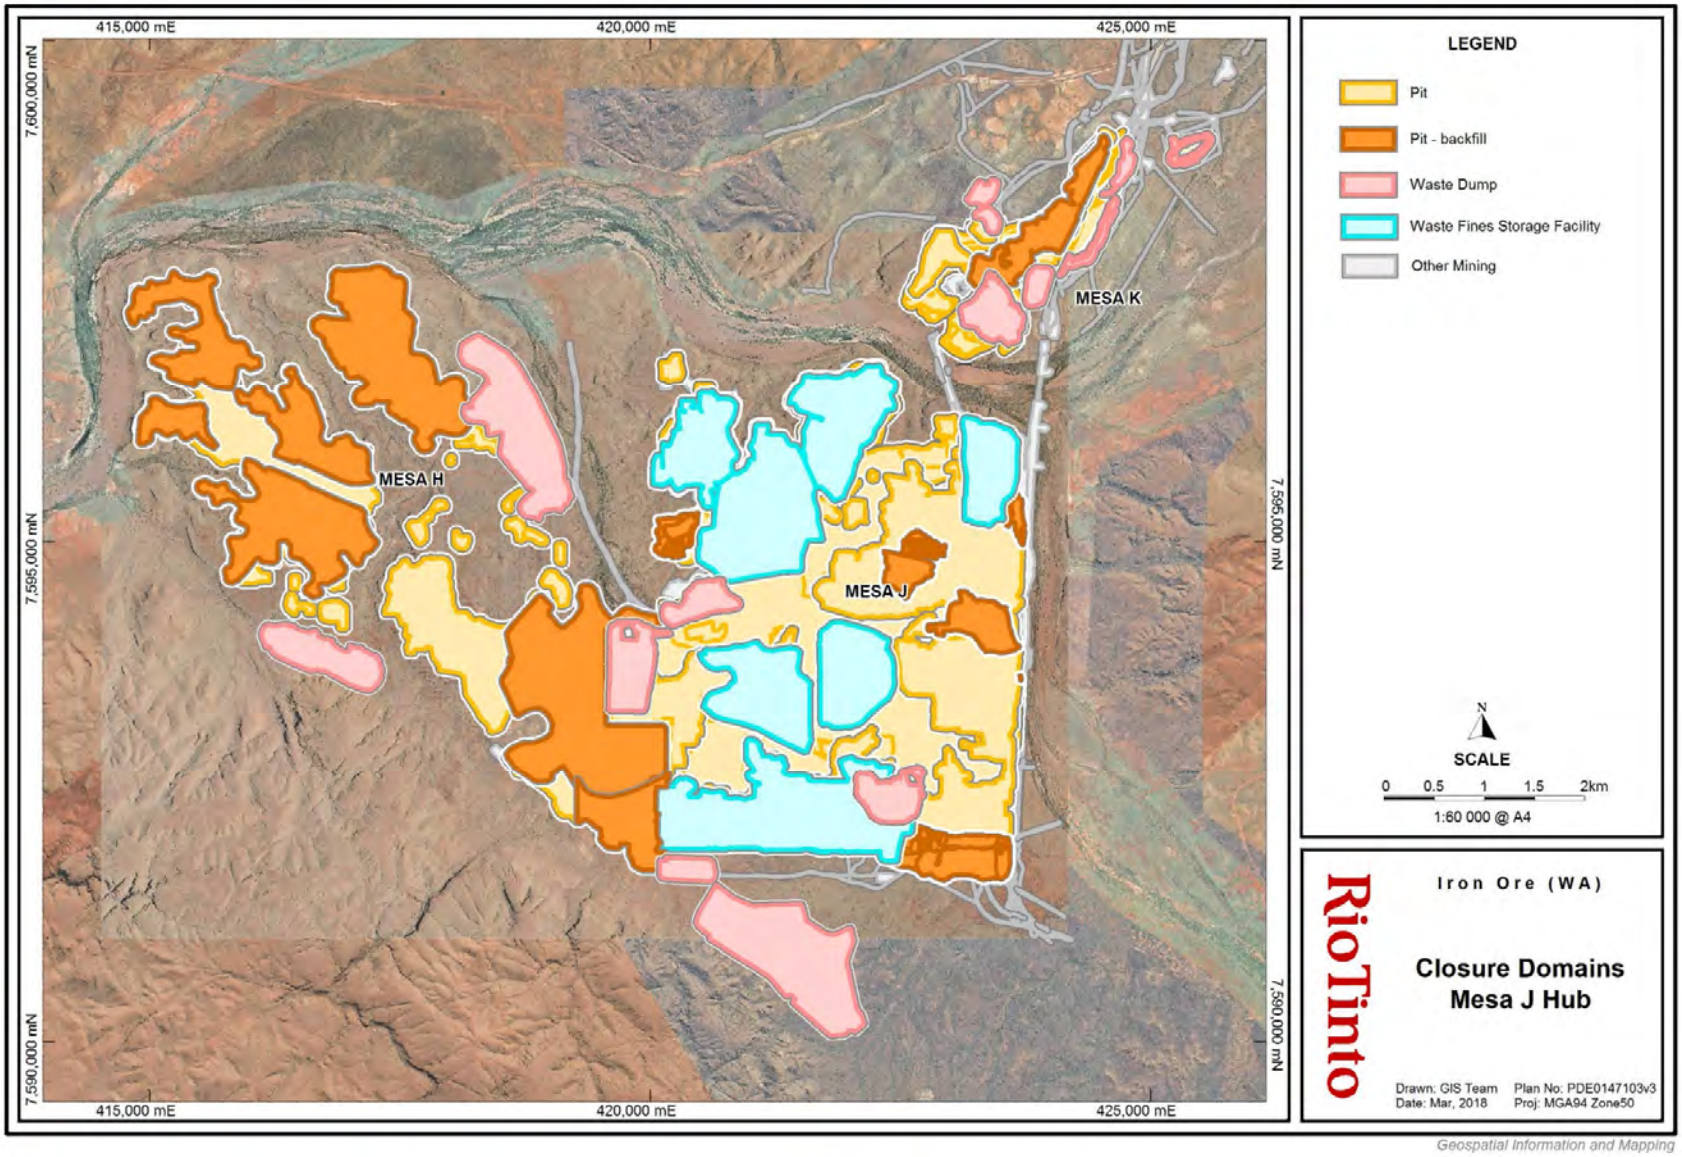

Figure 27: Closure Domains

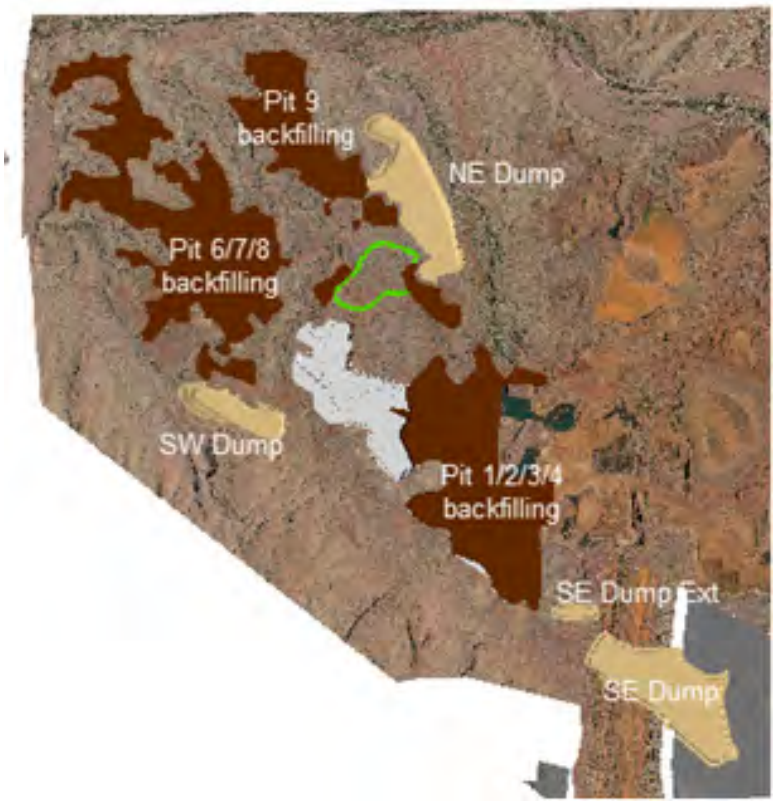

Figure 28: Mesa H post mining landform

Figure 29: Mesa H post closure landform

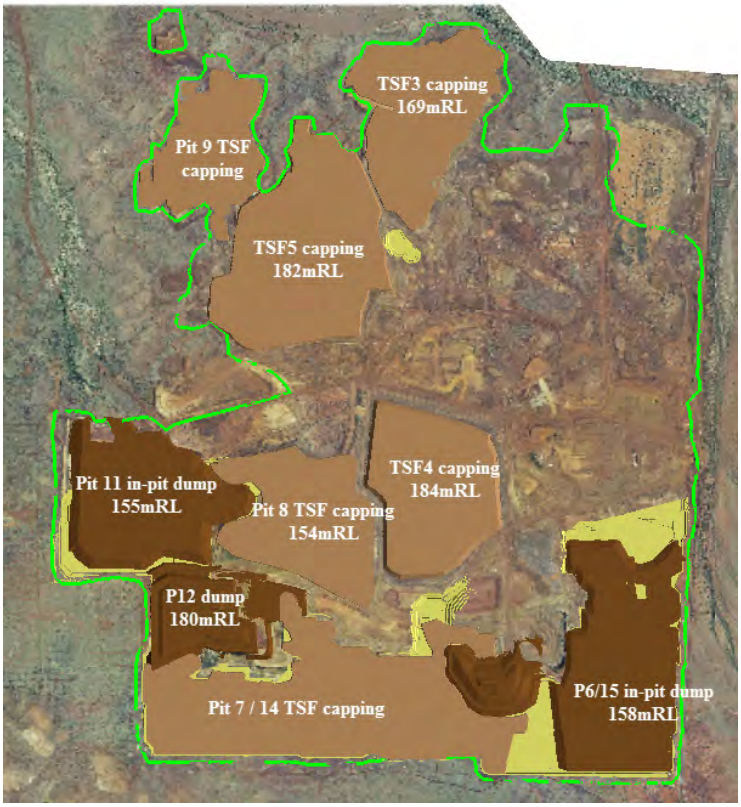

Figure 30: Mesa J post mining landform

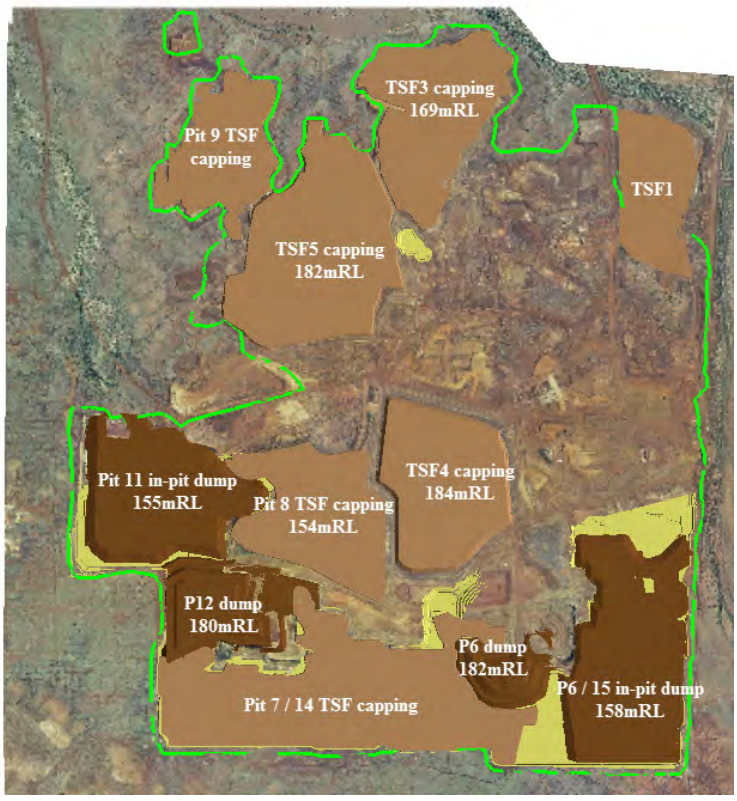

Figure 31: Mesa J post closure landform

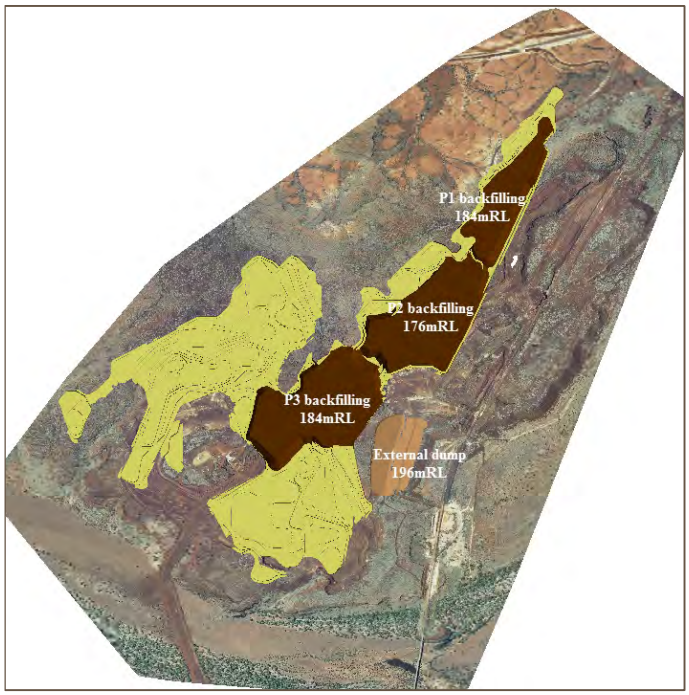

Figure 32: Mesa K post closure landform

21. Premature closure and other factors

The closure implementation schedule may be influenced by factors outside of the current mine plan. These factors include:

- suspension of operations under care and maintenance: this could occur if production costs exceed product value e.g. due to commodity price changes;
- unexpected closure: this could occur if there was major change in global demand for iron ore; and
- future proposals: there are multiple deposits in proximity to Mesa J that are likely to be developed in the future.

21.1 Care and maintenance

In the event of temporary closure, measures will be undertaken to transfer the site from operations into a care and maintenance regime and relevant authorities notified. A Care and Maintenance Plan would be developed prior to the care and maintenance period which demonstrates how on-going environmental obligations associated with the site will continue to be met during the period of care and maintenance. Social obligations and responsibilities will also be addressed in this plan.

21.2 Unexpected closure

Whilst the Company considers the risk of unexpected closure to be minimal, there are numerous factors that could force early closure of one or several sites. Even if some level of contraction were to occur, it is reasonable to assume that the Robe JV would continue to operate in the Pilbara and that it could continue to manage closure of its sites. It should be noted that the Company is one group within the global Rio Tinto group of companies, which further mitigates this risk.

In the event of unplanned or sudden closure, the Company will notify all relevant authorities including the DMP. The existing closure plan for the site would then be revised and a Decommissioning Plan prepared and submitted to the DMP and other relevant authorities within three months of notification of closure. The Decommissioning Plan will include undertaking detailed consultation with stakeholders. Once the plan is approved by the relevant authorities, work will commence on closure implementation activities.

21.3 Future proposals

The Robe JV hold mineral leases pursuant to the Agreement Act over multiple undeveloped deposits in the Robe Valley. Development of several of these deposits will potentially require continued utilisation of the Mesa J Hub infrastructure after completion of mining at the Mesa J, K and H deposits. These future developments are excluded from the scope of this current Mesa J Hub closure plan, but will be included in future closure plan updates with improved certainty of the specifics of these developments.

CLOSURE MONITORING AND MAINTENANCE

22. Closure monitoring program

The primary purpose of closure monitoring is to assess whether closure criteria have been met for the Mesa J Hub. A specific monitoring program will be finalised as the site approaches closure, and this current plan outlines the principles that will be employed rather than specific details.

22.1 Phases of monitoring

For the purposes of this plan, monitoring is assumed to be conducted in several phases including:

- Baseline monitoring, which is conducted as operations expand into new mining areas. Results that are relevant to closure are summarised in the environment knowledge base;
- Operational monitoring, which occurs throughout the life of the mine, in line with regulatory requirements and the Rio Tinto operational standards. Results that are relevant to closure are incorporated in the environment knowledge base when it is reviewed;
- Pre-closure monitoring, which occurs as the site approaches closure to underpin assessment of post-closure performance;
- Closure monitoring, which is conducted during the period of active site closure (approximately two years following the cessation of mining); and
- Post-closure monitoring, which is conducted on a regular basis until either:
  - There is a demonstration that closure objectives have been met and that the site is able to be relinquished; or
  - Parameters being monitored reach a steady state.

This plan considers pre-closure, closure and post-closure monitoring.

22.2 Indicative monitoring program

The monitoring program will be finalised during development of a Final Closure Plan as the site approaches closure. Specific and appropriate monitoring will be conducted to ensure data is obtained to allow assessment of performance against completion criteria (Section 8). The monitoring programme is likely to contain specific monitoring of the following key areas, as a minimum.

22.2.1 Rehabilitation monitoring

The purpose of the rehabilitation monitoring program is to evaluate successional development of rehabilitation areas and thereby provide useful feedback for the improvement of rehabilitation techniques, and to help assess progress towards long term rehabilitation objectives.

Rehabilitation monitoring also provides vital information which can be used to set realistic and achievable completion criteria. This can be achieved by examining changes in key parameters over time, and by comparing results from the rehabilitation with those from corresponding reference sites. Reference sites, also known as Controls or Analogues, are positioned within local areas of uncleared native vegetation.

Rehabilitation monitoring occurs on a scheduled basis, aimed at establishing trends for the locations return to self-sustaining status. The rehabilitation development is compared to the reference site values. Data analysis is undertaken to assess progress towards an acceptable outcome and a report produced to document findings.

22.2.2 Water monitoring

Water monitoring during closure will focus on confirming groundwater recovery and quality, and pit lake modelling predictions. A specific program of monitoring will be developed prior to decommissioning.

22.3 Heritage surveys

Heritage assessments are undertaken prior to closure to ascertain potential cultural heritage impacts of closure implementation, and inform the development of alternative strategies if required. Assessments are also undertaken post-closure to confirm that implementation has been undertaken in an appropriate manner.

23. Post-closure maintenance

Post closure, maintenance will continue as required until it is determined that the closure objectives have been met or it is otherwise agreed with Government to allow relinquishment of the site.

FINANCIAL PROVISION FOR CLOSURE

Rio Tinto considers specifics of the closure cost estimate to be commercially sensitive information. This section outlines the general process used to develop the closure cost estimate.

24. Principles of Rio Tinto closure cost estimation

Closure cost estimates are determined based on methods outlined in the Rio Tinto Closure Standard and the Rio Tinto Accounting Policy. Closure costs are considered in two formats:

- a Present Closure Obligation (PCO) which is indicative of costs associated with closure of the mine given its current footprint, this accounts for the progressive development of a site over time; and
- a Total Projected Closure (TPC) cost which predicts the cost (in current terms) associated with closure at the end of the life of the mine. The TPC includes areas that are not currently approved, but that feature within the life of mine plan and that are considered likely to be developed in the future.

The cost estimates consider the following components[10]:

- decommissioning (i.e. removal of infrastructure)[11];
- final landform construction;
- rehabilitation and biodiversity management;
- heritage management;
- workforce management (i.e. training costs and redundancy payments)[12];
- monitoring costs;
- costs associated with the development of a final closure plan;
- costs associated with undertaking a final shutdown of operations;
- allowance for failed rehabilitation or pollution that may necessitate rework of rehabilitation areas;
- assignment of indirect costs in accordance with Rio Tinto Accounting Policy; and
- a contingency factor.

25. Closure cost estimation methods

The closure cost estimation methodology is based on methods outlined in the Rio Tinto Closure Standard and Rio Tinto Accounting Policy, with the level of accuracy increasing as the site approaches closure[13]. The closure cost estimates are conducted based on the most recent information of mine plans and infrastructure. Closure costs estimate are generally undertaken by specialist external consultants. The PCO estimate for each site is revised on an annual basis to account for incremental mine development during the year. The TPC estimate is revised whenever a formal closure plan review is conducted to capture any changes to life of mine design. As part of Rio Tinto assurance processes these costs are audited by external financial auditors annually to ensure adequate closure provisions are maintained.

Note that for commercial reasons the actual estimate is not documented in this closure plan.

[10] Costs associated with decontamination are assessed during closure plan development but are costed separately as they are classified as operating costs, not closure costs.

[11] The decommissioning cost estimate assumes that infrastructure will be demolished and buried on site. The site is sufficiently remote that deconstruction for the purposes of materials salvage and recycling is likely to be cost prohibitive. However; opportunities for salvage and recycling will be sought as the site approaches closure.

[12] Workforce management costs have only been included in the TPC.

[13] The level of accuracy applied to Rio Tinto estimates is as follows:

- greater than 10 years from closure: ±30%;
- between 10 years and 5 years from closure: ±20%; and
- less than 5 years from closure: ±15%.

MANAGEMENT OF INFORMATION AND DATA

26. Data and information management

26.1 Iron Ore Document Management System (IODMS)

The Company operates a comprehensive document management system, with electronic records of all key information and data. The document system, known as Iron Ore Document Management System (IODMS) is linked to other business units within the Rio Tinto group of companies, and processes are in place to ensure that the data contained within this system is appropriately backed up and protected. Each document stored within this system is given a unique document number which identifies the document and enables it to be accessed. This system will continue to operate following site closure, and all relevant data will be retained according to appropriate data retention requirements.

An audit will be conducted prior to closure to ascertain whether there is any additional information stored in hard copy form at the site. Such data will be scanned and entered into IODMS to ensure that it is appropriately retained post-closure.

26.2 Closure knowledge base

The closure knowledge database is a knowledge management process designed to bring closure related research and monitoring outcomes together into one searchable location. It uses a single entry form to capture where the report is stored, and how and where the research can be applied for all new ongoing and completed closure related studies. This information is then managed by the Closure team within a secure database.

26.3 EnviroSys

EnviroSys is an environmental database that is used by Rio Tinto to manage environmental and hydrogeological data. The tool is used to store, monitor and analyse those parameters and report trends on data collections.

Data collected currently includes:

- groundwater – biological, chemical, field, levels, production;
- marine water – biological, chemical, field;
- soil chemistry;
- surface water – biological, chemical, field, levels, production;
- tonnes and moisture;
- rehabilitation;
- water meters; and
- weather (rainfall, temperatures etc.).

EnviroSys is used to support the building of closure knowledge bases, as well as ensure compliance with operating licenses pertaining to data management. At closure this data would be appropriately stored to allow for review of post closure completion criteria.

26.4 Legal and other requirements system

The Legal and Other Requirements System (LAORS) is used by the Company to manage the following:

- Approval and Legislation Reports which provide a high level snapshot of approvals and legislation and is used to check the status and expiry dates of approvals.
- Approval and Legislative Requirements Reports which lists
  - accountabilities for specific conditions within approvals and clauses within legislation;
  - required actions to comply with approvals and or legislation; and
  - due dates for specific requirements.
- Statutory Position Appointed Persons reports which list individuals appointed to a statutory position.
- Statutory Position Accountabilities Reports which identify clauses of legislation that the statutory position is accountable for.

This information is used to track legal requirements associated with closure and will be maintained during closure activities to ensure all requirements and obligations are met.

Appendix A – Register of key closure obligations

Ministerial Statement 208 (Mesa J Iron Ore Development)	
Condition No.	**Closure conditions**
4-1	Prior to construction at the site, the proponent shall prepare a Drainage Management Programme, to protect the Robe River - Jimmawurrada Creek system from the deleterious impacts of sedimentation and pollution from the project, to the satisfaction of the Minister for the Environment on advice of the Environmental Protection Authority, the Department of Conservation and Land Management and the Water Authority of Western Australia. The plan is to include but is not necessarily limited to: 1. a monitoring programme to detect impacts; 2. procedures for protecting the ecology of the system; 3. procedures for reporting on the programme; and 4. a commitment to ameliorate environmental impacts to the satisfaction of the Environmental Protection Authority if impacts are detected which are deemed unacceptable by the Environmental Protection Authority.
4-2	Subsequent to condition 4-1, the proponent shall implement the approved Drainage Management Programme to the satisfaction of the Environmental Projection Authority on advice of the Water Authority of Western Australia and the Department of Conservation and Land Management.
5-1	Prior to the commencement of dewatering, the proponent shall prepare a Dewatering Management Programme, to protect the Robe River - Jimmawurrada Creek system, to the satisfaction of the Environmental Protection Authority on advice of the Department of Conservation and Land Management and the Water Authority of Western Australia. The plan is to include but is not necessarily limited to: 1. a monitoring programme to detect impacts; 2. procedures for protecting the ecology and water quality of the permanent pools and associated vegetation; 3. procedures for reporting on the programme; and 4. a commitment to ameliorate environmental impacts to the satisfaction of the Environmental Protection Authority if impacts are detected which are deemed unacceptable by the Environmental Protection Authority.
5-2	Subsequent to condition 5-1, the proponent shall implement the approved Environmental Management Programme to the satisfaction of the Environmental Protection Authority on advice of the Water Authority of Western Australia and the Department of Conservation and: Land Management.
6-1	Within 12 months of the date of this statement, the proponent shall prepare a Rehabilitation Management Programme to the satisfaction of the Environmental Protection Authority on advice of the Department of Mines and the Department of Conservation and Land Management. The programme shall include but not necessarily be limited to: 1. proposals for rehabilitation of the project area; and 2. a monitoring programme to determine success of the rehabilitation. **CLOSED COMPLETE: Rehabilitation Management Plan satisfies this condition**
6-2	The initial programme shall be submitted to the Environmental Protection Authority, with subsequent programmes for the project to be updated annualy in conjunction with reporting requirements under the Iron Ore (Robe River) Agreement Act.
6-3	At least twelve months prior to the decommissioning, the proponent shall prepare a plan for decommissioning and rehabilitating the site, to the satisfaction of the Environmental Protection Authority on advice of the Department of Mines and the Department of Conservation and Land Management.

Ministerial Statement 208 (Mesa J Iron Ore Development)	
6-4	Subsequent to conditions 6-1 and 6-3, the proponent shall implement the approved programmes for rehabilitating and decommissioning the site, to the satisfaction of the Environmental Protection Authority on advice of the Department of Mines and the Department of Conservation and Land Management.
Commitment No.	**Closure commitments**
Commitment 6	The proponent will implement landform stabilization and revegetation programs in the project area for the duration.
Commitment 11	At the completion of the project, the proponent will prepare the site for abandonment in accordance with the requirements of the Mines Department and in recognition of the requirements of the Iron Ore (Robe River) Agreement Act, 1964, including, as applicable: 1. Re-establishment of pre-existing drainage patterns as far as practicably achieved; 2. The initiation of stabilisation and revegetation activities to stabilise structures and communities; and, 3. The mining plan will be modified to incorporate the return of as much waste rock to the mined out pit as can be practically achieved during the life of the project.

Ministerial Statement 776 (Mesa K Remnant Mining Project)	
Condition No.	**Closure conditions**
7-1	The proponent shall implement the proposal to achieve stable, self-sustaining and functioning ecosystem(s) that is/are consistent with the surrounding landscape and maintain(s) key environmental values over the long-term and to the satisfaction of the CEO of the Department of Environment and Conservation.
Commitment No.	**Closure commitments**
Schedule 1 - Mine and Mining	Waste Rock Disposal: Initially directed to surface waste dumps and, thereafter, used in progressive backfilling of mine pits as far as practicable

Iron Ore (Robe River) Agreement Act 1964	
Clause No.	**Closure obligations**
Schedule 1 10 e)	on the cessation or determination of any lease license or easement granted hereunder by the State to the Company or (except as otherwise agreed by the Minister) to an associated company or other assignee of the Company under clause 13 hereof of land for the plant site or the Company's wharf for any installation within the harbour for the Company's railway or for housing at the port or port townsite the improvements and things erected on the relevant land and provided for in connection therewith other than plant and equipment shall remain or become the absolute property of the State without compensation and freed and discharged from all mortgages and encumbrances and the Company will do and execute such documents and things (including surrenders) as the State may reasonably require to give effect to this provision. In the event of the Company immediately prior to such expiration or determination or subsequent thereto deciding to remove its locomotives rolling stock plant and equipment or any of them from any land it shall not do so without first notifying the State in writing of its decision and thereby granting to the State the right or option exercisable within three months thereafter to purchase at valuation in situ the said plant and equipment or any of them. Such valuation shall be mutually agreed or in default of agreement shall be made by such competent valuer as the parties may appoint or failing agreement as to such appointment then by two competent valuers one to be appointed by each party or by an umpire appointed by such valuers should they fail to agree;

Mining Act 1978	
Tenement No. AML70/00248 (ML248SA)	
Condition No.	**Closure conditions**
n/a	No conditions relevant to closure

Permit No. CPS4397	
Condition No.	**Closure conditions**
13	Retain vegetative material and topsoil, revegetation and rehabilitation The Permit Holder shall: (a) retain the vegetative material and topsoil removed by clearing authorised under this Permit and stockpile the vegetative material and topsoil in an area that has already been cleared; (b) within 12 months following clearing authorised under this Permit, revegetate and rehabilitate the area(s) that are no longer required for the purpose for which they were cleared under this Permit by: i) re-shaping the surface of the land so that it is consistent with the surrounding 5 metres of uncleared land; ii) ripping the ground on the contour to remove soil compaction; and iii) laying the vegetative material and topsoil retained under Condition 13(a) on the cleared area; (c) within 4 years of laying vegetative material and topsoil on the cleared area in accordance with Condition 13(b) of this Permit: i) engage an enviromnental specialist to determine the species composition, structure and density of the area revegetated and rehabilitated; and ii) where, in the opinion of an enviromnental specialist, the composition structure and density determined under Condition 13(c) (i) of this Permit will not result in a similar species composition, structure and density to that of pre-clearing vegetation types in that area, revegetate the area by deliberately planting and/or direct seeding native vegetation that will result in a similar species composition, structure and density of native vegetation to pre-clearing vegetation types in that area and ensuring only local provenance seeds and propagating material are used.
Permit No. CPS4442	
Condition No.	**Closure conditions**
12	Retain vegetative material and topsoil, revegetation and rehabilitation The Permit Holder shall: (a) retain the vegetative material and topsoil removed by clearing authorised under this Permit and stockpile the vegetative material and topsoil in an area that has already been cleared; (b) at an optimal time within 12 months following completion of works authorised under this Permit, revegetate and rehabilitate the area(s) that are no longer required for the purpose for which they were cleared under this Permit by: i) re-shaping the surface of the land so that it is consistent with the surrounding 5 metres of uncleared land; ii) ripping the ground on the contour to remove soil compaction; and iii) laying the vegetative material and topsoil retained under Condition 12(a) on the cleared area; (c) within 24 months of laying vegetative material and topsoil on the cleared area in accordance with Condition 12(b) of this Permit: i) engage an enviromnental specialist to determine the species composition, structure and density of the area revegetated and rehabilitated; and ii) where, in the opinion of an enviromnental specialist, the composition structure and density determined under Condition 12(c) (i) of this Permit will not result in a similar species composition, structure and density to that of pre-clearing vegetation types in that area, revegetate the area by deliberately planting and/or direct seeding native vegetation that will result in a similar species composition, structure and density of native vegetation to pre-clearing vegetation types in that area and ensuring only local provenance seeds and propagating material are used.

Permit No. CPS4598

Condition No.	Closure conditions
7	Retain vegetative material and topsoil, revegetation and rehabilitation The Permit Holder shall: (a) retain the vegetative material and topsoil removed by clearing authorised under this Permit and stockpile the vegetative material and topsoil in an area that has already been cleared; (b) within 12 months following completion of works authorised under this Permit, revegetate and rehabilitate the area(s) that are no longer required for the purpose for which they were cleared under this Permit by: i) re-shaping the surface of the land so that it is consistent with the surrounding 5 metres of uncleared land; ii) ripping the ground on the contour to remove soil compaction; and iii) laying the vegetative material and topsoil retained under Condition 7(a) on the cleared area; (c) within 4 years of laying vegetative material and topsoil on the cleared area in accordance with Condition 7(b) of this Permit: i) engage an enviromnental specialist to determine the species composition, structure and density of the area revegetated and rehabilitated; and ii) where, in the opinion of an enviromnental specialist, the composition structure and density determined under Condition 7(c) (i) of this Permit will not result in a similar species composition, structure and density to that of pre-clearing vegetation types in that area, revegetate the area by deliberately planting and/or direct seeding native vegetation that will result in a similar species composition, structure and density of native vegetation to pre-clearing vegetation types in that area and ensuring only local provenance seeds and propagating material are used.

Relevant Legislation

Closure planning and implementation requires consideration of general legislative requirements beyond those that apply to a specific site. A list of potentially relevant legislation is provided below, but is not necessarily exhaustive. A comprehensive legal review will be required as closure approaches to ensure that all relevant legislative requirements are identified.

Australian Commonwealth Legislation	**Western Australian State Legislation**
Environmental Protection and Biodiversity Conservation Act 1999	*Environmental Protection Act 1986*
Native Title Act 1993	*Environmental Protection Regulations 1987*
Aboriginal and Torres Strait Islander Heritage Protection Act 1984	*Environmental Protection (Controlled Waste) Regulations 2004*
Workplace Relations Act 1996	*Environmental Protection (Unauthorised Discharges) Regulations 2004*
	Contaminated Sites Act 2003
	Contaminated Sites Regulations 2006
	Conservation and Land Management Act 1984
	Mining Act 1978
	Mining Regulations 1981
	Parks and Reserves Act 1895
	Rights in Water and Irrigation Act 1914
	Wildlife Conservation Act 1950
	Aboriginal Heritage Act 1972
	Aboriginal Affairs Planning Authority Act 1972
	Mines Safety and Inspection Act 1994
	Mines Safety and Inspection Regulations 1995
	Occupiers Liability Act 1985
	Criminal Code Compilation Act 1913

Relevant Guidelines and Standards

Closure planning and implementation requires consideration of relevant guidelines and standards, some of which may have regulatory consequence through being referenced in regulatory documents. A list of key guidelines and standards that are routinely considered is provided below, but is not exhaustive due to the breadth of the closure planning discipline. This closure plan has been prepared so as to be considered with relevant content of these guidelines and standards.

Guideline or Standard	**Author**
Guidelines for the Preparation of Mine Closure Plans (2015)	Western Australian Department of Mines and Petroleum and Environmental Protection Authority
Mine Closure: Leading Practice Sustainable Development Program for the Mining Industry (2016)	Commonwealth Department of Industry, Innovation and Science
Mine Rehabilitation Handbook (1998)	Minerals Council of Australia
Guideline for the Assessment of Environmental Factors: Rehabilitation of Terrestrial Ecosystems (2006)	Western Australian Environmental Protection Authority
Australian and New Zealand Guidelines for Fresh and Marine Water Quality (2000)	Agriculture and Resource Management Council of Australia and New Zealand and the Australian and New Zealand Environment and Conservation Council
Mine Void Water Resource Issues in Western Australia (2003)	Western Australian Water and Rivers Commission
Contaminated Sites guideline series	Western Australian Department of Environment Regulation
Environmental Notes on Mining: Acid Mine Drainage (2009)	Western Australian Department of Mines and Petroleum
Environmental Notes on Mining: Waste Rock Dumps (2009)	Western Australian Department of Mines and Petroleum
Safety Bund Walls Around Abandoned Open Pit Mines (1997)	Western Australian Department of Industry and Resources
Global Acid Rock Drainage Guide (2014)	International Network for Acid Prevention
Australian Standard 2601: The Demolition of Structures (2001)	Standards Australia
Australian Standard 4976: The Removal of Underground Petroleum Storage Tanks (2008)	Standards Australia
Demolition Work Code of Practice (2015)	Safe Work Australia

Appendix B – Communications Register

Consultation Stage	Stakeholder	Date	Subject	Summary of discussion relevant to closure	Response
Referral	Environmental Protection Authority Service Unit	1991	Robe referral to EPA	Formal referral of the Mesa J Iron Ore development, Pannawonica under Clause 7A of the Iron Ore (Robe River) Agreement	
Ministerial Statement	Environmental Protection Authority Service Unit	1992	Acceptance of MS208	Formal acceptance of all conditions on Ministerial Statement 208.	
Operations	Environmental Protection Authority Service Unit	2005	Extension of Mesa J Pit Area-Section 45C	CALM: The proposal to retain the pit extension area as a deep water pit and not backfill it to groundwater level is no longer acceptable to CALM. The Ministerial approval for the original Mesa J mine was over 13 years ago, and is no longer consistent with current best practice environmental management, which is to ensure that mine pits are backfilled to the water table in order to mitigate any adverse water quality issues. Given that this is a new development, Pilbara Iron should improve its standards for environmental management and mine closure and decommissioning in order to comply with what is acceptable best practice today.	The material from the pit extension area will be used to backfill other parts of the pit. As stated in the original approvals documents for Mesa J, there will be insufficient material available to backfill all pits to above water table level. Robe is currently preparing a closure plan for the Mesa J mine site, with the aim to backfill as many pits as practicable at Mesa J to above water table level. Calculations to determine the amount of material which will be available for backfilling pits are currently underway and a study will be commissioned to model impacts of the proposed final landform on water quality. Under Conditions 6-3 and 6-4 of Ministerial Statement 208, Robe is required to prepare and implement a decommissioning and rehabilitation plan to the satisfaction of the Environmental Protection Authority on advice of DolR and CALM.
Ministerial Statement	Office of the Environmental Protection Authority	2005	Change to MS208	Pit extension and boundary update	Section 45C
Ministerial Statement	Office of the Environmental Protection Authority	2006	Change to MS208	New rail siding at Green Pool	Section 45C
Ministerial Statement	Office of the Environmental Protection Authority	2007	Change to MS208	Installation of fibre optic cable for railway communications system from the Cape Lambert administration offices to the 5km peg and from the 71km peg to the Mesa J mine operations at Pannawonica	Section 45C
Referral	Environmental Protection Authority Service Unit	2007	Robe referral to EPA	Formal referral of the Mesa K Remnant Mining Projecton Ore Mine under Section 38 of the EP Act.	
PER	Environmental Protection Authority Service Unit	2008	Bulletin 1283 - Initial EPA assessment of Environmental Impact Assessment	The EPA acknowledges that the proponent has committed to finalising the PRP included with the EPS and implementing the PRP prior to commencement of productive mining. Mesa K and the PRP will be incorporated into the Greater Pannawonica Closure Study prior to completion of mining at Mesa K. The EPA notes the relatively short project life of the Mesa K Remnant Mining proposal of 2 – 3 years. The PRP includes rehabilitation strategies designed to contribute to maintenance free closure over the long term. The EPA supports the objective of the PRP to ensure mine rehabilitation and closure planning commences in the early stages of project planning and is integrated with mine development planning and operations. The PRP includes a schedule for timing of closure, rehabilitation and monitoring. The PRP will be regularly reviewed during site operations to ensure it remains accurate and relevant.	
Ministerial Statement	Office of the Environmental Protection Authority	2009	Acceptance of the PRP to satisfy Condition 7-1 of MS776	As per our discussion, there is no formal requirement in Ministerial Statement 000776 for the EPA to sign off on the management plans prepared for the Mesa K proposal. The EPA Board were provided with copies of the draft management plans in its consideration of the Mesa K proposal and acknowledged in Bulletin 1283 that Robe were committed to finalising the management plans prior to commencement of productive mining, and specifically that the PRP will be incorporated into the Greater Pannawonica Closure Study prior to completion of mining at Mesa K.	
Operations	Department of Mines & Petroleum	2009	Mesa J Inspection 2008	Several erosion qullies were observed on the north face of T Dump and they should be monitored and mitigation measures implemented if they are observed to grow over time or effect the stability of the dump. The eastern end of the dump had yet to be rehabilitated and this area should be closed out as soon as possible to prevent erosion and/or weeds on the eastern end spreading to the rehabilitated areas. The south side of T dump has limited revegetation and significant erosion problems. It is likely that this side of the dump will have to be reworked to meet closure criteria.	Rehabilitation monitoring on the T dump is scheduled for June 2009 and will include an erosion assessment. Mitigation measures will be implemented if the monitoring demonstrates unacceptable stability of the landform. The eastern end of the T dump was not included in the original rehabilitation design due to the proximity of the dump to the rail line. An assessment of rehabilitation design which can be completed whilst the rail is operational will be assessed prior to the end of 2009. Regular weed inspections will be carried out and management programs implemented if an outbreak is recorded.

Consultation Stage	Stakeholder	Date	Subject	Summary of discussion relevant to closure	Response
Operations	Department of State Development	2010	Response to State Agreement reports 2009	No significant comments. DMP Comments: Areas displaying Improvements: • The establishment of reference sites to be used for the development of conceptual completion criteria at operating sites • The commencement of a 5 year seed science programme • Corrective actions requested as part of the 2008 DMP inspection have been completed or progressed Areas deficient in information I area of concern at several sites: • Limited progressive rehabilitation was noted • Although there was an improvement from the previous AER, for most sites there was limited information on rehabilitation monitoring results • Limited detail of erosion monitoring results	Positive aspects noted. • For concerns regarding limited progressive rehabilitation, a rehabilitation and closure team has been formed and is working to improve our planning and implementation of progressive rehabilitation projects. • Whilst there may not of been earthworks conducted at an individual site, a large proportion of works are involved in the planning stage for rehabilitation, including making improvements to historic designs, haulage of clean inert waste fill to enable future rehabilitation projects and a range of research and development activities to inform and guide future rehabilitation programs. • RTIO operations will not be able to demonstrate rehabilitation works being conducted at every site every year, due to the large and long time frames in which our operational areas remain active. • Identification and scheduling of areas available for rehabilitation across our operations are conducted over a 5 year time frame. This 5 year plan is updated through the 5 year mine planning and quarterly mine planning processes.
Operations	Department of State Development	2011	Response to State Agreement reports 2010	No significant comments. DMP Comments: A number of areas of improvement were noted across the RTIO sites. These include: • The Land Data Improvement Project continued during 2010, aiming to improve assessment and monitoring of disturbance footprints and rehabilitation areas; • Investigation of pit lake bioremediation options in conjunction with Edith Cowan University. • The commencement of investigations into alternative growth mediums. The concerns include: • RTIO are not planning to develop completion criteria for the closure of sites during the early stages of project development. The DMP encourages completion criteria to be developed during the early stages of the project because it sets a goal for the rehabilitation of the site and ensures closure is considered during the construction and operational phases of the project. It is acknowledged however, that during the early stages of project development the criteria can be quite conceptual and be further developed and refined as the project progresses. • Progressive rehabilitation is being carried out at some sites, with plans for future rehabilitation works noted. However a greater commitment to progressive rehabilitation should be achievable across most sites. It should be noted that progressive rehabilitation not only involves achieving actual rehabilitation on the ground but also includes researching knowledge gaps which may include setting up rehabilitation trials, gaining a better understanding of material characterisation etc.	RTIO agrees that completion criteria need to be developed and agreed prior to closure implementation (including progressive rehabilitation undertaken during the course of operations), but considers that any criteria drafted early in the development of a long-life mine need to be considered indicative only. RTIO is currently undergoing a project to develop criteria to measure the success of progressive rehabilitation, the status of which was included in the overview section of the report. RTIO has included indicative completion criteria in closure plans submitted to Government since publication of the new closure plan reporting guidelines, and will continue to do so. Over the past 3 years RTIO has increased the amount of rehabilitation planning, earthworks and research and development projects considerably. Areas available for progressive rehabilitation are identified for the RTIO business and scheduled as part of mine planning and business planning processes. The RTIO approach for sign off on rehabilitation areas ensures a reduction in the areas of rehabilitation being re-disturbed. This planned approach means that only areas that are scheduled for closure will undergo rehabilitation, thus not all sites will have rehabilitation occurring every year. RTIO is also planning on the achievement of quality hectares of rehabilitation rather than achieving hectares which may require rework in future. The RTIO closure planning and rehabilitation efforts and procedures are being informed by the learning's from our rehabilitation.
Operations	Department of State Development	2011	Response to State Agreement reports 2010	DMP Comments: The closure plan for the site dates back to 2005, with the next review not scheduled until 2012. As a guide, the DMP's new guidelines for Mine Closure Plans require a review every 3 years.	A decision was taken in 2010 to review the remaining reserves to inform the next closure plan. This work is in progress, and thus the timing for the closure plan has been delayed to ensure the correct data is utilised. The mine Mesa J/K operations do not have a requirement for a 3 year update schedule in their approvals.
Operations	Office of the Environmental Protection Authority	2012	Annual Audit Compliance Report 2011		Condition 6-1: Review of the Mesa J Environmental Management Programme including the rehabilitation management plan was conducted in 2011. At this time the Mesa J and Mesa K Environmental Management Programmes have been integrated. The Mesa JK integrated environmental management plan [RTIO-HSE-0013059] was submitted to the OEPA on the 29 October 2011 [RTIO-HSE-0127414].
Operations	Office of the Environmental Protection Authority	2012	Annual Audit Compliance Report 2011		Condition 7-1: Mesa K Preliminary Rehabilitation Plan [RTIO-HSE-0044852] was submitted to EPA on 14 January 2009 for formal sign-off following acceptance by DEC Environmental Management Branch [RTIO-HSE-0058967].

Consultation Stage	Stakeholder	Date	Subject	Summary of discussion relevant to closure	Response
Operations	Department of Mines & Petroleum	2012	Robe Valley Inspection 2012	Much of the rehabilitation on these dumps is progressing well. Investigation of some sections where vegetation has not established may be required. In the event that these dumps are removed to allow for mining, make sure that the topsoil and vegetation is pre-stripped from the rehabilitated areas. Rehabilitation of the Pit 7 Dump has been largely unsuccessful. Remedial work will be required. Despite the failings of this dump, any knowledge gained from this trial would assist in future waste dump designs.	
Ministerial Statement	Office of the Environmental Protection Authority	2013	Acceptance of the OEMP to satisfy Condition 6-1 of MS208 and 7-1 of MS776	The revised Plan has been reviewed by the OEPA and is considered to address the relevant implementation conditions above, relating to the Environmental Management Plan (MS 208) and the protection of troglofauna (MS776).	
Ministerial Statement	Office of the Environmental Protection Authority	2013	Change to MS776	Increase in disturbance footprint and removal of mine life	Section 45C
Operations	Office of the Environmental Protection Authority	2013	Annual Audit Compliance Report 2012		Condition 6-1: The Rehabilitation Management Plan for Mesa J and Nearby Mesas, Deepdale Area was submitted in November 1993 [RTIO-HSE-0043199]. This completed this preconstruction requirement. Refer below for on-going requirements.
Operations	Office of the Environmental Protection Authority	2013	Annual Audit Compliance Report 2012		Condition 7-1: Mesa K Preliminary Rehabilitation Plan [RTIO-HSE-0044852] was submitted to EPA on 14 January 2009 for formal sign-off following acceptance by DEC Environmental Management Branch [RTIO-HSE-0058967]. No rehabilitation was conducted at the Mesa K mine site during 2012. However work toward progressive rehabilitation and closure continued with the backfill of waste rock into Gravel Pit.
Operations	Department of State Development	2014	Response to State Agreement reports 2012	No significant comments. DMP Comments: DMP is very supportive of the proposed and existing research projects, including the seed provenance study, and request that updates and results relating to these projects are included in future TERs.	Noted
Closure Management	Office of the Environmental Protection Authority	2014	General correspondence from the OEPA regarding a joint BHP Billiton and Rio Tinto rehabilitation presentation	Correspondence from OEPA commending BHP Billiton and Rio Tinto on their joint presentation on rehabilitation success in the Pilbara. In its letter OEPA recognised that mine closure and rehabilitation is an important strategic issue and recognised the significant challenges remaining in this area. The OEPA referred to the Department of Mines and Petroleum/EAP Joint Mine Closure Guidelines as the primary document guiding mine closure and rehabilitation across all land tenures and sought written confirmation from both companies that they would abide by any contemporary version of the guidelines, irrespective of what the current Ministerial Statement conditions required in regard to closure and rehabilitation, or similarly what State Agreement Act conditions require on the same matter. OEPA indicated its desire to discuss the updating of existing Ministerial Statements to ensure they are contemporary with respect to mine closure and rehabilitation with both parties in future.	Rio Tinto acknowledged the feedback form OEPA and indicated it looked forward to continued involvement with government and industry partners in developing sustainable, long term improvements for rehabilitation and closure in Western Australia. In response to the request for mine closure plans to conform to the contemporary version of the Department of Mines and Petroleum/EAP Joint Mine Closure Guidelines, it is noted that Rio Tinto iron ore closure plans drafted to support new proposals are prepared in accordance with the Guidelines. These plans are prepared in consultation with the Department of Mines and Petroleum and other key stakeholders. To date eight closure plans have been prepared in accordance with the Guidelines and submitted to Government. Rio Tinto iron ore will continue with this process going forward. For existing Ministerial Statements, closure planning is undertaken in accordance with approval conditions and Rio Tinto standards. Of particular note, compliance to the Rio Tinto standard is required irrespective of what the current Ministerial Statement conditions and State Agreement requirements are on this matter. Rio Tinto's standards require the preparation of closure plans for each aspect of an iron ore operation, and plans are revised at a frequency that is appropriate to the life and scale of the operations, and take into consideration the objectives and intended outcomes of the contemporary Guideline. We will continue our closure planning in accordance with our approval conditions, and Rio Tinto standards. This process will ensure that our plans are progressively updated to align with contemporary Guidelines. Rio Tinto iron ore considers this a practical approach which is consistent with requirements for closure planning in Western Australia. (Our reference: RTIO-HSE-0229340).

Consultation Stage	Stakeholder	Date	Subject	Summary of discussion relevant to closure	Response
Operations	Office of the Environmental Protection Authority	2014	Annual Audit Compliance Report 2013		Condition 6-1: The Rehabilitation Management Plan for Mesa J and Nearby Mesas, Deepdale Area was submitted in November 1993 (Our ref: RTIO-HSE-0043199).
Operations	Office of the Environmental Protection Authority	2014	Annual Audit Compliance Report 2013		Condition 7-1: Mesa K Preliminary Rehabilitation Plan [Our ref: RTIO-HSE-0044852] was submitted to EPA 14 January 2009 for formal sign-off following acceptance by DEC Environmental Management Branch [Our ref: RTIO-HSE-0058967]. Note that a subsequent change to the Project approved by the OEPA through a section 45C application 25 February 2013 [Your ref: A579133: OEPA 2012/000541][Our ref: RTIO-HSE-0178454] changed the project life element. This change renders rehabilitation timeframes proposed in the Mesa K Preliminary Rehabilitation Plan [Our ref: RTIO-HSE-0044852] no longer applicable. Rehabilitation of 4.48ha occurred at Mesa K Gravel Pit during the reporting period.
Operations	Department of State Development	2014	Response to State Agreement reports 2013	No significant comments. DMP Comments: It should be mentioned that the information provided relating to rehabilitation monitoring offers a good overview of the progression of historical rehabilitation.	Noted
Operations	Office of the Environmental Protection Authority	2015	Annual Audit Compliance Report 2014		Condition 6-1: The following documents were submitted and approved: The Rehabilitation Management Plan for Mesa J and Nearby Mesas, Deepdale Area, November 1993 (Our ref: RTIO-HSE-0043199). The Rehabilitation Management Plan for Mesa J and nearby Mesas, Deepdale Area Addendum, June 1994 (Our ref: RTIO-HSE-0115345), The Rehabilitation Management Plan Addendum Report, November 1994 (Our ref: RTIO-HSE-0043199).
Operations	Office of the Environmental Protection Authority	2015	Annual Audit Compliance Report 2014	Proponent stated in correspondence dated 19 January 2015 that no mining or associated activities occurred at this site during the 2014 calendar year and that no rehabilitation occurred at Mesa K during this time (2015-0001039637). The OEPA strongly encourages the proponent to commence rehabilitation in areas of the mine site where operational activities are unlikely to recommence.	Condition 7-1: Mesa K Preliminary Rehabilitation Plan [Our ref: RTIO-HSE-0044852] was submitted to OEPA 14 January 2009 for formal sign-off following acceptance by DEC Environmental Management Branch [Our ref: RTIO-HSE-0058967]. Note that a subsequent change to the Project approved by the OEPA through a section 45C application 25 February 2013 [OEPA ref: A579133: OEPA 2012/000541] [Our ref: RTIO-HSE-0178454] changed the project life element. This change renders rehabilitation timeframes proposed in the Mesa K Preliminary Rehabilitation Plan [Our ref: RTIO-HSE-0044852] no longer applicable. No rehabilitation was undertaken at Mesa K during the reporting period.
Operations	Department of State Development	2015	Response to State Agreement reports 2014	No significant comments. DMP Comments: It is positive to note that all the AER's provide information on rehabilitation monitoring and offer a good overview of the progress of rehabilitation towards analogue sites. It is also positive to note the continuation of research and trials, including (but not limited to): • The Seed Provenance Study in collaboration with the Department of Parks and Wildlife for collection of material occurred in 2014 and it is noted that support from a second Pilbara mining company was secured for the project. DMP supports a collaborative and targeted research approach; • Final Landform Project; • Priority Flora Species establishment; • Native Pivot Trial; and • Pit Void Guidance.	

Consultation Stage	Stakeholder	Date	Subject	Summary of discussion relevant to closure	Response
Operations	Department of Mines & Petroleum	2015	Mesa J Inspection 2015	1) Check the due date for the closure plan and advise DMP of when it will be provided for comment. 2) RTIO to consult with RSD regarding closure options for pit areas (for example, the steep pit face on the northern end of Pit 10) and provide written evidence to DMP that: a) consultation has taken place; and, b) what action will be undertaken at closure. 3) RTIO to provide a plan to DMP of areas that will be rehabilitated at Mesa J and Mesa K and evidence that commitment has been sought from the LOM planners to designate and sign off areas for rehabilitation.	1) The closure plan is currently under review as part of a potential referral. Submissions of the closure plan will comply with the relevant Ministerial Conditions. 2) Initial conversations have been held with the Resources Safety Division generally. One issue discussed is the use of natural features to aid in access restrictions as an alternative to construction of bunds. A directed engagement on abandonment bunds is planned for 2016. 3) Identification of areas for progressive rehabilitation informs all RTIO Closure Plans, and will be part of the closure plan review currently being undertaken. The need to better integrate closure planning into site mine planning is noted. RTIO has recently made organisation changes that see the closure function now co-located with the mine planning function to improve integration.
Operations	Kuruma Marthudunera Working Group	2016	Robe River pool impacts	Key concerns relate to Robe Pools at Mesa H Details of pumping rates from CWP and sites requested.	RTIO will continue to provide updates on study progress, including details of the proposals, hydrogeological outputs and visual impact assessment input. Heritage surveys and support will continue to be requested through the normal channels. The GWOS set strategies for maintaining and running the borefield, with the final level of control being closure of the borefield.
Operations	Office of the Environmental Protection Authority	2016	Annual Audit Compliance Report 2015		Condition 6-1: The following documents were submitted and approved: The Rehabilitation Management Plan for Mesa J and Nearby Mesas, Deepdale Area, November 1993 (our ref: RTIO-HSE-0043199). The Rehabilitation Management Plan for Mesa J and nearby Mesas, Deepdale Area Addendum, June 1994 (our ref: RTIO-HSE-0115345), The Rehabilitation Management Plan Addendum Report, November 1994 (our ref: RTIO-HSE-0043199).
Operations	Office of the Environmental Protection Authority	2016	Annual Audit Compliance Report 2015		Condition 7-1: Mesa K Preliminary Rehabilitation Plan (our ref: RTIO-HSE-0044852) was submitted to OEPA 14 January 2009 for formal sign-off following acceptance by DEC Environmental Management Branch (our ref: RTIO-HSE-0058967). Note that a subsequent change to the Project approved by the OEPA through a section 45C application 25 February 2013 (OEPA ref: A579133: OEPA 2012/000541, our ref: RTIO-HSE-0178454), changed the project life element. This change renders rehabilitation timeframes proposed in the Mesa K Preliminary Rehabilitation Plan (our ref: RTIO-HSE-0044852) no longer applicable. No rehabilitation was undertaken at Mesa K during the reporting period as future mining is planned for Mesa K.
Operations	Kuruma Marthudunera Working Group	2016	Mesa Facades	Retention of mesa facades along Robe River key requirement. Preference facades are 50m width rather than 30m. Preference to retain facades along central watercourse.	Mesa facades along Robe River will be retained. Will further assess geotech stability and resource impact of 50m vs 30m facades. Central watercourse: will assess impacts to resource and discuss options further with K&M.
Closure Management	Department of State Development	2016	General mine closure plan discussions held with DSD. (Formal written communication from Rio Tinto to DSD dated 11th July 2016).	DSD held discussions and sent various correspondence to Rio Tinto requesting that all State Agreement proponents: • Prepare and submit mine closure plans in accordance with the Guidelines for Preparing Mine Closure Plans (compliant mine closure plans) for all mine operations, including those where there is no current legal obligation to do so; and • Report land disturbance data consistent with Mining Rehabilitation Fund (MRF) categories in our State Agreement Annual Environmental Reports (AER).	In relation to mine closure plans Rio Tinto indicated that it was willing to voluntarily provide the State with the material requested on the following basis: • A timeframe of at least three years to progressively prepare and lodge compliant mine closure plans for operations where modern closure conditions do not currently apply; • Assurance that Mine Closure Plans will only be reviewed on a triennial basis by the Department of Mines and Petroleum (DMP) in accordance with the Guidelines; and • Confirmation that mine closure plans will not be connected in any formal way with the operation of our State Agreement mining approvals, such that changes to our mine plan will not mandate the need for revision of our mine closure plans, except at the regular triennial review period. As part of this Rio Tinto provided a suggested submission schedule which was subsequently agreed to by the DSD. Mesa A was nominally planned for submission in 2017.
Closure Management	Department of Mines & Petroleum	2016	Robe referral to EPA	Clarification sought whether the diversion controls being considered will apply for operation only or will they remain post closure, and would pooling/damming of surface flow occur.	Further modelling and consideration being undertaken for closure requirements, but the current design is intended for the diversion structures to allow for surface flows coming off the hills to be diverted into existing drainage into Robe River. Low risk of pools being created and structures not designed for damming flows.

Consultation Stage	Stakeholder	Date	Subject	Summary of discussion relevant to closure	Response
Closure Management	Department of Mines & Petroleum	2016	Abandonment bund placement prior to disturbance	Comment that abandonment bund placement and actual installation need to be considered early in mine planning and mine development to ensure they are not precluded from being installed at closure	RTIO acknowledged closure plans would reflect current requirements.
Closure Management	Department of Mines & Petroleum	2016	PMP/PMF modelling for closure planning	DMP acknowledged that achieving stability of large waste landforms is challenging, even under current 'reasonable climatic conditions'. DMP has observed many cases across the Pilbara and the State more broadly where rehabilitation areas have performed poorly or failed, often over a reasonably short time frame. Guidance is expected to be risk based and not a 'one size fits all' approach. It was suggested that high risk dumps (e.g. those containing designated fibrous or PAF waste) may need to be designed to withstand larger or more intense rainfall events than small, inert, low risk waste dumps.	RTIO will wait for the landform design document which will include guidance on the PMP/PMF issue.
Operations	Department of State Development	2016	Response to State Agreement reports 2015	DMP supports the inclusion of rehabilitation monitoring data and photographs. Rehabilitation appears to be progressing well with only a small number of sites yielding poor results. Rework should be monitored for success and an update provided in future AERs and TERs.	
Operations	Kuruma Marthudunera Working Group	2016	Jirti Thalu access	The importance of Jirti Thalu to the K&M people was highlighted, and that they had concerns about the safety of certain community members if the place was impacted.	Mine planning will run options to test the impact with Jirti Thalu removed form the mine schedule.
Closure Management	Department of Mines & Petroleum	2016	Public safety risk mitigation requirements for closed mine sites	Environmental inspectors regulate safety through Mining Regulations 1981 Regulation 28 "…all holes, pits, trenches and other disturbances to the surface of the land made whilst mining which in the opinion of an environmental officer are likely to endanger the safety of any person or animal will be filled in or otherwise made safe to the satisfaction of the environmental officer". The DMP intends to revise its abandonment bund guidance to become less prescriptive and more outcomes focused. There would not be an expectation to batter down and rehabilitate large faces – abandonment bunds to prevent inadvertent access would be more appropriate. Vegetation on a slope would help prevent access, but should not be relied upon as a primary control as it could be lost to fire etc. Similarly, fences should not be considered a permanent control.	RTIO is considering options.
Operations	Department of Mines & Petroleum	2017	2017 Robe Valley closure plan overview	RTIO presented an overview of the Mesa A Hub and Mesa J Hub closure plans, including scope, risks, gaps and actions. The DMP feedback was positive and they look forward to receiving the plans. Their interest was in the waste dump designs and management of erodible material and abandonment bunds. They were happy to hear that the business has a project planned for this year to incorporate the inclusion of abandonment bund considerations into study outputs (likely at FS level).	The closure plans will likely contain some discussion on abandonment bund options but not detailed designs for all areas at this stage. Completion of this is included in the closure task list.
Closure Management	Department of Environmental Regulation	2017	Contaminated Sites		Contaminated sites are managed as an operational issue, using a risk based approach. Closure is considered in the risk rating based on estimated closure dtae. Focus is currently on the higher risk areas, with 19 locations to be investigated and managed in the next five years.
Operations	Kuruma Marthudunera Working Group	2017	Water monitoring Site Visit	Traditional owners attended a monitoring run with the hydrology team to download dataloggers in pools along the Robe River. A summary of the locations visited and photos of the monitoring work were provided to KMAC for awareness.	

Consultation Stage	Stakeholder	Date	Subject	Summary of discussion relevant to closure	Response
Closure Management	Department of Water and Environmental Regulation	2017	General Closure Plan schedule	Overview provided of closure plans that Rio Tinto (iron ore) is currently working on in 2017 and planning for 2018 to either support approvals in process, for compliance purposes or to meet commitments made to the Department of State Development in 2016 to submit closure plans for all operations over a three year period. These include: - Silvergrass East - Hope Downs 1 - Mesa A hub - Mesa J hub - Paraburdoo - Tom Price - Brockman 4 - Hope Downs 4 - Eastern Range - Channar	

Appendix C – Closure knowledge database (Confidential)

Rio Tinto Mesa J hub closure knowledge database

The closure knowledge database is a summary of the technical reports that directly or indirectly contribute to the development of the closure plan. These documents do not form part of the report and are for indicative purposes only.

The knowledge and understanding of closure issues and management strategies evolve and improve over time, coincident with the development of the mining operation. As a result, some components of some reports and studies may be superseded by new research or studies. While the closure plan addresses the current state of understanding and strategy for closure, the closure knowledge database captures the historical development of closure knowledge, and demonstrates how experience and knowledge developed at other Rio Tinto sites has been considered during the development of the closure plan and across the life of the operation. Accordingly, some information presented in the closure knowledge database may be obsolete.

Technical reports supporting the closure of the operation will be presented as part of the last plan produced prior to the implementation of closure (also known as the Decommissioning Plan).

CONFIDENTIAL

Geochemical characterisation

Review of Waste Rock Geochemistry a) General Overview of Acid Base Accounting **2006**

This report contains a general overview of acid base accounting and a summary of the geochemical test work that has been previously completed for various sites and lithologies.

Internal reference: RTIO-PDE-0021130

There are large discrepancies in the total sulfur concentration measured using XRF and LECO machines. The XRF machine underestimates the sulfur concentration at values greater than 2%. Materials with total sulfur concentrations less than 0.1% can contain low capacity PAF material, however, it is considered only to be low additional acid and metalliferous risk if the boundary for inert material and potentially acid forming material is shifted from 0.02%S to 0.1%S. A paste pH result of less than 7 should be sent to the black shale dump and a paste pH result of greater than 7 can be sent to an inert material waste dump.

Mineralogical Analysis of Potentially Acid Forming Materials **2008**

Quantitative mineralogy (QEM-Scan) for samples of rock collected from Tom Price, Channar, West Angelas, Brockman, Paraburdoo, East Extension, Western Turner Syncline and Hope Downs 1 North was undertaken. Comparisons were made between two methodologies use to characterise potentially acid forming materials; acid base accounting and mineralogical analysis.

Internal reference: RTIO-PDE-0053725

All samples contained elevated total sulfur concentrations and the lithologies were either shale, banded iron formation or dolomite. Pyrite was the dominant mineral contributing to acidity and the dominant sulfate secondary mineralisation consisted of alunite and jarosite.

Determination of ARD potential of Rio Tinto Iron Ore (WA) Waste Rock Samples **2008**

This report investigates the use of mineralogy to predict acid and metalliferous drainage potential. Analysis of numerous rocks was undertaken using QEM-SCAN.

Internal reference: RTIO-PDE-0051613

Areas of waste rock which have underdone oxidation can be identified where sulfur-bearing minerals vary between samples in the form of pyrite, alunite and jarosite. The variability of gangue mineral phases suggest that some areas of composite waste rock pile may provide some neutralising potential while other areas will have no neutralising potential. Variable textural and mineralogical controls on sulfide mineral occurrence result in decreased accessibility of pyrite to oxidising fluids.

Environmental Status of Selenium (Se) in the Pilbara Region of Western Australia – Potential Risk from Iron Ore Mining **2011**

This report includes information about Selenium geochemistry, distribution in the environment, occurrence in rocks in the Pilbara and potential risks to the environment.

Internal reference: RTIO-PDE-0103857

The Selenium (Se) content of shales containing significant pyrite should be recorded as part of the overall risk assessment for acid and metalliferous mine drainage. However, it should also be noted Se solubility is far less constrained by pH than in the case of metals and near neutral drainage may contain significant Se concentrations in solution. It would be most useful to study the Selenium budget of the wetlands in the Pilbara as, apart from the chance poisoning of livestock from the consumption of plants that have taken up high concentrations of Selenium, impacts are most likely to be felt in wetlands receiving mine site drainage.

Contaminant Leaching from Non-Sulfidic Waste Material **2011**

The available leach extract data and information pertaining to the distribution of metals and metalloids in non sulfur materials at neutral pH was reviewed. Based on this review conceptual models for controls on their leaching and mobility were developed.

Internal reference: RTIO-HSE-0145041

The review found that contaminant leaching from non-sulfidic materials was generally very limited. Usually the pH in leach tests was near-neutral (pH 6 to 8), and dissolved contaminant concentration were at or below detection limits. It is believed that a primary leachable contaminant source is the oxidation of sulfide minerals. Release from oxidising sulfides leads to release of soluble reaction products. Under neutral pH conditions, there is the potential for release of these contaminants when those products dissolve.

Contaminant Leaching from Low-Sulphur Waste Minerals (Summary) **2011**

Internal reference: RTIO-PDE-0090689

RTIO's Geochemical Database was reviewed and based upon this data, conceptual models for controls on the leaching and mobility of a range of metals and metalloids were developed. This summary also describes potential controls on the amount of dissolved element that may be released. This is a summary of a comprehensive report RTIO-PDE-0100104.

For most contaminants, dissolved concentrations at circum neutral pH (pH 6 to 8) were very low, typically at or below detection limit. Geochemical modelling indicates that water-rock interactions are controlled by equilibrium, for salt, carbonates and sulphates this equilibrium is often source term limited whilst hydroxyl-sulphates and hydroxides are solubility controlled. Results also indicate that sorption plays an important role in solute concentration; weak (but detectable) sorption occurred for selenium and zinc whilst the strongest sorption was evident for cobalt. The review suggested that storage waste facilities containing low-sulfur materials pose a low level of environmental risk however, there is a small risk of increased in mobility of some contaminants if acidic conditions arise. Acidic conditions can sometimes arise from the interactions between iron and aluminium hydroxyl-sulphates and hydroxides.

Geochemical Assessment of Tailings from Yandi, Paraburdoo, Tom Price, Brockman 4 and Mesa J **2014**

Internal reference: RTIO-PDE-0123030

This report presents the results from geochemical testing and saline solution extraction of tailings samples from Yandi, Paraburdoo, Tom Price, Brockman 4 and Mesa J deposits.

Overall the tailings from these operations are unlikely to generate acid and are not expected to leach significant levels of metals under oxidising or saline conditions.

Oxidation and solute accumulation in dewatered pit wall rocks **2014**

Internal reference: RTIO-PDE-0109045

Dewatering and removing the water table may result in de-saturation of sulphide-bearing lithologies. This study was undertaken to review how oxygen ingress and consequent sulphide oxidation of Mount McRae Shales could impact water quality when the groundwater table rebounds after mining.

Large Scale Column Construction Procedure and Initial Chemistry **2014**

Internal reference: RTIO-PDE-0123894

Large scale column experiments have been constructed to examine the reactivity of hot and cold black shale material in an operational environment. The memo describes the construction of the columns and the first geochemistry data collected after small rainfall events at Rhodes Ridge.

Initial results suggest that effluent water retains the chemistry of the incident rainfall. Constituents to note in the initial chemistry include nitrate and ammonia detected in the hot black shale effluent. This study provides an important comparison between laboratory characterisation studies and field reactivity of waste rock. Data from the large scale column tests can be applied to reactivity of in pit waste/talus as well as waste rock dumps. It can be used as an intermediate to predict long term reactivity of waste rock.

Robe Valley AMD Risk Assessment **2015**

Internal reference: RTIO-PDE-0061933

This report presents an updated (from 2000) risk assessment associated with acid and metalliferous drainage in past, current and possible future deposits at the Robe Valley. Note, conservative assessment values have been assigned where drilling information is sparse and subsequent material characterisation understanding is limited. These risks will be reviewed as more information becomes available.

Sites with a low to no risk for acid and metalliferous drainage (AMD) are Warramboo, Highway, Tod Bore, Dinner Camp Bore, Mesa A, Mesa B, Mesa C, Mesa F, Mesa G, Mesa H, Mesa I, Mesa J, Mesa K, Mesa L, Mesa M, Mesa N, Middle Robe and Omega. Sites with moderate AMD risk are Bungaroo and Jimmawurrada Creek.

Robe Valley Geochemical Assessment **2016**

Internal reference: RTIO-PDE-0142883

The overall objective of the geochemical assessment was to geochemically characterise reverse circulation drill samples selected and collected by RTIO from their Robe Valley operations. Samples from seven deposits across RTIO's Robe Valley operations were selected by RTIO and delivered to OKC's laboratory in Osborne Park for a range of geochemical analyses. The laboratory analyses were completed over two stages with results from the first stage influencing the second stage of testing. This report includes results and interpretations of the geochemical characterisation program.

All samples showed low AMD risk.

Updated AMD Risk Assessment Summary for Inclusion into 2016 Robe Valley Closure Plan (Mesa H, Mesa J and Mesa K) **2016**

Internal reference: RTIO-PDE-0147826

A review of the AMD risk assessment has been completed to support the development of a Robe Valley closure plan focusing on the Mesa H, Mesa J and Mesa K mining and project areas. This update is based the latest (2015/2016) available drillhole data and proposed final pit shells.

The overall AMD risk for these areas remains low following an update to the assessment. However, it is recommended that the AMD risk assessment be reviewed for the Mesa H project area once 2015/2016 drillhole interpretation is finalised, and also upon completion of the Mesa J/K drillhole re-interpretation being undertaken to support Mesa H pre-feasibility studies.

Mesa H 2017 AMD Risk Assessment Update Summary (memorandum) **2017**

Internal reference: RTIO-PDE-0154172

A review of the acid and metalliferous drainage (AMD) risk associated with mining in the Mesa H project area has been completed to support the referral of the Mesa H Iron Ore Project Feasibility study. This review considers recently available (July 2017) drillhole data and mine planning data.

The overall AMD risk for the Mesa H area remains low following an update to the initial assessment.

Physical characterisation

Characterisation of Mesa J TSF1 Tailings and Vegetation **2009**

Internal reference: RTIO-HSE-0083225

The purpose of this study is to provide an understanding of the chemical, physical and biological properties present at the Mesa J Tailings Storage Facility (TSF1). The study investigates the spatial distribution of the coarse, transition and fine zone surface tails, as well as characterising the material properties for comparison with surrounding analogue soils.

Despite some differences in physical characteristics between the different tailings zones, in general, the tailings are considered suitable for plant growth. The fine tailings zone supports water dependent vegetation, the transition zone supports mixed low closed shrubland and also most alien species. The coarse tailings zone supports scattered tall Acacia shrubs and low trees. Root penetration into the TSF1 is expected to enhance cracking and the development of soil structure and also further drying of the soil beneath. Top soil stockpiles have been identified as a source of native seed.

Net solute load response to the installation of infiltration limiting dry cover systems over acid forming waste piles **2014**

Internal reference: RTIO-PDE-0128431

This work was conducted to verify the central design concept of store-and-release covers over sulfidic above water table waste dumps that is, whether limiting net percolation volume through the cover results in a lesser sulfate and acidity load being realised generated and passing through the dump.

The results from this thesis project confirm that the central aim of store-and-release covers to reduce net percolation volume is a valid measure for reducing the net loading of sulfate and acidity. The mechanism through which decreasing net percolation (applied water volume) results in a lesser sulfate and acidity load was identified, however further work in a site context is needed to assess how this relationship between percolation volume and loading persists in the real-world environment.

Mesa H Geological Modelling and Resource Estimation Report **2014**

Internal reference: GDSR 6103

Document information collected about local geology and extent of resource.

Mesa H is one of a group of oolitic to pisolitic goethite-hematite deposits of Tertiary age which have formed in ancestral drainage channels of the Robe River, in the western Pilbara region of WA. This group is known as the Lower Robe (or Deepdale) group and comprises fourteen mesas or cuestas (which are identified by the letters A to N, commencing from the mouth of the Robe River).

Modelling and Resource Report - Mesa J South **2016**

Internal reference: GDSR 6360

Document information collected about local geology and extent of resource.

Mesa J is one of a group of oolitic to pisolitic goethite-hematite deposits of Tertiary age which have formed in ancestral drainage channels of the Robe River, in the western Pilbara region of WA. This group is known as the Lower Robe (or Deepdale) group and comprises fourteen mesas or cuestas (which are identified by the letters A to N, commencing from the mouth of the Robe River).

Waste characterisation and erodibility assessment for landform design : Tertiary Pisolite Clay **2017**

Internal reference: RTIO-HSE-0304816

The objective of this report is to define appropriate landform batter characteristics for the Tertiary Pisolite Clay materials supplied from the Mesa H deposit.

The results indicate that for the TPC materials at Mesa H (using a climate sequence developed for Mesa J), a lift height of 10m is achievable. Minimum berm widths vary with lift height (and slope length). A 20 degree lift at Mesa J sheeted with TPC material would require a 15m wide, 5% backsloping berm in order to store runoff from a rain event with a 200 year return period, and sediment generated from the slope for a period of 200 years. Lift options other than a 20 degree linear slope are also provided. This includes a concave option that indicates that a single lift (without a berm) that is 35m high could be constructed.

Growth Media Characterisation **2018**

Internal reference: RTIO-HSE-0324326

This report provides an interpretation of material characterisation data for a total of 53 potential growth media samples made up of 34 samples for which data has been previously collected by Outback Ecology Services on behalf of Rio Tinto, 11 samples for which data has been previously collected by Landloch on behalf of Rio Tinto as part of previous erosion studies and 8 additional samples collected and analysed as part of this project. Based on this characterisation, each material was classified as either suitable or not suitable for use as a growth medium.

Properties tested for included pH1:5 (water), salinity (EC1:5, EC1:2), exchangeable cations (K+, Ca2+, Mg2+, Na+, Al3+), effective cation exchange capacity (ECEC), exchangeable sodium percentage (ESP), particle size distribution (fine fraction<2mm), coarse fraction (> 2mm), particle size distribution (all material), texture, emerson class, dispersion potential rating, rock particle density, rock water absorption and rock cover of rain-armoured surface. A classification scheme for key parameters was then developed to classify a material as suitable or unsuitable. Several materials have properties that were invariably suitable. In some cases, materials have some properties that are suitable and others unsuitable. In others, several of the properties are problematic. Suitable materials represent those that have base properties that are not likely to impede vegetation. Marginal materials are those that are likely to support vegetation but that have some properties that may limit establishment and growth. Unsuitable materials are those that have properties that are likely to significantly impact on vegetation growth either through being saline, prone to dispersion, and having pH values quite different to those typically observed. Of the 53 samples, 21 were recommended as suitable growth media, 25 were assessed as marginal growth media and 8 were not recommended as growth media. Samples which were recommended were sourced from Yandicoogina, Channar, Mesa J, Mesa K, Eastern Range, Paraburdoo and Parker Point. Marginal samples were sourced from Brockman 4, Brockman 2/Nammuldi, Mesa A, Mesa J, Channar, Eastern Range, Paraburdoo, Yandicoogina and Hope Downs 4. Samples which were not recommended were sourced from areas at Greater Paraburdoo (Paraburdoo and Eastern Range), West Angelas, Western Turner Syncline and Parker Point.

Groundwater

Mesa J Water Management Study - Groundwater Modelling **2007**

Internal reference: RTIO-PDE-0033605

This report details the modelling work undertaken during this study, but summarises also any relevant previous hydrogeological and modelling work done for the Mesa J site.

There are three major aquifer units in the Jimmawurrada – Bungaroo Creek valley: • Alluvial overburden: is a major unconfined aquifer, if saturated. In the Mesa J area, the alluvial overburden is relatively thin and rises above the water table such that it is largely unsaturated, except in the Robe River and along the Jimmawurrada Creek. • Robe Pisolite: forms the main regional aquifer. In the Mesa J area, the pisolite is unconfined. The Robe Pisolite is bounded to the east and west of Mesa J by basement highs. To the north, the aquifer is dissected by the Robe River and is in hydraulic continuity with the Robe River valley. • Yarraloola Conglomerate and weathered/fractured dolomite of the Wittenoom Formation: Aquifer potential in the Yarraloola Conglomerate is consistent with the findings of other recent work in the area (such as the water supply investigations undertaken at Warramboo). This aquifer is the target of the recently drilled water supply bores DWB11 to 20.

Pannawonica and Mesa J Groundwater Operating Strategy **2014**

Internal reference: RTIO-HSE-0017341

This document forms the Groundwater Operating Strategy for Pannawonica Town and Mesa J Borefields.

The Mesa J mine is situated in the Jimmawarruda-Bungaroo Creek Valley. There are several major aquifer units in region. The highly permeable alluvial is found in the river beds and flood plains of the local watercourses. The ore body itself forms an unconfined aquifer of highly variable permeability. Beneath the Robe Pisolite is the Yaraloola Conglomerate. In the mining area the basement units are from the Wittenoom and Marra Mamba Formation.

Mesa H 2016 Pre-Feasibility Study: Hydrogeological Drilling Program Completion Report **2016**

Internal reference: RTIO-PDE-0142386

This report presents drilling and construction details for works completed as part of the Mesa H Pre-Feasibility Study (PFS).

Drilling results helped define the extent of the Robe Pisolite (CID) underneath the Robe River alluvium, identify the Paraburdoo Member and the Bee Gorge Member of the Wittenoom Formation as local aquifers and at the same time classify the unmineralised BIF (whenever underlying the CID) as an aquitard.

Mesa H Conceptual Hydrogeology **2016**

Internal reference: RTIO-PDE-0147732

Dewatering is required with a max drawdown of ~20m (current water table). Permanent pools, riparian vegetation and 2 x Rights Reserve sites have to be protected during mining operations.

Permanent pools and riparian vegetation are sustained by the Robe River aquifer. Storage of the Rove River aquifer likely to be very high. Lowering the water table in the CID could cause localised drain of the Robe River aquifer. Lowering of the water table in the Wittenoom Aquifer unlikely to affect the Robe River Aquifer.

Mesa H Surface and Groundwater Chemistry Interpretation **2016**

Internal reference: RTIO-PDE-0144245

An interpretation of chemistry and isotope data has been conducted for Mesa H in an attempt to establish whether Robe River pools are groundwater fed and hydraulically connected to the CID and/or Wittenoom aquifers. This Technical Memorandum summarises the methodology and results of this assessment.

Available chemistry and isotope data indicate that the Robe River pools are likely connected to the alluvial aquifer, and that the CID and Wittenoom aquifers are mainly comprised of fresh recharge. However, the latter aquifers appear to be receiving unusually high saline recharge at different locations particularly along the topographically low part of the mesa located to the west of Mesa H and down-gradient of the tailings pond. It is unclear whether the high salinity recharge observed in outlier CID/Wittenoom bores results from diffuse recharge due to local topography or geology, seepage from the tailing pond or an unknown recharge mechanism.

Mesa H Conceptual Hydrogeology **2016**

Internal reference: RTIO-PDE-0147733

The main objectives of this conceptual hydrogeological study are to define aquifer types and hydraulic characteristics, define groundwater boundaries, define recharge and discharge systems and volumes, assess the Robe River permanent pools hydraulics and groundwater dependency, and identify the risk of groundwater abstraction to impact sensitive ecological and heritage receptors.

The main findings observed in this study were: • Three regional aquifers: Wittenoom Aquifer, CID Aquifer and Robe River Aquifer; • Three no-flow boundaries: Marra Mamba Iron Formation, Brockman Iron Formation and Boolgeeda Iron Formation; • One partially confining layer: Tertiary Basal Pisolite; • Robe River pools chemical signature are associated mostly with the Robe River Aquifer with lesser correlation to the other regional aquifers; • Dewatering of the CID has the potential to locally lower the water level in the Robe River Aquifer draining the alluvium depending on the duration and extent of the groundwater abstraction; • Impact to the Rights Reserve pool to the west of Mesa H (KM-RR16) is unlikely; and • Impact to the Rights Reserve to the northeast of Mesa H (KM-RR21) is possible.

Robe River catchment water strategy **2016**

Internal reference: RTIO-PDE-0147734

The Iron Ore Water Strategy 2016 aims to support business value by reducing water-related constraint in current operations and future developments, and strengthen our licence to operate through responsible water management.

The environmental and cultural values of the Robe River are considered to be of high significance to the Kuruma Marthudunera (K&M) people, government regulators and the broader community. Water-related activities required to enable the 5-year plan are achievable. The water-related challenges facing the development of the Bungaroo and Jimmawurrada deposits remain significant.

Review of Depth to Groundwater at Mesa K **2016**

Internal reference: RTIO-PDE-0023804

Geological Support hydrogeologists were asked to assess the depth to groundwater and to determine if mining would intersect the water table.

Indications are that the maximum extent of potential mining would intersect the water table at Mesa K.

Robe Valley Mesa H Pre-Feasibility Study – Dewatering, Water Supply and Impact Assessments **2017**

Internal reference: RTIO-PDE-0149724

RTIO is undertaking a PFS study to expand into Mesa H. As part of the PFS, dewatering estimation, assessment of potential drawdown impacts on the Robe River, assess potential water supply for the mine and groundwater recovery are required to support the Environmental Review.

During closure, the drawdown front is predicted to have moved further to the north, reaching Robe River and surface water polls along its path. The model predicts peak drawdown of ~0.5m in the Robe River area, north of the Mesa H – Pit 8 and Pit 9 in 2042. Full system/aquifer recovery associated with the groundwater levels is predicted to occur within 50 years after the end of dewatering.

Independent peer review of the Environmental Risk Assessment for "Mesa J Tailings Storage Facilities (TSF)" **2018**

Internal reference: RTIO-PDE-0161266

This report provides a simple, screening-level assessment of the potential for Contaminants of Potential Concern (COPC) to be transported from Mesa J TSFs to receptors along Robe River and associated tributaries. The overall approach was to use an existing numerical groundwater model to predict chloride transport as conservative proxy for all COPC, which include chloride, copper and nitrate. Predictions were made at the end of the model calibration period (Dec. 2016), at the end of Mesa H operations (Dec. 2037), and at 190 years after mine closure (Dec. 2227). Based on the model results, dilution factors were calculated and applied to TSF monitoring bore concentrations in order to estimate exposure concentrations.

Whilst this review finds the overall approach to be appropriate, it is recommended that further modelling and statistical treatment of the monitoring data is warranted to provide a range of possible exposure concentrations and thus a more defensible risk characterisation. Model structural uncertainty and parameter uncertainty should also be discussed and investigated if either/both are deemed to have a significant influence on results.

Surface water

Mesa K surface water management **2007**

Internal reference: RTIO-PDE-0032034

This memo outlines the catchment hydrology of the Mesa K deposit, and the current surface water management practices.

Prior to historical mining activities, this area would have originally drained directly into the Robe River. The Mesa proper has been heavily disturbed and as a result is now largely internally draining, intercepting 0.03% of the flow contribution to the Robe River.

Long Term Ecological Research on a Pilbara River System **2009**

Internal reference: RTIO-PDE-0147723

The Robe River alluvial aquifer has been identified as a potential water source in the Pilbara regional water plan and previous regional hydrogeological assessments. This document summarises the groundwater dependent values associated with the Robe River alluvial aquifer and describes the links between these ecosystems and the aquifer.

The Robe River, like most Pilbara rivers is ephemeral, with a highly variable flow regime reliant on summer cyclones and autumn thunderstorms. The alluvial aquifer is recharged from direct infiltration through the riverbed during these unpredictable river flow events. River pools, riparian vegetation and aquifer ecosystems are identified as being sustained, at least in part, by water from the alluvial aquifer, particularly during periods of no river flow. The river and riparian ecosystems are of conservation significance at the local scale and provide valuable habitat for several priority fauna species, two federally protected migratory birds and a potentially new fish species. The aquifer ecosystem with its distinct stygofauna species is expected to be of high conservation value.

Mesa J & K Surface Water Management **2011**

Internal reference: RTIO-PDE-0068650

This report describes the interaction between natural surface water runoff, the local environment and the Mesa J and Mesa K mine sites.

Mining operations in Mesa J have intercepted the local Western Creek. The termination of this ephemeral creek into Pit 11 South results in a catchment area reduction of over 60% for the local Western Creek. The Mesa J mine is protected by the railway embankment in addition to the Southern Levee which affords the Mesa J mine flood protection against a 50 year flood event. The Mesa J to K causeway crosses the Robe River immediately north of Mesa J mine operation. The causeway consists of a number of culverts and a spillway that will be overtopped during a 1 in 2 year ARI flood event. A section of the causeway, known as the Plug, will preferentially erode away once the causeway is overtopped.

Mesa J and K Mine Site Flood Risk Assessment **2014**

Internal reference: RTIO-HSE-0235234

The objectives of this assessment are to define the hydrological characteristics of the area and assess current flood risks in order to facilitate management of surface water runoff and minimise resulting production loss at the Mesa J. Mesa K remains inactive over this wet season.

The Mesa J causeway causes minor impoundment and ponding of surface water by intercepting surface water runoff from the upper Robe River catchment. A “plug” has been incorporated into the causeway bridge that should preferentially erode when windrows have been breached and the causeway is being overtopped. Two levee banks are in place to protect the south eastern portion of the Mesa J mine and borefield from local runoff and Jimmawurrada Creek flood waters.

Five Year Surface Water Management Strategy: Mesa J and K 2014 to 2019 **2014**

Internal reference: RTIO-PDE-0147726

This report summarises the known surface water management strategy, risks to plan and opportunities to the mine site and co-commitments required to implement the strategy for the next five years of mining (2014-2019)

At Mesa J and K, four key risks have been identified relating to surface water. The first risk focuses on pit inundation, particularly Pit 11. This pit is sacrificial and has storage for a ARI 50 year event. The second risk is around landform erosion, and is managed using landform design. The third is operational, when the river floods and removes access to the mine. The fourth is also operational, in how to manage discharge to the creek during floods. All risks have been assessed and the residual risk is Low or Moderate.

Aquatic Ecosystems Study: September 2015 **2015**

Internal reference: RTIO-HSE-0290103

The current program outlined in this report assesses impacts, if any, from mining activities on Robe River pools. This on- ground program incorporates an annual aquatic ecosystem survey of Robe River pools as part of an on-going commitment to assess any environmental impacts of mine development on the adjacent and downstream aquatic ecosystem.

In September 2015, there were no significant changes to the river pools from the long-term mean position. The long term database that exists from these Robe surveys allows informed analysis and interpretation of these changes. The current survey supports previous findings that difference in environmental characteristics of pools are primarily a result of overriding climatic influences determining pool permanence and local morphology. To date, there have been no detectable changes in the aquatic ecology of the Robe River that could be attributed to mining operations.

Mesa H Order of Magnitude Design Flood Estimation and Floodplain Mapping **2016**

Internal reference: RTIO-PDE-0139440

The objective of this investigation is to provide design flood estimates and floodplain mapping for the Mesa H deposit. The results of this investigation will inform the development of surface water management options for the proposed mine.

The results from the hydraulic modelling indicate that, for the most part, Mesa H lies beyond the 1% AEP floodplain and is not vulnerable to riverine flooding (Figure 12). The 1% AEP flood depths are predominantly shallower than 1 m and the corresponding velocities are generally lower than 2 m/s.

Mesa J Life of Mine Pit UF14.18 Design Hydrology Review **2016**

Internal reference: RTIO-PDE-0147721

This memo details the current understanding flood management practices and risks at Mesa J in preparation for the update to the mine plan.

The existing southern levee and the levee southeast of the mine prevent rising floodwater from Jimmawurrada Creek entering the mine. Local runoff is trapped behind the levees and left to dissipate naturally via infiltration and evaporation. The southern cutback pits, including Pit 11, Pit 12, Pit 14, Pit 7 and Pit 6, are exposed to surface water flows from the southern catchments and moderate to high surface water risks have been identified. The flood water is either managed in pit by sump pump measure or defended by the local dumps and flood protection bunds. At Pit 11, two options for flood protection bunds have been assessed to divert the southern creek into the existing diversion drain (an upgrade of the drain has also been investigated) which flows into a natural creek at its northwest extent.

Flora

Baseline Flora and Vegetation Assessment of Robe Valley Mesas (Mesas B, C, D, E, F, H and I) **2011**

Internal reference: RTIO-HSE-0111431

This report documents the methods, results and key findings of the baseline flora and vegetation survey within the study area. It provides an assessment of the vegetation communities and flora species recorded.

Biota Environmental Sciences (Biota) was commissioned in August 2010 to conduct a biological survey of various mesas in the vicinity of Pannawonica. Fifty vegetation units, including three mosaic units, were identified and mapped within the study area. None of the vegetation units within the study area comprise TECs. A total of 221 species were recorded within the study area. Three species of Priority flora (Triodia sp. Robe River (M.E. Trudgen et al. MET 12367), Ptilotus mollis and Rhynchosia bungarensis) were recorded from the study area. Fifteen species of introduced flora were recorded in the study area.

Statement Addressing the 10 Clearing Principles: Mesa J Southern Cutback Flood Protection Bund **2013**

Internal reference: RTIO-HSE-0187908

This desktop report has been prepared from a review of existing biological information, including available databases and various studies in the Mesa J locality. It is intended that this report will be used as supporting documentation for Rio Tinto's NVCP application.

The landforms, vegetation, flora and fauna habitats are well represented within the Mesa J locality and the broader Pilbara region. The study area does not contain any TECs pursuant to the EPBC Act 1999, ESAs pursuant to the EP Act 1986, or PECs listed by the DEC.

Mesa J Road Reconstruction Flora and Fauna Assessment **2013**

Internal reference: RTIO-HSE-0192503

The study area extends from Pannawonica to Mesa J (Figure 1.1) and comprises approximately 12 km of established road covering a total area of 69 ha. The purpose of this assessment was to undertake adequate surveys to provide the necessary information required to support a NVCP Application, and undertake a rare flora assessment of area prior to ground disturbance works commence.

Rio Tinto Iron Ore commissioned ecologia Environment to undertake a single-phase Level 1 flora and vegetation and a Level 1 vertebrate fauna survey prior to the reconstruction of the Mesa J Access Road. A total of 154 plant taxa were recorded and fully identified. No plant taxa listed under the EPBC Act or the WC Act have been recorded in the study area. Twelve weed species were recorded within the study area, seven of which have been assessed within the DEC (now DPaW) environmental threat assessment of weeds for the Pilbara bioregion. Thirty-one fauna species (three mammals, 29 birds and two reptile species) were opportunistically recorded during the survey, including the conservation significant Rainbow Bee-eater (EPBC Act Migratory, WC Act S3).

Mesa K Gravel Pit South Rehabilitation Record **2013**

Internal reference: RTIO-HSE-0246225

This report summarises the rehabilitation of the gravel pit south area at Mesa K Operations, completed in 2013 by the RTIO Rehabilitation team, with the assistance of Mesa J/K Operations team.

The 4.5ha gravel pit south rehabilitation area consisted of two separate elevations joined together via a gentle slope (batter). A track along the bottom edge of the higher elevation was left in situ to service the area. Windrows were installed around the outer edges of all rehabilitated areas to stop water flowing off the top berms and down the outer slopes. No topsoil was imported as the area had very good natural regrowth prior to commencement of rehabilitation; the land was scalped and re-spread as part of the rehabilitation process.

Mesa J, Pit 10 Rehabilitation Record 2014 **2014**

Internal reference: RTIO-HSE-0300385

This report summarises the rehabilitation of part of the Pit 10 area at Mesa J Operations that was completed in 2014 by the RTIO Rehabilitation team, with the assistance of Mesa J Operations team. Threshed and non threshed spinifex seeds were trialled.

Two sections of Pit 10, totalling ~11.5 hectares, were rehabilitated. Rehabilitation earthworks involved areas with unconsolidated waste, such as minor ramps and small piles of dirt near pit walls, to be re-profiled and blended in with the surrounding terrain to ensure appropriate drainage. The area was re-profiled to level out material on the pit floor, and topsoil was applied and spread to ~2.86 ha in the northern section of the pit. The northern section of the pit had been fallow for 8 years and little vegetation growth had occurred during that time. Both areas were ripped along the contours and seeded with native seed of local provenance. The pit walls were not treated. On two 1 hectare blocks, threshed *Triodia wiseana* seeds were spread to measure germination success against non threshed (control) seeds. No topsoil was applied to these areas to ensure seeds stored in the seed bank did not impact the germination results.

Flora, Vegetation and Fauna Habitat Assessment at Jimmawurrada **2014**

Internal reference: RTIO-HSE-0220213

This report is intended as a supporting document for an NVCP application by Rio Tinto, as required by Section 51A of the Environmental Protection Act 1986 (EP Act). The report has been prepared on the basis of a review of existing information for the project area, combined with two site visits. This report describes the methodology employed for the flora, vegetation and fauna habitat assessment of the study area, and documents the results of the survey. In particular, this report identifies vegetation, flora and fauna habitats of conservation significance relevant to the study area.

Six broad fauna habitats were recorded within the study area; low hills and hill slopes, plains, floodplain, mosaic, major drainage lines, and soak. A total of 284 native taxa from 135 genera belonging to 51 families were recorded by Biota. An additional 18 taxa were recorded during the current study. Five conservation significant species were recorded within the study area.

Desktop Flora, Vegetation and Fauna Habitat Assessment at Robe Valley **2015**

Internal reference: RTIO-HSE-0257758

Approval for clearing of native vegetation associated with the proposal is required via a Native Vegetation Clearing Permit (NVCP) under Section 51A of the Environmental Protection Act 1986 (EP Act). Vegetation, flora and fauna assessments at Robe Valley (the study area) were required to address the 10 Clearing Principles as part of the NVCP application process.

One Priority 3 flora taxon has been previously recorded in the study area, Triodia sp. Robe River (M.E. Trudgen et al. MET 12367). Four weed species were previously recorded within the study area. Six vegetation associations were described from Hills and Slopes, eight units from Plains and one unit from Flowlines. Four conservation listed terrestrial fauna species have been previously recorded from the study area.

Mesa H Project – Level 2 Vegetation, Flora and Fauna Assessment – Phase 1 Summary **2015**

Internal reference: RTIO-HSE-0243872

The objective of the assessment was to complete Phase 1 of a two-phase biological survey of vegetation, flora and fauna of the Mesa H survey area and provide a brief summary presenting the key findings of the survey.

Astron was engaged to undertake a Level 2 vegetation, flora and fauna assessment for the Mesa H Project. Siz broad fauna habitat types were recorded in the survey area: Riverine, Gorge, Drainage, Breakaway, Rocky Hills, Low Hills/Slopes, Loamy/Stony Plain. One hundred and forty-three vertebrate fauna species were recorded within the survey area during the survey, of which eight were conservation significant. Two hundred and thirty-seven vascular flora species from 48 families and 125 genera were recorded in the survey area.

Mesa J Mine Extension – Level 2 Vegetation and Flora Assessment **2015**

Internal reference: RTIO-HSE-0280041

The objective of the assessment was to provide a single season Level 2 assessment of vegetation and flora values through a desktop assessment and field survey. The resultant data will be utilised to produce a report to support and inform the environmental assessment process for the Mesa J Mine Extension project.

Astron was engaged to undertake a Level 2 flora and vegetation assessment for the Mesa J Mine Extension. One hundred and thirty-six flora species, Representing 78 genera from 35 families were recorded in the survey area. No Threatened flora was recorded during the survey. Two State-listed Priority flora were identified in the survey area. Seven introduced flora species (weeds) were recorded in the survey area, none of which are listed as a declared pest.

Middle Robe and Eastern Deepdale Level 2 Vegetation and Flora Assessment **2015**

Internal reference: RTIO-HSE-0279582

Astron was engaged to undertake a Level 2 flora and vegetation assessment for the Middle Robe and East Deepdale Iron Ore Mine and Infrastructure Project the results of the assessment are presented in this report.

Vegetation condition ranged from ‘very poor’ to ‘excellent’. Fourteen of the 23 mesas within the survey area have been at least partially mined previously. Areas with clay soils typical of the Robe River floodplains were generally degraded from cattle grazing and weed proliferation, while vegetation associated with undisturbed mesas, hilltops and slopes was generally intact with very low weed abundance and little to no other signs of disturbance. Many of the permanent and semi-permanent pools and drainage channels of the Robe River area are relatively undisturbed. Six state-listed Priority flora were identified in the survey area. Twenty-five introduced flora species (weeds) were recorded in the survey area, none of which are listed as a declared pest for the Shire of Ashburton nor are they Weeds of National Significance. *Cenchrus ciliaris (Buffel Grass) and *C. setiger (Birdwood Grass) were the dominant weed species recorded, often characterising the understory of alluvial plains and drainage lines.

Desktop Flora, Vegetation and Fauna Habitat Assessment at Robe Valley **2016**

Internal reference: RTIO-HSE-0282048

Approval for clearing of native vegetation associated with the proposal is required via a Native Vegetation Clearing Permit (NVCP) under Section 51A of the Environmental Protection Act 1986 (EP Act). Vegetation, flora and fauna assessments at Robe Valley (the study area) were required to address the 10 Clearing Principles as part of the NVCP application process.

None of the three Threatened flora species known from the Pilbara region have been recorded from the study area. No conservation listed flora species have been previously recorded within the study area. One broad habitat type was described from the study area Plains. This broad habitat has been split into two categories; Stony Plain and Acacia on Stony Plain. Evidence of one conservation listed fauna species has been recorded in the study area, inactive mounds of the Western Pebble-mound Mouse.

Mesa H Level 2 Vegetation and Flora Assessment **2016**

Internal reference: RTIO-HSE-0300719

The objective of the assessment was to undertake a two-phase Level 2 assessment of vegetation and flora values through a desktop assessment and field survey. The resultant data will be utilised to produce a report to support and inform the environmental assessment process for the Mesa H project.

Astron Environmental Services has been commissioned to undertake a two-phase Level 2 vegetation and flora assessment in the Mesa H survey area which is approximately 4,930 hectares in size. There were 310 vascular flora species from 53 families and 150 genera recorded in the survey area. Three State-listed Priority flora were identified: Indigofera sp. Bungaroo Creek (S. van Leeuwen 4301) P3, Triodia sp. Robe River (M.E. Trudgen et al. MET 12367) P3 and Rhynchosia bungarensis P4.

Mesa H Riparian Vegetation – Baseline Monitoring **2016**

Internal reference: RTIO-HSE-0298821

Rio Tinto engaged Astron to establish and survey permanent transects downstream and upstream of proposed discharge locations within the Robe River and relevant tributaries, to record baseline riparian vegetation data. This data will provide a baseline with which ongoing monitoring data can be compared in subsequent years to identify any potential impacts to riparian vegetation from discharge.

In anticipation of potential impact to riparian vegetation due to increased stream flow, Rio Tinto has engaged Astron to establish a monitoring program to compile baseline data on the existing riparian vegetation and its condition. Data were also compiled for riparian vegetation upstream of the discharge point which acts as a reference area. There were 118 plant species from 36 families and 82 genera recorded from the 126 quadrats. No Threatened or Priority taxa were recorded within the transects, however one Priority flora species, Rhynchosia bungarensis P4, was recorded opportunistically within adjacent areas of the Robe River. Sixteen weed species were recorded within the transects.

Fauna

Middle Robe and East Deepdale - Mesa Façade Assessment **2015**

Internal reference: RTIO-HSE-0275944

Astron was engaged to undertake a mesa façade ecological value assessment for the Middle Robe East Deepdale Iron Ore Mine and Infrastructure Project. The purpose of the mesa facade assessment was to assist in determining which mesa facades should be retained if the Proposal proceeds.

The assessment concluded that 7% of the total length of the mesa facade within the survey were rated as high priority for retention. Mesa facades on four mesas were rated as high priority for retention; 37% of Mesa L, 10% of Mesa M, and 100% of Mesas 2400A and 2400C (both Mesas 2400A and 2400C are undisturbed by mining). Mesa that have impacted/disturbed facades were found to have low priority for retention and low ecological value based on the assessment parameters.
Mesa L and Mesa M are previously impacted mesas, however, they still retained breakaway habitat with ecological features important to fauna species of conservation significance. In addition the Priority 3 Ecological Community 'Triodia sp. Robe River assemblages of mesas of the West Pilbara' potentially occurs over the mesa and Triodia sp. Robe River (Priority 3) was present.
Mesa 2400A was rated as a high priority for retention due to the presence of a confirmed Pilbara Olive Python den and high suitability of habitat for the Northern Quoll. Mesa 2400C was rated as a high priority for retention due to multiple records of Northern Quolls indicating denning and shelter habitat. Both mesas were intact and provide important refuge and shelter opportunities for Matters of National Environmental Significance fauna species.

Middle Robe and East Deepdale Level 2 Fauna Assessment, August 2015 **2015**

Internal reference: RTIO-HSE-0280204

Astron was engaged to undertake a two-phase Level 2 vertebrate and short range endemic invertebrate fauna assessment for the Middle Robe and East Deepdale Iron Ore Mine and Infrastructure Project.

Six broad fauna habitat types were recorded in the survey area: Riverine, Drainage, Mesa, Breakaway, Stony Hills and Slopes, and Grassland Plains. Areas of disturbed habitat were also present within the survey area, particularly previously mined mesas. The Riverine and Breakaway habitats in the survey area are considered significant for fauna due to the microhabitats they provide such as caves and water pools. The Breakaway in particular contains a high diversity of microhabitats; it is an important site of refuge due to its location within isolated mesas and as habitat for conservation listed fauna. Nine conservation listed fauna species were recorded. The three targeted Matters of National Environmental Significance species, Pilbara Olive Python, Northern Quoll and Pilbara Leaf-nosed Bat were recorded frequently within the survey area. The two most prospective habitat types for short range endemic fauna, Breakaway and Stony Hills and Slopes, supported a moderately diverse short range endemic community of both specialist and relict short range endemic fauna species. The six potential short range endemic species were recorded.

Mesa J Mine Extension – Level 2 Fauna Assessment **2015**

Internal reference: RTIO-HSE-0279183

The objective of the assessment was to provide a single phase biological survey of vertebrate and SRE invertebrate fauna values through a desktop assessment and field survey. The resultant data will be utilised to produce a report to support and inform the environmental assessment process for the the Mesa J Mine Extension Proposal.

Rio Tinto engaged Astron to undertake a Level 2 vertebrate fauna and Short Range Endemic (SRE) invertebrate fauna assessment for a proposed extension to the Mesa J Mine. Three broad fauna habitat types were recorded in the survey area: Low Hills and Slopes, Loamy/Stony Plain and Drainage Line. Seventy-eight vertebrate fauna species comprising 20 reptiles, 48 birds and 10 mammals were recorded during the survey. Three conservation significant species were recorded during the survey.

Mesa H Level 2 Fauna Assessment **2016**

Internal reference: RTIO-HSE-0300720

The objective of the assessment was to undertake a two-phase Level 2 vertebrate fauna assessment and targeted SRE invertebrate fauna assessment, and to incorporate data from previous biological surveys to provide a report that meets Environmental Protection Authority (EPA) requirements.

Astron Environmental Services has been commissioned to undertake a two-phase Level 2 vertebrate and Short Range Endemic invertebrate fauna assessment in the Mesa H survey area.Seven broad fauna habitat types were recorded in the survey area: Riverine, Drainage Line, Gorge, Breakaway, Rocky Hills, Low Hills and Slopes, and Loamy/Stony Plain. There were 169 vertebrate fauna species recorded within the survey area. Seven conservation listed fauna species were recorded.

Mesa H – Riparian Community Assessment **2016**

Internal reference: RTIO-HSE-0298820

In anticipation of potential impact due to increased stream flow, Astron Environmental Services has been commissioned to undertake a Level 2 flora and vegetation assessment and Level 1 vertebrate fauna and aquatic fauna assessment in the Riparian Community survey area which is 2,105 hectares in size.

In anticipation of potential impact due to increased stream flow, Astron Environmental Services has been commissioned to undertake a Level 2 flora and vegetation assessment and Level 1 vertebrate fauna and aquatic fauna assessment in the Riparian Community survey area which is 2,105 hectares in size. There were 124 plant species from 37 families and 82 genera recorded from sampling sites and opportunistically throughout the survey area. No Threatened taxa were recorded, however three Priority flora species were recorded within the Robe River and its tributaries.

Biodiversity improvement studies

Evaluation of mine waste materials as alternative rehabilitation growth medium **2010**

Internal reference: RTIO-HSE-0109961

This study reviewed the physical and chemical properties of soil, tailing and mineral waste from select Pilbara mining operations, to identify waste material and material combinations for use as a topsoil substitute or supplement.

The study showed plant-available nutrients held within the waste materials, although variable, was characteristically low and comparable to natural soils in the region. The majority of the waste materials had macro and micro nutrient concentrations within the range or above the levels measured in benchmark Pilbara topsoil and rehabilitated soils. The pH and phosphorus buffering index of most waste materials were also comparable to that of the benchmark topsoil materials. However, some of the waste types and tailings may need to be mixed with rocky material due to poor physical / erodibility characteristics.

Genetic diversity in Eucalyptus leucophloia across the Pilbara: Provenance zone implications **2011**

Internal reference: RTIO-HSE-0108843

This study was undertaken to define the provenance seed collection zones for a common species of the Pilbara, Eucalyptus leucophloia (Snappy Gum). This report details information on genetic analysis conducted on E. leucophloia. Collections of E. leucophloia were made from 20 populations across the Pilbara bioregion and genetic analysis was conducted using microsatellite markers.

Genetic diversity in E. leucophloia was high and was typical of that found in other eucalypt species with wide spread distributions. Across the species the level of population differentiation was low and the majority of the diversity was maintained within populations with only 6% of variation partitioned between populations. Genetic variation in E. leucophloia showed little structure across the Pilbara with no clustering of populations based on any geographical proximity or in association with obvious topographical, physiogeographical or geological features such as the Hamersley or Chichester Ranges. Populations towards the edges of the species distribution within the Pilbara showed greater levels of differentiation from populations within the species main range. The high levels of genetic diversity and low levels of differentiation within E. leucophloia implies that seed resources for rehabilitation can be selected from a wide range within the Pilbara.

Genetic diversity in Acacia ancistrocarpa across the Pilbara: Provenance zone implications **2011**

Internal reference: RTIO-HSE-0119260

This study was undertaken to define the provenance seed collection zones for Acacia ancistrocarpa (Fitzroy Wattle). This report details information on genetic analysis conducted on Acacia ancistrocarpa. Collections were made from 24 populations across the Pilbara bioregion and genetic analysis was conducted on 16 populations using microsatellite markers.

Genetic diversity in A. ancistrocarpa was high but lower than that in E. leucophloia, another widespread species in the Pilbara. Across the species Pilbara range the level of population differentiation was low and the majority of the diversity was maintained within populations with only 3% of variation partitioned between populations. Genetic variation in A. ancistrocarpa showed little structure across the Pilbara with no clustering of populations based on geographical proximity or in association with obvious topographical, physiogeographical or geological features. Populations towards the edges of the species distribution within the Pilbara showed greater levels of differentiation from populations within the species main range. The high levels of genetic diversity and low levels of differentiation within A. ancistrocarpa implies that seed resources for land rehabilitation and mine-site revegetation programs can be selected from a wide range within the Pilbara

Root hydraulic conductance and aquaporin abundance respond rapidly to partial root-zone drying events in a riparian Melaleuca species **2011**

Internal reference: RTIO-HSE-0252171

This study examined partial root zone drying (PRD) responses of Melaleuca argentea.

The results demonstrate that PRD can induce rapid changes in root hydraulic conductance and aquaporin expression in roots, which may play a role in short-term water uptake adjustments, particularly in species adapted to heterogeneous water availability.

Baseline Terrestrial Fauna Assessment of Pilbara Rehabilitation Areas **2012**

Internal reference: RTIO-HSE-0134168

In 2011 a fauna survey was conducted within established rehabilitation areas at Brockman 2 and Tom Price mine sites, with the aim of identifying whether fauna is recolonising rehabilitation sites in assemblages comparable to reference sites.

The study found that at least 85 species of native vertebrate fauna, as well as representatives from each of six major groups of invertebrate fauna, are using rehabilitation areas at Brockman 2 and Tom Price, with species compositions that were broadly similar to reference sites. Ant collections were typical of the Pilbara bioregion, with an absence of invasive ant species. The study found greater data correlation between monitoring sites at a particular mine site (Tom Price or Brockman 2) than between rehabilitation and reference sites, indicating the importance of selecting local reference sites. The study concluded that the best candidates for bio-indicators are ants and reptiles.

Hay Project – Native Seed Orchard **2012**

Internal reference: RTIO-HSE-0141263

Commencing in 2011 (and still ongoing), a trial irrigated seed orchard was established at the Hamersley Agriculture Project (Marandoo). The purpose of the trial was to identify an alternate method of addressing seed deficits. If successful, the project may be implemented at other Rio Tinto operations, such as the Nammuldi agriculture project.

Genetic diversity in Aluta quadrata:Implication for management and provenance zone **2012**

Internal reference: RTIO-HSE-0156732

This study was undertaken to define the provenance seed collection zones for Aluta quadrata. This report details information on genetic analysis conducted on Aluta quadrata. Collections were made from 8 populations across the Pilbara bioregion and genetic analysis was conducted using microsatellite markers.

Genetic diversity in A. quadrata was moderate and lower than in the other two more widespread Pilbara species, E. leucophloia and A. ancistrocarpa. The findings suggest that its populations may have fluctuated significantly in size over time with genetic drift and possibly inbreeding resulting in a reduction in genetic variability, particularly in rare alleles. Despite the narrow geographic range, the level of population differentiation in A.quadrata was relatively high with 25% of the genetic variation maintained between populations and 19% due to differences between the three different locations. This significant genetic structure indicates that A. quadrata consists of three conservation or management units, Western Ranges, Pirraburdoo and Howie's Hole.

Genetic diversity in Acacia atkinsiana across the Pilbara: Provenance zone implications **2012**

Internal reference: RTIO-HSE-0187256

This study was undertaken to define the provenance seed collection zones for Acacia atkinsiana (Atkins wattle). This report details information on genetic analysis conducted on Aluta quadrata. Collections were made from 16 populations across the Pilbara bioregion and genetic analysis was conducted using microsatellite markers.

Genetic diversity in A. atkinsiana was low and lower than that observed in its congener Acacia ancistrocarpa, a widespread species across northern Australia. The level of population differentiation was high and 30% of the diversity was partitioned between populations across the range of A. atkinsiana. Genetic variation in A. atkinsiana showed some structure across the Pilbara with clustering of populations in the western part of the distribution and from the Hamersley Range, along with other populations that were divergent from these groups. The low levels of genetic diversity and high levels of differentiation within A. atkinsiana implies that seed for land rehabilitation and mine-site revegetation programs should be restricted to specific zones. For rehabilitation of sites within the Hamersley Range we recommend seed collections be restricted to that region. Similarly, for rehabilitation in the part of the distribution west of Pannawonica, seed collections should be restricted to that area.

Rehabilitation Quality Metric (RQM) Project **2012**

Internal reference: RTIO-HSE-0164020

Western Australia has no formal process to measure habitat quality and as such RTIO has needed to design its own customised metrics. Vegetation condition scoring has previously been developed by RTIO through a Biodiversity Net Positive Impact Assessment, but a more precise metric was needed. The Rehabilitation Quality Metric (RQM) project was developed to provide a repeatable method to assess rehabilitation quality against pre-determined reference sites, on a site by site basis, to predict rehabilitation ecosystem quality at the time of relinquishment.

The RQM methodology employs seventeen parameters to characterise the landscape, including vegetation, fauna habitat, fauna presence, erosion, and ecosystem function. Parameters are tailored to be an applicable measure for both rehabilitation and native vegetation (reference sites). Parameters are scored, based on measured or observed characteristics, with a value between 0 and 1, with 1 being functional (terrestrial ecosystem is functioning for the maintenance of biodiversity values at a local or property scale) and 0 being dysfunctional (terrestrial ecosystem is failing; indicators of ecosystem function have scored below acceptable levels). Both rehabilitation areas and reference sites are scored. Scores are subsequently determined for the entire mine lease, based on the condition of the land before mining (extrapolated from the reference sites, area weighted) and the likely post-mining conditions (extrapolated from the rehabilitation areas and expected closure domain distribution, area weighted, ie pits with no rehabilitation score 0). The difference between the pre-mining and post-mining scores represents the residual impact of mining.

Propagation of Pilbara spinifex (Triodia sp.) **2012**

Internal reference: RTIO-HSE-0169744

Triodia has often been observed to have very poor establishment from broadcast seed. This project investigated alternatives to growing Triodia (spinifex) from seed, focussing on ways to propagate seedlings from wild harvested material.

The project found the most successful propagating material was stolons. Greatest propagation success was achieved when Triodia were collected when semi to fully dormant (mid Winter-Spring). The 'Moist Root Induction Method' recommended by previous researchers was less successful than the standard propagation techniques employed in this project. Success varied notably between populations. Consequently, any future collections of propagating material should target multiple populations to maximise potential for success.

Pilbara Seed Science Project, Part 2 Final Report Jan 2012 **2013**

Internal reference: RTIO-HSE-0174944

Undertaken between 2009-2012, this seed research investigated germination, biology, dormancy classification and treatments for dormancy alleviation for a range of species from the Pilbara.

The *Acacia atkinsiana, Indigofera monophylla and Sida echinocarpa* seed lots have physical dormancy. Heat treatments and mechanical scarification improved germination on dormant seeds, however, heat treatments killed non-dormant seeds. The treatments used for *Goodenia stobbsiana* seeds failed to overcome dormancy, suggesting deep physiological dormancy. The *Hakea lorea/ chordophylla* seed lots were found to be non-dormant, with very high germination results in the controls. As such, they will not require any pre-treatments prior to direct seeding. The florets surrounding the *Triodia pungens* and *T. wiseana* seeds were found to restrict germination, however, many of the freshly extracted seeds out of the florets were found to be physiologically dormant. Treatments for dormancy include mechanical scarifier to rupture seed coat, hot water (noting potential damage to immature or non-dormant seeds) and increases to germination through wet / dry cycling and / or temperature cycling.

Morphological variation in the western rainbowfish (Melanotaenia australis) among habitats of the Pilbara region of northwest Australia. **2013**

Internal reference: RTIO-HSE-0252169

The aim of this honours thesis was to determine and quantify the extent of morphological variation present in M. australis and relate this to environmental variables, which will provide the first step to understanding how the species copes with environmental change.

This results of this thesis found that there was limited evidence that fish morphology correlated with environmental variables

Patterns of water use by the riparian tree Melaleuca argentea in semi-arid northwest Australia **2013**

Internal reference: RTIO-HSE-0249538

This thesis examines the water use physiology of the riparian tree Melaleuca argentea, and the ways in which this species may respond to anthropogenic disturbances to hydrologic processes.

M. argentea displays highly plastic root-level responses to heterogeneous water availability and to waterlogging, facilitating high rates of water use and growth in the riparian wetland habitats of the Pilbara. Mature M.argentea trees appear to tolerate groundwater drawdown of at least several metres, most likely by employing the same plastic root strategies to access deeper water. M.argentea can also withstand short periods of severe drought, by adopting a 'waiting' strategy of ceasing growth and shedding leaves to avoid moisture loss, a state from which they can then recover. M. argentea populations are unlikely to thrive under large and prolonged reductions in water availability.

Priority Species Seed Quality and Germination Final Report **2013**

Internal reference: RTIO-HSE-0207487

This study investigated the quality and germination biology of a range of priority and keystone (Triodia) plant species from the Pilbara.

Eremophila magnifica subsp. Magnifica has physical & physiological dormancy. Propagation methods other than seed may be more successful. Geijera salicifolia and Olearia mucronata has physiological dormancy. Temperature cycling may be required to stimulate germination. Indigofera ixiocarpa and Indigofera sp. Bungaroo Creek has physical dormancy or is non-dormant. Mechanical scarification may be required. Ptilotus subspinescens is non-dormant and will germinate easily without removal from the perianth sheath. However, seed is likely to lose viability with a few years. Sida echinocarpa and Sida sp. Barlee Range has physical dormancy. Seeds should be removed from the mericarp and then scarified in order to germinate. Triodia pungens has T. wiseana non-deeep or deep physiological dormancy. Germination of de-husked seeds can be improved by applying gibberellic acid or 1% smoke water and wet/dry cycling.

Early physiological flood-tolerance and extensive morphological changes are followed by slow post-flooding root recovery in the dryland tree Eucalyptus camaldulensis subsp. Refulgens **2014**

Internal reference: RTIO-HSE-0252170

This study investigated physiological and morphological response to flooding and recovery in Eucalyptus camaldulensis subsp. Refulgens, a riparian tree species from a dryland region prone to intense episodic flood events.

E. camaldulensis subsp. Refulgens underwent considerable morphological changes during flooding, including extensive adventitious root production, increased root porosity and stem hypertrophy. Physiologically, net photosynthesis and stomatal conductance were maintained for at least 2 weeks of flooding before declining gradually. Despite moderate flood-tolerance during flooding and presumably high environmental selection pressure, recovery of reduced root mass after flooding was poor.

Priority Species Project Progress Report 2013 **2014**

Internal reference: RTIO-HSE-0207486

The Priority Species Project, initiated in 2012, aims to improve knowledge of priority plant species and develop methods to successfully germinate and establish priority species, to enable priority plant species to be integrated into Rio Tinto rehabilitation programmes. This work is being undertaken in conjunction with the Department of Parks and Wildlife.

13 plant species were selected as being potentially suitable for establishment in rehabilitation: Eremophila magnifica subsp. magnifica, Indigofera sp. Bungaroo Creek, Indigofera sp. gilesii, Acacia bromilowiana, Sida sp. Barlee Range, Ptilotus subspinescens, Ptilotus mollis, Acacia subtiliformis, Isotropis parviflora, Grevillea sp. Turee, Hibiscus sp. Canga, Themeda sp. Hamersley Station, and Aluta quadrata. Indigofera sp. Bungaroo Creek and Ptilotus subspinescens were found to readily germinate in laboratory conditions, and a field trial was established at Brockman 4 late in 2013.

Regional Variation in Metal Concentrations of Pilbara Fish in Relation to Concentrations in Water and Sediments **2014**

Internal reference: RTIO-HSE-0216967

This study aimed to characterise and document natural, background metal concentrations in freshwater fishes from different locations across the Pilbara in order to understand how local geology may affect baseline metal levels in fish tissues and surface waters. Metal concentrations were analysed from water, sediment and muscle and liver tissues from fish collected from up to 13 sites as yet unimpacted by mining across the Pilbara during October (dry season) of 2012.

Levels of dissolved metals from water samples were generally low. However, some elevated concentrations of Boron, Copper and Zinc were recorded. Concentrations of heavy metals in sediments were variable across the Pilbara. Generally, sediment concentrations were well below the Interim Sediment Quality Guidelines (ISQG). However, metal concentrations in excess of ISQG TVs were recorded for Chromium and Copper at some sites. There was no relationship between metal concentrations in sediment and those in water. Metal concentrations in fish tissue (muscle and liver) varied between species with some significantly higher in some particular species. The study concluded that variation in metal concentrations in water, sediment and fish across pools in the Pilbara was likely to be mainly dictated by the local geological setting in which the pool occurs.

Progress Report 2014, Ecological responses of native fishes to dynamic water flows in northwest arid Australia **2014**

Internal reference: RTIO-HSE-0246021

This three year Australian Research Council linkage Project commenced in 2013 and aims to increase understanding of the effects of altered stream flows on the Pilbara freshwater aquatic environment. Project aims: 1. Quantifying fish biodiversity and population structure in relation to hydrological and environmental parameters to identify thresholds of ecological concern for water management; 2. Determine the fundamental physiological, morphological and behavioural adaptations of fishes to variations in water quality using experimental manipulations; and 3. Examine spatial scales of gene flow to determine if increased flows increase genetic connectivity relative to natural-flow sites.

To date work has focuses on characterisation of baseline physicochemical parameters across aquatic habitats within the Fortescue River catchment (Aim 1), analysis of variation in rainbow fish morphometrics and mechanosensory lateral line systems in response to geographic region and water management regime (Aim 2), and extraction of DNA samples from 17 populations across the Fortescue River catchment (Aim 3). The project will culminate in the development of a predictive model for stream restoration relevant to future closure scenarios for above and below-groundwater mines. Results from an honours thesis indicate that rainbow fish body shape varies according to geographic region but fish from a dewatered site (WW Ck) were more streamlined than other populations from the upper Fortescue catchment. This statement of results has been superseded by the results of the actual thesis report RTIO-HSE-0252169.

Progressive rehabilitation

Ecosystem Function Analysis of Robe Valley rehabilitated areas **2014**

Internal reference: RTIO-HSE-0280240

Five rehabilitation areas were monitored in 2013 - S Dump and T dump at Mesa J, and the Pit Floor, West Waste Dump and Haul Road at Mesa K. Six reference transects were monitored for comparison to the rehabilitation. Mesa J Hub uses the EFA monitoring technique.

S and T dump have established well, with increasing cover and density since rehabilitation. T Dump has stopped increasing in 2010, indicating full establishment. T Dump has lower density than S Dump, potentially due to the topsoil differences. All areas at Mesa K are well established, reflecting the maturity of the rehabilitation.

Mesa J Tailings Storage Facility 1 (TSF1) Rehabilitation Record **2014**

Internal reference: RTIO-HSE-0246219

This report summarises the rehabilitation of 45Ha of TSF1 at the Mesa J Operations, completed in 2014 by the RTIO Rehabilitation team, with the assistance of a rehabilitation contractor and the Mesa J/K Operations team.

The project totalling 45 hectares (Ha) involved the removal and stockpiling of 15kt (6,000m3) of high grade ore, the removal and stockpiling of 160kt (64,000m3) of course material to be used as stemming and the import of 85kt (38,500m3) of capping material, prior to shaping, ripping and seeding of the entire rehabilitated surface.

2014 Robe Valley EFA Monitoring **2014**

Internal reference: RTIO-HSE-0266718

Three rehabilitation areas were monitored in 2014 - Pit 10 and TSF1 at Mesa J, and the Gravel Pit at Mesa K. Five reference transects were monitored for comparison to the rehabilitation. Mesa J Hub uses the EFA monitoring technique.

The vegetation communities on all rehabilitation sites were in the initial stages of ecosystem development. Cover and density was lower than reference sites, as would be expected from newer rehabilitation.

2015 Robe Valley EFA Monitoring **2015**

Internal reference: RTIO-HSE-0273809

Six rehabilitation areas were monitored in 2015 - S Dump, T dump, Pit 10, TSF1 and the Rail Upgrade construction areas at Mesa J, and the Gravel Pit at Mesa K. Five reference transects were monitored for comparison to the rehabilitation. Mesa J Hub uses the EFA monitoring technique.

S and T dump have established well, with increasing cover and density since rehabilitation until 2010 and 2015, when T Dump and S dump stopped increasing respectively, indicating full establishment. T Dump has lower density than S Dump, potentially due to the topsoil differences. Pit 10 North has good vegetation establishment with a range of native vegetation species. Pit 10 South has limited native perennial vegetation establishment, due to both the young age of the rehabilitation and the lack of topsoil. Vegetation establishment has been variable across TSF1, with the better establishement occurring on coarser tailings or rocky edges. Vegetation establishment along in the construction areas is beginning to occur, however vegetation parameters are low, reflecting the young age of the rehabilitation. Better establishment is shown where the surrounding area is not disturbed or used regularly. Vegetation atthe Gravel Pit is establishing well, with vegetation parameters comparable to the reference sites.

Landform design

Results of flume investigations of the stability of rock mulches **1998**

Internal reference: RTIO-HSE-0109221

This study assessed the potential for rock mulches to be stripped from the soil surface by overland flows.

Although 150-300mm diameter BIF was not removed by simulated overland flows, even for 100mm/hr simulated runoff on 55% gradients, considerable scour of the spoil between the rocks was observed, indicating potential for long-term development of rills or gullies if the level of rock cover was less than 100%. Large reductions in sediment concentrations were observed when finer rocks were mixed with BIF. The data indicate that it is crucial for any rock mulch to cover a wide range of particle diameters, including a component of finer rocks. The resulting mixed rock created a framework of large rocks that resist movement by flows, while the smaller rocks reduce erosion being anchored within the larger (framework) rock. For rock mulches with a mixture of rock diameters, 80% cover produced acceptable erosion rates. Sediment loads were slightly higher for 40% cover by rock of mixed diameters, and it was speculated that this may also achieve acceptable erosion rates with the addition of vegetation.

Final Landform Design Criteria for Use During Mine Planning **2012**

Internal reference: RTIO-PDE-0159989

Rio Tinto Iron Ore WA have historically designed closure landforms for waste materials with berms ~10 m, lifts ~20 m and ad hoc alterations to batter gradients where erosion rates have been perceived to be unacceptably high. This report integrates recent advances in characterisation and modelling of materials, climate and erosion processes to provide appropriate final landform batter characteristics for key Pilbara mineral wastes and soils.

Material properties of mineral wastes were assessed and classified for the range of mineral wastes found across Rio Tinto Pilbara sites. Climate sequences were used to model and test potential erosion rates for a range of batter configurations (shapes (linear, concave), heights, gradients, berm capacity) and validated against existing slopes for which material and climate data were available. This information was used to develop a searchable waste dump batter database for all major mineral wastes and soils, intended for use during mine planning design.

Mesa J TSF Concept Closure Study **2016**

Internal reference: RTIO-HSE-0300384

The purpose of this report was to develop a concept design for the future closure of the TSF's at Mesa J based upon the Robe Valley 2014 Life of Mine plan. The report considers which pits will be used for waste backfill and which for future Tailings dams. Designs for future facilities are conceptual and will be updated over time.

The report considers which pits will be used for waste backfill and which for future Tailings dams. Designs for future facilities are conceptual and will be updated over time. The information is incorporated into the Life of Mine plan and utilised by the closure plan. Generic requiremenrts for 2m of capping has been used.

Contamination

Pannawonica Preliminary Site Investigation & Sampling & Analysis Plan **2007**

Internal reference: RTIO-HSE-0057556

This preliminary site investigation was undertaken to determine areas of potential contamination associated with current and historical activities at the site.

Analysis of the site concluded that the highest ranked activities in terms of risk are: fuel storage/handling at Pannawonica Service Station, fire training activities, storage and handling of fuels and oils at the Mine Services Building and the Eastern Deepdale fuel storage/transfer area. Many sites have not undergone environmental investigation for their potential negative impacts. In all cases visual and/or anecdotal evidence suggest that potential adverse impacts exist to soil, groundwater or surface water, be it fuel spills, leaking tanks, ongoing run-off/infiltration or burning, had historically occurred at these locations. For each issue of concern, a soil and groundwater sampling and analysis plan has been developed.

Phase 2 Environmental Site Assessment Pannawonica Service Station **2007**

Internal reference: RTIO-HSE-0042275

The objective of this investigation was to identify the location of the underground storage tanks and associated fuel lines and assess whether the reported loss of integrity in the underground storage tanks system has resulted in any sub-surface impacts to soil or groundwater.

The results of the Environmental Site Assessment indicate that no impacts to the environment have resulted from the observed loss of integrity in the fuel storage system. Of the twelve (12) soil samples submitted, no samples reported detectable concentrations of total petroleum hydrocarbons, benzene, toluene, ethylbenzene or xylenes or polycyclic aromatic hydrocarbons above the laboratory limits of detection. Detectable concentrations of lead were reported in all samples however none exceeded guideline values. No visual or olfactory evidence of hydrocarbon contamination was noted in the samples.

Impact of Nitrogen from Explosives on Mine Site Water Quality **2008**

Internal reference: RTIO-PDE-0054638

The likely issues associated with the use of nitrogen based explosives on mineral waste and any leachate water are explored in this report. The amounts of explosives used on site are described, along with nitrogen chemistry and toxicity. Nitrogen concentrations for various mine sites and specific lithologies are presented which includes concentration in rock assays and liquid extracts.

It was concluded that the largest risk of nitrogen contamination is likely to arise from the discharge of surface waters that have been in contact with blasted materials and are discharged off site into creeks or waterways. This becomes a more significant issue if the water is also acidic. Algae (ie cyanobacteria) plumes have been identified in acidic water at Tom Price

Control Measures for Potentially Acid Forming Pit Wall Rocks **2010**

Internal reference: RTIO-PDE-0079541

Desktop study of potential strategies to manage exposed sulfidic materials and find viable options for management was conducted with a focus on the Hope Downs 1 and Tom Price sites.

Chemical treatments have the potential to be effective only in the short-term and only for minor water quality issues. Grouting of the pit walls is expected to have limited applicability, although grout curtains behind the wall may have success (untested). Cover technologies have the greatest potential to be effective over the long term, but would need to be resistant to puncture by underlying rocks, resistant to weathering and UV damage ie shotcrete, geomembranes. For long term performance the exposed surface need to be as stable and free of loose material as possible. Treatment effectiveness will also depend on the site conditions, eg chemical less effective at Tom Price.

Workshop Summary and Desktop Review: Dewatering and Sulfate Accumulation **2012**

Internal reference: RTIO-PDE-0101903

This is a summary of a workshop held to determine the risks of dewatering sulphides within the pit wall. The outcomes from this workshop will be used to develop models to estimate the mass of sulfate produced as a consequence of dewatering activities.

There are many processes that contribute to poor pit water quality. Most of these processes are known and accounted for in existing models. However, the science of fluid flow in fractured rock is not well developed and this lack of knowledge restricts the outcomes of studies on pit water quality. There is a general lack of empirical data for estimating parameters used in models, creating a large degree of uncertainty in predictive models. Sensitivity analysis can be used to overcome some of these challenges.

Updated Preliminary Site Investigation and Sampling Analysis Plan for Mesa J Final **2012**

Internal reference: RTIO-HSE-0148155

The objectives of the project were to update existing information relating to known or suspected contamination at Mesa J and surround areas and to subsequently develop a Sampling Analysis Plan in order to present an approach for future intrusive investigations designed to further characterise identified areas of interest.

The review of the Preliminary Site Investigation found that, in general, the existing findings are accurate and have been carried out and presented consistent with the Department of Conservation's Contaminated Sites Management Series. Results of the Sampling Analysis Plan conclude that potential areas of interest are: 1) Pannawonica Town - Substation, sewage treatment plant, service station, former minor and main landfill, Pannawonica MSB; 2) Middle Robe - Former power station, load out and laydown/park up areas, decommissioned 2E workshops, decommissioned vehicle refuelling areas, former ammonium nitrate shed, former Yaleen homestead, 2E former landfill; 3) Eastern Deepdale - Former workshops and refuelling areas, former sewage treatment plant, former landfill; 4) Mesa J - Workshop area, Mesa J tank farm, bulk lube storage area, light vehicle refuelling area; and 5) Mesa K - Groundwater.

Development of a conceptual model: Sulfate accumulation as a consequence of pit dewatering activities, memo **2012**

Internal reference: RTIO-PDE-0101903

Mine dewatering and the consequent lowering of the water table may result in desaturation of sulfide bearing lithologies. The objective of this work was to develop a conceptual model of the associated processes: where sulphide bearing rock intersects the pit walls, and where the sulphide bearing rock is located behind the pit walls but not directly exposed on the pit wall face.

The conceptual model developed estimates the mass of sulfate produced as a consequence of dewatering activities, considering processes during operations and after operations cease, and using sensitivity analysis where parameter inputs are uncertain. The model output provides the basis for an assessment of potential impacts on water quality for general risk assessment applications. Further work was identified to improve parameterisation of the model, including the collection of additional empirical data for pit wall fracturing, saturation of pit wall fractures and sulfide oxidation rates in talus and on pit walls.

Ethnographic or archaeological values

Water and Indigenous People in the Pilbara: A Preliminary Study, CSIRO: Water for a Healthy Country **2011**

Internal reference: RTIO-HSE-0218222

Water resources are vital to Indigenous identities, beliefs, environmental philosophies and livelihoods. This report provides a broad-scale scoping study of Indigenous relationships to water in the Pilbara and considers the potential impacts of Indigenous water values.

Indigenous belief systems perceive water as an elemental part of the broader cultural landscape, held and managed under customary systems of law. Water sources were derived during the Dreaming and are the most important features in the Pilbara cultural landscape. Interviews raised issues of long term drying, obstruction of water flow, over-extraction, inappropriate discharge from de-watering and access restrictions.

Ethnobotanical Survey for the RV region **2011**

Internal reference: RTIO-HSE-0122187

This survey outlines provenance species which Traditional Owners identified as important to include in rehabilitation work for the Robe Valley.

22 species were considered to have ethnobotanical significance, including species of Acacia, Aristida, Cleome, Corymbia, Cymbopogon, Enchylaena, Eucalyptus, Petalostylis, Ptilotus, Rhynchosia, Senna, Solanum, Trichodesma, Triodia and Typha. Traditional owner use these plant species for specific purposes, such as bush tucker, ornamental, medical or as a tool.

Appendix D – Closure risk assessment

Ref.				Risk Description					Risk Management C	
Risk Type (T=Th	Category	Subcategory	Item	Evaluated 20 of 20 risks (0 Remaining) Threat Title	Potential causes (Triggers / Indicators)	Impacts (Consequences)	Existing Controls and Commitments	Evaluation Rationale (Maximum reasonable consequence)		Detailed Action Descriptions
T	**A**			**Planning and knowledge**						
T	**A**	**01**		**Contaminated sites**						
T	A	01	1	Contaminated sites (Non AMD) lead to an ongoing environmental or financial impact	• Use of chemicals and hydrocarbons during operations • Housekeeping practice and maintenance of work areas and equipment	CAPEX / OPEX Environment	• Regular maintenance / inspection / audit of work place procedures • Spill management kits readily available • Contaminated sites register maintained across life of operation	Contamination is missed during closure phase and identified post-closure. Teams are required to mobilise to clean up the contamination.	II	
T	A	01	02	Under-estimated acid and / or metalliferous drainage management requirements during operations (pre-closure) & decommissioning phase	• Potential for acid / alkaline / metalliferous / neutral / saline drainage generation during operation of mine • Water management, storage and monitoring practices • Water quality prior to return to environment e.g. via infiltration or discharge Elevated salts observed around the tailings facilities	CAPEX Environment OPEX	• Geochemical characterisation of mineral waste material routinely undertaken during drill programs. • Mine does not intend to excavate any PAF materials • Discharge water quality monitored. Includes sampling and trigger / response requirements • Wet season management plans used to control run off. • Groundwater operating management plan to monitor groundwater quality	Highly saline water generated as part of waste fines management results in neutral mine drainage i/ groundwater salination ssues during operations and continues throughout closure (including impacts to permanent Robe River pools).	II	
T	A	01	03	Acid and / or metalliferous drainage generation (after closure) creates a contaminated site	• Interaction of water and mineral waste or tailings could generate acid / alkaline levels that leach metals / salts from the mineral waste or local environment • Presence of temporary or permanent open water bodies, enabling evapoconcentration to occur with creation of alkaline / hypersaline water quality • Ability of metals / salts to move through environment to impact a sensitive receptor, to meet definitions in Contaminated Sites Act 2003	CAPEX Environment OPEX	• Mine does not intend to excavate any PAF materials	Pit wall erodes and collapses post-mining revealing PAF materials that impact water quality (including impacts to permanent Robe River pools).	II	
T	A	01	04	Human health impacts from in situ fibrous material exposures	• Hazardous fibres exposed in situ by mining, mined and moved to encapsulated areas or naturally present in soils disturbed by mining / rehabilitation activities • Erosion of materials containing hazardous fibres post-closure	Health	• Physical materials characterisation for fibres routinely undertaken as part of drilling campaign (part of Fibrous materials management program) • Physical materials characterisation complete, no fibres present in mineral waste or mineralised materials.	Pit wall erodes and collapses post-mining revealing fibrous materials.	II	
T	**A**	**02**		**Void management**						
T	A	02	01	Pit lakes or Tailings have undesirable impacts on local ecosystem function	• Open water bodies in Pilbara naturally attract fauna (feral and native species) for food/ water/ refuge, safe access to water required • Concentration of natural groundwater or mineral waste derived salts through evapoconcentration in open water bodies • Release of metals from natural geology or mineral waste into water (infiltration or groundwater flow) • Water provides opportunity for plant /weed growth, good and bad (toxic algal blooms, noxious weeds) • Certain plant / animal species bio-accumulate / magnify toxic metals • Instability associated with saturated, unconsolidated ground, can be increased by high trafficability	Safety Environment Community Reputation Compliance CAPEX OPEX	• Void closure management guidance • Geochemical waste characterisation, good understanding of water chemistry / reaction chemistry • Physical waste characterisation • Rehabilitation handbook • Landform design guidance • Aquatic fauna research underway to understand natural levels of toxic metal accumulation / impact on native species	Cattle regularly access pit lakes for water. The lake fringe suffers severe erosion, becoming boggy, such that cattle regularly become stuck in pit area, die and contaminate water source.	II	RV03: Confirm the assumption that pit lakes will not be formed above WFSF at closure by conducting a water balance analysis for Mesa J waste fines storage facilities. RV04: Undertake a review of predicted water quality for the Mesa J reservoir to assess viability of leaving this areas as pit lakes. RV64: Develop detailed closure designs for existing WFSF's at Mesa J
T	A	02	03	Pit lakes or tailings have undesirable impacts on downstream ecosystem function	• Concentration of natural groundwater or mineral waste derived salts through evapoconcentration in open water bodies • Groundwater flow through pit lake / Tailings or mineral waste with connection to regional aquifer • Density driven saline groundwater flow from groundwater sink-style pit lakes • Downstream groundwater users (people, plants or animals) Alternate ecosystem may develop at discharge points leading to stakeholder concern when discharge ceases, However changes may not have been explained at commencement of project	Health Environment Community Reputation Compliance	• Any proposed pit lakes would be assessed in accordance with Void closure management guidance • Environmental surveys include regional groundwater dependent ecosystem • Geochemical waste characterisation, no PAF excavation planned	Higher saline groundwater from the former mining areas seeps into the Robe River pools, impacts local pool water quality / flora / fauna	III	RV10:Review environmental reports on potential impacts of mining activities on Robe River permanent pools and compare waters level and water quality. Determine key environmental receptors and potential ecological impacts. Determine if effects / impacts are masked by other impacts, such as discharge to Jimmawurrada Creek. RV15: Document and distribute conceptual understanding of pool supplement water supply post closure to mitigate drawdown impacts on Robe River pools.

Ref.				Risk Description					Risk Management C	
Risk Type (T=Th	Category	Subcategory	Item	Evaluated 20 of 20 risks (0 Remaining) Threat Title	Potential causes (Triggers / Indicators)	Impacts (Consequences)	Existing Controls and Commitments	Evaluation Rationale (Maximum reasonable consequence)		Detailed Action Descriptions
T	A	02	06	Pit wall stability compromises closure outcomes	• Influence of erosion, subsidence, seismicity, wall slip • Influence of groundwater recovery and surface water flow on stability. • Creek system neighbouring or within zone of instability, potential stream capture • Ecosystem downstream of void dependent on surface water flows • Poor communication of zone of instability to facilitate identification of important features • Clay zones not previously identified in the footwall compromise pit wall stability	Safety Environment Community Reputation Compliance CAPEX OPEX	• Geotechnical assessments for wall stability and zone of collapse part of mine design reviews • Mesa A façade / MEZ preservation required.	An area of the pit wall facade collapses, and some troglofauna habitat, heritage sites and caves are lost.	II	RV67: Incorporate any Troglofauna pit boundary changes into closure plan at Mesa K.
T	**A**	**03**		**Heritage**						
T	A	03	01	Heritage site condition / cultural value is degraded as a result of implementing the closure plan	• New (previously unidentified) heritage sites, not considered in existing assessment, discussions, agreements or with authority to disturb • Changes to landforms on closure have potential to alter conditions at downstream sites, e.g. consider drainage, landform footprint, erosion implications • Cessation of maintenance of / to heritage site Cultural values not considered in rehabilitation strategies Presence of heritage sites in close proximity to mining areas Downstream area of significant value to traditional owners	Community Reputation Compliance	• Internal ground disturbance approval request system • GIS system includes results from heritage surveys • Heritage sites within mine area, S18 application etc. prior to disturbance • Ongoing consultation with Traditional Owners • Geotechnical assessments • Exclusion area for homestead outstation Heritage management plan Environmental groundwater and pools monitoring regime in place during operations	Failure to stabilise the Homestead outstation landform leads to significant erosion of the remaining in situ topography and eventual loss of the site.	III	
T	A	3		**Closure Landforms**						
T	A	3	01	Built landforms (excluding mine void areas) erode and / or collapse	• Physical material properties considered in design • Drainage and erosion management • Construction of landforms / waste dumps to design requirements • Sensitive receptors identified downstreamadily modelled Design does not consider PMP/PMF events Wbo surface water model not completed	Environment OPEX	• RTIO Rehabilitation handbook used for general rehabilitation activities Landform design guidelines Rehabilitation designs approved by multiple disciplines including geology, geo-tech and hydrology Rehabilitation designed to be stable without vegetation	Waste dump erodes due to poor surface water management practice, causing rehabilitation to fail and necessitating post-closure repair.	III	RV24: Identification, segregation and stockpiling of competent materials to allow for armouring of erosive final landform surfaces to be encountered at Mesa H. RV61: Confirm material types contained in the Mesa K waste dumps. Closure plan assumes all hydrated waste RV63: Complete a rehabilitation design incorporating hydrological considerations for the Mesa K Northern waste dump, including the River and landform location RV66: Complete a surface water closure design for Mesa H, J and K
T	A	3	02	Vegetation does not meet completion criteria	• Vegetation established, but does not re-seed in same abundance • Weed competition • Species selection / insufficient species diversity • Animal interference i.e. feral animals eating new growth • Changes to soil water conditions e.g. salinity, water logging etc. Potential shortfall of topsoil and subsoil for use in rehabilitation Potential shortfall in seed procurement to meet closure schedule	Environment Community OPEX	• Rehabilitation handbook provides guidance on seed selection for appropriate diversity • Top soil stockpiles provide seed bank • Wetland rehabilitation trial established to assist in appropriate species selection for post-closure soil water conditions • Invasive species management plan will be developed as part of decommissioning activities • Geochemical materials characterisation complete. Material is inert and general expected to be acceptable growth media. • Rehabilitation handbook provides direction on surface treatment options • Annual stockpile reconciliation of top soil and sub soil stockpiles, return of 200mm to create quality surface growth media • Wetland rehabilitation trial established at Yandi will provide feedback on general waste erosion performance, will look at value of adding mulch	Vegetation establishment is below expectations leading to rework and additional seeding or more intensive and costly revegetation techniques	III	

Ref.				Risk Description					Risk Management C	
Risk Type (T=Th	Category	Subcategory	Item	Evaluated 20 of 20 risks (0 Remaining) Threat Title	Potential causes (Triggers / Indicators)	Impacts (Consequences)	Existing Controls and Commitments	Evaluation Rationale (Maximum reasonable consequence)		Detailed Action Descriptions
T	**A**	**04**		**Other regional considerations**						
T	A	04	01	Environmental outcomes outside of disturbance areas do not align with approved environmental impacts	• New (previously unidentified) environmental sites, not considered in existing environmental impact assessment • Changes to environmental conditions due to cessation of artificial support / mitigation activities, e.g. water supplementation • Change to drainage patterns on closure e.g. removal of temporary diversions, drains etc.	Environment Community Reputation Compliance	• Internal ground disturbance approval request system to prevent inadvertent disturbance • Baseline biological / ecosystem health surveys and existing monitoring to define post-mining status • GIS system includes results from all flora, fauna, vegetation surveys • Operational management plan for discharge includes actions relating to water quality and discharge extent targets, to ensure environmental issues are managed during operations • Significant species management plan implemented during operation to minimise impact to select species • Vegetation management plan implemented during operations to monitor and manage impacts to vegetation (riparian, understorey and weeds)	Waste dump failure causes downstream silting of water cause and impacts riparian ecosystem health	**II**	
T	A	04	02	Adverse impact to flora or fauna with conservation status or wider regional impact to high value environment	• Scheduled, listed or declared rare and / or threatened species of flora or fauna present in/adjacent to site • Downstream regional area of high value • Environmental conditions post-closure differ significantly from pre-mining conditions • Post-mining land use differs from pre-mining land use	Environment Community Reputation Compliance CAPEX	• Internal ground disturbance approval request system to prevent inadvertent disturbance • Baseline biological / ecosystem health surveys and existing monitoring to define post-mining status • GIS system includes results from all flora, fauna, vegetation surveys e.g. Mesa A MEZ exclusion zone • Operational management plan for discharge includes actions relating to water quality and discharge extent targets (proximity to Fortescue Marsh), to ensure environmental issues are managed during operations • Significant species management plan implemented during operation to minimise impact to select species • Vegetation management plan implemented during operations to monitor and manage impacts to vegetation (riparian, understorey and weeds)	Weeds florish in the rehabilitation areas and spread, increasing the weed growth in the surrounding undisturbed landscape.	**II**	
T	**B**			**Stakeholders**						
T	**B**	**01**		**Consultation**						
T	B	01	01	Consultation fails to identify stakeholder concerns	• Large number of stakeholders in the project • Clarity of explanation / prediction of closure outcomes, communication styles, long term engagement of agreed outcomes through generational change. • Stakeholder expectations change over time, due to changing global benchmarks for mine rehabilitation success, intergenerational change, regulatory changes etc. • Stakeholders do not endorse site closure as their issues / concerns were not addressed	CAPEX OPEX Reputation	• RTIO stakeholder engagement practice with key stakeholders i.e. Traditional Owner M&L, etc. • Ad hoc consultation with key stakeholders • Detailed engagement planned during decommissioning study • Stakeholder engagement register	A stakeholder comes forward during the decomissioning phase and requires different closure outcomes than planned.	I	
T	**B**	**02**		**Key stakeholder expectations**						
T	B	02	01	Closure outcomes do not meet stakeholder(s) / community expectations	• Absence of rehabilitation trial or data to support predicted outcomes, closure activities fail to achieve completion criteria • Communication of anticipated closure outcomes and post-closure land use needs i.e. wrong plant species established • Unrealistic expectations for economic potential opportunities / post-closure land use capability i.e. aquiculture in pit lakes Visual ammenity not considered in landform design	CAPEX OPEX Reputation Community	• RTIO stakeholder engagement practice with key stakeholders • Monitoring established for water, rehabilitation trials started • Numerical completion criteria established for some aspects	Historic rehabilitation outcomes are no longer acceptable to key stakeholder and re-work is required.	**III**	RV36: Review Mesa J proposed waste dumps to ensure in-pit backfill is maximised where practical and impacts to visual amenity are minimised. This may mean an increase to waste fines storage facility capping thickness
T	B	02	02	A stakeholder's expectations conflict with that of another stakeholder, causing delays to plan approval and / or closure	• Conflicting stakeholder expectations or areas of authority e.g. different regulators for environment, heritage, health, economic, tourism • Conflicting legal obligations e.g. State Agreement and EPA • Interactions between catchment land uses, including mining developments, at different points in time	Community Reputation	• RTIO stakeholder engagement practice with key stakeholders	Stakeholder disagree on decommissioning strategy, requiring extensive re-negotiation and delaying closure.	**II**	
T	B	2	3	Inability to achieve closure objectives and criteria due to cumulative impacts from third parties	Regional approach not taken No forum currently available for sharing information with other mining companies	Cost Reputation Compliance	Development of a business policy is underway to allow Rio Tinto to discuss rehabilitation and closure with third parties	This is not currently viewed as a serious credible threat for the Robe Valley		

Mesa J Hub Closure Risk Assessment

Ref.				Risk Description					Risk Management C	
Risk Type (T=Th	Category	Subcategory	Item	Evaluated 20 of 20 risks (0 Remaining) Threat Title	Potential causes (Triggers / Indicators)	Impacts (Consequences)	Existing Controls and Commitments	Evaluation Rationale (Maximum reasonable consequence)		Detailed Action Descriptions
T	B	2	04	Closure strategy prevents or limits future exploitation of resources	• Backfill sterilises ore reserves • Lakes or habitat restoration prevent / limit future access to adjacent resources	Community	• RTIO stakeholder engagement practice with key stakeholders • Integration of potential Billiards North expansion deposits into current closure plan options	Closure of the Mesa J site is compromised by future approvals to mine adjacenrt deposits	I	
T	**B**	**03**		**Other expectations**						
T	B	03	01	Mine closure has a significant, long-term detrimental impact on local communities	• Local communities receive direct support from operation for basic community services e.g. doctor • Significant proportion of community are directly or indirectly employed by operation	Reputation	• Pannawonica township is owned by Rio Tinto, houses Mesa J personel • Mesa A is FIFO site, with independent workers camp	Closure of the Robe Valley mines result in loss of tourism	I	
T	**C**			**Obligations**						
T	**C**	**01**		**Agreements and commitments**						
T	C	01	01	Closure is not implemented in accordance with the approved closure plan	• Mine development changes prevent closure plan from being implemented as planned • Implementation results in a different outcome than anticipated	CAPEX OPEX Community	• Integration of closure plan with LoM plan • Mesa A Troglofauna Management Plan Ministerial statement Stakeholder input and review of closure plans	Closure commitment to re-establish troglofauna habitat is mis-interpreted and does not meet approved closure plan requirements	**III**	

Appendix E – Task, Research and Trial Activities Schedule

Ref	Task	Indicative timeframe
RV03	Confirm the assumption that pit lakes will not be formed above WFSF at closure by conducting a water balance analysis for Mesa J waste fines storage facilities.	Next Closure Plan
RV04	Undertake a review of predicted water quality for the Mesa J reservoir to assess viability of leaving this areas as pit lakes.	Next Closure Plan
RV10	Review environmental reports on potential impacts of mining activities on Robe River permanent pools and compare waters level and water quality. Determine key environmental receptors and potential ecological impacts. Determine if effects / impacts are masked by other impacts, such as discharge to Jimmawurrada Creek.	Next Closure Plan
RV15	Document and distribute conceptual understanding of pool supplement water supply post closure to mitigate drawdown impacts on Robe River pools.	Before OoM
RV24	Identification, segregation and stockpiling of competent materials to allow for armouring of erosive final landform surfaces to be encountered at Mesa H.	During operations
RV36	Review Mesa J proposed waste dumps to ensure in-pit backfill is maximised where practical and impacts to visual amenity are minimised. This may mean an increase to waste fines storage facility capping thickness	Next LOM Plan
RV50	Review post-closure access road and road designs with key stakeholders to establish long-term liability and ownership for road maintenance at Mesa J hub	OoM
RV51	Review access to open faces, placement of abandonment bunds or reshape landform as appropriate (Mesa J hub)	Next LOM Plan
RV61	Confirm material types contained in the Mesa K waste dumps. Closure plan assumes all hydrated waste.	Next Closure Plan
RV62	Complete landform designs for any backfilled waste materials in the Mesa J pits to meet Landform Design Guidelines.	Next Closure Plan
RV63	Complete a rehabilitation design incorporating hydrological considerations for the Mesa K Northern waste dump, including the River and landform location	Next Closure Plan
RV64	Develop detailed closure designs for existing WFSF's at Mesa J	Next Closure Plan
RV66	Complete a surface water closure design for Mesa H, J and K	Before OoM
RV67	Incorporate any Troglofauna pit boundary changes into closure plan at Mesa K.	Next Closure Plan
RV68	Pit 11 backfill – refine location where the backfill volume is likely to come from and the respective rehabilitation design for this area	Next LOM Plan

Appendix F – Landform design criteria

The following tables provide summaries of the key design criteria (where available) of the waste landforms associated with Mesa J Hub.

Please note that these are interim rehabilitation designs and will be refined as the dump approaches rehabilitation.

Mesa H SW Dump (Dump 2)

Waste volume		
Erodibility ranking	Moderate - High	
Classification	Inert ☒	Capping required at closure:
	PAF ☐	-
	Fibrous minerals ☐	-
	WFSF ☐	-
Overall height (m)	30	
Topsoil required (Mm^3)	95,074 m^3	

	Construction Specifications	**Rehabilitation Specifications**
Slope angle (deg)	37°	20°

PEER REVIEW: MESA H: H3 HYDROGEOLOGICAL ASSESSMENT

INTRODUCTION

The Robe River Joint Venture (the Proponent) is undertaking studies to support additional mining operations that will sustain production from the Robe Valley. A number of channel iron deposits (CID) resources in the Robe Valley have been considered.

Mesa H is proposed as the next development to sustain the Mesa J hub production and is scheduled to commence Q1 2020 utilising existing Mesa J infrastructure including existing wet processing facilities.

Mining at Mesa H is scheduled to extend over a period of about 18 years. Water levels in much of the Mesa H mine area have been lowered significantly by dewatering activities at the adjacent Mesa J but further dewatering will be required as approximately 13% of the resource lies below the current water-table (BWT). Water supply augmentation for the expanded mining and processing requirements is also planned.

Pre-Feasibility Studies (PFS) have been completed and it is currently anticipated that the works will progress to a Feasibility Study (FS) in 2017/2018 with planned Implementation in 2019. The Proponent is currently planning to submit API/PER approval documents to in Q4 2017 seeking to obtain a Part IV approval by Q4 2018 / Q1 2019.

PROJECT OVERVIEW

Mesa H is located immediately west and adjacent to the existing Mesa J mine, downstream from the confluence of the Robe River and Jimmawurrada Creek.

The deposit is bounded in the north and northwest by the Robe River where riparian vegetation is extensive and a series of pools exist. One of these pools - Yeera Bluff - is a Rights Reserve site of high significance to the traditional owners.

Dewatering at Mesa H, combined with operations at Mesa J, has potential to lower water levels along the drainage courses.

A significant data base and dewatering/water supply experience has been gained over many years at the adjacent Mesa J site, where similar geological conditions exist, but there have been limited investigations at Mesa H prior to 2015.

A detailed PFS investigation was undertaken through 2015-2016 to address hydrogeological risks identified during an earlier Order of Magnitude (OoM) study – specifically, identifying dewatering requirements and assessing potential associated impacts to the Robe River. The 2016 programme comprised drilling, construction and testing of four (4) water bores with 32 associated monitoring bores the results from which were used (in conjunction with Mesa J data) to develop a conceptual hydrogeological model and subsequent groundwater numerical model.

PEER REVIEW

Provisions were made in August 2016 for an independent peer review of the hydrogeological assessments of the Robe Valley projects.

The key objectives of the review were identified as:

- Review and verify the quantity and quality of hydrogeological information considered as part of the assessment is sufficient to satisfy PFS level understanding and to support API/PER approval submissions
- Review and verify the current conceptual hydrogeological models including an assessment of technical robustness, rigour and level of confidence in the interpretations and analyses;
- Review and verify the numerical groundwater model inputs, design, calibrations and outputs and assess in terms of National Water Commission's Australian Groundwater Modelling Guidelines (2012);
- Provide recommendation to address gaps in the conceptualisation and numerical models.

Independent Groundwater Consultants Pty Ltd was commissioned to undertake the review which has been undertaken by Graham Smith, a professional hydrogeologist with 40 years of local and international experience specializing in arid zone hydrogeology with familiarity of the Pilbara and Robe River through site visits, a number of mine development projects and previous Rio Tinto commissions (e.g. member of Expert Panel; 2015 Pre-Feasibility Study for the Bungaroo mine; Peer Reviewer hydrogeological assessments for Warramboo, Mesa C and West Angelas C&D).

The review has involved review of project technical documentation, a site visit and several discussions with technical personnel as the studies have progressed.

This report presents comment on the H3 Assessment Report for Mesa H with primary attention given to data availability, hydrogeological conceptualisation, analysis and assessment methods, groundwater modelling, impact assessments, mitigation measures if/as appropriate, water management planning and proposed future work programmes. The review of the hydrogeological conceptualisations and groundwater models draws on the Australian Groundwater Modelling Guidelines (Barnett et al, 2012).

Key Documents

The primary reference document provided for review was:

- Mesa H: H3 Hydrogeological Level Assessment v4.0 (RTIO, October, 2017).

Supporting documentation included:

- Mesa H: 2016 Pre-Feasibility Study Hydrogeological Drilling Program Completion Report (RTIO, May 2016).
- Mesa H: Groundwater Modelling rev.E (RPS, October, 2017).

Report Overview

The primary report has been well-prepared and is well supported by figures, tables and Appendices providing detail on the bore completions, the numerical model and an assessment of surplus water discharge extent. It includes the following Sections:

Introduction – provides an overview of the deposit (local aquifers, nearby water courses and environmental setting) and the adjacent Mesa J mine where dewatering occurs to facilitate BWT mining and provide process supplies.

Climate and Rainfall – describes climatic conditions, provides annual rainfall data, outlines contributing catchments and provides Robe River annual streamflow data (from upstream Ngalooin Pool and downstream Yarraloola).

Hydrogeology – describes local geology, aquifer occurrence (CID, Wittenoom and Robe River alluvium) well illustrated with cross-sections, hydrographs illustrating water level drawdown resulting from Mesa J dewatering and responses to rainfall, predicted pre-mining and current water level contours, recharge/discharge processes, water balance, an extended section on Robe River hydraulics where an estimate of mean annual flow (50GL/year) is given and contributing factors associated with the occurrence and status of permanent and semi-permanent pools occurring along the drainage are discussed, with supporting hydrographs. This is followed by an overview of flooding within Jimmawurrada Creek and connectivity with upstream Bungaroo palaeochannels.

Four (4) hydrogeological conceptualisations are presented in recognition of stated uncertainties around the characteristics of the Brockman Iron Fm and continuity of the Wittenoom Fm. Constraints associated with the heterogeneity of the local Robe River alluvial aquifer and the paucity of drilling information north of Mesa H and in Jimmawurrada Creek are also identified.

Existing Groundwater Use – describes dewatering (sumps/trenches), abstraction from an external borefield (Southern Cutback Borefield – SCB – that provides process and potable water supplies) and re-cycling at Mesa J, the Pannawonica town supply borefield drawing ~0.7GL/yr since 1981 from the Robe River alluvium (~10km northwest of Mesa H) and the Bungaroo Coastal Water Supply borefield (permitted to supply up to 10GL/yr for the West Pilbara Water Scheme) located upstream ~20km southeast of Mesa H.

Groundwater Investigation – summarises the extensive hydrogeological investigations to support water supply and dewatering at Mesa J since 1987, establishment of 14 monitor bores at Mesa H in 2015 and the 2016 works comprising installation of four (4) test production bores and 18 monitor bores (with reference to bore completion reports given as Appendix A). A summary of pumping tests and results (3 bores in Mesa H and 18 in Mesa J) is provided. Reference is made to RTIO-PDE-0143871 (not sighted) in presentation of Robe Rive alluvial aquifer characteristics as determined from analysis of long-term abstraction from the Pannowonica town supply borefield.

Groundwater Chemistry – presents detail on extensive programme of groundwater (43 bores) and surface water (7 pools) sampling and analysis (since 1993 at Mesa J) with discussion of

major ions, minor ions and isotopic composition to characterise the three main aquifers at the site and assess their potential contribution to the Robe River alluvial aquifer.

Groundwater Flow Model – summarises previous modelling works to predict inflows to Mesa J (initiated in 2002 and subsequently updated in 2003, 2004 and 2006), describes development of a new groundwater model in 2016 that combines both Mesa H and Mesa J (Modflow_Surfact v4.0 with Groundwater Vistas graphical user interface). Reference made to details provided in supporting Appendix B – Groundwater Numerical Model.

Difficulties associated with steady-state calibration and need for a dynamic calibration process are described with resultant good agreement between conceptual and model inflows and outflows.

Transient calibration, using annual time steps, compared predicted and observed groundwater levels through period 1990-2017 (using 37 bores with long-term records and 33 recently installed bores). Calibrated aquifer parameters are tabulated and a water balance presented. Zone budget analyses are described for the confluence of the Robe River and Jimmawurrada Creek and sites of inflow/outflow from the Robe River alluvium.

Model predictions are provided for dewatering of Mesa J and Mesa H and drawdown along the Robe River; these include augmentation of the SCB with an additional 3-5 water supply bores to meet the increased demand of the wet plant (8.7GL/yr) and continued discharge of surplus water along Jimmawurrada Creek the footprint of which as determined from a separate model. Reference made to details provided in supporting Appendix C –Surplus Water Discharge Extent Assessment.

Prediction uncertainty is discussed and eleven (11) additional model runs described for uncertainty analysis.

Assessment of Potential Impacts – using predicted 2037 water level drawdown resulting from dewatering and water supply discusses potential impacts (on water levels, the Robe river and Jimmawurrada Creek environments and the aquifer including predictions on post-mining water level recovery).

Site Water Balance – presents a detailed site water balance for each year through 2019-2037 identifying supply sources to meet demand for wet plant processing, infrastructure and dust-suppression.

Groundwater Monitoring – provides information on current (and planned) monitoring schedule from the approved site Groundwater Operating Strategy. Ongoing monitoring of flora, fauna and pools will continue in accordance with the Mesa J Environmental Management Plan. Risk to the environment with development of Mesa H is cited as high with acknowledgement that formal triggers (biological and water levels) will need definition prior to commencement of dewatering at Mesa H in 2024.

Management Approach/Conclusions – outlines defined Water Strategy, discharge system, maintenance and monitoring.

Key Findings

The key findings reported may be summarized as follows:

Aquifers

Groundwater occurs in three (3) main aquifers – the Robe River alluvials, the CID and the weathered basement (Marra Mamba Iron and Wittenoom Formations). Connectivity between the CID (to be dewatered during mining) and the underlying basement is constrained by the basal pisolites. Regional groundwater throughflow (CID and weathered basement) is estimated to be ~1.6GL/year.

Depth to water along the Robe River channel is shallow (2-5mbgl) and may fluctuate up to 3m annually in response to high rates of recharge and evapotranspiration. Natural groundwater throughflow is estimated to be ~0.8GL/year.

Conceptualisation

Groundwater flow in the CID and basement is from SE to NW following the trend of the CID palaeochannel deposits from upstream Bungaroo valley. The CID and Wittenoom aquifers are bounded by bedrock aquicludes (in the east by fresh Marra Mamba Iron Formation and by the Brockman Iron Formation in the west). Natural recharge is limited to direct inputs from rainfall but this has been locally augmented by leakage from Mesa J reservoirs.

Groundwater throughflow in the streambed alluvials of the Robe River and Jimmawurrada Creek naturally follows the drainage courses and are primarily recharged by infiltration of surface water flows that are generated by major rainfall events (supplemented locally by discharge of surplus water). The two principal drainages coalesce just upstream of Mesa H.

The pools that occur along the Robe River appear to be related to the alluvial aquifer and are groundwater dependent in drought periods.

A number of key uncertainties have been identified all of which may have significant impact on groundwater flow processes and responses to dewatering; these include aquifer characteristics of the Robe River and Jimmawurrada Creek alluvial systems. Four (4) different concepts are presented to accommodate primary uncertainties related to (a) whether the Brockman Iron Formation underlying Yeera Bluff is impermeable and (b) whether flow in the Wittenoom Formation discharges into the overlying Robe River alluvium or continues to the north.

Dewatering

Dewatering at Mesa H will commence 2024/2025 and, for all years, can be affected by in-pit sump pumping. Peak abstraction of 6.5ML/day will occur in 2033; total abstraction during LoM will be 11.3GL. Total abstraction 2019-2037 from the combined Mesa H and Mesa J operations, including water supply, will be 170GL with a peak of 9.5GL/year.

Water Disposal

Surplus water will be discharged to Jimmawurrada Creek at average rate of 2.1GL/year (peak 4.5GL). With potential discharge rates in range 5-30ML/day, the distance travelled by the surface water flow is predicted to be between 3.5km to 11.8km.

Water Demand and Supply

Water demand is dominated by the requirements of the Wet Plant which will require between 8.8 GL/year to 14.2 GL/year (average 11.9GL/year). Total water demand (including evaporative losses from on-site reservoirs) will range from 9.5GL/year to 15.6GL/year (average 13.3GL/year).

Dewatering product, seepage and decant recovery will make a significant contribution to supply but an external source will continue to be required; expansion of the SCB is planned to meet a maximum requirement of 8.5GL/year.

Impacts

Discharge of surplus water from Mesa J operations to Jimmawurrada Creek has likely contributed to maintaining water levels in the alluvial aquifer where no evidence of any impact on the aquatic environment has been found.

Combined dewatering operations at Mesa H and Mesa J will have minimal (<1m) impact on water levels along the Robe River north of the mines.

It is not expected that there will be significant impact to permanent pools in the Robe River (e.g. Yeera Bluff) but shallow semi-permanent and seasonal pools may dry out at a faster rate during prolonged periods when no surface water flows occur. Significant water level drawdowns will occur along a 9km reach of Jimmawurrada Creek as a result of the cumulative, combined impacts of Mesa J dewatering, abstraction from the SCB and the upstream Coastal Water Supply (CWS) borefield operation.

It is not anticipated that there will be any significant impact to riparian vegetation along the Robe River but there will likely be impact on phreatophytic vegetation along a 4-9km reach of Jimmawurrada Creek. Reductions in stygofauna habitats may also occur with lowering of water levels there but this is expected to be localised and minor.

Natural water levels will recover to pre-mining levels after 60 years.

Uncertainties

Inherent uncertainties exist with the parameters adopted to describe the hydrogeological system. Uncertainty analysis has been undertaken to evaluate conceptual model, climate change and numerical model uncertainties; results tend to confirm conceptualization and model behaviour.

Mitigation

The requirement for a mitigation strategy to supplement water to the permanent and semi-permanent pools in Robe River from 2030 (given uncertainties, values and ecosystem sensitivity) is identified. It is envisaged that monitoring of water levels in the Robe River pools and the area predicted to be impacted along Jimmawurrada Creek will be used to develop and trigger mitigation actions Options for mitigation have been identified (eg supplemental discharge, modification of abstraction regime, aquifer reinjection, etc.).

Planned Future Works

Planned works, cited in Scope of Work Mesa H FS Hydrogeology Drilling June 2017 v2.2, seek to address the hydrogeological risks identified in the PFS and include:

- Installation of up to six (6) test bores, eleven (11) monitor bores and two (2) VwP.
- Aquifer testing of all installed bores.
- Discharge trial (up to 30 days) in the Robe River (to support design of an impact mitigation strategy for local pools).
- Investigation of water supply sources for construction camp.

Review Comments

Field Investigations

The PFS investigations have been conducted to a high standard. Drilling, monitor and test production bore construction methods and aquifer testing conform to best-practice, are well documented and provide a sound data set for the Mesa H mine area.

Data Availability

Available rainfall and Robe River streamflow records have been included in the assessment; these demonstrate frequency of major rainfall and flood events. Groundwater levels and quality are well established with an extensive monitor bore network. Whilst there is limited discrete aquifer data, the adopted parameters conform to experience in similar environments and appear reasonable. No test data is provided to support the assumption that the basal pisolites constrain flow between the CID and underlying bedrock aquifers; based on the recorded lithology and thickness, however, this is considered a reasonable assumption. Data to characterize the alluvial aquifers associated with the Robe River near Mesa H and Jimmawurrada Creek near Mesa J are similarly absent. Aquifer parameters deduced from operation of the Pannawonica borefield appear reasonable and provide support for the parameters adopted for the Robe River alluvial aquifer. Uncertainties remain with regard to the alluvial system associated with, and surface water flows within, Jimmawurrada Creek. Notwithstanding the above, the cumulative data set is considered to provide an adequate technical foundation for the conceptualisations and detailed numerical modelling process.

Hydrogeological Conceptualisation

The geological model and characteristics of the primary hydro-stratigraphic units are well-established and provide a sound foundation for hydrogeological assessment. The conceptual model is based on the integration of all available information including background information from previous investigations, extensive experience in water management gained over many years at Mesa J where similar hydrogeological conditions exist, ongoing monitoring at Mesa J and information generated by specific investigations.

The concepts re: pools and alluvial aquifer processes is based on detailed assessment of available water level and water quality data and appear sound.

Uncertainties in conceptualisation have been clearly identified and adequately addressed in the modelling process.

Modelling

The objectives of the modelling are clearly stated and the model set-up honours the documented hydrogeological conceptualisation. Standard modelling packages and techniques have been deployed and what appear to be appropriate boundary conditions established.

Calibrated aquifer parameters are in general conformity with field-derived values; adopted low fresh bedrock values are considered appropriate. Inherent uncertainty exists with storage parameters.

Model predictions accommodate a number of assumptions related to many operational processes. These appear well-considered and further demonstrate a sound site water management plan. The assignment of surface water flows in Jimmawurrada Creek as a proportion of Robe River flows (based on contributing catchment areas) is supported.

Uncertainty analysis has usefully assessed conceptualisation and climate variables. Summary results indicate that drawdowns in the Robe River alluvials in excess of 1m are predicted to only occur in the sustained absence, or large-scale reduction, of flood flows. It is noted, however, that drawdowns of similar magnitude are predicted with modification of the general head inflow boundary associated with the Robe River which warrants further assessment.

The documentation for the modelling effort is of high standard and well-presented. The claimed model confidence level classification – Class 2 – is supported.

Dewatering

The predicted rates/volumes appear reasonable and gain support from the longer-term experience gained in the adjacent Mesa J pits where similar conditions prevail.

Impacts

Potential impacts have been identified and assessed. The dominance of surface water flows in the water balance (or indirect recharge derived therefrom) has, as would be expected, been clearly demonstrated.

The prediction that impacts along the Robe River north of Mesa H and Mesa J will be minor appear sound. Under average annual streamflow conditions and assumption of vertical flow constraints imposed by the basal pisolites underlying the CID aquifer, such impacts are less than natural seasonal variations and consequently considered unlikely to be of such a magnitude to pose any threat to local environmental values. Any water level drawdowns in the alluvials that do result from dewatering operations will, however, be naturally augmented in the absence of flood events. The contention that there will be natural mitigation of minor drawdown impacts along the Robe River by infiltration of surface water flows is supported by hydrographs from monitor bores showing water level responses associated with significant rainfall events (and assumed floods) along the Robe River (at Pannawonica) and Jimmawurrada Creek (near Mesa J) and appears reasonable.

The predicted significant drawdown impacts along a section of Jimmawurrada Creek are as would be anticipated given location near the SCB and predicted groundwater flow reversal resulting from continued operation of the upstream CWS borefield.

Uncertainties

A number of uncertainties have been identified that primarily relate to the aquifer characteristics of various formations, groundwater flow paths and hydraulic connectivity between formations. These should be adequately addressed in the planned, follow-on work programmes with further insight provided by continued monitoring.

Summary

The quantity and quality of hydrogeological information presented is considered sufficient to satisfy PFS-level understanding and to support API/PER approval submissions.

The current conceptual hydrogeological models have been developed on an extensive data set taking due account of local geology, hydrology, hydrogeology and historic site water management and are supported; uncertainties have been identified and will be addressed in follow-on programmes.

The numerical groundwater model honours the hydrogeological conceptualization and is considered fit for purpose meeting key objectives of quantifying required dewatering rates and potential impacts. Design conforms with standard practices and is based on a sound geological model; calibrated parameters are in accordance with field-derived or acceptable values. Information on calibration, predictions and uncertainty runs is well documented. In terms of the National Water Commission's Australian Groundwater Modelling Guidelines (2012), the reported Class 2 level of confidence is supported.

Model predictions indicate that:

- dewatering drawdown impacts along the Robe River will be minor and less than natural water fluctuations. Evidence exists to support contention of natural mitigation through infiltration of surface water flows.

- significant water level drawdowns will occur along a reach of the Jimmawurrada Creek as a result of abstraction from the nearby SCB and upstream CWS.

A requirement for mitigation measures has been identified; options exist and are to be further assessed.

Recommendations

Whilst the proposed work to advance hydrogeological understanding to Feasibility Level and continued monitoring should address the key uncertainties that have been identified, consideration should also be given to:

- Augmentation of the monitoring network with facilities to record flood events along both the Robe River and Jimmawurrada Creek and water levels/quality in any pools therein.

- Further examination of the available data sets with a view to confirming the areal extent, thickness and hydraulic properties of the basal pisolite layer.

- Obtaining discrete hydraulic properties of the key formations.

In addition, as a prelude to future modelling work, a re-assessment of boundary conditions would be prudent and further analysis of zonal water balances to confirm, and improve definition of, expected fluxes between the key formations.

Surplus water discharge extent assessment: Mesa H

Overview

The Mesa H deposit is located approximately 11 km southwest of Pannawonica and adjacent to the Robe JV Mesa J mine, downstream of the confluence of the Robe River and Jimmawurrada Creek (Figure 1). Approximately 40% of the resource is below the current water table (which has been lowered by dewatering at Mesa J). Consequently, approval will be sought to commence mining below water table, which will require dewatering.

Management of water on Rio Tinto sites follows strict environmental and water use standards (refer to Rio Tinto Environmental Standards). These standards align with the "Pilbara Water in Mining Guideline" (DoW, 2009) which identifies options for use and/or release of dewatering discharge:

- Efficient on-site use, including mitigation of any impacts.
- Used for fit for purpose activities (such as processing and dust suppression). The proponent needs to demonstrate that the water is of suitable quality for the end use.
- Transferred to meet other demand including other proponents in the area and public water supply, as approved by the Department. Where it is proposed to use the water for public supply, a drinking water source protection plan should be developed and approved by the Department of Water and the Department of Health.
- Injection back into the aquifer at designated sites determined by the proponent and agreed by the Department.
- Controlled release to the environment where the dewater release is allowed to flow (either through a pipe or overland) into a designated water course or wetland and determined by the proponent and agreed by the Department.

Management of surplus water at Mesa H may include the controlled discharge of surplus water at existing discharge locations at Mesa J, namely Discharge point 5 (Jimmawurrada Creek) or Discharge Point B (Robe River tributary immediately west of Mesa J). Therefore, the objective of this study was to estimate the extent of impact of surplus water discharge along the respective watercourses. The methodology to achieve this objective is outlined below:

- Develop a 2D hydraulic model of the river system downstream of the proposed discharge location.
- Determine the hydraulic characteristics that are not inherently accounted for by the 2D hydraulic model, i.e. saturated hydraulic conductivity of the soils.
- Estimate the maximum possible extent that surplus water discharge will flow under steady-state conditions.
- Investigate multiple steady-state scenarios, namely a continuous discharge rate of 5, 10, 15, 20, 25 and 30 ML/day.

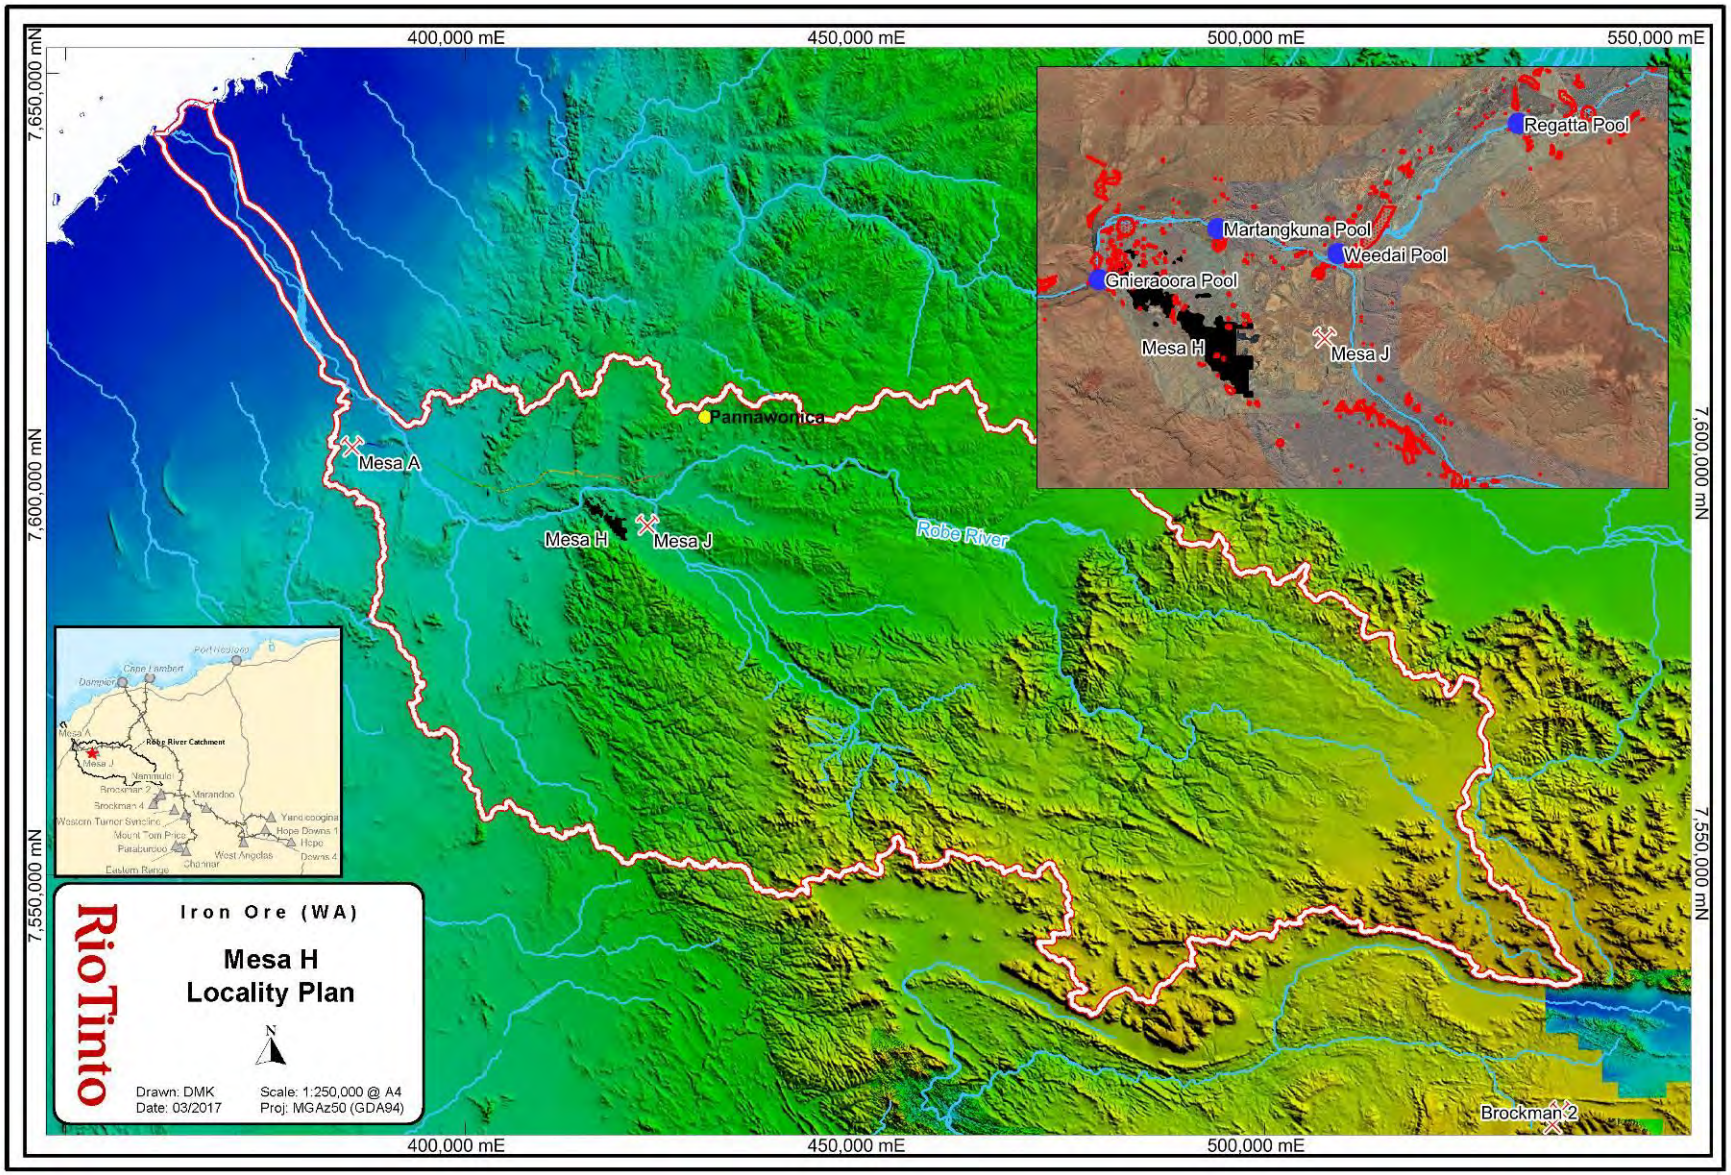

Figure 1: **Mesa H surplus water discharge study location plan**

Modelling Approach

Water flowing in a watercourse is removed from the surface via two mechanisms, namely: evaporation and infiltration. However, these hydrologic processes are inextricably intertwined with the flow characteristics, and hence the hydraulics, of the river system. The braided nature of typical Pilbara watercourses creates a complex hydrodynamic environment where the flow behaviour is essentially 2D in nature, which may be poorly represented using a 1D model.

Recent developments to the **T**wo-dimensional **U**nsteady **Flow** (TUFLOW) model have effectively transformed TUFLOW into a 2D coupled hydrologic-hydraulic modelling system, with the ability to model soil infiltration in both unsaturated and saturated conditions. This makes the TUFLOW model a useful tool for the estimation of surplus water discharge extent.

This section documents the process and assumptions made in developing the 2D hydraulic model for the Mesa H surplus water discharge.

TUFLOW hydraulic model

For this study, TUFLOW's GPU Module was adopted. This is a powerful new solver built into the TUFLOW software, which utilises the substantial parallel computing ability of modern Graphics Processor Units, or GPUs (TUFLOW, 2014). TUFLOW GPU is an explicit solver for the full 2D Shallow Water Equations, including a sub-grid scale eddy viscosity model. The scheme is both volume and momentum conserving. Owing to the power of modern GPUs very large models (>100 million cells) with fine grids can now be run within a sensible timeframe (TUFLOW, 2014). This allowed for a high resolution 1 m DEM, derived from LiDAR, to be used to describe the topography of the river system. This represents a major advantage of this approach. The model configurations are shown in Figure 2.

Manning's roughness coefficient *n*

Surface roughness is defined using the Manning's *n* roughness coefficient. The roughness coefficients adopted for this study were determined according to Chow (1959), which takes into consideration channel irregularities, variation in cross section, obstructions, vegetation density and meandering of the reach. These factors were assessed using aerial photography and confirmed during a site visit. The adopted Manning's *n* roughness coefficient for the Robe River and Jimmawurrada Creek was 0.045, while the Robe River tributary immediately west of Mesa J was assigned a Manning's *n* roughness coefficient of 0.035. These values were applied to all applicable active cells in the model, which was limited to the river/creek channels, as can been seen in Figure 2.

Model inflows

Multiple steady-state scenarios were assessed, namely a continuous discharge of 5, 10, 15, 20, 25 and 30 ML/day.

Model outflows

The maximum discharge extent is achieved when equilibrium is reached between the inflows to and the outflows from the system. Water flowing in a watercourse is removed from the surface through evaporation and/or infiltration.

Evaporation

Annual and monthly potential evaporation rates (A-pan) are available from the Bureau of Meteorology (BoM) website. However, evaporation from open water bodies can be significantly less than A-pan estimates owing to a variety of climatic factors. As such, correction factors are often required to relate A-pan evaporation to evaporation from open water bodies. From Figure 3 it can be seen that evaporation from open water bodies for most of the Pilbara region of Western Australia is between 60-70% of the A-pan evaporation rates.

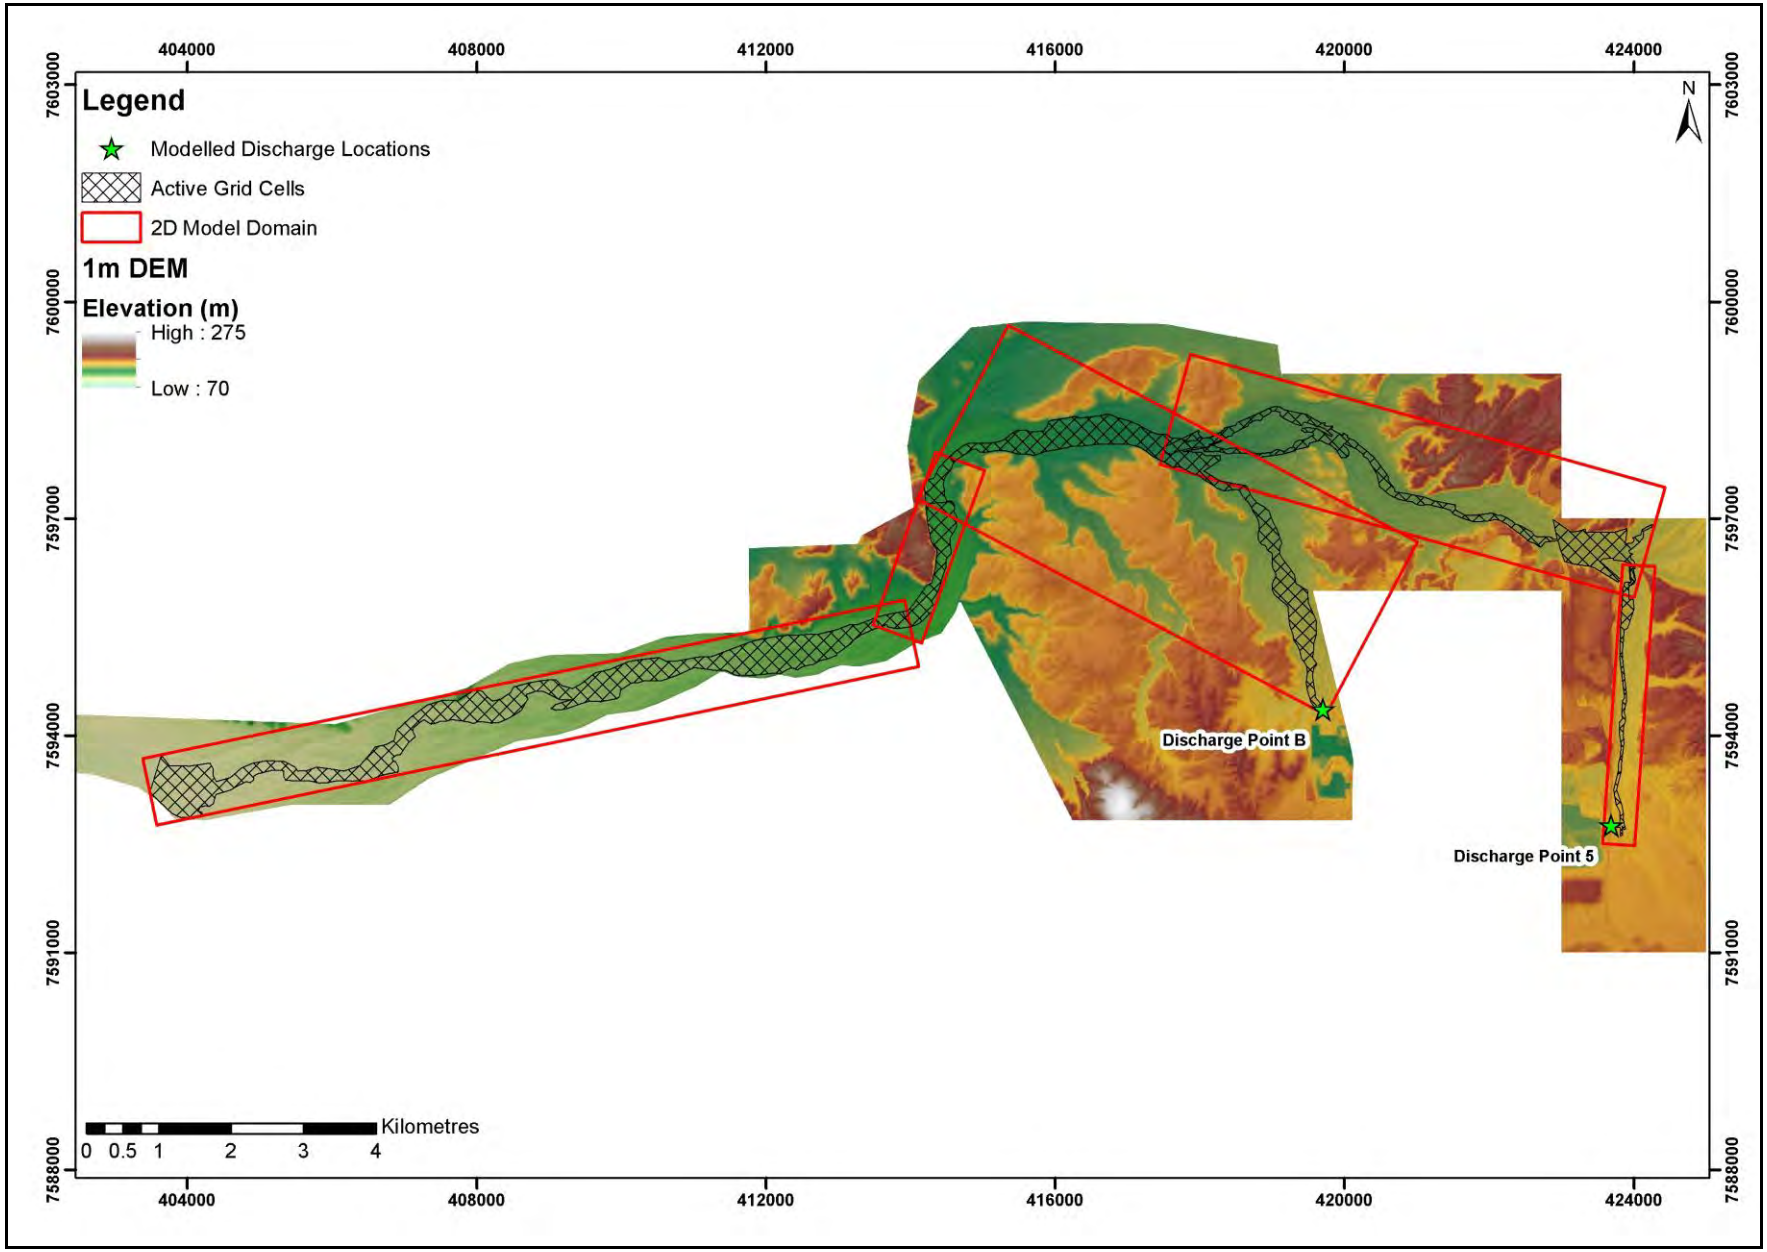

Figure 2: TUFLOW model configuration

From Figure 3, the A-pan evaporation rate for Mesa H was determined to be 3400 mm per year. However, the lowest monthly A-pan evaporation occurs in June (157 mm). This was multiplied by 0.65 (Luke et al., 1987) to relate A-pan to open water body evaporation. Consequently the adopted evaporation rate was 102 mm per month, which translates to an average rate of 0.14 mm/h.

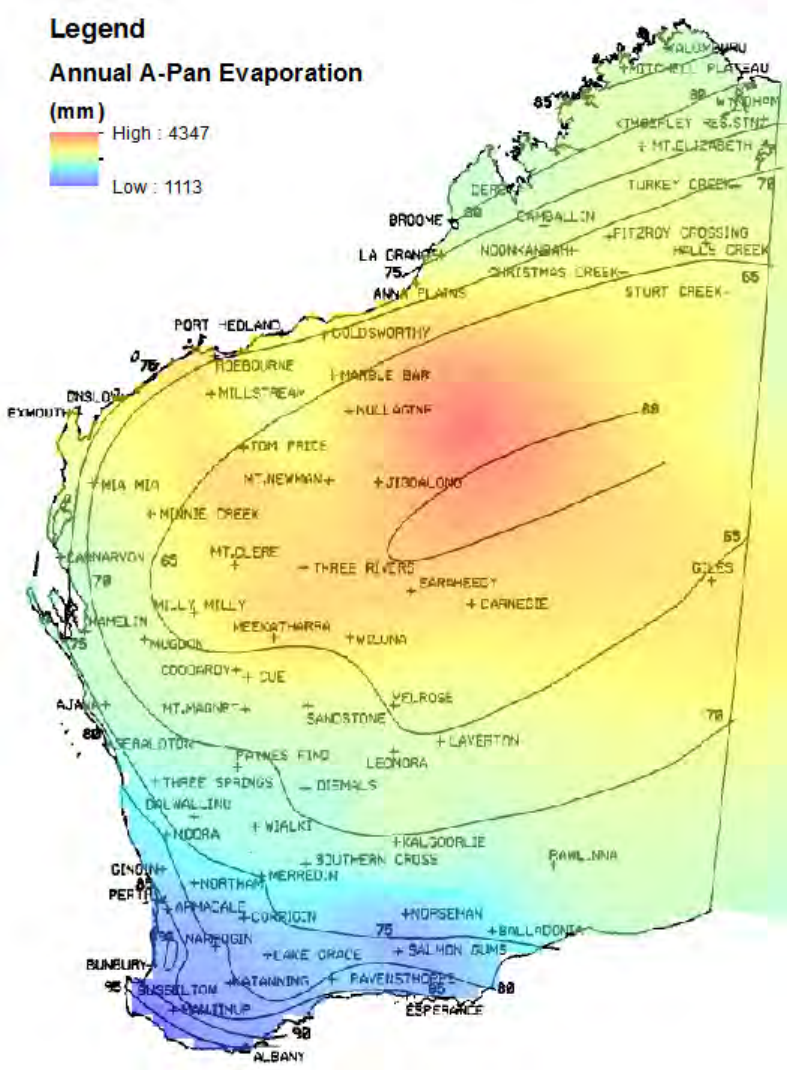

Figure 3: **Gridded annual A-pan evaporation and A-pan correction factors (contours) for Western Australia (from BoM and Luke et al., 1987)**

Infiltration

The maximum discharge extent is achieved when equilibrium is reached between the inflows to and the outflows from the system. As the soil moisture content increases so the infiltration rate of the soil decreases until the saturated hydraulic conductivity (K_{sat}) of the soil is reached. Consequently, equilibrium between the inflows and outflows, and hence the maximum discharge extent, can only be achieved once the soils have reached saturation. As such, when the aim of the discharge extent modelling is to determine the maximum discharge extent for long-term discharge there is no need to simulate losses in unsaturated conditions, and a continuing loss equal to K_{sat} may be adopted.

Although the Soil Hydrological Properties for Australia (Western and McKenzie, 2006) provides K_{sat} values for the whole of Australia, experience has shown that these values can be up to three orders of magnitude too high, thereby overestimating losses from the system and drastically under estimating the maximum discharge extent. As a result, a texture based approach to estimate K_{sat} in the absence of measured data has been applied. This approach derives a weighted clay content for each Map Unit in the Atlas of Australian Soils (Northcote

et al., 1960-1968), which places the Map Unit into one of six Texture Groups documented by McKenzie et al. (2000), shown in Table 1.

Table 1: Texture groups according to clay content - adapted from McKenzie et al. (2000)

Weighted Clay Content (%)	Texture Group	Texture Grade
0 – 8	Sands	Sand Clayey Sand Loamy Sand
8 – 17.5	Sandy Loams	Sandy Loam Fine Sandy Loam Light Sandy Loam
17.5 – 25	Loams	Loam Loam, Fine Sandy Silt Loam Sandy Clay Loam
25 – 35	Clay Loams	Clay Loam Silty Clay Loam Fine Sandy Clay Loam
35 – 47.5	Light Clays	Sandy Clay Silty Clay Light Clay Light Medium Clay
47.5 – 100	Clays	Medium Clay Heavy Clay

The least permeable texture grade is adopted as the representative texture for each Texture Group, and is therefore considered to be a conservative estimate. The adopted K_{sat} values for each Texture Group are presented in Table 2.

Table 2: Saturated hydraulic conductivities for different texture groups – adapted from Clapp and Hornberger (1978), Cosby et al. (1984) and van Gool et al., (2005)

Texture Group	Adopted K_{sat} (mm/h)
Sands	50.6
Sandy Loams	18.8
Loams	10.1
Clay Loams	6.1
Light Clays	3.7
Clays	3.0

Figure 4 shows that the creeks and rivers downstream of the discharge locations cross four different soil Map Units, namely, B27, Fa13, My1 and Oc66. Using the approach outlined above the Texture Group and K_{sat} for each Map Unit was derived, and is presented in Table 3.

Table 3: Soil Map Units in study area and adopted saturated hydraulic conductivities

Soil Map Unit	Weighted Clay Content of Limiting Soil Horizon (%)	Texture Group	Adopted K_{sat} (mm/h)
B27	30.0	Clay Loams	6.1
Fa13	27.5	Clay Loams	6.1
My1	36.5	Light Clays	3.7
Oc66	44.0	Light Clays	3.7

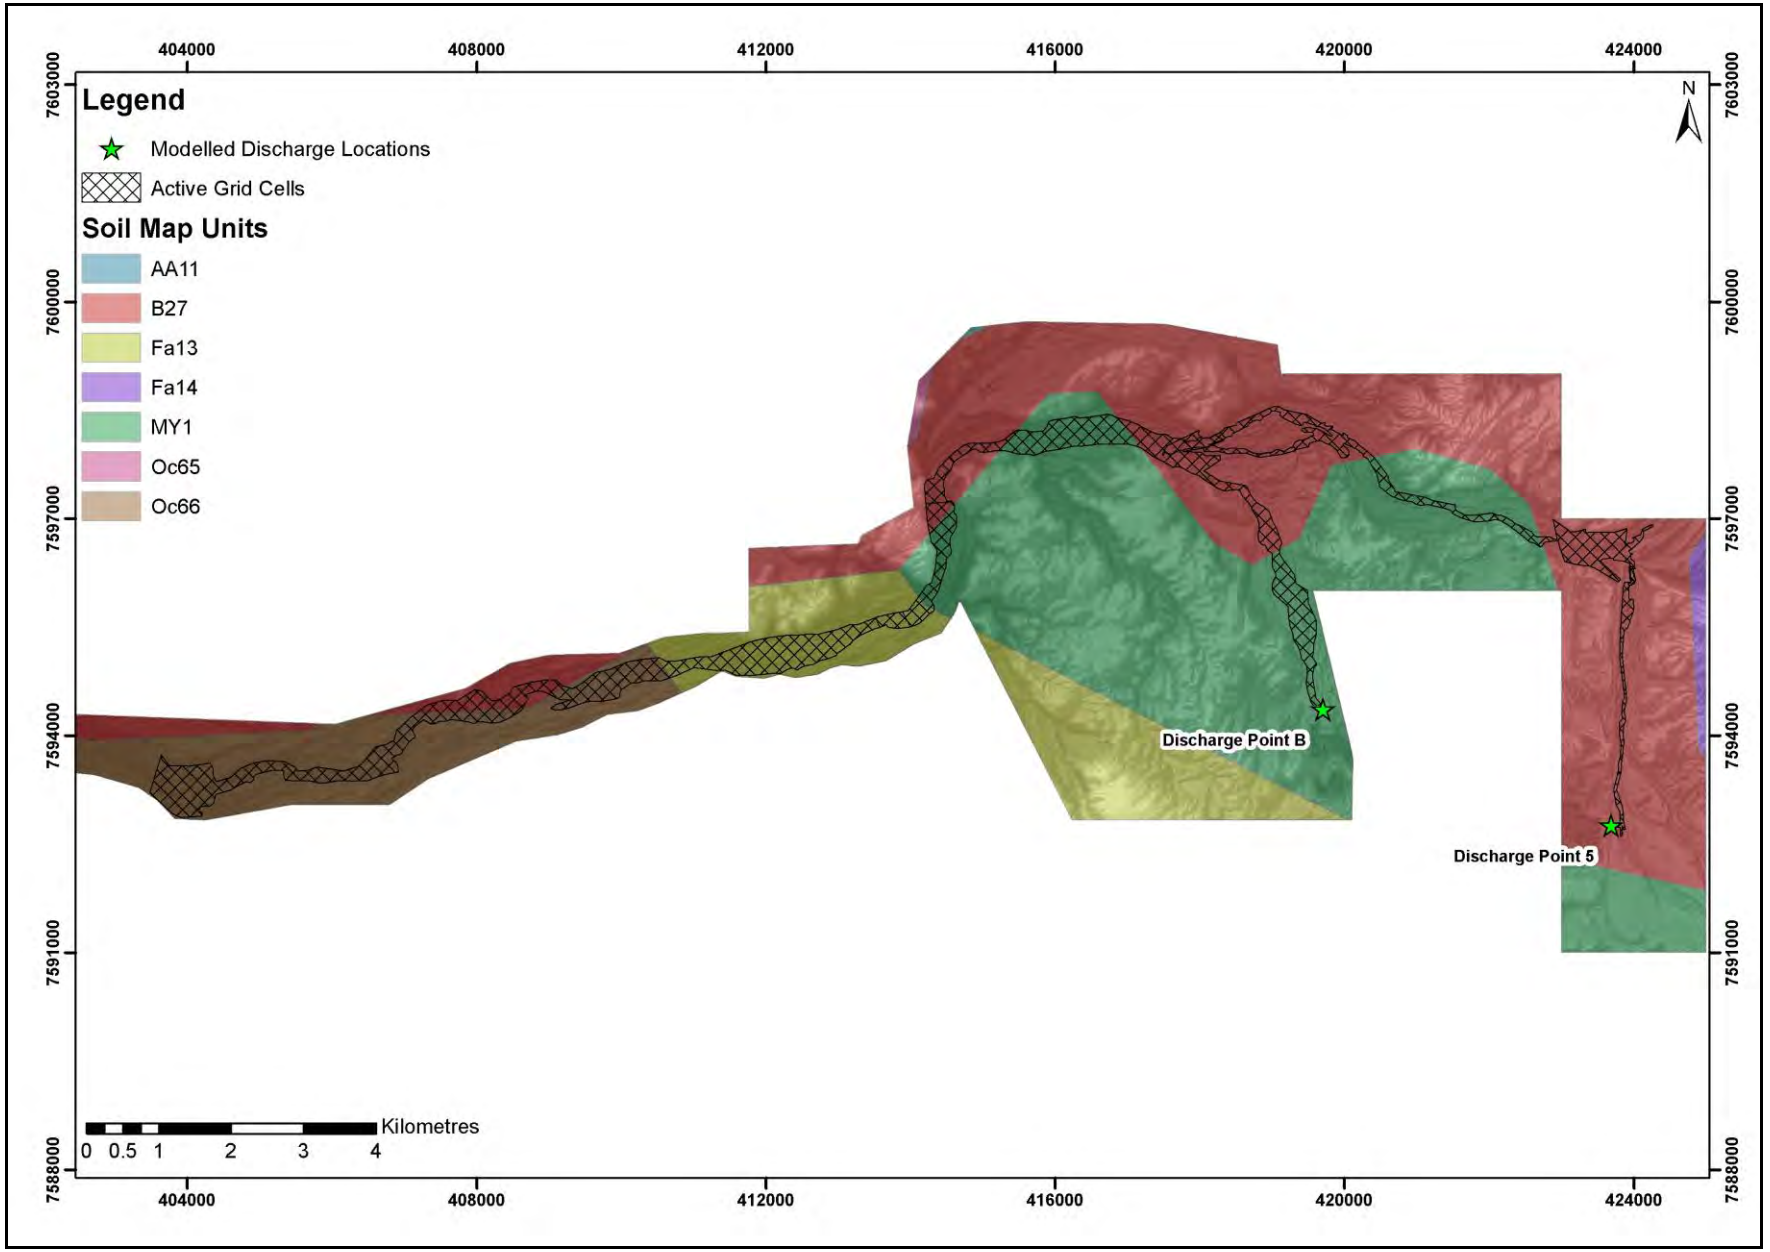

Figure 4: **Soil Map Units intersected by the watercourses downstream of the proposed surplus water discharge locations**

Results

Results for the various discharge modelling scenarios are presented in Table 4 and Figure 5. It is estimated that the surplus water discharge extent will range from 3.5 km to 20 km down gradient of the assumed discharge point depending on the discharge rate and discharge location, before completely infiltrating/evaporating.

Table 4: Estimated discharge extent from discharge location for various discharge rates

Scenario	Distance Travelled (km)	
	Discharge Point 5	Discharge Point B
5 ML/d	3.5	4.7
10 ML/d	5.2	8.8
15 ML/d	5.2	11.8
20 ML/d	5.9	14.4
25 ML/d	9.3	17.2
30 ML/d	11.8	19.9

The braided nature of typical Pilbara watercourses creates a complex hydrodynamic environment where the flow behaviour is essentially 2D in nature. Often braided flows are thought of as a consequence of flooding where flows break out onto poorly defined floodplains. Figure 6 clearly demonstrates that complex bifurcations can also be a characteristic of the low flow regime, and was found in this assessment to be typical in the Robe River, thereby justifying the selection of a 2D hydraulic model.

The surplus water discharge volume would be significantly smaller than the volume generated by the catchment during flood events. Based on model results, discharged water would be contained within the low flow channel/s, hence overtopping of the creek banks in dry conditions is not anticipated.

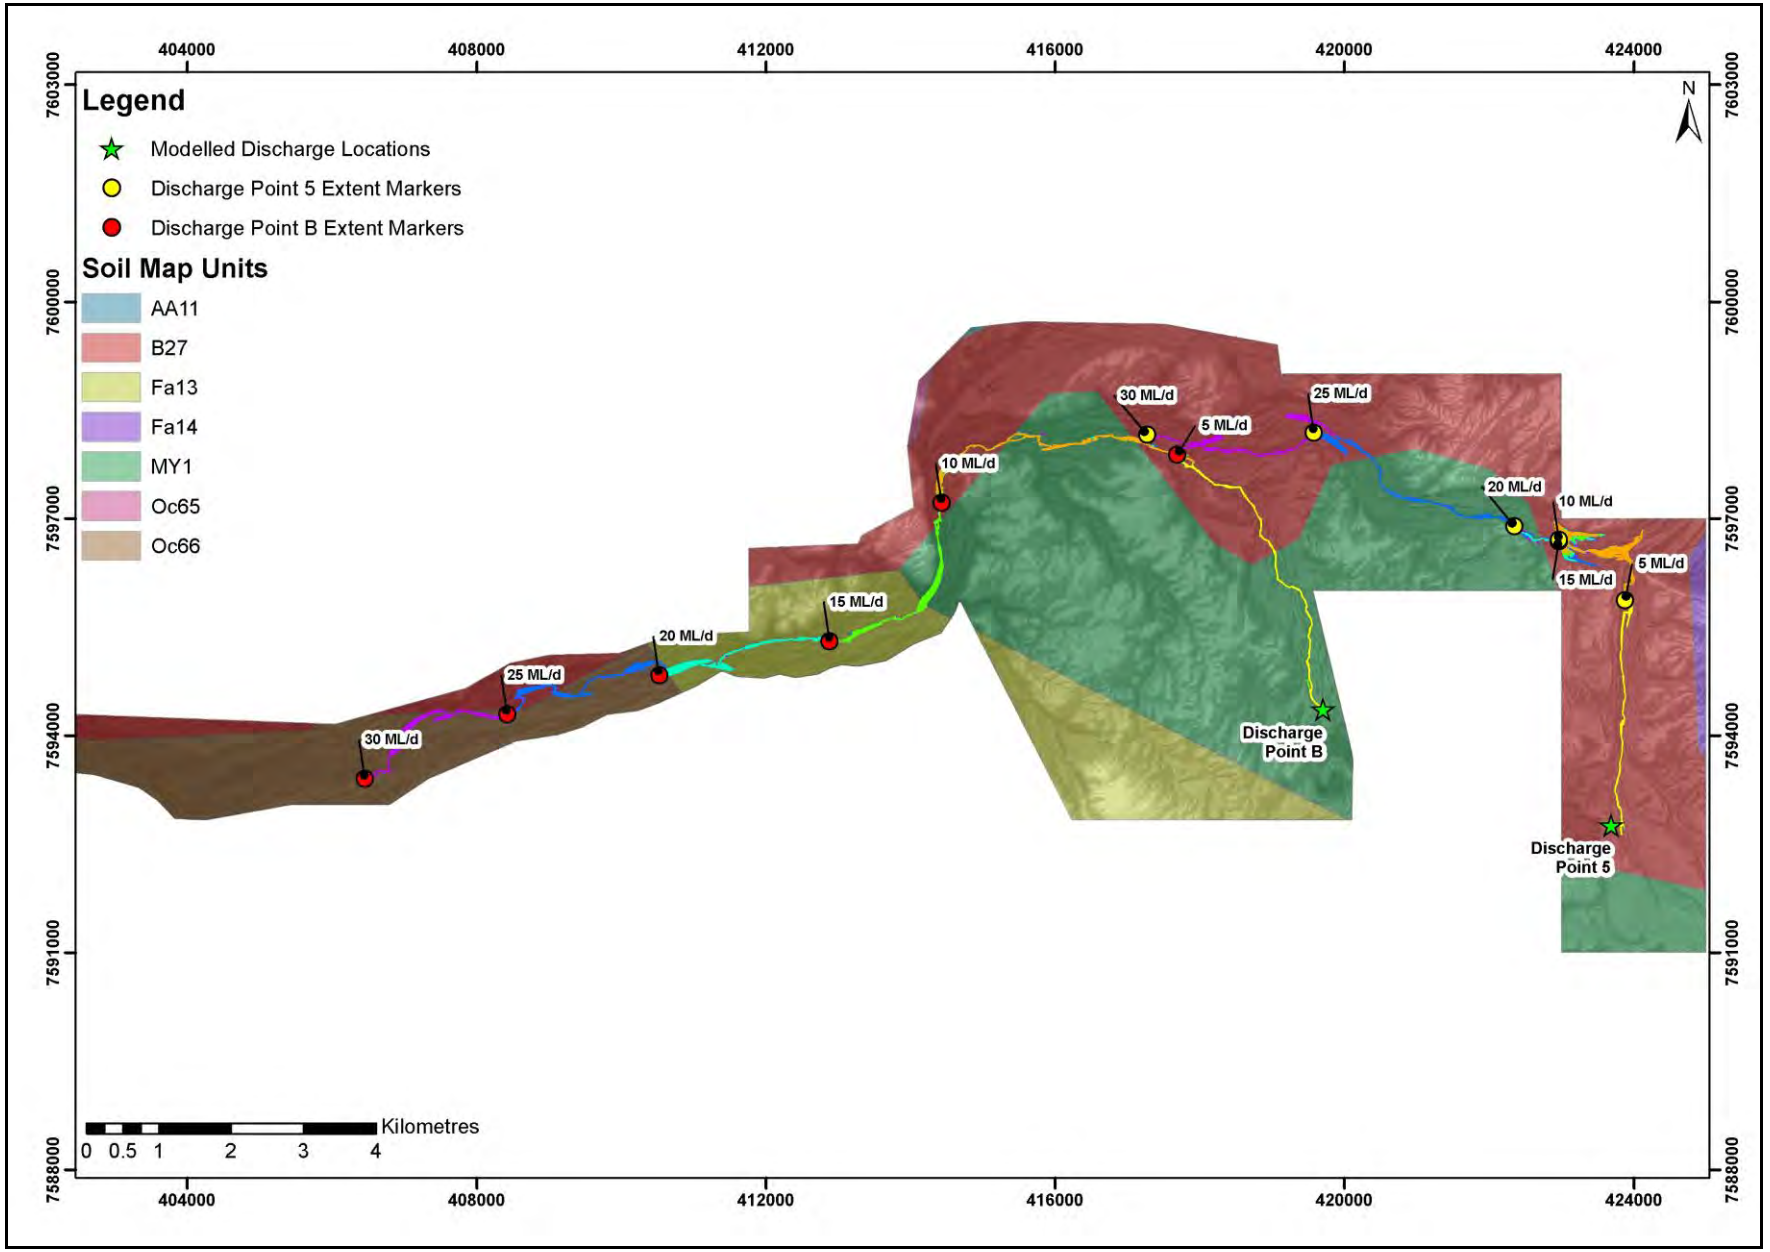

Figure 5: **Modelled maximum discharge extents for various discharge rates**

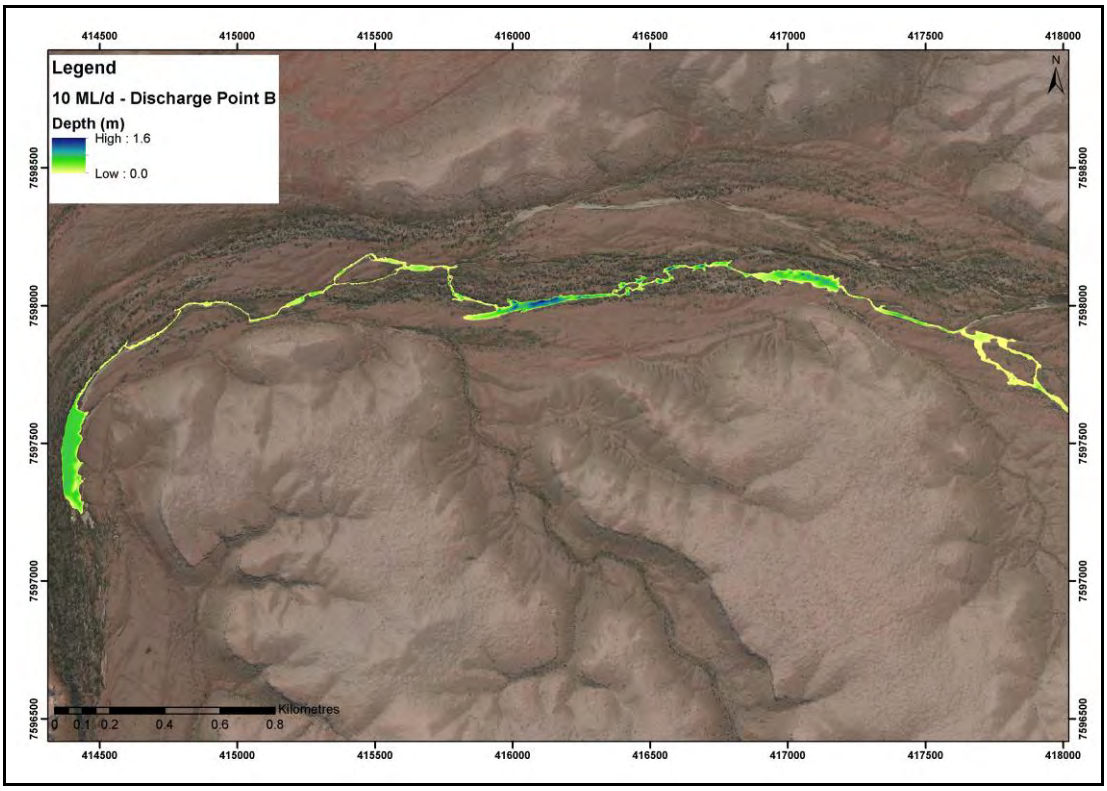

Figure 6: **Complex flow regime of the Robe River modelled in TUFLOW**

Conclusion

A 2D hydraulic model of the Robe River and relevant tributaries has been developed to estimate the extent of future potential surplus water discharge from the proposed Mesa H operations. The key advantage of the approach was the ability to hydraulically simulate the complex hydrodynamic environment while simultaneously accounting for hydrologic processes such as infiltration and evaporation.

The maximum surface water extents from five discharge scenarios were modelled: namely a continuous rate of 5, 10, 15, 20, 25 and 30 ML/day. It is estimated that the surplus water discharge extent will range from 3.5 km to 20 km down gradient of the assumed discharge point depending on the discharge rate and discharge location, before completely infiltrating/evaporating.

The surplus water discharge volume would be significantly smaller than the volume generated by the catchment during flood events. Based on model results, discharged water would be contained within the low flow channel/s, hence overtopping of the creek banks in dry conditions is not anticipated.

Mesa H 2017 AMD Risk Assessment Update Summary

Introduction

A review of the acid and metalliferous drainage (AMD) risk associated with mining in the Mesa H project area has been completed to support the referral of the Mesa H Iron Ore Project Proposal under Section 38 of the *Environmental Protection Act 1986*. This review considers recently available (July 2017) drillhole data and mine planning data.

The overall AMD risk for the Mesa H area remains low following an update to the initial assessment [RTIO, 2016]. This memorandum presents a summary of information as documented in the *AMD Risk Assessment for the Robe Valley* [RTIO, 2017].

Background Information

Rio Tinto has undertaken an extensive program of geochemical testing over several years to understand the potential for acidification and/or metalliferous drainage to occur as a result of exposing various waste rock types common to mining operations in the Pilbara. The geochemical characterisation process aims to assess sulfur content as an indicator of acid generation potential, and to undertake static (acid base accounting) and, if appropriate, kinetic testing of materials. This information is applied to the geological and mining models to ensure materials posing potential geochemical risks are identified prior to mining and managed appropriately. This work is in accordance with the *Rio Tinto Iron Ore (WA) Mineral Waste Management Plan for Undeveloped Resources and Studies* and the *Spontaneous Combustion and Acid Rock Drainage (SCARD) Management Plan*.

The most significant geochemical risk posed by mining iron ore deposits in the Pilbara is associated with the sulfide mineral pyrite (FeS_2), which can form sulfuric acid when exposed to oxygen and water. The unoxidised Mount McRae Shale, most commonly associated with pyrite and AMD, will not be exposed during mining at Mesa H. However, pyrite may also occur in Banded Iron Formation (BIF) of the Marra Mamba Iron Formation (MM), as well as within the Wittenoom Formation (WD), which are known to underlie the channel iron deposit (CID) in the Mesa H area. Other sulfate minerals, such as alunite and jarosite, may also pose a geochemical risk, albeit the risk is usually lower due to self-limiting chemical processes.

Total Sulfur Analysis of Mesa H Drillhole Samples

A sulfur cut-off value of 0.3% is generally relevant to rock types associated with the Robe Valley area (e.g., BIF and detritals). However, for rock types containing black shale, where sulfur is likely to be in the form of pyrite and containing minimal acid neutralising capacity, a sulfur cut-off of 0.1% is applicable. In addition, material associated with elevated-sulfate (where sulfur values may range from 0.1% to greater than 1%) is also considered to be potentially acid forming in a low capacity. Sulfur cut-off values of both 0.1% and 0.3% are considered in this assessment.

The analysis of total sulfur content in drillhole data (covering historical drilling to 2017) was undertaken to identify the rock types which require further investigation relating to AMD risk. The risk is assessed by comparing the occurrence of total sulfur content greater than 0.1% and 0.3% in drillhole samples against the total number of samples which have been assayed for sulfur. This task was completed for all Mesa H project area drillhole samples, as well as those drillhole samples located within the proposed final pit shell. These results are summarised in Table 1, and documented in *Robe Valley AMD Risk Assessment* [RTIO, 2017]. **The risk of acid drainage being generated during operations and upon closure is low for Mesa H.**

In the Mesa H project area, 0.5% of approximately 81,650 drillhole samples have a sulfur content greater than 0.1%. Less than 1% of *waste* drillhole samples have sulfur values greater than 0.1%. If exposed during mining in this area, Wittenoom Formation located below the water table (BWT), which may include black shale, is considered to pose an AMD risk. This is based on the association of pyrite and relatively high sulfur content. However, based on the current final pit shell for the BWT pit, it is unlikely that this rock type will be exposed in significant (if any) volumes.

Table 1: Acid-forming potential risk based on sulfur values of drillhole samples.

Project Area	All waste drillholes		In-pit waste drillholes*		AMD Risk	Comments
	Rel.% with S>0.1%	Rel.% with S>0.3%	Rel.% with S>0.1%	Rel.% with S>0.3%		
Mesa H	0.7%	0.3%	0.3%	0.1%	Low	WD located BWT poses an AMD risk if exposed.

* *mesah_kn_ult_cf01* final pit shell considered (July 2017).

Geochemical Analysis of Mesa H (Robe Valley) Drillhole Samples

Drillhole data from various Robe Valley mining and project areas were combined to assess the geochemical characteristics of rock types that may be exposed in the greater Robe Valley area. When compared to the *average crustal abundance* [Bowen, 1979], most rock types are enriched or elevated in iron, correlating with the iron mineralisation. As with many Hamersley Group deposits, arsenic is enriched in all rock types, while tin is enriched or elevated.

Drillhole data were also contrasted with Ecological Investigation Levels (EILs) and Health Investigation Levels (HILs) provided in the *Contaminated Sites Management Series Assessment Levels for Soil, Sediment and Water* [DEC, 2010], as well as *US EPA Ecological Soil Screening Levels* (Eco-SSLs) [US EPA 2005, 2010]. In general, all Mesa H rock types (CID ore and waste, and basement lithologies) are considered to have higher

levels of Co, Cr, Mn, Pb and V compared to these guideline values. However, it should be noted that these guideline values may not be the most appropriate for Pilbara-specific receptors. Furthermore, material from RTIO mine sites is mostly rock, and not soil, and therefore whilst the EILs, HILs and Eco-SSLs discussed above are useful for screening purposes, they may not be appropriate to use as management triggers.

In summary, the elements **Fe, As, Co, Cr, Cu, Mn, Pb, Se and Zn** have been identified as being enriched in some Robe Valley rock types and should be considered in any source-path-receptor modelling related to potential AMD impacts. However, it should be noted that whilst some elements of potential environmental concern are considered enriched, these elements will not necessarily mobilise into groundwater. For instance, iron oxy-hydroxides such as hematite and magnetite have high sorption capacities for arsenic, and the release of manganese may be limited by solubility controls.

As part of a recent characterisation programme with a focus on elevated-sulfur samples and certain elemental enrichments, 191 samples collected from the greater Robe Valley area have been submitted for acid base accounting (ABA) and geochemical test work. Samples were collected from Mesa J, Mesa A/Warramboo, Mesa B, Mesa F, Mesa H and the Middle Robe areas and represent a range of rock types considered to be analogous across the greater Robe Valley.

A total of 96 (of 191) samples were collected from the Mesa H project area and the adjacent Mesa J mining area. Results are provided in *Robe Valley Geochemical Assessment* [O'Kane, 2016] and sample collar locations relative to drillhole locations at Mesa H are shown in Figure 1.

The 96 Mesa H/Mesa J samples submitted for ABA and geochemical test work comprise a variety of rock types including alluvium/detritals (ALL) waste rock (19 samples), pisolite/CID ore and waste rock (42 samples), Wittenoom Formation (WD) waste rock (32 samples) and Marra Mamba Iron Formation (MM) waste rock (3 samples). The CID samples have been further sub-divided based on ore-type/position within the orebody (i.e., hardcap (HTP), hard pisolite (TPH), mixed pisolite (TPM), clayey pisolite (TPC) and basal pisolite (TPB)).

Sulfur content for the 96 Mesa H/Mesa J samples range from 0.001% to 5.4%, where 23 of those samples have sulfur content greater than 0.1%. Eleven (11) of the 23 elevated-sulfur samples are classified as potentially acid forming (PAF) and represent the WD rock type (10 samples) and MM rock type (one sample). A summary of the total sulfur analysis compiled for all 191 geochemical samples is shown in Figure 2. Relatively higher *average* sulfur values for certain rock types (i.e., WD and MM) are indicative of sampling bias towards elevated-sulfur samples; the average total sulfur content for each rock type based on all Mesa H drillhole data is also shown and is more representative of the calculated *median* values (median values have been considered in this assessment).

A summary of the rock types tested relative to the tonnes of waste material expected during mining at Mesa H is shown in Table 2. The majority of Mesa H waste is expected to represent the TPC, TPM, ALL and HTP rock types, and basement lithologies including WD and MM are not expected to be exposed in significant quantities. **Waste material associated with elevated-sulfur is not expected to be mined in bulk at Mesa H.**

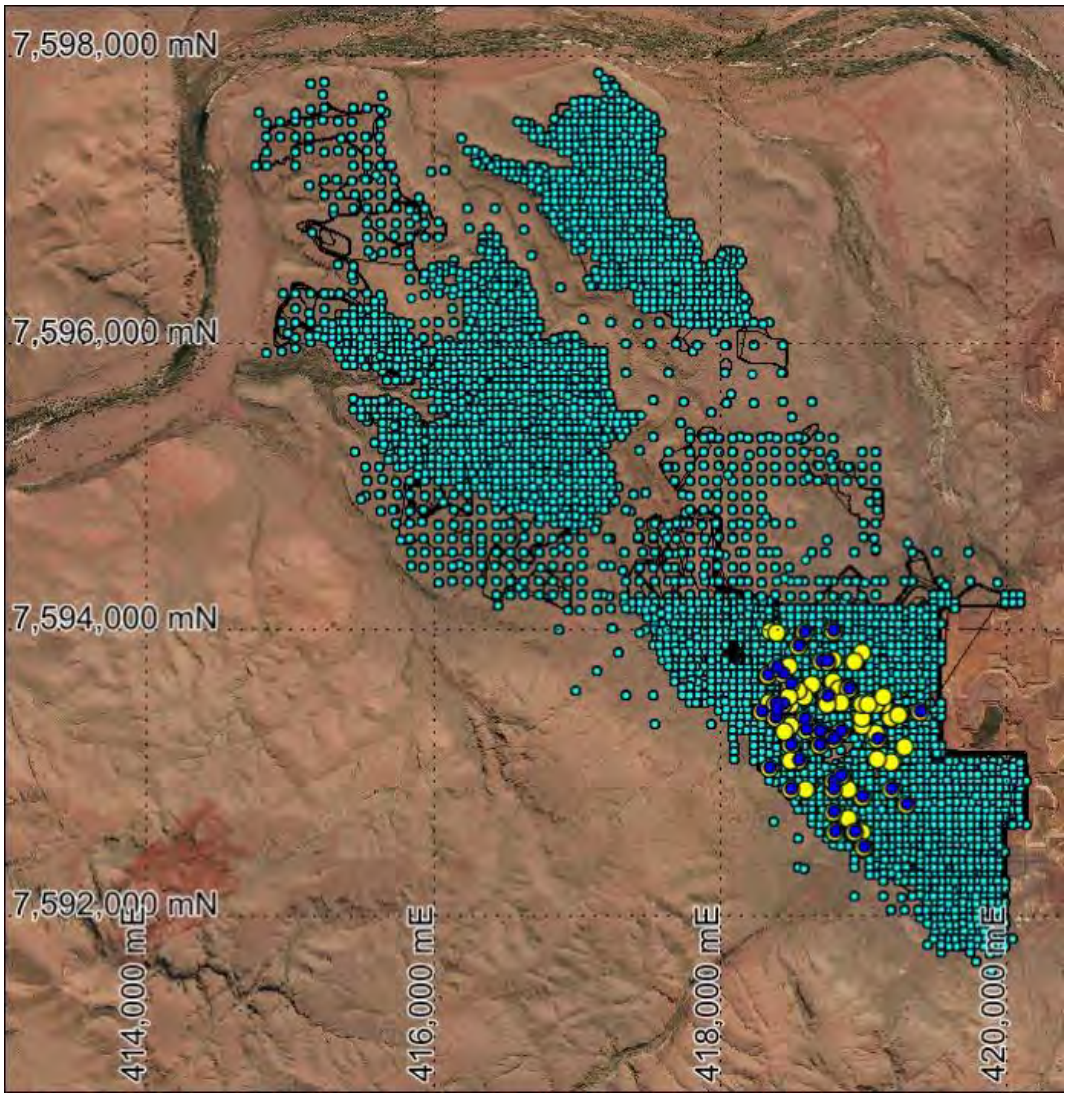

Figure 1: Plan view of Mesa H project area showing proposed final pit shell outline, drillhole locations (blue dots), collar locations of ABA/geochemical samples (yellow dots) and collar locations of samples associated with static leach tests (dark blue dots).

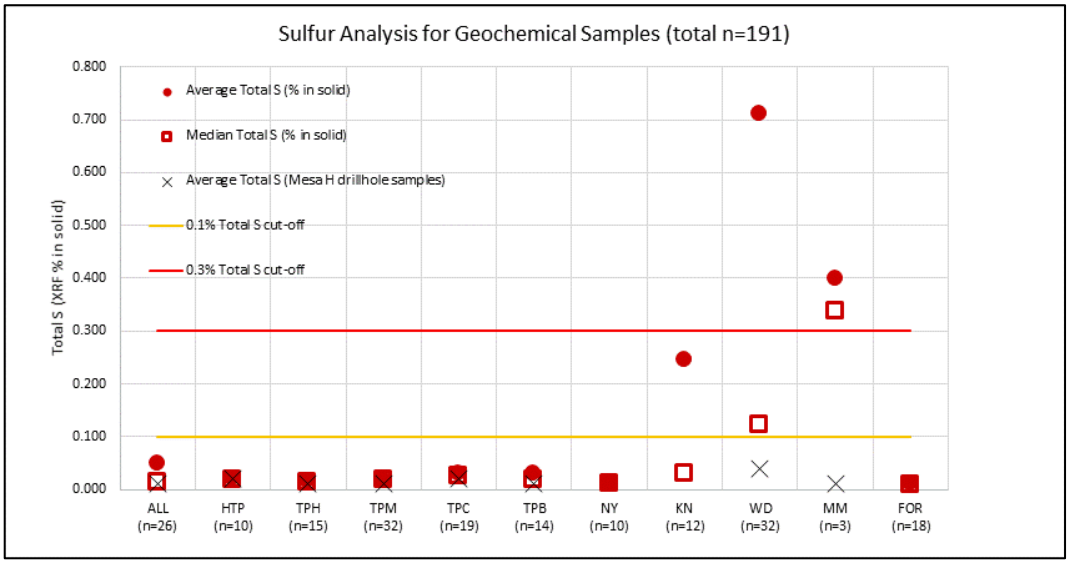

Figure 2: Total sulfur analysis compiled for all 191 geochemical samples, relative to total sulfur analysis of Mesa H drillhole data.

Table 2: Mesa H waste rock types relative to total waste expected to be mined, and number of ABA/geochemical characterisation samples collected from greater Robe Valley area.

Static Leach Test Analysis of Mesa H (Robe Valley) Samples

In addition to the ABA test work described above, static leach tests using deionised water were also carried out on 100 selected samples from the greater Robe Valley area [O'Kane, 2016]. Considering the finding that Fe, As, Co, Cr, Cu, Mn, Pb, Se and Zn may be enriched in Robe Valley rock types, the leach data has been analysed to focus on those parameters in addition to sulfate, nitrate, Al, B, Hg, Mo, Ni and U which also correspond to ANZECC/ARMCANZ [2000] and NHMRC/ARMCANZ [2011] assessment criteria. Results are summarised in Table 3, where the calculated *median* values are considered. As noted previously, sampling was biased toward elevated-sulfur and certain elemental enrichments, and the outlier data influencing higher calculated average values (e.g., for NO_3, Mn and Se) are currently being investigated further.

Table 3: Summary of static leach data relative to ANZECC/ARMCANZ [2000] and NHMRC/ARMCANZ [2011] assessment criteria.*

* the generally more conservative aquatic ecosystem criteria are considered (highlighted in orange), and exceedances (calculated median values) are highlighted in red.

** guideline values have not been adjusted for hardness.

It is important to note that since the physical and chemical conditions of the leach test will not be the same as those expected in the 'as placed' environment (e.g., due to solubility constraints, liquid to solid ratios, etc.), the leachate composition from these tests is not expected to be representative of that which may develop in the field. As such, the results should not be directly extrapolated to predict the actual water quality expected to seep from a waste rock dump, but are useful in providing an indication of the readily leachable elements that may be present. Furthermore, the characterisation programme had a focus on elevated-sulfur samples and certain elemental enrichments, therefore, the observation that several parameters show a greater leach potential is expected under acidic conditions.

The majority of Mesa H waste is expected to represent the TPC, TPM, ALL and HTP rock types, while basement rock including WD and MM are expected to be exposed in minimal quantities. Considering the calculated median values compiled for each rock type, the concentration of most parameters does not exceed the more conservative assessment criteria (typically the ANZECC/ARMCANZ [2000] trigger values applying to 95% protection level for slightly-moderately disturbed ecosystems). Exceptions are for concentrations of aluminum and iron; while the release of aluminum is likely to be limited by solubility controls [SRK, 2017], further work is ongoing to investigate the release of iron, as well as the release of other parameters under different conditions (e.g., multi-step leaching, saline leach solutions, and low-contact liquid to solid ratios [SRK, 2017]).

The analysis of static leach test results are provided in Appendix A.

Geochemical Analysis of Mesa J Tailings Samples

Geochemical test work was also carried out on five Mesa J tailings samples [EGi, 2014]. The samples are classified as non-acid forming and considered enriched in As, Fe and Se, and elevated in Bi, Co, Mn and Sb when compared to the average crustal abundance.

The analysis of tailings liquor show the majority of metals and metalloids are either at low concentrations or below the detection limit. Supplemental static leach tests were also undertaken using deionised water and saline solution, where results indicate relatively higher concentrations of copper and zinc in the saline extractions, which is likely due to a combination of cation exchange which increases their solubility [EGi, 2014]. Relatively lower concentrations of iron are associated with the saline extracts.

In general, the results indicate tailings, as represented by the samples provided, are unlikely to result in low pH conditions or metals leaching under oxidising conditions [EGi, 2014].

Fibrous Minerals

Fibrous minerals present a health hazard if fibres of a (defined) respirable size become airborne and are inhaled. The most common mineral associated with fibrous minerals encountered within the iron formations present in the Robe Valley area is riebeckite. Riebeckite is usually found in fresh (unweathered) BIF. The asbestiform variety of riebeckite is crocidolite, or blue asbestos. The presence of riebeckite does not necessarily pose a fibrous mineral risk but it is a precursor mineral to crocidolite, therefore, there exists a likelihood of encountering crocidolite.

If present, crocidolite seams would primarily occur within the unmineralised Marra Mamba Iron Formation that underlies the CID at Mesa H. In addition, crocidolite may also occur in BIF clasts found within overlying alluvium cover or within the basal pisolite horizon (i.e., TPB).

Crocidolite has not been intersected to-date in any drillholes within the Mesa H project area. However, the underlying Marra Mamba Iron Formation, as well as the TPB horizon in the Mesa H area, are considered to pose a potential fibre risk if exposed.

The *Rio Tinto Iron Ore (WA) Fibrous Minerals Management Plan* describes guidelines for the management of fibrous minerals encountered during mine production, however, based on current drilling and mine planning information, which indicates that basal or basement lithologies can generally be avoided during operations, *potentially hazardous* or *designated hazardous* areas are not expected within the life of mine or upon closure in these areas.

Disclosure

This report (version 6.0) is the amalgamation of the original “H3 Hydrogeological Assessment” report (version 5.0) and the “H3 Update Memo” prepared in June 2018 based on the results of the Feasibility drilling and test programme, revised conceptualisation and updated numerical model. Both reports have been peer reviewed by “Independent Ground Water Consultants” and “RPS” consultant companies, respectively. The purpose of the consolidation of reports is to facilitate third party (EPA, Commonwealth and public) assessment and review of this document, through merging the most recent data analysis, conceptualisation, drilling and test pumping results, numerical model calibration and results and proposed management of groundwater resources in a single report.

Additional historical drillhole assessment was carried out between December 2018 and January 2019 aiming to better define the Jimmawurrada Creek base surface. This additional work was not peer reviewed, although it does not affect the hydrogeological conceptualisation and unlikely will influence the numerical model calibration and prediction, although it was used to support impact prediction of stygofauna habit along the creek.

Executive Summary

Mesa H is a channel iron deposit (CID) located immediately west and adjacent to the existing Mesa J operations, downstream from the confluence of the Robe River and Jimmawurrada Creek. It is anticipated ore extraction will occur over a mine life of approximately 18 years at combined rate with Mesa J of 15 to 20 Mtpa. Approximately 13% (~20 million tons) of the reported iron ore resource occurs below current water table (BWT) and active dewatering will be required to access ore unhindered.

Groundwater abstraction associated with dewatering and water supply has the potential to impact the ecological and heritage sensitive receptors located along the Robe River and Jimmawurrada Creek. These include riparian vegetation and associated groundwater dependant ecosystems located immediately north and west of the Mesa H deposit, and east of Mesa J. Furthermore, two Rights Reserve (KM-RR16 and KM-RR21) sites are located to the northwest and northeast of the Mesa H deposit; noting that one of these sites (KM-RR16) is associated with what is considered a permanent pool.

Based on continuous consultation with the Kumura Marthudunera people (K&M), and concerns related to the potential environmental impact caused by water table drawdown along the Jimmawurrada Creek (riparian vegetation and Blind Cave Eel habitat), Rio Tinto reviewed a number of options to reduce water demand for the Mesa J Hub. The most effective option considered viable is to include a thickener plant in order to increase reclaimed water volumes and reduce cumulative groundwater drawdown along the Jimmawurrada Creek.

Through the use of a non-toxic and non-hazardous high molecular weight anionic polyacrylamide flocculant, the inclusion of a thickener will reduce the groundwater demand by 35% or 50 billion litres (GL) during Life of Mine (LOM). This reduction in groundwater abstraction is predicted to lower the water level along the Jimmawurrada Creek by approximately 9 m immediately to the east of the Southern Cutback Borefield, having comparatively reduced impact on the local riparian vegetation and stygofauna habitat. Otherwise, without the thickener, the drawdown was estimated to be up to ~18 m, estimated to potentially cause severe stress to the local phreatophytic vegetation and locally desaturating a section of the alluvial aquifer known to support stygofauna. The reduction in the water demand and consequent limited impact to the local alluvial aquifer will have reduced impact to riparian vegetation and to stygofauna (including the Blind Cave Eel) habitat and a sustainable continuous volume (of the habitat) will be preserved.

The hydrogeological assessment described herein sets out to describe relevant field investigations, conceptual hydrogeology of the project area, groundwater flow model development and model predictions to inform assessment of impact. Key findings of this study include:

- Groundwater occurs within four main aquifers throughout the project area, specifically:
    - Robe River alluvium
    - Jimmawurrada Creek alluvium
    - Channel-iron deposits (CID)
    - Weathered basement (Marra Mamba Iron Formation and Wittenoom Formation)
- The Tertiary Basal Pisolite sits between the CID and Basement Aquifers and acts as partial barrier to groundwater flow reducing the hydraulic connection between both aquifers.
- Groundwater flow follows the CID palaeo-channel deposit from the Bungaroo valley up-gradient, down to the confluence with the Robe River immediately down-gradient of Mesa H;

- Water table in the Robe River pools are generally lower than the water level in the CID aquifer suggesting that the pools are groundwater dependent in periods of prolonged drought;
- Robe River pools chemical signatures are associated mostly with the Robe River alluvium aquifer with lesser correlation to the other regional aquifers;
- Mesa H dewatering is anticipated to start from 2024/25 with peak groundwater abstraction in 2033 of 7.1 ML/day, with a total of 15 GL to be dewatering during the life of the mine;
- The total groundwater abstraction between 2019 and 2037 from both Mesa H and Mesa J, (based on dewatering and water supply operational requirements, but excluding surface water management, seepage from waste fines storage facility and water reservoir to open pits and decant water recovery), will be approximately 100 GL with a peak of ~8 GL/a;
- Peak water abstraction, including pit dewatering, borefield water supply, direct rainfall management required to meet site water demand / management is 15 GL/a.
- Annual discharge to the environment (Jimmawurrada Creek) will range between 1 – 7 GL/year (excluding major cyclonic events).
- The surplus water discharge footprint is not expected to extend beyond 8 km from the discharge point(s), and remain within the existing Mesa J Operations discharge footprint (on dry conditions).
- Lowering of the water table across Mesa H and Mesa J is not expected to cause significant impacts to the permanent pool (Yeera Bluff) located on the Robe River northwest of Mesa H, however shallow (<0.5m) semi-permanent and seasonal pools may dry out during prolonged periods of drought as a result of natural seasonal variation combined with pit dewatering;
- Given the significance of the semi-permanent and permanent pools in the ecosystem and to the Kuruma Marthudunera People, mitigation strategies have been developed to avoid dewatering impacts to the pools by providing supplementary water directly to the permanent pools; or ceasing below water table mining in Pit 7 (Mesa H) during dry periods;
- A combination of water supply abstraction from the Southern Cutback Borefield, Mesa J dewatering and Coastal Water Supply borefield operation will lower the water table across a 12 km section of the Jimmawurrada Creek, with a maximum predicted drawdown of 9 m across a 6.5km stretch by 2030;
- If natural recharge is reduced by 50% due to an extended dry period (numerical model uncertainty run 2), the drawdown could increase by up to ~3 m, in addition to the natural seasonal fluctuation. This would translate to the water table lowering to 18 m bgl to the east of the Southern Cutback Borefield by 2030.
- Aquifer recovery is modelled to take up to 60 years to fully recover to pre-mining levels within the Mesa H and J areas. However, water levels along the Jimmawurrada Creek and Robe River are expected to mostly recover after the first significant streamflow event caused by a cyclonic event, except the permanent pool near Yeera Bluff, which will take an additional 40 years to recover the last 20cm of drawdown.
- Local and sub-regionally significant groundwater dependent vegetation communities comprising obligate phreatophytic vegetation (i.e *Melaleuca Argentea*) are present and distributed throughout sections of the Robe River, including around semi-permanent and permanent pool areas. Abstraction which leads to the reduction of groundwater levels in the river bed alluvials below the 5 percentile

level for more than 6 months is predicted by DoW (2010) to cause significant decline in resident high risk groundwater dependant ecosystems (GDE's). However, modelling for Mesa H suggests the groundwater level changes predicted are limited (<1m).

- Riparian Vegetation along the Robe River is not expected to be significantly impacted; however, facultative phreatophytic vegetation (*Eucalyptus camaldulensis* and *Eucalyptus victrix*) will likely be impacted along an approximate 12 Km section of Jimmawurrada Creek, with the main impact predicted along a 6.5km section, corresponding to the maximum area of modelled drawdown of 9m (~14mbgl);
- Within the numerical model domain, the habitat of the blind cave eel and other stygofauna in the Jimmawurrada alluvium aquifer will be reduced to approximately 44-52% of the pre-mining volume by 2030 (peak drawdown), assuming the worst case scenario (recharge reduction and maximum seasonal variation); however the central case suggests that approximately 64% of the habitat will be preserved below the water table.
- Impact to the lower Robe River is not expected to occur due to the minimal reduction of the alluvium aquifer throughflow in comparison to the stream flow volumes that recharge the aquifer yearly and proposed contingency actions (water supplementation to the permanent pool or avoidance of mining below the 120mRL in Pit 7 during dry conditions).

Bore completion reports and pumping test results can be found in the Appendix A, the latest groundwater numerical model report in Appendix B, surplus environmental discharge model extent in Appendix C and peer review reports in Appendix D.

Section 1 - Introduction

The Mesa H deposit (the **Project**) is located approximately 110 km southwest of Karratha in the Pilbara region of Western Australia, directly adjacent to the Mesa J iron ore mining operation, and approximately 20 km southwest of the Pannawonica Township (Figure 1). The Mesa J mine is operated by Robe River Mining Company Pty Ltd, as manager and agent for and on behalf of the participants in the Robe River Joint Venture (the **Proponent**).

The Proponent currently draws groundwater at Mesa J to facilitate below water table (**BWT**) mining and satisfy process and potable water demand. This occurs in accordance with the conditions of Groundwater Licences GWL 107678-12, issued under the Rights in Water and Irrigation Act 1914 (RiWI Act) and administered by the Department of Water (**DoW**).

Mesa H is a channel iron deposit (**CID**) deposit that forms part of a sinuous chain of mesas (from A to N) which define the palaeochannel of the Robe River and its associated tributaries. The Project is located downstream from the confluence of the Robe River and Jimmawurrada Creek. The deposit contains high grade and low grade mineralisation, with a combined Mineral Resource of 207 Mt at 54.3% Fe. Approximately 34% of the reported resource occurred below the pre-mining water table, however due to the lowering of the water table caused by dewatering activities relating to the operation of Mesa J, the reported resource at Mesa H is approximately 13% below the present-day water table.

The local hydrogeological regime is defined by the occurrence of four major aquifers: the basement aquifer comprising the weathered Paraburdoo and Bee Gorge Members of the Wittenoom Formation and weathered Marra Mamba BIF, hereafter referred to as the “Wittenoom Aquifer”, overlayed by a sequence of pisolitic sediments, hereafter referred to as the “CID Aquifer”, the “Robe River Alluvium Aquifer” which occurs within the shallow alluvium adjacent to the Robe River and associated tributaries, and the Jimmawurrada Alluvium Aquifer which occurs within the Jimmawurrada creek bed and associated flood plain.

The Robe River regional catchment spans approximately 7,500 km^2. Major watercourses occurring within the catchment include the Robe River and the Jimmawurrada, Bungaroo and Mungarathoona Creek’s. The major water courses generally flow from the southeast to the northwest through high relief areas of the Hamersley Ranges on to the more gently sloping areas of the coastal plain before discharging into the ocean approximately 150 km south of Dampier.

Surface water runoff in the project area is typical of the Pilbara, generally only occurring following significant or long duration rainfall events. The Robe River is an ephemeral river, which carries a significant underflow in its alluvial bed. This sub-surface flow maintains permanent, and at some extent, semi-permanents pools in the river channel, and these pools play an important role in the river ecosystem, supporting a diverse range of aquatic fauna and acting as refuges during periods of drought.

The Bungaroo creek joins the Jimmawurrada creek in lower Bungaroo. The Jimmawurrada Creek catchment has an area of about 470km^2, but the upstream valley is a lot narrower than Bungaroo Creek; however the flood plain is wider in lower Bungaroo upstream of Bungaroo-Jimmawurrada creek confluence. The Jimmawurrada Creek is an ephemeral river, which carries limited underflow in its alluvial bed.

Section 2 - Climate and Rainfall

Rainfall in the Pilbara is highly variable, temporally and spatially, predominantly occurring in summer (Figure 2), with major events typically associated with tropical cyclones, low pressure systems and convective thunderstorms. However, the Robe Valley can also receive winter (June through August) rainfall from frontal systems that cross the southwest land division and extend to the southern Pilbara and rain-bearing northwest cloud bands.

Climatic conditions experienced within the vicinity of Mesa H and the Robe Valley more broadly, are categorised on the basis of the Köppen classification scheme (BoM, 2006), as grassland: hot (summer drought). Details of the four long-term rainfall stations operational in the Robe Valley are summarised in Table 1. The long-term mean annual rainfall for the Mesa H project is 342 mm; however, this is highly variable, historically ranging between 54 mm and 736 mm (BOM, 2009).

The mean annual pan evaporation is 3,400 mm (BOM, 2008) which greatly exceeds the mean annual rainfall, highlighting the water limited environment. This is particularly relevant given the presence of permanent water bodies proximal to Mesa H.

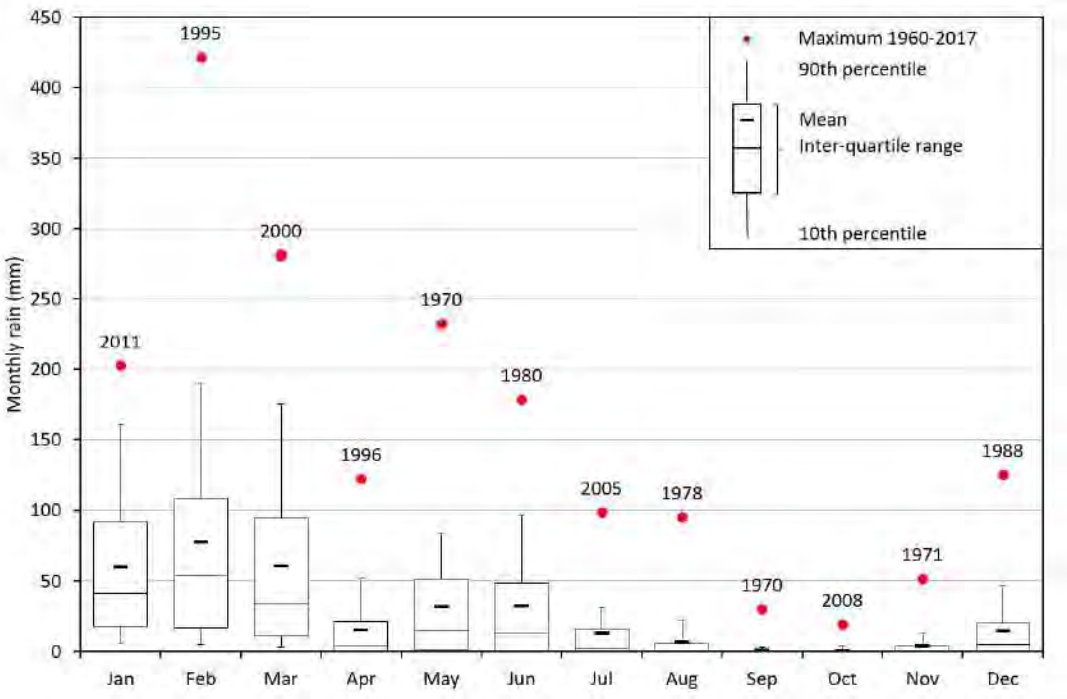

Figure 2: Mesa H monthly rainfall distribution (derived from BoM, 2009)

Table 1: Current operating, long term daily rainfall stations in the Robe River catchment

Number	Name	Location	Record Period	Data Recorded
005032	Yarraloola	383,897 mE 7,614,316 mN	1899-present	94%
005022	Red Hill	403,499 mE 7,569,646 mN	1898-present	92%
005029	Yalleen	437,182 mE 7,602,834 mN	1930-present	53%
005069	Pannawonica	430,750 mE 7,606,959 mN	1971-present	80%

While the Yarraloola station has a long rainfall record period and 94% of the data is available, gaps in the data record occurred in the most recent period (1999-present). To provide a complete and representative rainfall dataset for the Project, the BoM's long-term daily gridded rainfall data has been adopted (BOM, 2009). The annual gridded rainfall series is shown in Figure 3. On average, the Mesa H deposit experiences 36 rain days per year, with daily rainfall totals larger than 50 mm being uncommon.

The total catchment area contributing flow to the Robe River in the Mesa H project area is approximately 34 km^2 (Figure 4). The Jimmawurrada catchment area is approximately 470 Km^2 , however flows from the Bungaroo catchment (800 km2) merge to the Jimmawurrada Creek as presented in Figure 5 and discharge in the Robe River immediately northeast of Mesa J.

Geospatial Information and Mapping

There are two stream gauge stations located up gradient (Ngalooin Pool, Site Ref 707004) and down gradient (Yarraloola, Site ref 707002) from Mesa H deposit, approximately 34 Km and 36 Km respectively. The Ngalooin Pool records from 1976 and 1999 shows that the average annual flow through the Robe River was 42 GL, meanwhile the Yarraloola records indicate over the period from 1974 to 2016, that the mean annual flow through Robe River was 119 GL. Figure 6 shows the annual total recorded flows.

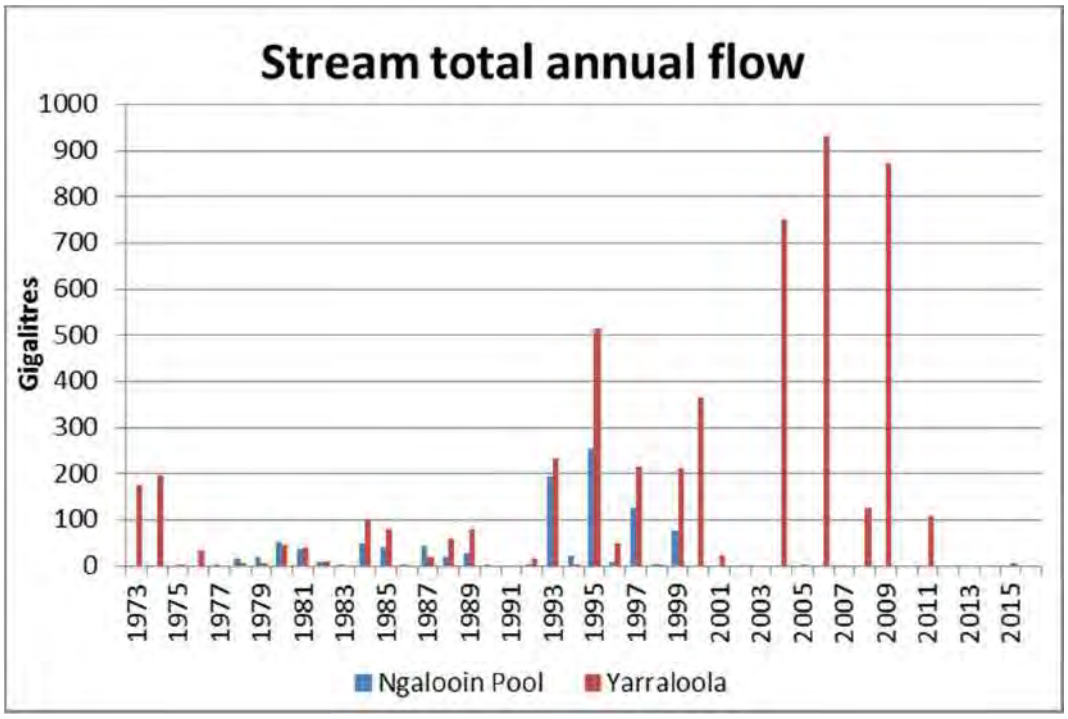

Figure 6: Stream gauging stations annual total flows

Section 3 - Hydrogeology

Groundwater within the Pilbara region originates from direct infiltration of rainfall and indirectly from surface water flows. The occurrence of groundwater within the project area is predominantly associated with primary porosity of the creek alluvials where saturated, primary porosity of the CID with secondary weathering induced permeability and with secondary permeability and porosity developed as a result of weathering in the Marra Mamba and Wittenoom Formation.

The conceptual hydrogeological model presented in subsequent sections of this report provides more detail on the overall hydrogeology and specifically on the key hydrogeological features that will determine dewatering and water supply requirements and the potential impacts of groundwater abstraction on local and regional water resources and environments that depend on groundwater.

The conceptual hydrogeological model is based on the integration of all available information, including background information from previous investigations, ongoing monitoring at Mesa J and information generated by the specific investigations described in Section 5. The conceptual hydrogeological model represents a simplified understanding of the natural behaviour and dynamics of the aquifer systems and provides the technical foundation for the detailed numerical modelling process described in Section 8.

3.1 Hydrostratigraphic units

Groundwater flow occurs from the southeast to northwest along the Jimmawurrada catchment. A series of cross-sections through the project are presented in Figure 7 to Figure 11. Pre-mining depth to groundwater is generally between 25 and 45 mbgl (Figure 12 and Figure 14). Groundwater occurs predominantly within four key aquifers:

- Wittenoom Aquifer: consisting of *weathered* dolomite and dolomitic shale (Paraburdoo and Bee Gorge Member) and *weathered* BIF (Marra Mamba Iron Formation.) with approximately 25 m thickness;
- CID Aquifer: consisting of channel iron deposit pisolitic sediments with an average of 20-30 m thickness below the pre-mining water table;
- Robe River Alluvium Aquifer: consisting of Quaternary alluvial sediments deposited along the Robe River with an approximate 20 m thickness and average width of 400 m.
- Jimmawurrada Creek Alluvium Aquifer: consisting of Quaternary alluvial sediments deposited along the Jimmawurrada Creek and associated flood plain with a maximum observed thickness of 40 m thickness along the thalweg.

The basal Robe Pisolite (TPB) is a 5 to 10 m thick layer deposited at the base of the CID Aquifer, consisting of a variable clay-rich pisolite. Hydraulic properties have not been defined, however, due to the largely impermeable physical characteristics of the unit; it is expected to function as a partial

barrier to horizontal groundwater flow between the CID Aquifer and the underlying Wittenoom Aquifer.

The Wittenoom Aquifer and the CID Aquifer are bounded by the unmineralised fresh Marra Mamba Iron Formation in the east and the Brockman Iron Formation in the west. The CID Aquifer is bound to the north by the Robe River, and although the Wittenoom Aquifer continuity to the north of the Robe River was confirmed (through drilling of 3 production bores and 6 monitoring bores), he groundwater flow direction from the north has an southern direction towards the Robe River, therefore the CID and basement flow from Mesa J and H discharges in the Robe River

Although the water level between the CID and the basement formation is broadly the same, pumping test data carried out in bores slotted against the each unit shows a much higher drawdown in the basement than in the CID, suggesting the confinement of the weathered Wittenoom and Marra Mambas Formations in areas of limited vertical extension.

Table 2 summarises characteristics of the 4 key hydrostratigraphic units identified in the study area.

Table 2: Summary of local key hydrogeological characteristics

Unit	Aquifer Type	Formation Name	General Lithology	Hydraulic Characteristics
Robe River Alluvium	unconfined, sedimentary, vertical isotropy, regional	Quaternary alluvium	Shingles, conglomerates and coarse sand	heterogeneous, high permeability, high storage, horizontally and vertically limited
Jimmawurrada Alluvium	unconfined, sedimentary, vertical anisotropy, local	Quaternary alluvium	Conglomerates coarse to fine sand and silt / clay in the base	heterogeneous, high permeability, high storage, horizontally and vertically limited
Channel Iron Deposit	unconfined, sedimentary, vertical anisotropy, local	Robe Pisolite	clay-rich basal layer, pisolite ore, and hard-capped pisolite	heterogeneous, high and low permeability, horizontally limited
Basement	confined, weathered, fractured, anisotropic, regional	Wittenoom Formation and Marra Mamba Iron Formation	Dolomite, shale and BIF	highly heterogeneous, permeability domains associated with faults and fracturing, permeability decreases with depth

3.2 Groundwater levels

Contours reflecting the regional water table are presented in Figure 13. The regional groundwater level prior to mining activity at Mesa J ranged between 150 mAHD to the south declining to about 120 mAHD at the confluence of Robe River in the northwest, under a relatively low hydraulic gradient of 0.003.

The groundwater level has been altered significantly by pit dewatering and water supply at Mesa J, with groundwater levels declining by between 4 and 20 metres since 1995, extending approximately 3 Km laterally, especially towards west. Present day groundwater levels contours are presented in Figure 12. Figure 14 shows the hydrograph of two monitoring bores installed at Mesa H approximately 400 m west of Pit 11 (Mesa J) highlighting a decline in groundwater level of 20 meters between 1995 and 2015.

Depth to water in the Robe River ranges between 2 and 5 mbgl, whilst along the Jimmawurrada Creek between 4 and 12 metres.

3.3 Recharge and throughflow

Recharge to the Wittenoom and CID Aquifers occurs as a result of multiple inputs, specifically:

- Recharge from rainfall has been estimated at **20 ML/year** over a 50 km^2 model domain, which equates to 3.5 mm or 1.1% of annual rainfall. This is determined on the basis of chloride concentrations in groundwater whereby:

$$Rainfall\ recharge\ (mm) = \frac{Rainfall^{Cl} \times Ave.Rainfall}{Groundwater^{Cl}}$$

$$Rainfall\ recharge\ (mm) = \frac{0.65\ mg/L \times 340mm}{64\ mg/L}$$

- Leakage from the waste fines storage facility (WSFS) at Mesa J and the water reservoirs (Lake Phil and / or Dan's Dam) is estimated to be approximately **0.5 GL/year**. Calculated as the area of the WFSF / water reservoir (430,000 m^2) adopting a vertical conductivity of 3 m/day.

Aquifer recharge resulting from leakage of the WFSF and water reservoirs appear to play an important role in limiting the extent of the dewatering cone of depression from mine dewatering to the north towards the Robe River, based on several observations:

- Monitoring of the Robe River ecosystem indicates no measurable ecological impact from more than twenty years of dewatering (RTIO-HSE-0211538);
- Dewatering drawdown has expanded towards the west of the deposit rather than down gradient (where the WFSFs are located) with the long-term monitoring indicating less than 20 metres of drawdown at Mesa H.

Throughflow is estimated across a 3500 m section of the valley south of Mesa H / J using a saturated profile of 60 m and 7 m/day horizontal hydraulic conductivity with a gradient of 0.004; the throughflow is estimated as 1.6 GL/year. This is consistent with findings of a previous study in the Bungaroo valley, up gradient from Mesa H, which indicated groundwater throughflow of between 1.8 and 3.8 GL/year (RTIO-PDE-0081114).

3.4 Groundwater discharge

Pan evaporation in the local catchment is estimated at 3400 mm/year. Evapotranspiration in within the project area is considered to occur in two primary systems, specifically:

- Evaporation from the water reservoirs and WFSFs: estimated to be in the order of **1.4 GL/year**;
- Evaporation from Mesa J trenches and in-pit sumps: estimated to be in the order of **0.2 GL/year**.

Groundwater discharge occurs via:

- The fractured bedrock: however it is unclear if this discharge follows the shallow aquifer flow direction to the west along the Robe River alluvium aquifer, or if it flows underneath the Robe River to the north continuing through the basement, the throughflow has been estimated at **1.4 GL/year** (10 km x 25 m x 5 m/day x 0.003).
- The CID Aquifer discharge to the Robe River with an estimated throughflow of **0.2 GL/year** (10 Km x 10 m x 2 m/day x 0.003);

Annual groundwater abstraction at Mesa J from sump-pumping and water supply bores is approximately **7 GL**. Discharge of surplus water to the environment is between 1.5 and 3 GL/year with most of the discharge occurring in Jimmawurrada Creek, east of Mesa J, reaching the Robe River downstream and partially recharging the alluvial aquifer, however this is considered to be a low volume in relation to the storage volume in the Robe River alluvium.

Natural evapotranspiration in the Mesa H / J was considered negligible due to depth to water greater than 20 m.

3.5 Water Balance

To meet water demand for process plant water supply, Mesa J has also harvested surface run-off from the Mesa H central catchment drainage, which runs in a north-easterly direction, into Pit 11 at Mesa J which couldn't be estimated due to lack of appropriate data.

A summary of the current estimated water balance in-flows and out-flows, excluding the Robe River and Jimmawurrada Creek flows, is presented in Table 3.

Table 3: Water Balance summary

Inflow	ML/year	Outflow	ML/year
Throughflow	1600	Throughflow	1600
Rainfall recharge	20	Evaporation	1600
Seepage	500	Abstraction (Environmental Discharge)	7000 (3000)
Loss of storage (drawdown)*	8080		
Total	**10020**	**Total**	**10020**

**value likely overestimated due to inability to precisely calculate seepage*

3.6 Robe River Hydraulics

A major alluvial aquifer underlies the lower Robe River. It consist of gravels beds with a saturated thickness of up to 25 m adjacent to the river; gradually reducing in thickness laterally from the river and downstream locally creating surface expressions of groundwater. Underlying this is the CID consisting of pisolitic sediments of Tertiary age over the Hamersley Group basement, comprising the Marra Mamba Iron Formation or Wittenoom Formation represented largely by the Paraburdoo Member.

There is potentially a strong hydraulic correlation between the Robe River alluvium and the underlying aquifer, the direction of interaction changes seasonally in response to stream flow events and evapotranspiration. Streamflow events also recharge groundwater, causing the groundwater level to rise creating large and continuous pools. After a period of no flow the hydraulic gradient between the groundwater and the pools reverse and groundwater discharges into the pools. Ephemeral pools will eventually become disconnected from intermittent pools and as surface water evaporates these pools reduce in size or disappear.

Drought conditions and declining groundwater levels result in shallower pool depths and semi-permanent pools becoming disconnected from the groundwater. Permanent pools have long-term connectivity to the groundwater and are expected to be maintained by groundwater discharge during drought periods (Department of Water, 2010). Figure 15 shows a conceptual cross-section of the interdependency between ephemeral, semi-permanent and permanent pools and surface water / groundwater interaction.

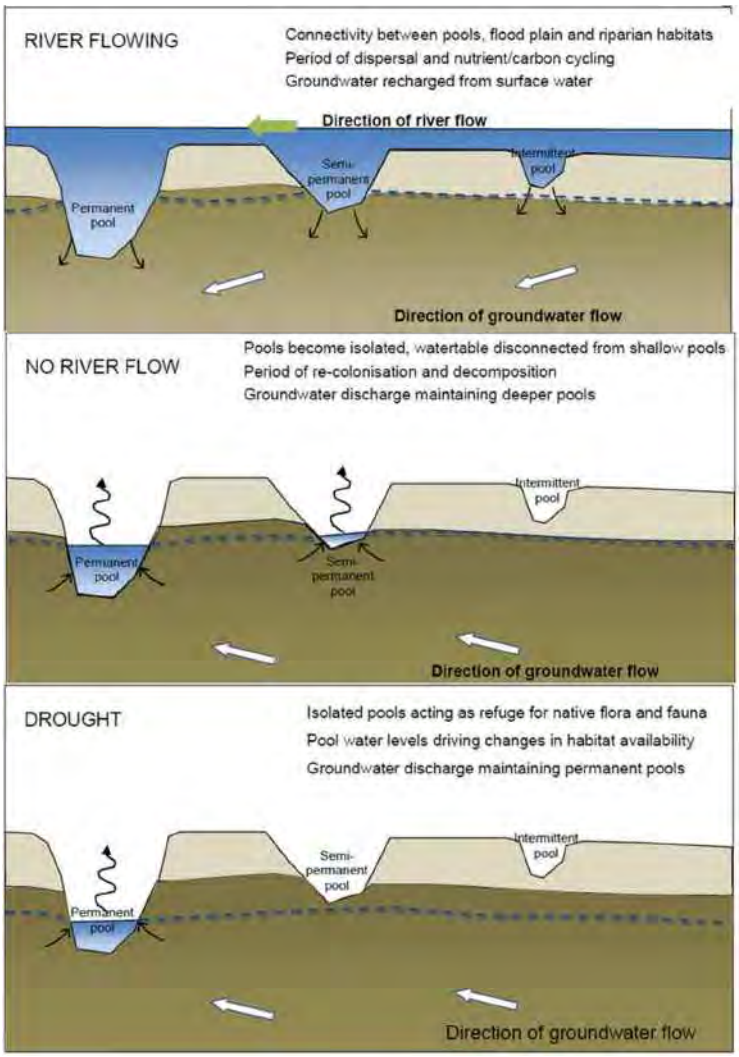

Figure 15: Conceptual diagram of a longitudinal cross-section of the Robe River during seasonal climate changes (Department of Water, 2010)

Depth to groundwater along the Robe River channel is shallow (2 – 5 mbgl) and has the potential to fluctuate up to 3 m annually in response to high rates of recharge and evapotranspiration (Department of Water, 2012). Aquifer recharge occurs through river recharge and rainfall via infiltration through the alluvial riverbed. Due to the high effective porosity of the aquifer it has the potential to absorb a significant volume of the river flow. The recharge volume is controlled by the frequency, size and duration of flow events, as well as the available storage of the aquifer, i.e. antecedent water levels. Average stream flow is estimated to be in the order of 50 GL/year in the section of the Robe River north of Mesa H.

Pre-mining groundwater throughflow is estimated across a 400 m section using a saturated profile of 20 m and 100 m/day hydraulic conductivity (RTIO-PDE-0143871) with a gradient of 0.0028; the throughflow is estimated as 820 ML/year. Due to the continuous mine surplus water discharge into the Jimmawurrada Creek, the groundwater throughflow has been potentially increased locally due to this extra recharge (~2 GL/year) up gradient. This discharge makes it difficult to understand the chemical signature of the down gradient pools along the river through surface and groundwater chemical analysis (RTIO-PDE-0144245).

The Robe River is dry for most of the time with large flows usually associated with cyclonic activity or rain bearing depressions bringing high intensity rainfall. After the recession of surface flow and extended periods without recharge, the Robe River is reduced to a series of isolated pools which, as suggested by available water chemistry and isotope data, are sustained by groundwater and as such, are a surface expression of the alluvium aquifer (RTIO-PDE-0149324). When a rainfall event occurs, the underlying alluvium aquifer is recharged causing the water table to rise and groundwater daylights through local depressions as pools. These pools may last for considerable periods, however, extended dry periods will lower the water table resulting in shallower pools or drying up altogether.

As the pools are located within the channel it is likely that any river flow event will result in recovery of the pool water levels (Charles et al., 2015). Therefore, the frequency of full water level recovery of the pools will be defined by the frequency of streamflows (Charles et al., 2015). Furthermore, the position of the pools tends to change following seasonal flood events. It therefore follows that the regime of the pools is dictated by both the surface water and groundwater regimes, and their interactions. However, as reported by Dobbs and Davies (2011), the greatest influence on pool morphology, water chemistry and the resulting aquatic fauna is rainfall and river flows.

These Robe River pools play an important role in the river ecosystem, by supporting a diverse range of aquatic fauna and acting as refuges during periods of drought (RTIO, 2011). This has been acknowledged in this study with the installation of 9 monitoring sites specifically targeted at pool locations (Figure 16). The aim of this monitoring programme is to assist in understanding the baseline hydrologic conditions of the region and will form an integral part of an adaptive management strategy for the pools during operations.

Initial results of the monitoring for two selected sites are presented in Figure 17, which shows the response of the respective pools after a 50 mm rainfall event on 29/30 January 2016. The record

at both locations indicates water level recovery in response to the rainfall/flow event. The water level at Medawandy (located ~10km northeast of Mesa J) is shown to decline at a uniform rate after the event, whereas at Yeera Bluff, the water level remains relatively constant, which is likely owing to the potential impermeable underlying geology at Yeera Bluff.

Geospatial Information and Mapping

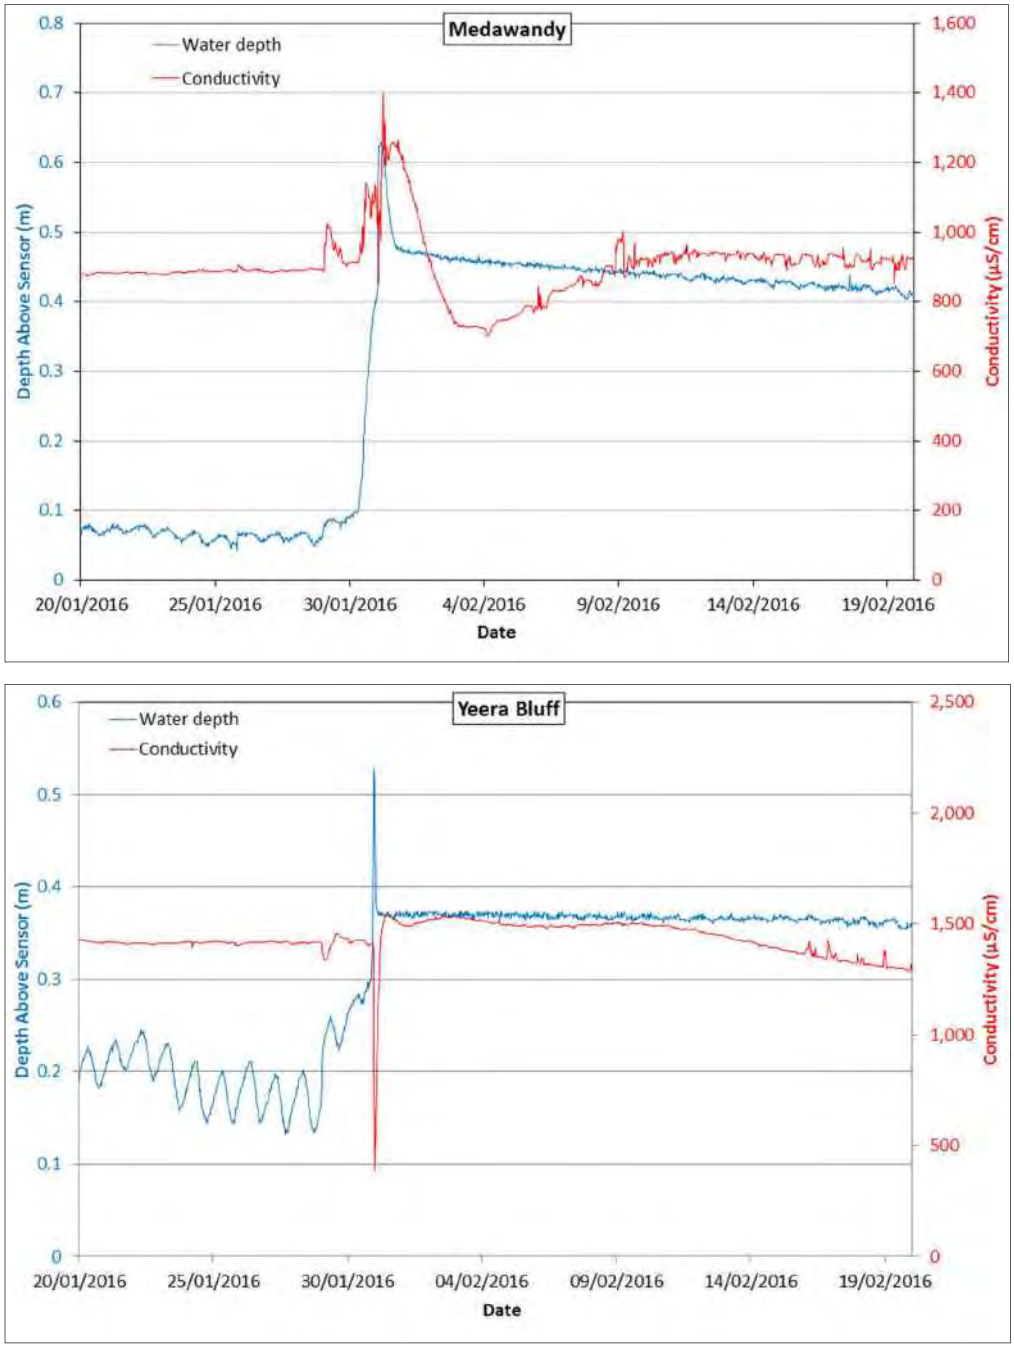

Figure 17: Observed response at SW16MESH003 (Medawandy) and SW16MESH001 (Yeera Bluff) to January 2016 rainfall event

A typical conductivity response to the January 2016 rainfall event is evident at Medawandy, with an initial spike in conductivity as the accumulated salts in the riverbed are flushed through pool, followed by a freshening up of the water before returning to approximately the pre-event conductivity levels (Figure 17). In contrast, the conductivity recorded at Yeera Bluff declines quickly initially and then increases to moderately above pre-event conductivity levels. This may be indicative of a flush of fresh water entering the pool directly from the catchment to the north of the pool, which in turn blunts the subsequent spike that would have resulted from the flow coming down

the Robe River. The declining conductivity (freshening of the water) that occurs approximately 2 weeks after the event at Yeera Bluff may be the delayed response of subsurface flow from the same event. That this response is not evident at Medawandy may be indicative of contributions from Jimmawurrada Creek.

A further observation from Figure 17 is the difference in conductivity between Medawandy and Yeera Bluff. These findings are consistent with long-term monitoring conducted by Dobbs and Davies (2009) who analysed a 17 year Robe River pools dataset and identified a salinity gradient from upstream to downstream, with salinities increasing along the length of the river. Notwithstanding this salinity gradient, the water in these pools is categorised as fresh (Dobbs and Davies, 2009).

At Yeera Bluff the effects of the relatively dry period since 2000/2001 is reflected in Figure 18, which shows relatively stable conductivity trends during periods of regular flow, but increasing conductivity trends during extended dry periods resulting from the evapo-concentration of salts in the pool. This provides valuable information regarding the water quality response of this pool to a lowering water table, whether by extended dry periods or artificial drawdown.

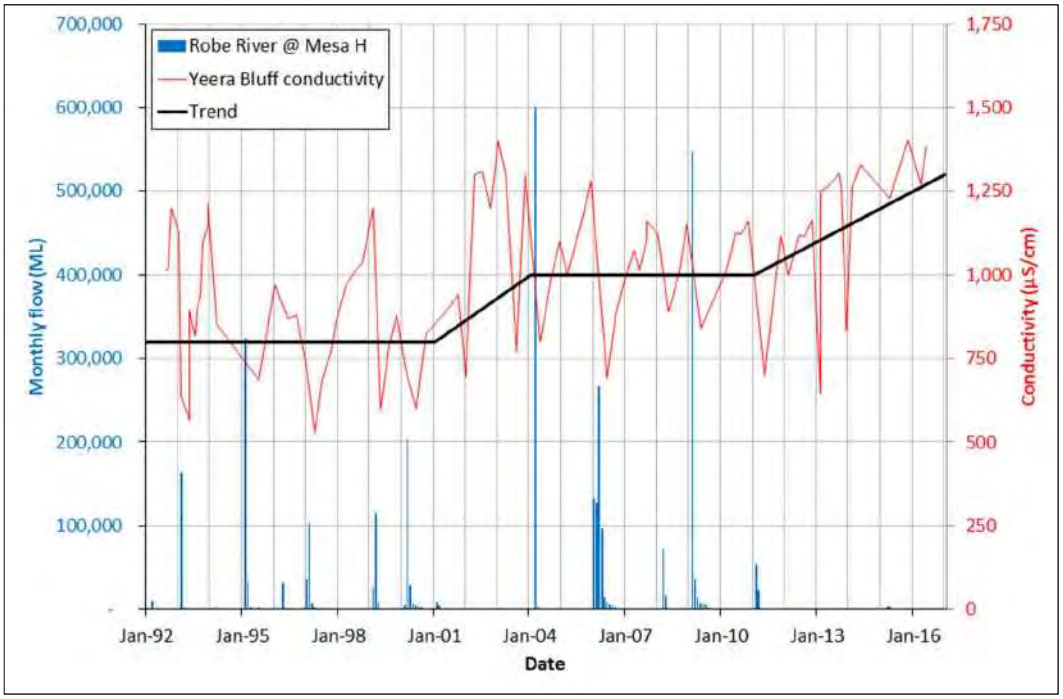

Figure 18: Long-term conductivity measurements at Yeera Bluff vs flow at Mesa H

Figure 19 shows the relative water level between bores slotted in the Wittenoom, CID and Robe River alluvium aquifers in relation to the water level in the pools (as per October 2016). Groundwater level from the aquifers is higher than the water level in the pools suggesting the groundwater gaining characteristics of the pools. The bore located north of the Robe River and slotted against the basement (Wittenoom Formation) indicates a water level lower than the pool and overlying aquifer, hence suggesting the groundwater in the basement flows from south to north

perpendicular to the Robe River, and has possibly very little (or no) contribution to the Robe River pools.

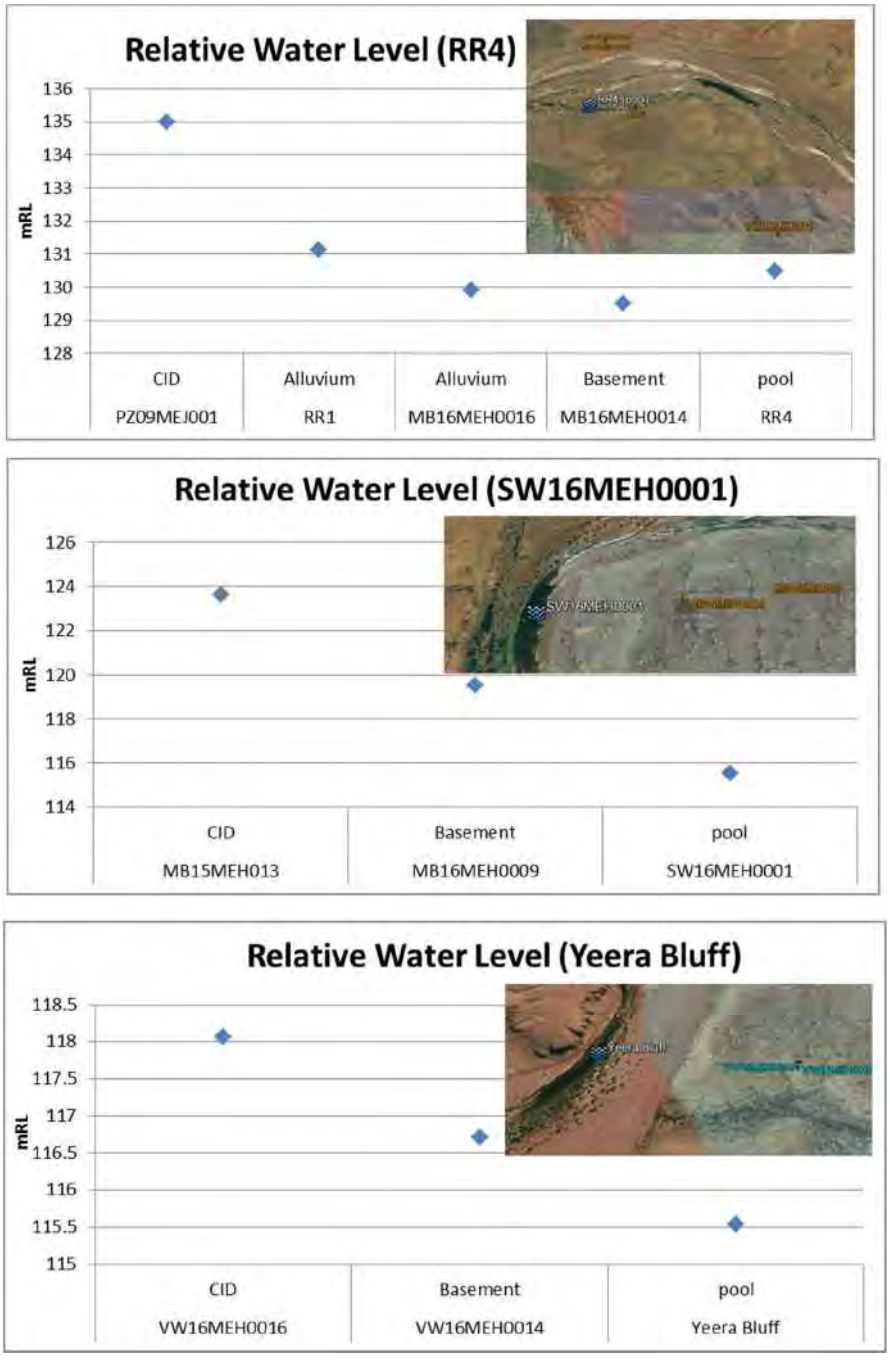

Figure 19: Relative water level between aquifers and pools

A survey was undertaken to determine the depth of nine pools located to the north of Mesa J and H along the Robe River. This survey consisted of an assessment of the bathymetry of major permanent and semi-permanent pools utilising a remote controlled boat with an inbuilt sonar recorder mounted underneath. The determination of the pools depth was undertaken over two sampling events between 2016 and 2017 to define minimum and maximum seasonal depth of the

pools. For example: for pools with 2-4m depth, the lowering of the water table by 0.5m is not considered significant, although the same impact could be significant for a pools with less than 1m depth. The results from this survey are summarised in Table 4.

Table 4: Bathymetry of the Robe River Pools

Pool Name(s)	Pool Type	Measured Depth (April – Oct 2016 extended dry)	Measured / Modelled depth (June 2017 – Seasonal high)
Partolyu	Semi - permanent	N/A	2.7m (137.3 m RL)
Tula Tamarall	Semi - permanent	N/A	2.3m (135.7 m RL)
Martu Nyunangka / Japanese Pool	Semi - permanent	1.5m	2.5m (130.5 m RL)
Duck Pool	Intermittent	Dry	N/A

Watpari	Semi - permanent	N/A	2.4m (120.6 m RL)
Parkunya / New Yinta	Semi - permanent	2.4m	3.2m (116.3 m RL)
Nyithura / Yeera Bluff	Permanent	3.6m	4.1m (112.3 m RL)
Downstream Nyithura / Yeera Bluff	Semi - permanent	N/A	3.2m (113.2 m RL)

N/A: not assessed

3.6.1 Yeera Bluff

Based on the structural analysis of Mesa H and J, the Yeera Bluff pool is believed to be a surface expression of the groundwater controlled by geological structures and a complex fault system that has displaced the basement to the west of the pool with the basement outcropping in both sides of the valley (Figure 20). This structural feature has caused a sharp curve of the Robe River to the south and constrained the groundwater flow within a very narrow gap between the hill and Mesa

H, causing the water table to be locally “trapped” and raised, resulting in a steeper hydraulic gradient to the west beyond the basement constriction. The Brockman Iron Formation underlying Yeera Bluff was confirmed to be impermeable through the drilling of a water bore at the edge of the Mesa H, this bore produced no water (“dusty”) and was later decommissioned / capped.

3.7 Jimmawurrada Hydraulics

To estimate the flows for the Jimmawurrada creek a rainfall-runoff routing 2D model (RORB) was developed for Bungaroo and Jimmawurrada catchments and calibrated to the Yarraloola (707002) gauging station located approximately 57 km downstream from the Jimmawurrada / Bungaroo Creek confluence. The modelled 100 year average recurrence interval (ARI) design peak flow was estimated to be 3,100 m^3/s for Bungaroo Creek and 2,100 m^3/s for Jimmawurrada Creek, hence the lower Jimmawurrada Creek estimated peak flow is greater than 5,000 m^3/s in the modelled 100 year occurrence.

Qualitative evidence of flooding in Bungaroo Creek is available from photographs (Figure 23) and video footage collected on an ad hoc basis during mining operations at Mesa J and exploration activities within the Bungaroo Valley. At least four significant flow events have occurred in Bungaroo Creek in the last fifteen year. Other significant events within the last thirteen years include Tropical Cyclone (TC) Monty in February 2004 and an unnamed tropical low depression system in February 2009. The qualitative evidence from TC Clare, a 20 year ARI event, provides some validation of the 2D hydraulic model, with modelled flood levels from a 20 year ARI design rainfall event comparable to flood levels observed from photographs of the event.

Figure 21 Significant flows upstream of the Jimmawurrada study area (TC Clare, 2006).

Shallow groundwater table exists in much of the Jimmawurrada flood plain area where the water table ranges between 4 m and 12 m below ground level. Concentration of salts due to evaporation was observed in some parts of the Jimmawurrada area. Airborne geophysical data interpretation

suggests that there is a fair degree of hydraulic connectivity between the Jimmawurrada Creek sediments and Bungaroo palaeochannels aquifer in the Upper Jimmawurrada area. The water bores constructed in Quaternary and Tertiary material in Jimmawurrada flood plain were capable of producing modest bore yields (15-20L/s).

Based on available data along the Jimmawurrada Creek alluvium, geological cross sections and a Leapfrog model were prepared to support the assessment of potential impact to the riparian vegetation and stygofauna habitat caused by the lowering of the water table. A revision of historical drillholes was completed in 2019 to further refine the model resulting in an observed thalweg thickness between 28 and 40 m (Figure 22), with the deepest part located east/southeast of the SCB borefield.

Figure 22 also presents the pre-mining water level, and predicted water levels by 2030 (base case), additional drawdown caused by a reduction in the rainfall recharge events (uncertainty run #2) including an assumed seasonal variation buffer; numerical model predictions are presented on Chapter 7.3.

3.8 Conceptual model uncertainties

During the development of the hydrogeological conceptualisation of the project area, a series of unknowns and uncertainties have been recognised (and even addressed during the Feasibility Study phase of the project) which could potentially affect the determination of potential impact to the Robe River pools, specifically:

- *The Brockman Iron Formation underlying Yeera Bluff is impermeable;* The conceptual model for Brockman Iron Formation northwest of the deposit underlying the Yeera Bluff pool and whether it is considered an aquiclude or an aquifer could have direct repercussions for the predicted impacts on the Robe River pools, although drilling has confirmed it as an aquiclude, fractures could still cause preferential pathways to the groundwater flow;
- *Wittenoom Aquifer continuity*: uncertainty with respect to individual basement heads and flow direction owing to lack of bores north of the Robe River. The Wittenoom Aquifer flow direction could continue under the Robe River to the north or discharge into the Robe River and flowing westward. This uncertainty was confirmed during the Feasibility drilling program indicating the Wittenoom Aquifer discharging directly to the Robe River alluvium; and
- *Alluvial aquifer heterogeneity*: Local alluvium aquifer permeability and specific yield can vary greatly locally and regionally with inferred numbers based on very limited data.

Based on the unknowns, the numerical model was calibrated to one Base Case and three conceptual uncertainties were run to predict potential changes based on a multiple conceptualisation approach to the project. Table 5 shows a summary of the four conceptualisations predicting, the “base case” and “worst case” scenarios, in terms of potential impact to the Robe River pools.

Table 5: Summary of hydrogeological conceptualisations

Permeability \ Throughflow	Wittenoom aquifer flow continues north under Robe River Alluvial Aquifer	Wittenoom aquifer flow discharges into Robe River Alluvial Aquifer flowing west
Brockman Iron Formation underlying Yeera Bluff pool is aquiclude	Conceptualisation 1	Conceptualisation 3 (*Base Case*)
Brockman Iron Formation underlying Yeera Bluff pool is permeable	Conceptualisation 2 (*Worst case - increased risk of dewatering impacts on pools*)	Conceptualisation 4

Section 4 - Existing Groundwater Use

4.1 Mesa J

The Mesa J operation, located immediately to the east of Mesa H, is covered under GWL 107678(12) with a maximum approved annual abstraction licence of up to 30 GL for operational supply, mineral ore processing, dust suppression and dewatering purposes. Dewatering is achieved through the use of in-pit sumps and trenches, with external borefields (e.g. Southern Cutback Borefield) providing process water supply and potable water. A large supply of water used for mine process purposes is recycled at Mesa J through the use of decant water from WFSF.

The total groundwater abstraction currently averages 11 GL per year, representing approximately 36% of the allocated licence. Figure 23 and Figure 24 shows the Mesa J groundwater abstraction, rainfall and hydrographs from selected monitoring bores.

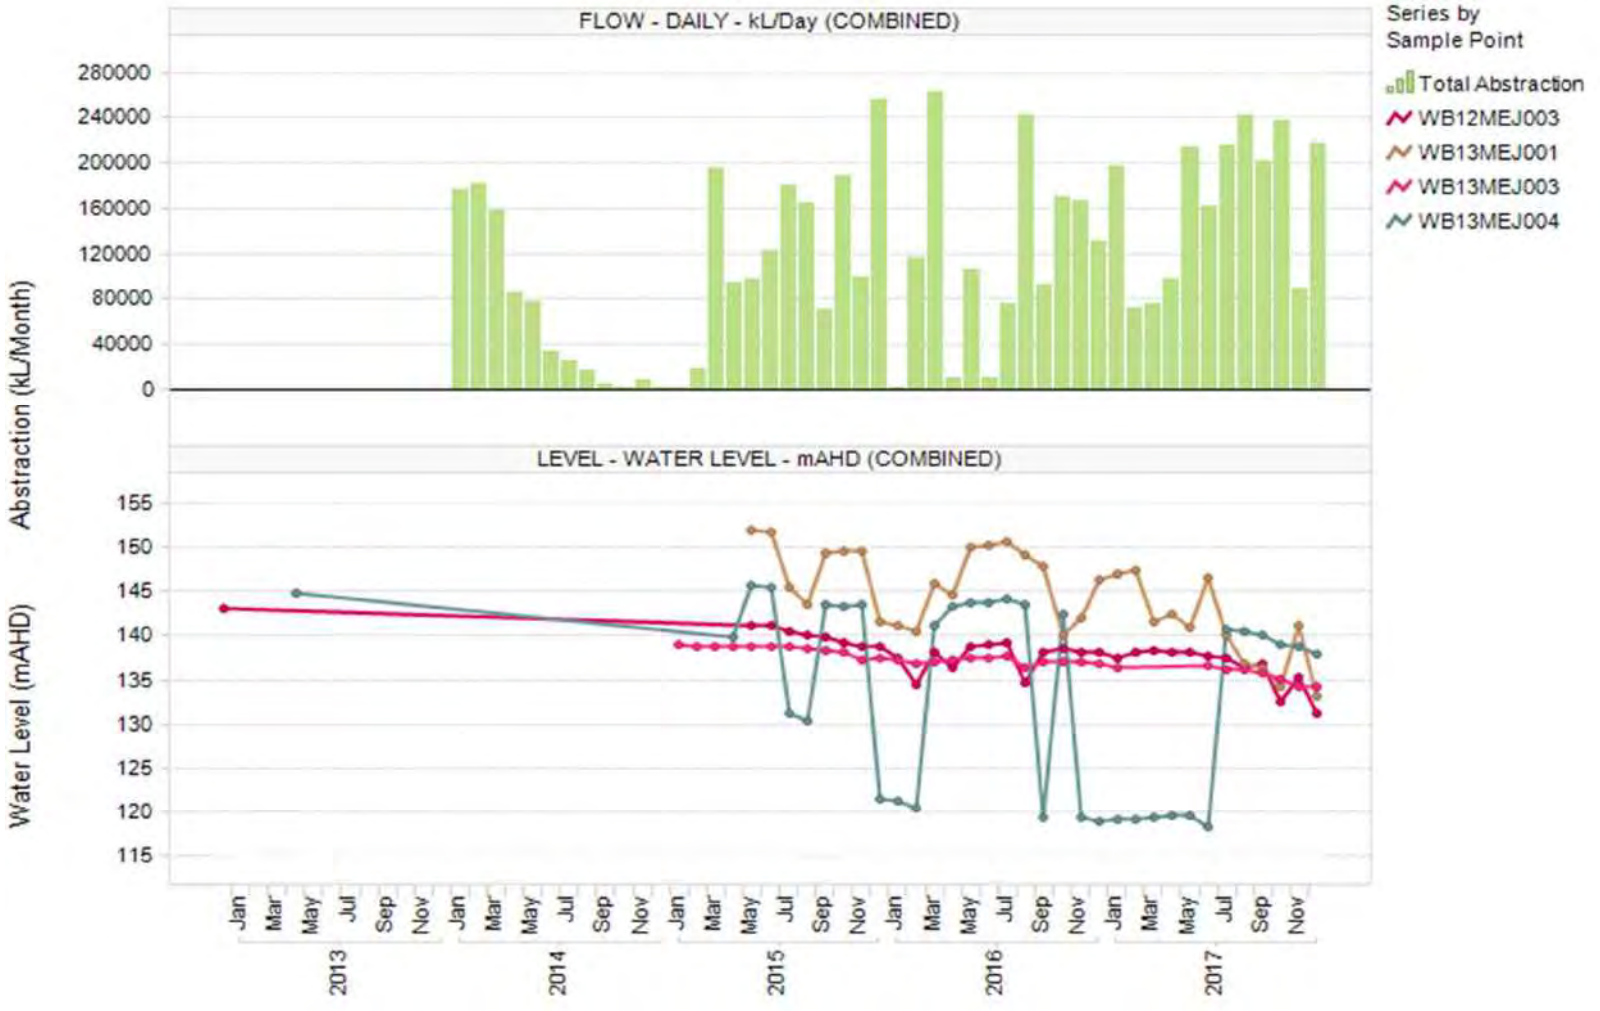

Figure 23: Mesa J Abstraction Vs Water Level hydrographs

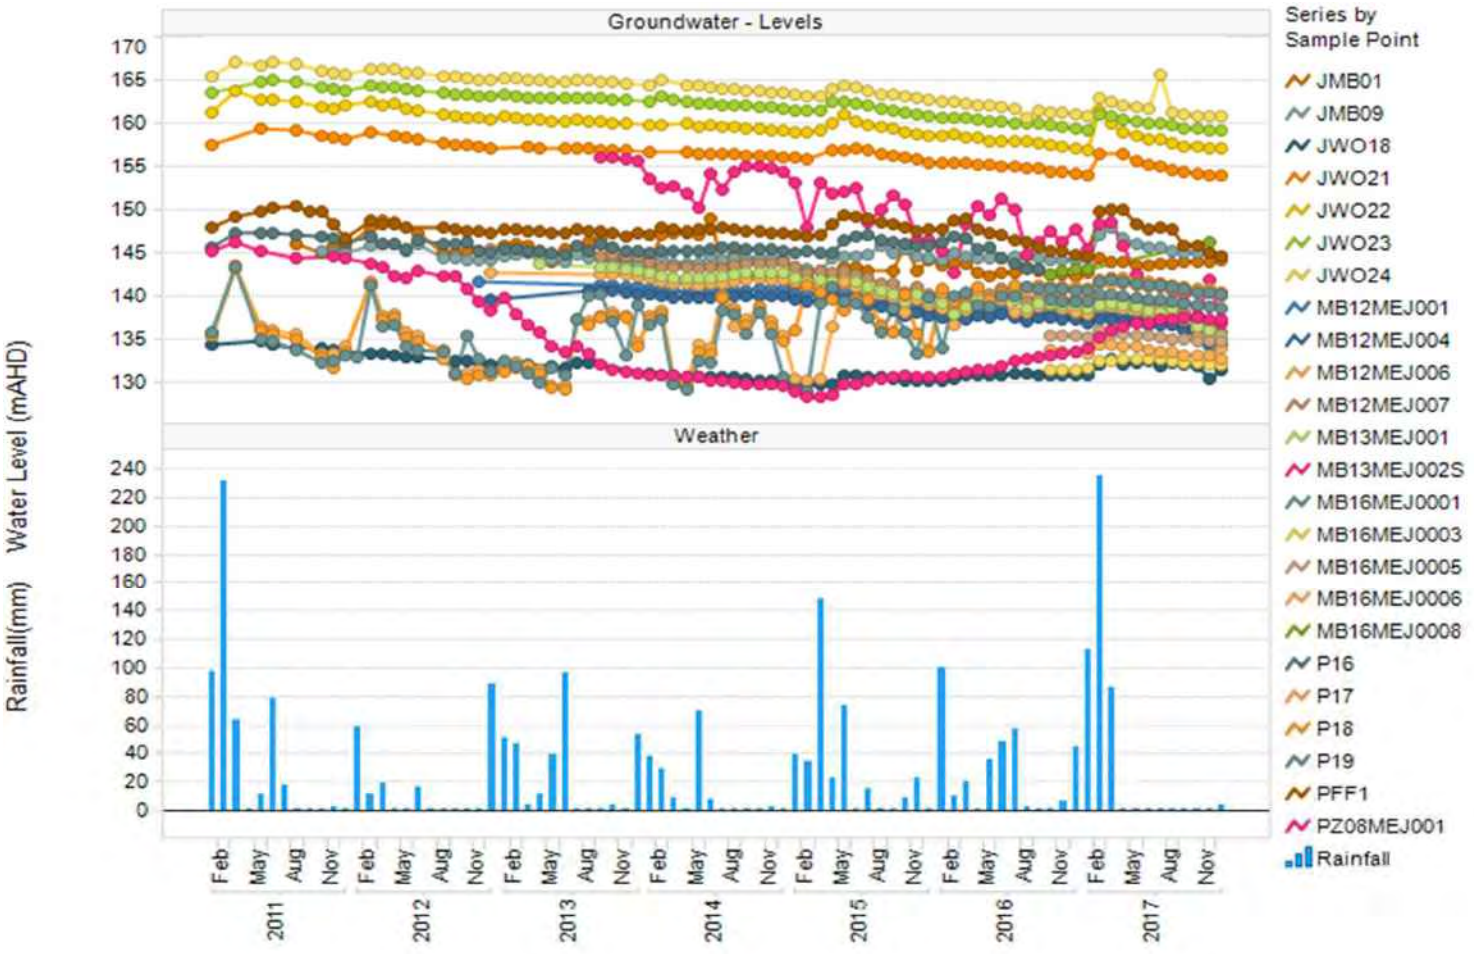

Figure 24: Mesa J Rainfall Vs Water Level hydrographs

The SCB is located immediately to the south of Mesa J, approximately 2 Km west of the Jimmawurrada Creek, and consists of five production bores ranging between 70 and 110 m deep, slotted against the CID and the Basement aquifers, capable of producing between 20 and 70 L/s. The six monitoring bores located to the east of the SCB, close to the Jimmawurrada Creek, indicates a continuous decline in the water level since 2010 (Figure 25) possibly attributed to a combination of long period of drought, Mesa J dewatering, SCB operation and Coastal Water Supply throughflow reduction.

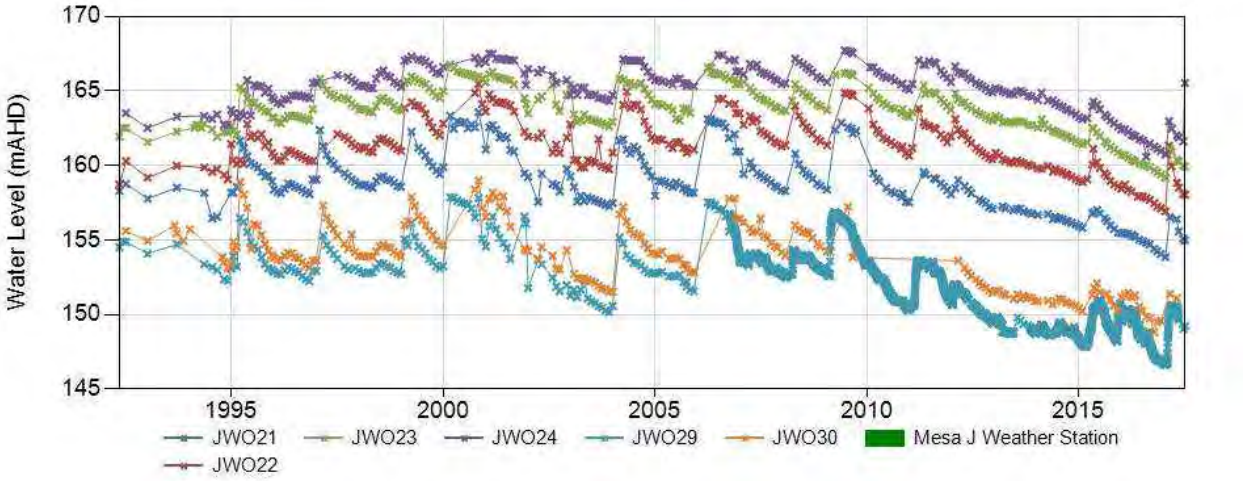

Figure 25: Water Level hydrographs close to Jimmawurrada Creek

4.2 Pannawonica

The Pannawonica town borefield is located approximately 5 km south of the Pannawonica town site in the Robe River flood plain. The Pannawonica town borefield abstracts groundwater for the purpose of potable water supply and dust suppression. Groundwater abstraction is covered under the licence GWL 107677 (7) and permits abstraction of up to 700,000 kL/year.

The borefield comprises of five active production bores screened within the Robe River alluvium, with an average abstraction of 650,000 kl/year. Long term data indicate the Pannawonica Town aquifer is periodically recharged by direct rainfall and or stream flow events.

A steady decline of up to 2m in the water level caused by the groundwater abstraction can be observed in the monitoring bores immediately adjacent to the borefield (Figure 26 and Figure 27), however, such decline is temporarily lessened by seasonal recharge.

Groundwater quality also remains consistent and in line with long term trends. Groundwater quality of the aquifer has not been impacted by abstraction activities at the Pannawonica Borefield.

Figure 26 and Figure 27 shows the Pannawonica groundwater abstraction, rainfall and hydrographs from selected monitoring bores.

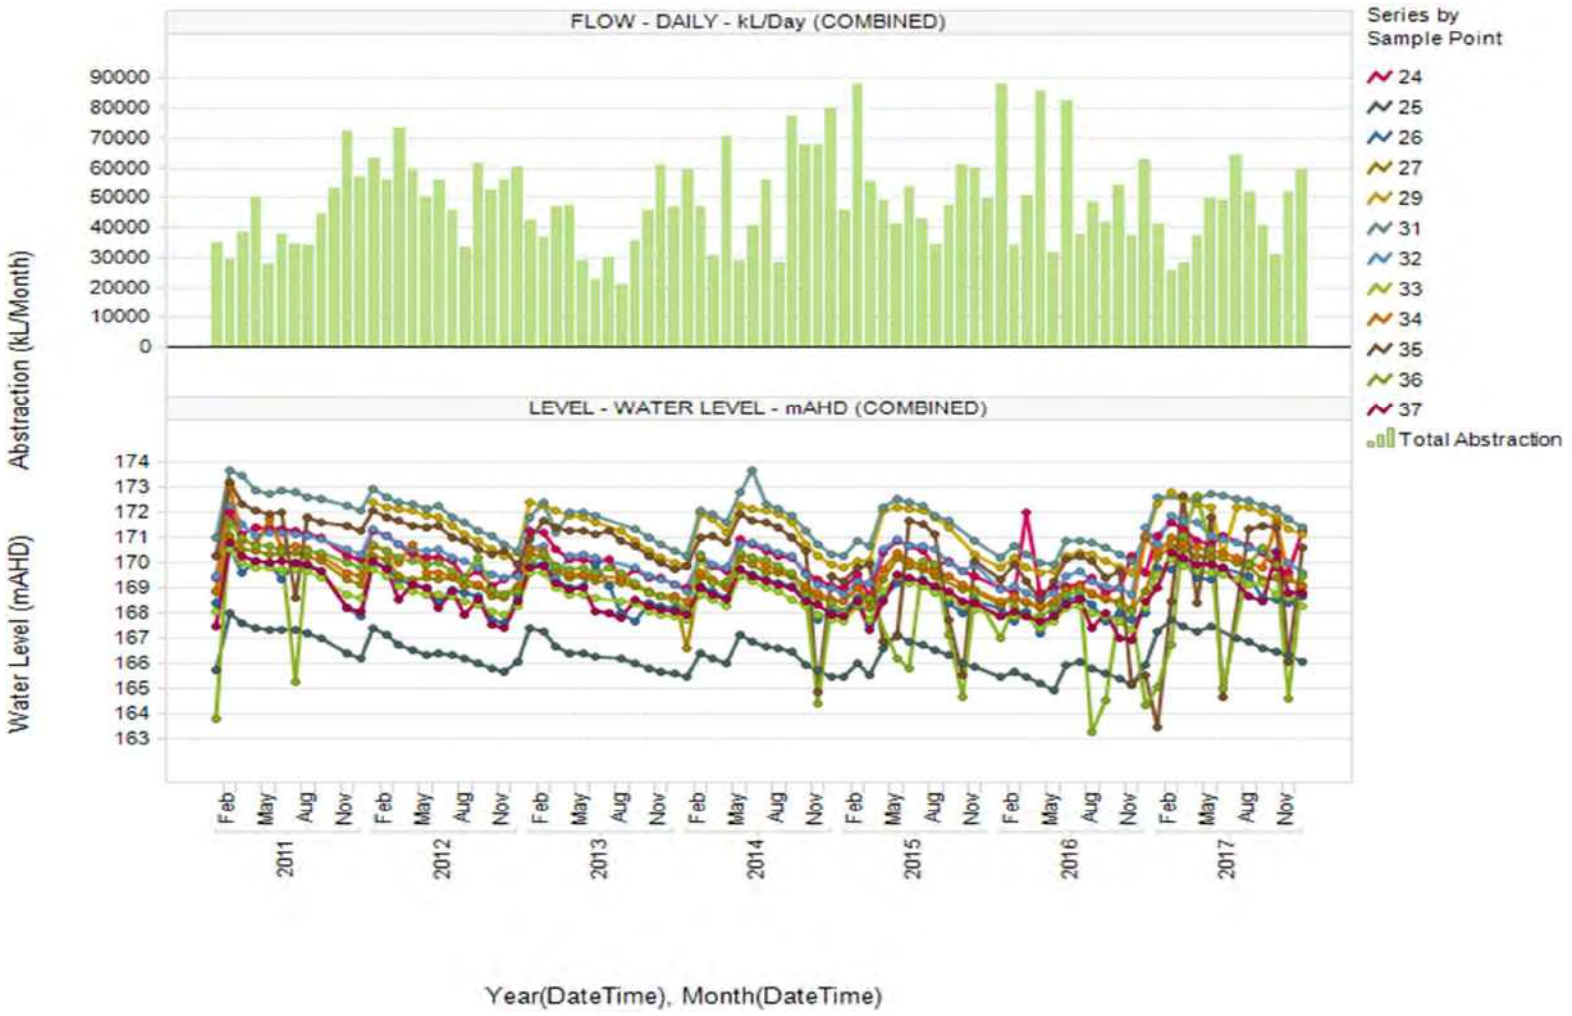

Figure 26: Mesa J Abstraction Vs Water Level hydrographs

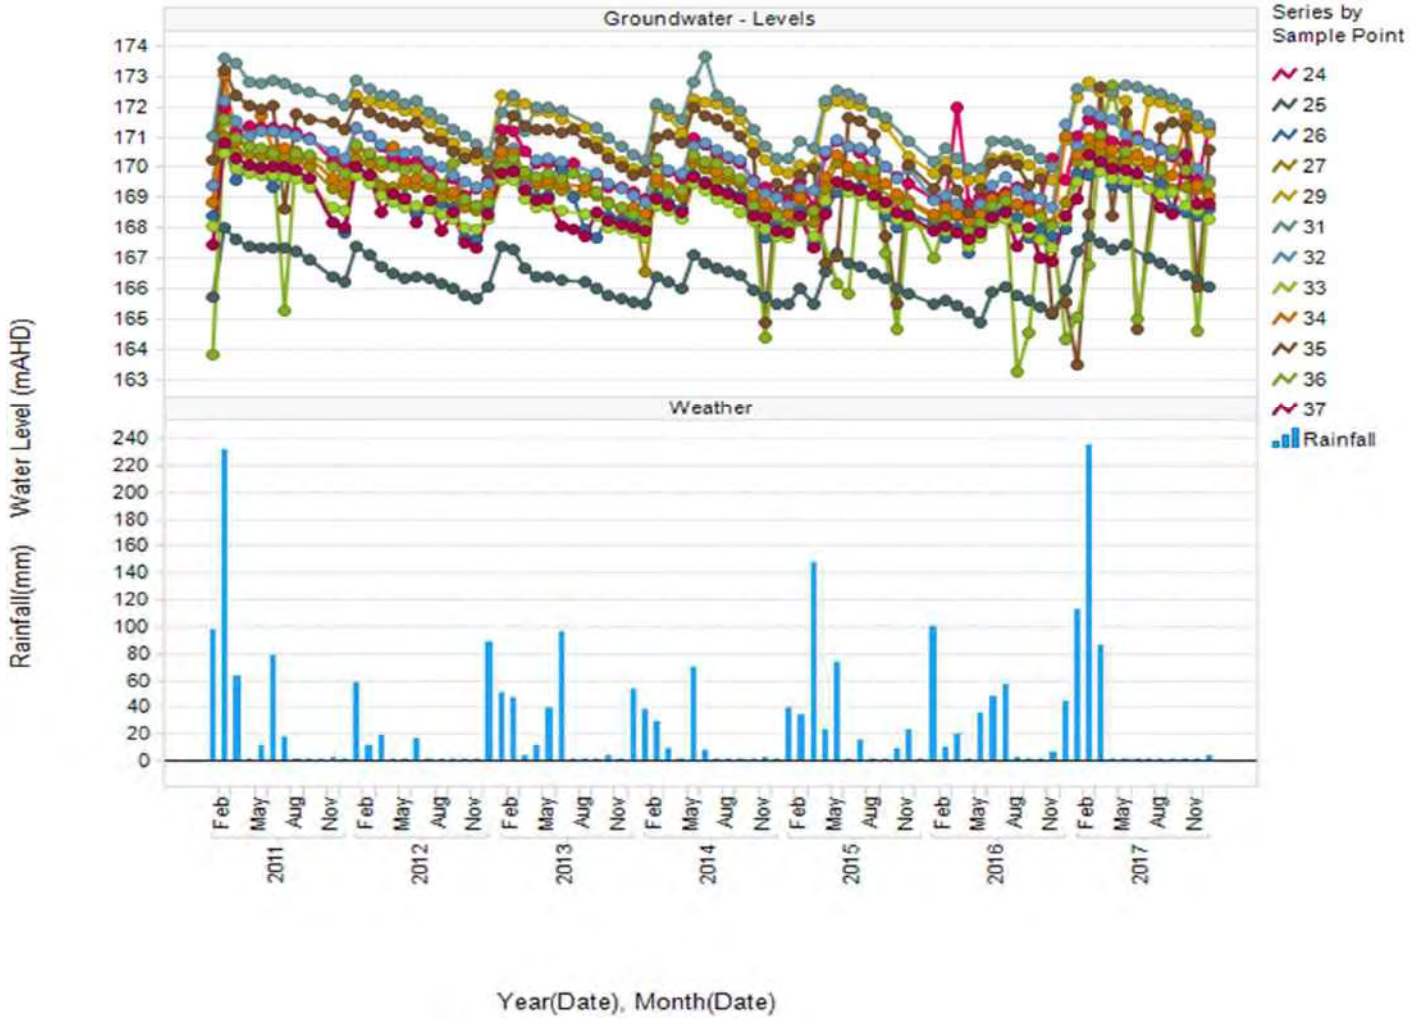

Figure 27: Mesa J Rainfall Vs Water Level hydrographs

4.3 Coastal Water Supply

The Bungaroo Coastal Water Supply (CWS) borefield is located 35 km south-east of Pannawonica and approximately 20 km south-east of Mesa H. The borefield consist of nine supply bores that have been abstracting groundwater from the Bungaroo Valley aquifers and conveying it to the Millstream Water Corporation facilities to supplement the West Pilbara Water Scheme.

The Bungaroo Borefield is licensed under GWL No. 171733 (5), which permits annual abstraction of up to 10,000,000kL. The borefield was formally introduced into supply in February 2014, and monitored under the Bungaroo Coastal Water Supply Borefield Water Resources Management Operating Strategy (WRMOS) 2013. Total groundwater abstraction for the Bungaroo Borefield was 7,586,167kL in 2016.

Figure 28 and Figure 29 shows the CWS groundwater abstraction, rainfall and hydrographs from selected bores.

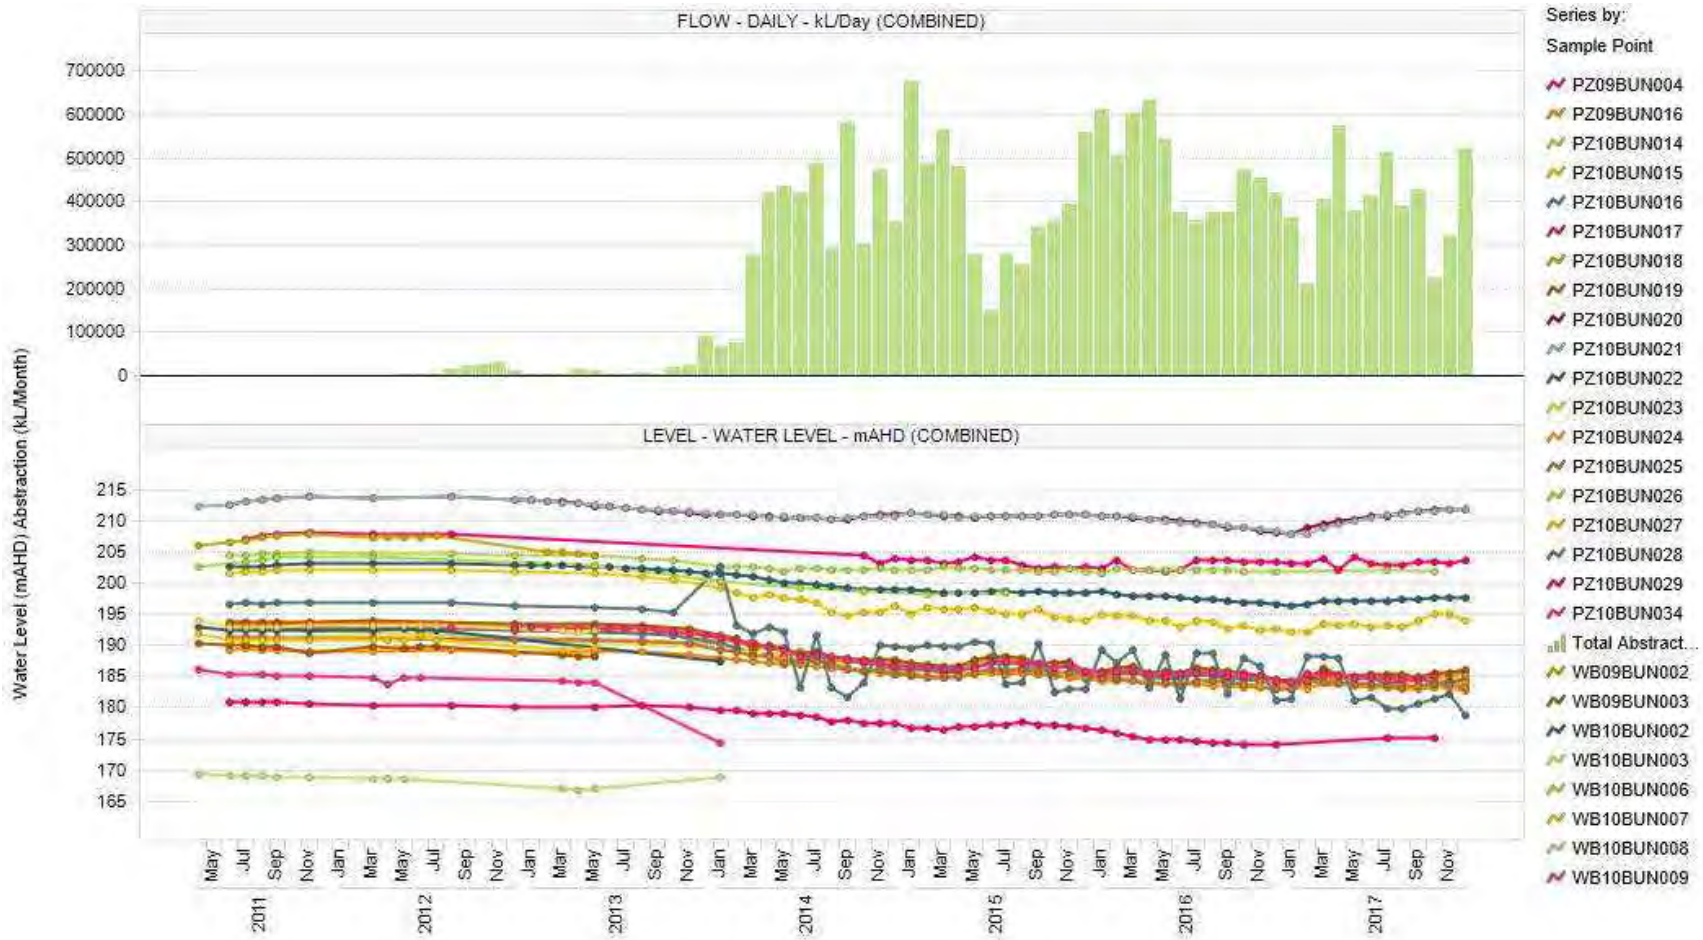

Figure 28: CWS Abstraction Vs Water Level hydrographs

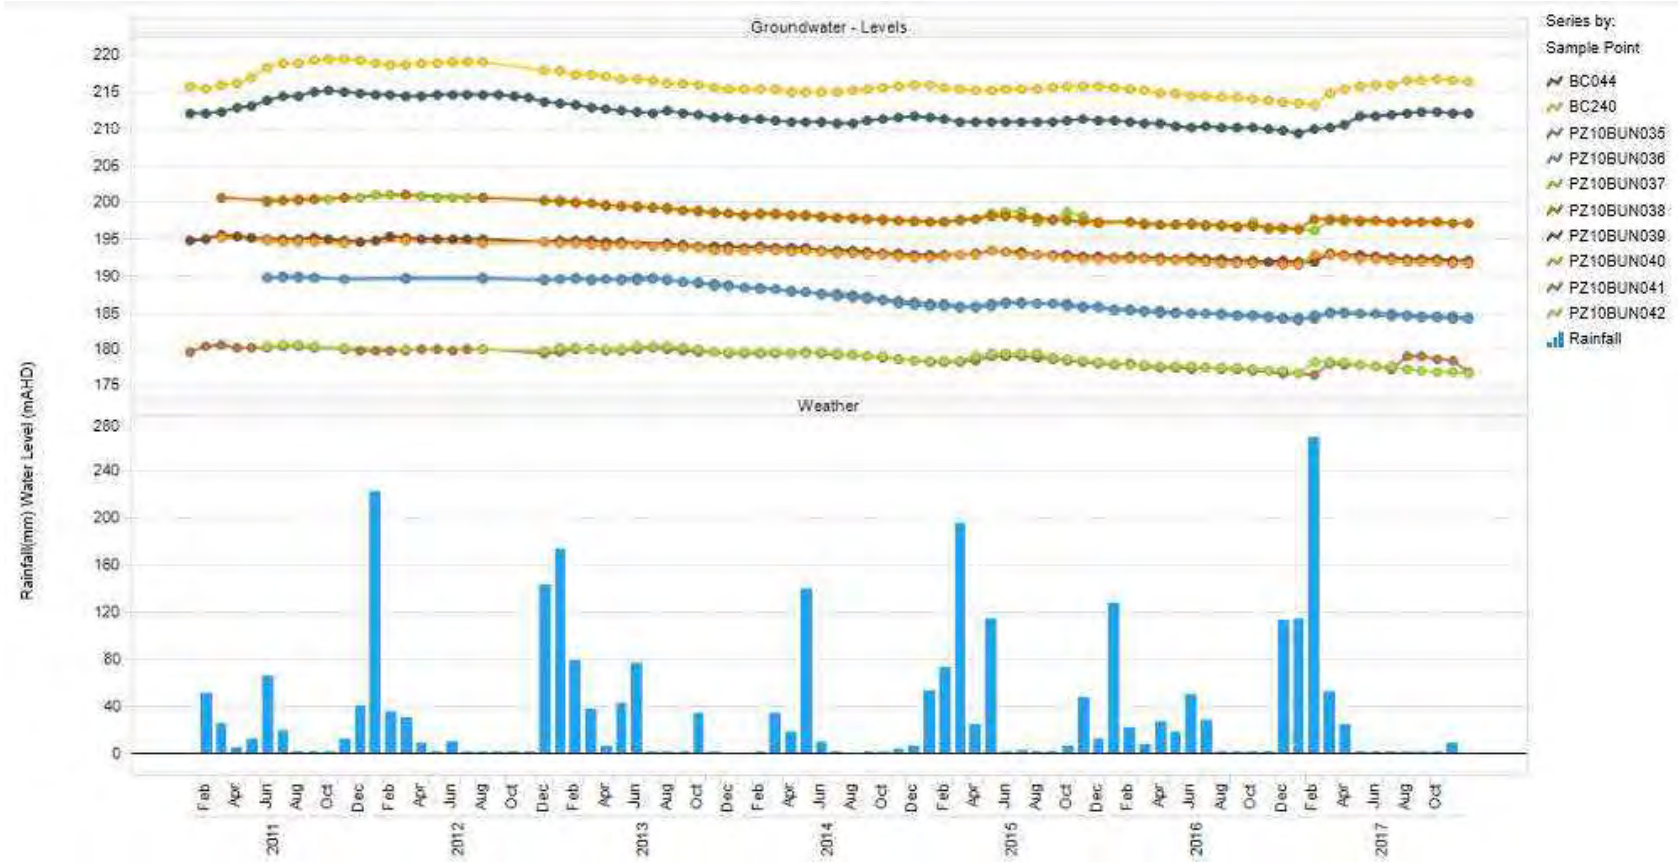

Figure 29: CWS Rainfall Vs Water Level hydrographs

Section 5 - Groundwater Investigation

Three hydrogeological investigations of the Mesa H deposit were completed to support this study. However, investigations to support water supply and dewatering for mine operations have been ongoing at the adjacent Mesa J site since 1987. These investigations were determined to be relevant, given the Mesa J hydrogeological setting is considered to be analogous to Mesa H:

- In total, 18 water bores and 61 monitoring bores have been installed at Mesa J to support mine dewatering and water supply; these bores are operated and monitored according to the Mesa J groundwater operating strategy with many of them decommissioned over the years.
- In 2015, 14 reverse circulation (RC) drill holes in the Mesa H deposit were converted to monitoring bores. The monitoring bores were designed specifically to support stygofauna sampling, and aim to improve the understanding of the extent of Mesa J's dewatering impact on the water table at Mesa H.
- In 2016, 4 water bores and 18 monitoring bores were installed in the Mesa H deposit to support the aquifer assessment and the development of a groundwater numerical model to assess dewatering requirements and potential dewatering impacts in the Robe River pools as part of a Pre-Feasibility Study (Appendix A).
- In 2017, 5 water bores, 15 monitoring bores and 2 vibrating wire piezometers were installed in the Mesa H deposit and surroundings to close conceptual uncertainties identified during the Pre-Feasibility Study (Appendix A).

5.1 Aquifer testing

A total of 26 production bores were pump tested in the Mesa H and Mesa J areas for hydraulic parameters and bore efficiency. Tests were conducted in 2004, 2013, 2015, 2016 and 2017 after the completion of different hydrogeological drilling programs. Production bores were constructed with screens over multiple lithological units including alluvium, CID, conglomerate and basement formations (Wittenoom or Marra Mamba). Aquifer parameters therefore are a combination of all the identified hydro-stratigraphic units (alluvium, CID and basement aquifers). For the majority of tests, aquifer analysis assumed semi-confined to confined conditions due to the presence of prominent clay content in the CID and at the base of the CID. Pump testing is summarised below:

- Bores screened across CID, Conglomerate and Basement Formations (Wittenoom or Marra Mamba) were tested between 6 and 70L/s;
- Bores screened in CID and Wittenoom Formation (Paraburdoo Member) were tested between 2.5 and 35L/s;

- Bores screened in CID and BIF (Marra Mamba Formation) were tested between 7 and 85L/s;
- One bore was screened in Dolerite and tested at 14L/s.
- Bore screened in the Robe River alluvium were tested between 5.5 and 18 L/s.

Drawdown analysis indicates a combination of unconfined, leaky and confined aquifer systems. Interpreted hydraulic conductivity and specific yield / storage of each test is summarised in Table 6.

*No Storage coefficient available from 2004 Aquaterra reports for individual tests however modelling has lumped the confined storage of various aquifer types as 0.0001.

Aquifer testing analyses of results are as follows:

- The CID aquifer hydraulic conductivity ranges between 0.5 and 4 m/day with a storage coefficient ranging between 0.01 and 0.0001.
- The Wittenoom aquifer hydraulic conductivity ranges between 0.5 and 20 m/day with a storage coefficient between 0.002 and 0.00005.

- The bulk hydraulic conductivity of the CID and Wittenoom Aquifers ranges between 5 and 20 m/day with a storage coefficient in the order of 0.002.
- Broadly, higher drawdown in the basement formation in comparison to the CID were observed, suggesting the confinement of the weathered Wittenoom and Marra Mamba Iron Formations in areas of limited vertical extension.
- The Robe River alluvium aquifer hydraulic conductivity ranges between 0.5 and 109 m/day with a specific yield ranging between 0.3 and 0.001.
- There has not been any local testing of the Jimmawurrada alluvium aquifer to date.

The Pannawonica town borefield is located approximately 10 northwest of Mesa H, abstracts water from the Robe River Aquifer for the purpose of dust suppression and potable water supply to Pannawonica Township, and has been in operation since 1981 abstracting approximately 700ML/year. An assessment of the long term abstraction data to estimate aquifer parameters was developed and presented in RTIO-PDE-0143871, aiming to assist in characterising the Robe River Alluvial Aquifer. Data analysis suggests specific yield of up to 0.25 and hydraulic conductivity ranging from 60 to 380 m/day.

Section 6 - Groundwater chemistry

Groundwater and surface water samples have been collected from Mesa J mine site since 1993 as part of the site Groundwater Operating Strategy (GWOS), additionally, to support the Mesa H development, several pools up gradient and down gradient from Mesa H were collected on a fortnightly basis during 12 months, including isotopes, to assess the potential contribution of local aquifer (CID and Wittenoom aquifers) to the Robe River Alluvium aquifer.

A total of 43 bores from Mesa H, Mesa J, Pannawonica and Jimmawurrada Creek were analysed, together with surface water chemistry data from seven pools along the Robe River including Yeera bluff, Medawandy and Japanese Pool (Figure 16). Although available data represent a good spatial coverage of the Mesa H area, temporally the data, particularly from groundwater, are limited to only one or two data points per bore (RTIO-PDE-0144245).

Available chemistry and isotope data indicate, as expected, that the pools are largely connected to the Robe River alluvium aquifer, and that the CID and Wittenoom aquifers are mainly comprised of fresh recharge. However, the latter aquifers appear to be receiving unusually high saline recharge at different locations particularly along the topographically low part of the mesa located to the west of Mesa H and down-gradient of the tailings pond. It is unclear whether the high salinity recharge observed in outlier CID/Wittenoom bores results from diffuse recharge due to local topography or leakage from the Robe River alluvium recharging the basement. Because these high salinity recharge areas extend from the Mesa J mine to the Robe River near Yeera Bluff pool, interactions between the Robe River pools, the alluvial aquifer and CID/Wittenoom aquifers cannot be ruled out at this point.

The groundwater within the local catchment is described as fresh, with recorded salinities typically around 64 mg/L, though readings up to 2,800 mg/L have been recorded; and circum-neutral pH between 6 – 8. The CID and Wittenoom aquifers generally comprise fresher water than the alluvial aquifer and the Mesa H pools.

In order to chemically characterise the three aquifers identified at Mesa H, bores have been grouped based on the geological formation they have been screened against. Bores screened across multiple aquifers have been grouped separately. Additionally, bores outside Mesa H including those from Pannawonica and Mesa K have been removed from the major and minor ion analysis as their chemistry was found to be very different from that of Mesa H bores.

6.1 Major ion data

The analysis of chemical signatures based on major ions suggests the following:

- Except for the Medawandy pool, chemical compositions of Robe River pools are homogeneous.

- All aquifers and pools show similar cation composition while significantly differing in anion composition. This appears to be due to the increasing chloride predominance in pools, alluvial bores and some Wittenoom bores. This trend is typically observed for waters that have undergone varying degrees of evaporation.
- While the CID and Wittenoom aquifers appear to have much fresher water than the alluvial aquifer and the Mesa H pools, outliers to this general trend exist (see bores plotting within the blue circle or above it on Figure 30).

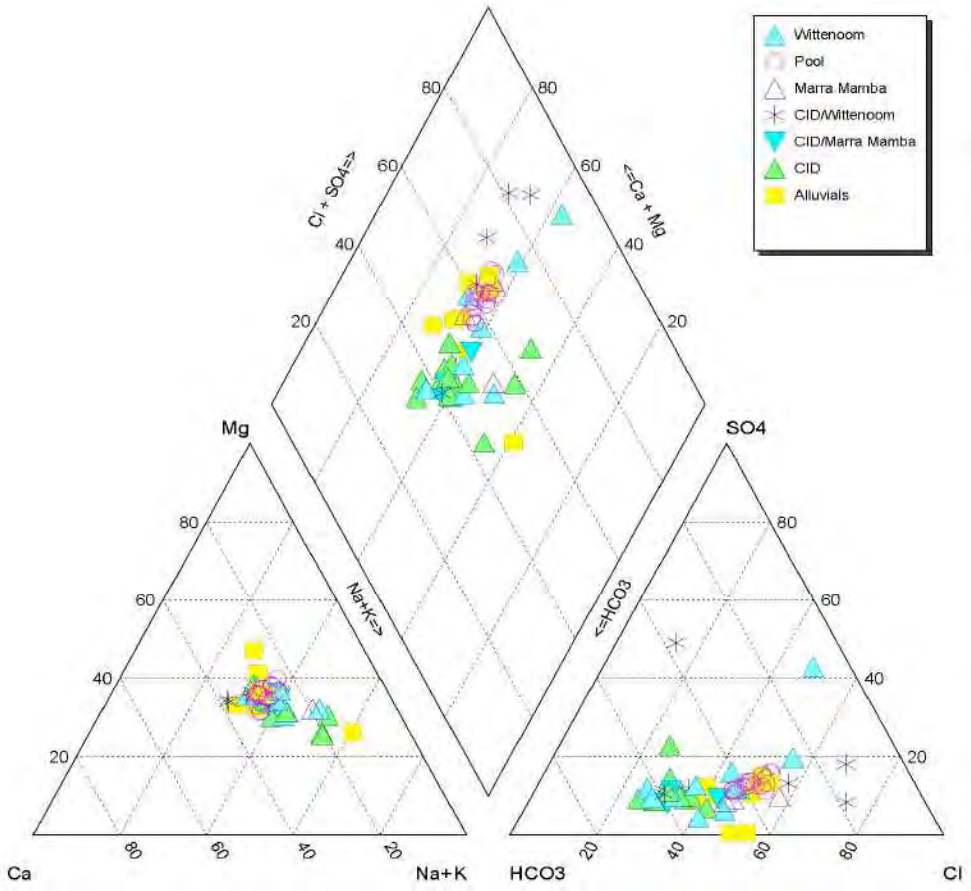

Figure 30: Piper plot of major ions. Encircled are data from those aquifers considered closely related to Mesa H pools and/or located in the Robe River floodplain

6.2 Minor ion data

Though Robe River pools have not been consistently analysed for minor ions including F, Br, and B, these parameters tend to be ubiquitous in Pilbara groundwater and their relative proportions can be useful in assessing connectivity between different aquifers, mainly because some of these anions tend to be very conservative in the environment and thus can be used as tracers.

As indicated in Figure 31, the pools are more closely related to the alluvial aquifer; and show in general greater bromide predominance than the CID or Wittenoom aquifers. However, here again there are outliers to the CID and Wittenoom aquifers, all of which had already been identified as having chemical compositions different than the bulk of the CID or Wittenoom bores and closer to the alluvial bores and pool`s. Thus, the minor ion data would confirm that along the topographically low part of the mesa located to the west of Mesa H the CID and Wittenoom aquifers appear to be receiving high salinity water from diffuse surface water recharge and recharged by the Robe River alluvium.

Additionally, the minor ion data do not align with most CID/Wittenoom outliers (depicted in green on Figure 32) are indeed outliers to the CID and Witttenoom aquifers and appear to be unusually enriched in bromide. Bores located close to the Robe River have water with salinity and bromide values even higher than those seen in Mesa H pools (see Figure 31) possibly caused by the pools getting periodically flushed with spikes in chloride.

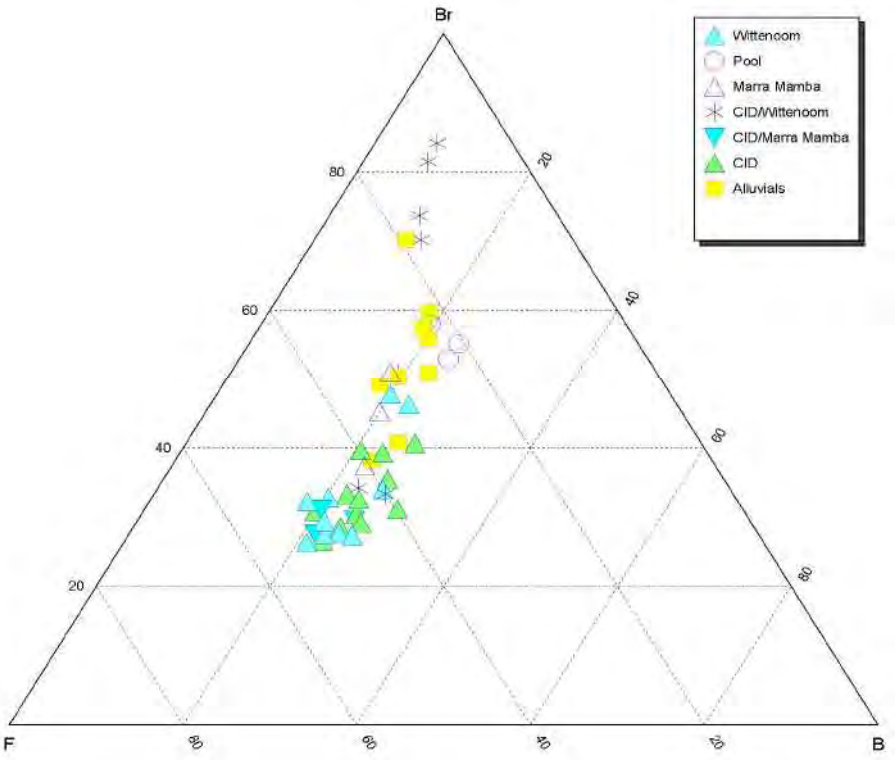

Figure 31: Ternary plot of minor anions. Encircled are data for those aquifers considered closely related to Mesa H pools

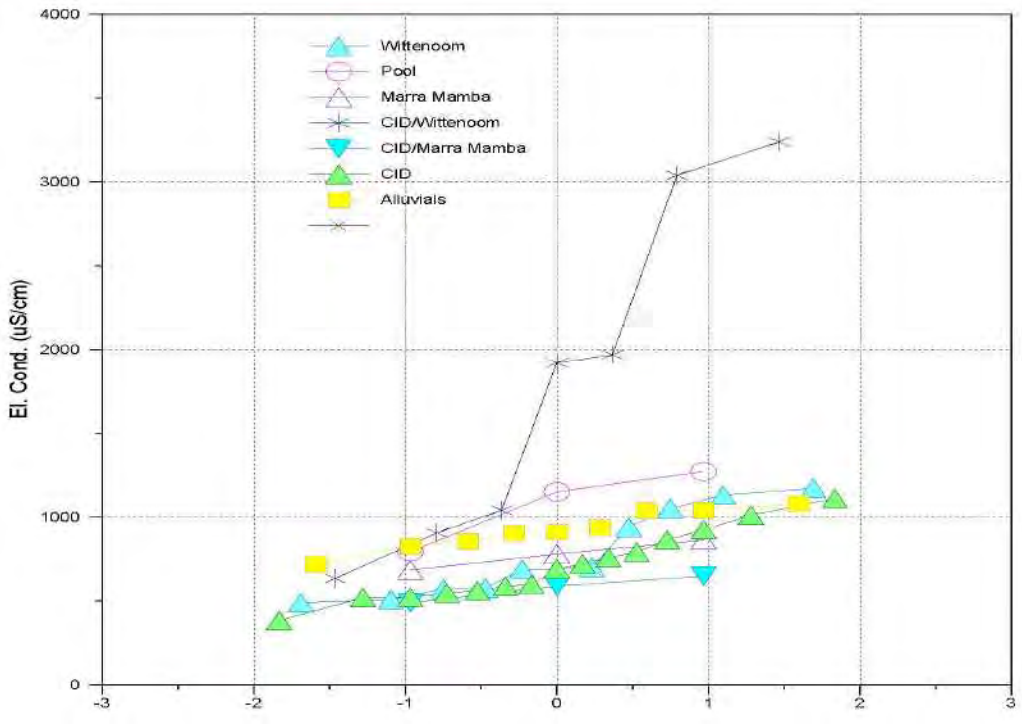

Figure 32: Distribution of electrical conductivity among different aquifers/formations

6.3 Isotope data

Isotope data have been collected from the Robe River pools and Mesa H bores. Figure 33 shows these data along with the Local Meteoric Water Line (LMWL) for the Hamersley Basin obtained from Dogramaci, et al., 2012; while Figure 34 and Figure 35 show isotopic data plotted against chloride concentrations. Isotopic data indicate the following:

- Robe River pools and groundwater at Mesa H plot below and to the right of the LMWL indicating a general heavier ^{18}O isotopic composition but lighter deuterium composition than the Hamersley Basin precipitation. This is consistent with isotopic fractionation that occurs when meteoric waters undergo different degrees of evaporation (Mazor, E. 2004).
- In general, Robe River pools and alluvial bores have heavier isotopic composition than CID and Wittenoom bores, (plot above $d^{18}O$ of -6.5 and $d^{2}H$ -42; while most CID and Wittenoom bores plot below these cut-off values). This is expected as both pools and alluvial bores undergo a greater degree of evaporation than the CID or Wittenoom bores.
- Bores within the CID and Wittenoom aquifers have water samples showing lighter isotopic composition than the Robe River pools or bores slotted in the Robe River alluvium aquifer, indicating that these aquifers may be comprised of fresh recharge. Outlier bores plotting close to pools and alluvial bores may indicate that at some locations, the CID and Wittenoom aquifers may be receiving diffuse surface water recharge or seepage,

corroborating the theory that higher salinity water, periodically, recharges the CID/Wittenoom aquifers at these locations.

- Isotope data plotted against chloride on Figure 34 and Figure 35 suggest water within the Robe River pools and alluvial aquifer originate from the same water source as the CID and Wittenoom aquifers, and that later fractionation occurs in pools and the alluvial aquifer due to evaporation. This conclusion is reached because both datasets (i.e: alluvium and basement aquifers) meet (within the instrumental error of +/- 5‰) at the origin (i.e. chloride = 0), which would approximate the composition of rain.

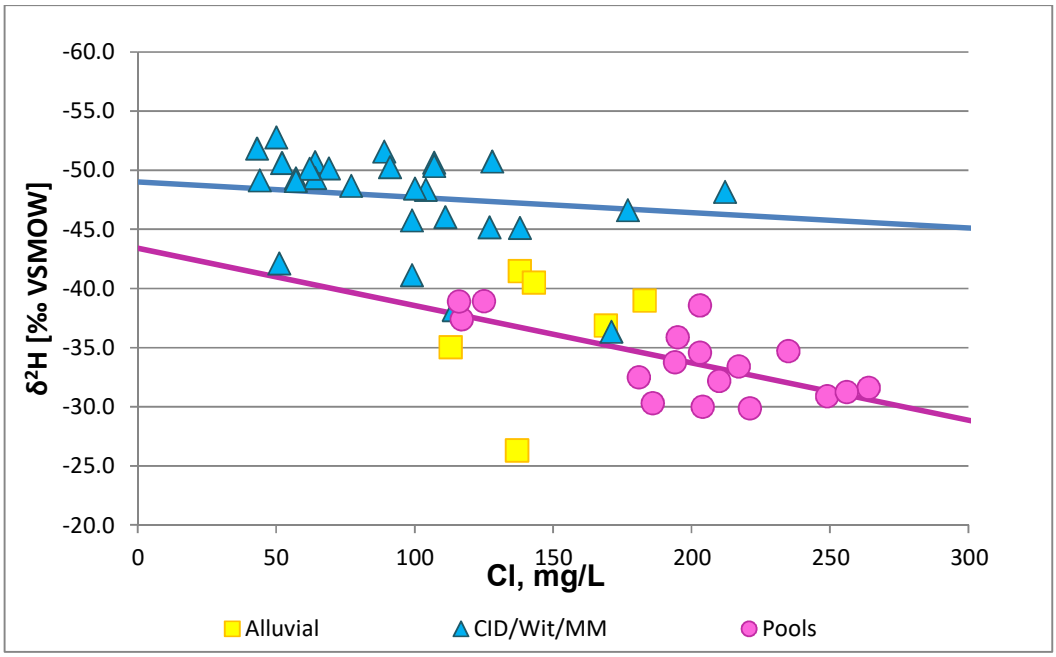

Figure 34: d^{2}H versus chloride for Robe Valley pools and Mesa H bores

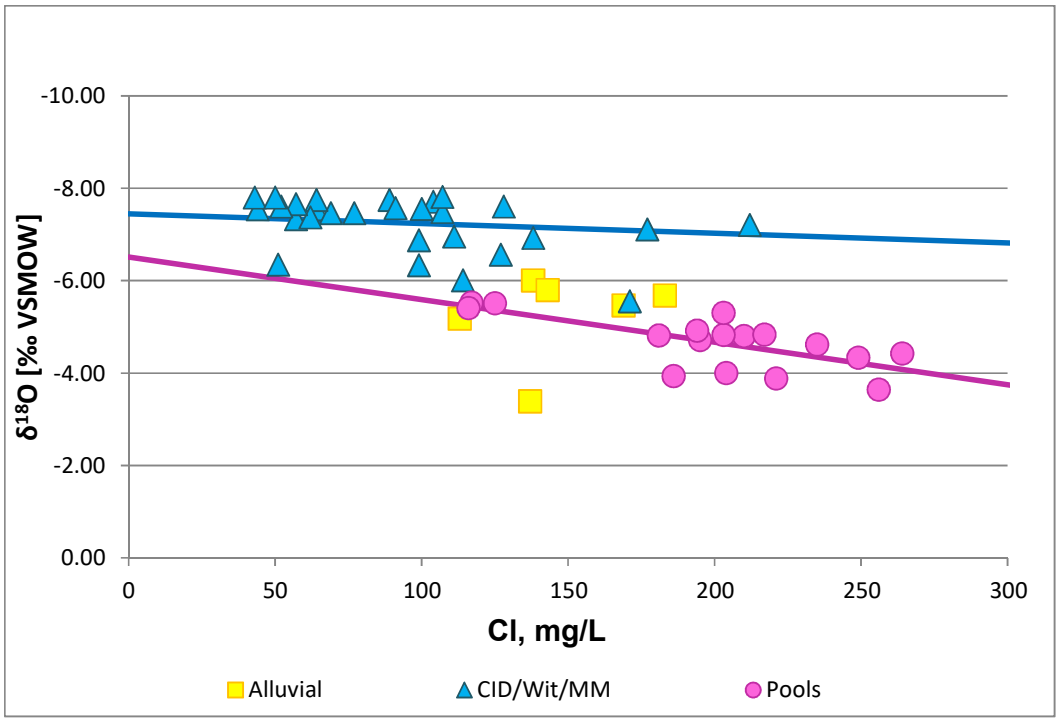

Figure 35: d^{18}O versus chloride for Robe Valley pools and Mesa H bores

Section 7 - Groundwater flow model

A groundwater numerical model was initially developed in 2002 to predict inflows to the open pit workings for the Mesa J mine (Aquaterra 2002a). This model was sequentially updated and refined by Aquaterra in 2003, 2004 and 2006. As part of the 2016 dewatering and impact assessment of the proposed Mesa H mine, RTIO developed a new model which incorporated both Mesa H and Mesa J mines for the first time; results from this model have been peer reviewed by RPS, which prompted the development of a new numerical model to address identified issues with the model build.

The foundation of the current numerical groundwater model (Appendix B), presented in this H3 level assessment, is based on the latest conceptual hydrogeological model, and utilises the results and setups of previous models (RPS 2016/17 model), and further updated based on the Base Case conceptualisation presented in this report.

7.1 Numerical Model Set-up

The numerical groundwater flow modelling package Modflow-Surfact (Version 4.0, Hydrogeologic Inc 1996) has been used to develop the model operating under the Groundwater Vistas graphical user interface (Version 6.52, Rumbaugh and Rumbaugh 1996–2011). The Modflow-Surfact numerical code was chosen to allow simulation of shallow water tables, reduction of water levels in mining areas and subsequent groundwater recovery.

The model confidence level classification (as per the National Water Commission 2012) is Class 2 due to the spatial and temporal coverage of the monitoring data not being extensive in some areas of the model domain.

7.1.1 Boundary Conditions

Figure 36 shows the model is bounded in the east and west by the basement outcrops, represented by no flow boundaries. The Stream Package (STR1 package) of Modflow Surfact is used to represent the Robe River and its tributaries (Jimmawurrada Creek and West Creek) within the model domain. The stream stages of the Robe River were set 2 m above the derived streambed elevations and 0.5 m in the Jimmawurrada Creek and the West Creek, adopting a conductance of 100 m^2/d, roughness of 0.045 and slope of 0.00245.

The Robe River also carries a significant underflow in its alluvial bed. This subsurface inflow and outflow are simulated using the GHB package in Modflow-Surfact with the underflow boundaries assigned to the Robe River valley at the model edges.

In the south, the groundwater inflow from the Bungaroo Creek palaeo-valley is represented by a general head boundary. In the north, the groundwater outflow from the Wittenoom aquifer to the north is also represented by a general head boundary.

Inflow to the Robe River was based on recorded flows at Ngalooin Pool Station 707004, located approximately 18 km upstream from the Mesa J mine site (Figure 5). Flow records are available from 1977 until 1999. From 1999 onwards for the remainder of the calibration period historical flow data was replicated to simulate variable annual Robe River flows.

Due to a lack of gauging stations along the Jimmawurrada Creek, it was assumed that each time the Robe River was flowing, that Jimmawurrada Creek also had surface flow. With an approximate area of 1,270 Km^2 the Bungaroo / Jimmawurrada catchment represents about 20% of Robe catchment, thus an assumed 20% of the Ngalooin Pool recorded data was used to simulate stream flows along the Jimmawurrada Creek. No natural flow was assigned to the West Creek.

Recharge to the groundwater system is assumed to occur via rainfall recharge over the model domain using gridded rainfall data (BOM, 2009). It is specified as a percentage of the recorded annual rainfall, distributed as follows:

- 0% BIF outcrop
- 15% Robe River alluvium
- 2% Jimmawurrada Creek alluvium
- 1% CID outcrop

Evapotranspiration occurs from the shallow water table (between 2 and 5 mbgl) within the Robe River and Jimmawurrada Creek where surface pools and vegetation occur. Elsewhere, the water table is generally substantially more than 10 m below the surface and losses from the water table to the atmosphere are negligible. Evaporation from riparian vegetation and from the shallow or near surface water table was modelled using the Evapotranspiration package (EVT) in Modflow-Surfact. The ET surface was set consistent with topographic (1m contour) with extinction depth of 5m. Evapotranspiration was assigned a constant value of 0.0065 m/d or 70% of long term measured average pan evaporation of 3,400 mm/year.

During mining at Mesa J surplus dewatering was historically discharged at two locations (Jimmawurrada Creek and West Creek) and the transient model includes both. Discharge to the creeks is applied as stream inflow at designated locations based on the recorded discharge data.

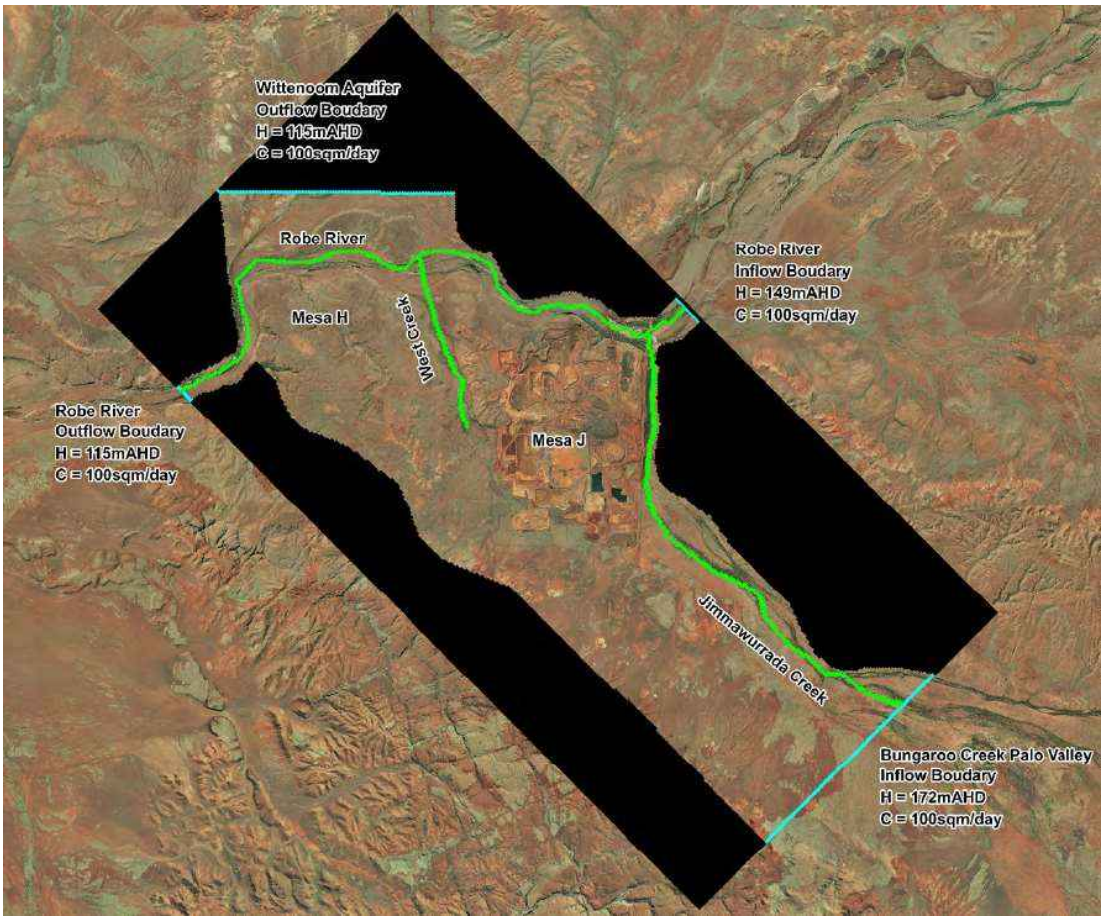

Figure 36: Numerical model domain and boundary conditions

7.2 Model Calibration

The focus of the steady state calibration was to calibrate the model to interpreted pre-development groundwater levels and flows across the catchment. However, the time variant monitoring data covering the period 1990 to 2016 indicates a seasonal trend in water levels, in the order of several meters resulting from the wet and dry season recharge pattern. Thus the groundwater conditions within the catchment are not readily described by an average or steady state set of water level conditions. To accommodate this, a set of initial conditions was generated using a dynamic calibration process. This process involved going back and forth between the steady state and transient models, fine tuning model parameters until a set of conditions were generated that closely matched the start of the calibration period and satisfied the time variant trends.

The steady state water balance is presented in Table 8.

Table 8: Numerical vs conceptual water balance

Flow Component	RTIO Water Balance (ML/year)	Numerical Model (ML/year)
Inflow from the Bungaroo paleo-valley	~1,500	Inflow from the GHB = 800 Inflow from the Jimmawurrada Creek = 700 TOTAL = 1,500
Robe River underflow (inflow from the upstream)	>900	Inflow from the GHB = 430 Inflow from the stream leakage = 420 TOTAL = 850
Robe River underflow (outflow to the downstream)	>900	Outflow through the GHB = 290 Inflow from the stream leakage = 330 TOTAL = 630
Robe River flow (inflow from the upstream)	-	43,860 ML/year
Jimmawurrada Creek flow (inflow from the upstream)	-	8,770 ML/year
Robe River flow (outflow to the downstream)	-	51,100 ML/year

As presented above the conceptual and model inflows from the Bungaroo paleo-valley and outflow through the Wittenoom aquifer are very well matched.

Model performance was tested (transient calibration) by comparing predicted and observed time variant groundwater levels over the period 1990 to 2016. The model calibration includes annual time increments from 1990 to 2016. This encompasses:

- Mesa J mine dewatering to date
- historical mine water supply pumping in the area
- discharge to Dan's Dam, Jimmawurrada Creek and West Creek.

In total 37 bores with long term monitoring records and 33 bores with recent monitoring records (both regional bores and Mesa J mine monitoring bores) were used as a representative calibration dataset. Measured groundwater levels and trends are generally well matched by the model. In the immediate vicinity of the Mesa J mine the decreasing water level trend associated with dewatering is well replicated by the model.

Long term monitoring records in the Mesa H area or along the Robe River are not available at this time. Model performance was tested against the short term monitoring records at 33 recently installed monitoring bores. There is a good match to the measured groundwater levels at these bores especially to the bores closest to the Robe River and to the north of the Robe River.

The aquifer parameters adopted for the calibrated model are summarised in Table 9. Assigned aquifer parameters are consistent with available hydraulic testing data, previous groundwater models, published data and similar hydrogeological environments.

Table 9: Calibrated Aquifer Parameters

Formation	Kh (m/d)	Kv (m/d)	Specific Yield (%)	Confined Storage
Robe River Alluvium	100	50	30	0.0001
Jimmawurrada Creek Alluvium	5	0.5	20	0.0001
CID	4	2	10	0.0001
Tertiary Pisolite TPB	1	0.1	6	0.0001
Weathered Basement	8	8	1-10	0.0001
Fresh basement	0.0001	0.0001	0.1	-

The predicted groundwater balance for December 2016 (i.e. the end of the calibration) is presented in Table 10. The water balance shows that inflow from upstream (Robe River) dominates the inputs to the modelled catchment. Besides replenishing the surface water pools along its path, the Robe River also feeds the partially dewatered aquifers which are in direct hydraulic connection with the river. Inflow from the Robe River into the model (modelled aquifers) is 51% of the overall water balance. Dewatering and borefield pumping combined provide the greatest outputs (35% of the overall water balance).

Table 10: Modelled Water Balance

Flow Component	Inflow (ML/y)	Outflow (ML/y)
Storage	3,515	900
Borefield Pumping		1,170
Dewatering		4,640
Rainfall Recharge	695	
Discharge to Dan's Dam	510	
Evapotranspiration		2,880
Groundwater Inflow / Outflow	1,430	290
Stream Leakage	5,900	2,170
Total	**12,050**	**12,050**

Zone budget analysis indicates the interaction between the Robe River and Jimmawurrada Creek depends on the assigned stream flows where during periods of low flows Robe River alluvium feeds the alluvium associated with Jimmawurrada Creek at a minimal rate. However when river and creek are flowing the Robe River alluvium gains ~1 ML/day from the Jimmawurrada Creek alluvium.

The Robe River alluvium loses water to the undelaying CID (TPB unit). Predicted inflow from the alluvium to the TPB ranges between 1.5 and 4 ML/d, additionally the Robe River also loses water to the north along the weathered Wittenoom Formation (~ 1ML/d).

7.3 Model Predictions

The calibrated model was used to complete dewatering predictions for Mesa J and Mesa H and to predict mine dewatering and drawdown along the Robe River alluvium. The predictions were completed as outlined below:

- Initial groundwater level/flow conditions were derived from the end of the transient calibration (December 2016).
- The prediction period starts in January 2019.
- The model was run for a period of 19 years (January 2019 to December 2037).
- The model predictions were run using annual time increments (stress periods). Steady state evapotranspiration rates were used in the prediction model.
- As mentioned in the model setup sections Robe River flow records exist until 1999. For the 19 year prediction period, the last 19 years of recorded Robe River flows were used (from 1981 to 1999). Consistent with that, rainfall recharge data from 1981-1999 was used in the prediction model.

- Dewatering at Mesa J and Mesa H was simulated using the Drain Package (DRN) in Modflow Surfact. Drain elevations were set consistent with the proposed mine plan. Drain bed conductance was set consistent with the calibrated model (i.e. 1,000 m^2/d).
- Discharge to Dan's Dam was applied using the Recharge Package (RCH) in Modflow Surfact at average recorded discharge rates from the calibration period.
- Surface water discharge to Jimmawurrada Creek and West Creek was assumed to cease and resume only if required for seasonal surplus water management.
- The impact of the Costal Water Supply system, proposed to take place in the Bungaroo Creek valley, was taken into account based on the results of separate groundwater modelling undertaken by Rio Tinto to support the CWS project and approvals process. Predicted drawdown impacts were accounted in the prediction model by lowering the southern inflow General Head Boundary consistent with the predicted drawdown impact. The Bungaroo model predicts 6 m of drawdown after five years, 8 m after 10 years, 9 m after 15 years and 11 m after 30 years of water supply pumping from the CWS. The GHB was lowered linearly to account for the predicted impact.
- The volume of abstraction for water supply required was calculated as the difference between the projected water demand and the predicted total dewatering. The pumping rates required were calculated using an iterative process and the prediction model was re-run until the assigned borefield pumping and predicted dewatering satisfied the water demands. Seven existing and nine nominal bores were used to simulate water supply pumping when required.

Two predictions were simulated:

- Scenario 1: No water return from TSFs due to the commissioning of a thickener plant (82.8 GL total demand)
- Scenario 2: higher water demand (no thickener plant) (141.5 GL total demand)

Due to the fact the inclusion of a thickener plant is the base case to avoid significant impacts to environmental and heritage values, this H3 update only describes the Scenario 1 results. However, for comparative purposes, results of both predictions are depicted in the model report (Appendix B).

In order to simplify the computational prediction (Scenario 1), the water demand was averaged at 5 GL/y between 2020 and 2033 and reduced to 4 GL/y until 2037, totalling 86 GL.

Prediction runs have been completed using a conservative approach (i.e. reduced inflow from the southern model boundary, no surface water discharge to creeks when dewatering exceeds water supply requirements, and no seepage from the TSFs) to allow prediction of maximum potential groundwater drawdown throughout the modelled catchment

7.3.1 Mesa J Dewatering

BWT mining at Mesa J is ongoing and planned to continue until 2029. Dewatering from 2019 was simulated using drains cells set accordingly with the proposed mine plan (Table 11), as a result, predicted water levels closely follow the mining schedule.

Dewatering at Mesa J is predicted to peak at 8.2 GL/y in 2023 (with pumping from pits 6, 12 and 15), with another peak of up to 7.2 GL/y in 2027 (with pumping from pits 7, 12, 14 and 15). Mining at Mesa J is scheduled to end in December 2029, with the model drains associated with dewatering at Mesa J set as 'inactive' from January 2030 onwards. The simulation also predicts a total of approximately 54 GL will be required to be removed between 2020 and 2029. Figure 37 shows the simulated dewatering annual average rates the drain package took out over the simulation period

Table 11: Mesa J BWT Mine schedule

End of year	Pit 3	Pit 5	Pit 6	Pit 7	Pit 8	Pit 9	Pit 11	Pit 12	Pit 14	Pit 15
2019	146		182	138	126	158				142
2020	146		174	134		158				134

**cells highlighted blue denote benches below pre-mining water level*

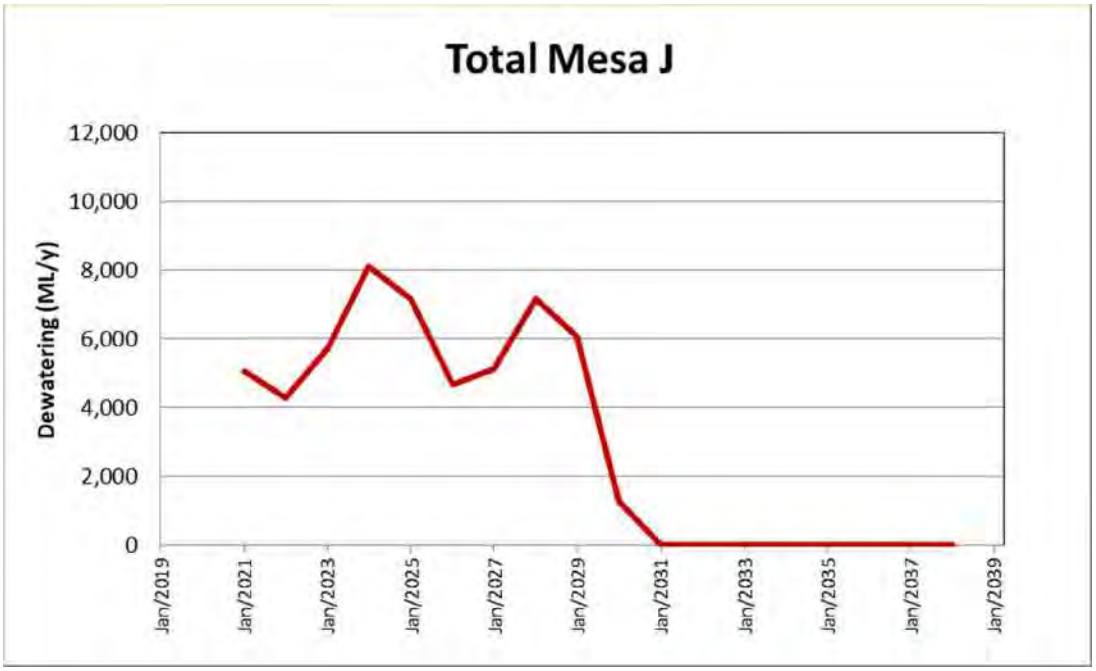

Figure 37: Dewatering rates and cumulative volumes

7.3.2 Mesa H Dewatering

BWT mining at Mesa J is expected to start in 2024 at Pit 6. Dewatering was simulated using drains cells set accordingly with the proposed mine plan (Table 12), as a result, predicted water levels closely follow the mining schedule.

Dewatering rates from Mesa H are predicted to reach a maximum of ~3 GL/y in 2033 mostly as a result of mining and dewatering at Pit 2. Dewatering is predicted to decrease to 2.5 GL/y by 2035. After 2035 dewatering is predicted to decrease to 1.3 GL/y in 2037 with no further declines before the end of mining. The simulation also predicts a total of approximately 15 GL will be required to be abstracted to achieve the LoM. Figure 38 shows the simulated dewatering annual average rates the drain package took out over the simulation period.

Table 12: Mesa H Mine schedule

End of year	Pit 1	Pit 2	Pit 3	Pit 4	Pit 5	Pit 6	Pit 7	Pit 8
2019								
2020						162

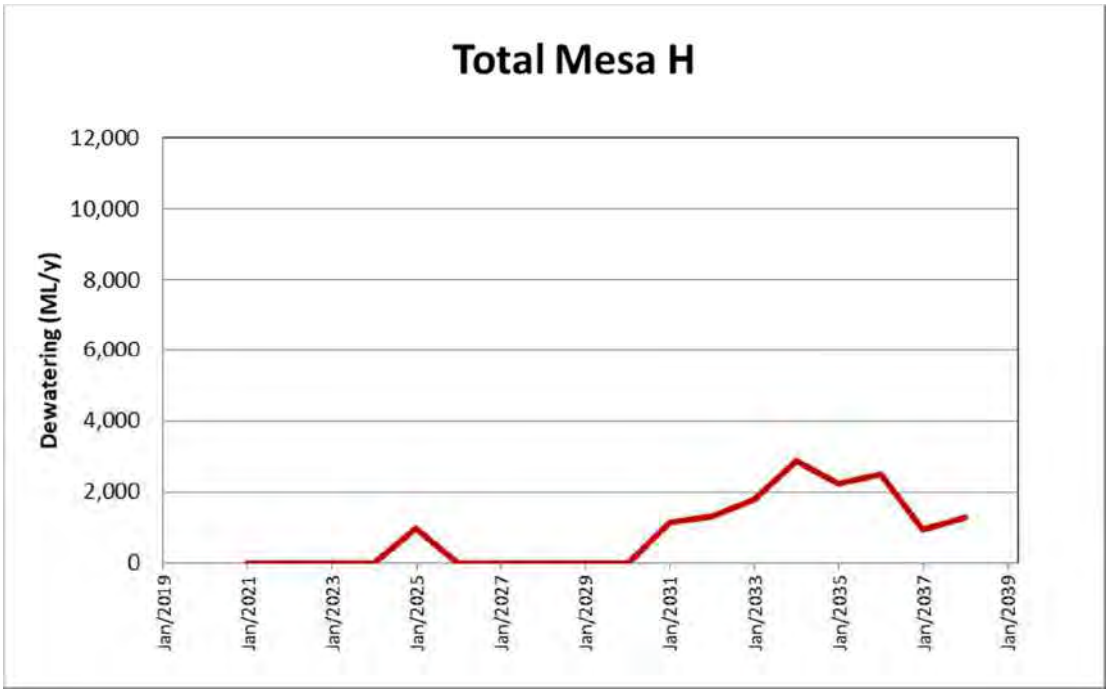

Figure 38: Dewatering rates and cumulative volumes

7.3.3 Water Supply

To sustain the water requirement of the Mesa J / H dry and wet plants, the estimated water demand is required to be consistent with the implementation of the thickener plant. The Southern Cutback Borefield (SCB) is predicted to successfully meet shortfalls in predicted surplus water availability from mine pit dewatering. Assigned SCB pumping rates in conjunction with mine pit dewatering surplus volumes are predicted to meet the projected J / H operational water demand of up to 7 GL/year.

7.3.4 Model Water Balance

The model predicted water balance (average inflows and outflows over the life of mine) is presented in Table 13. Consistent with the calibrated model the sources of inflow are depletion of aquifer storage (by dewatering) and borefield pumping, replenished by the stream leakage (from the Robe River and Jimmawuarrada Creek). Major outflow components are pumping from the water supply borefield and mine dewatering.

It should be noted that changes made to the prediction model to account for the impact of Coastal Water Supply pumping reversed the boundary fluxes at southern inflow boundary, making it an outflow boundary from 2021 onwards. In addition, some of the stream leakage from the Jimmawurrada Creek predicted to flow to the south, toward the CWS rather than downstream towards the Robe River, which is considered to be a conservative assumption.

Figure 39 shows the predicted cumulative Mesa H and Mesa J dewatering volumes, water supply abstraction rates vs predicted water demand. The simulation predicts a cumulative total of approximately 100 GL will be required to be abstracted between 2020 and 2037.

Figure 39 also indicates the direct rainfall plus surface water run-off, and seepage recirculation from waste fine storage facilities and water reservoir into active pits; these volumes will be abstracted through the same sump-pumping system used to measure pit dewatering rates, hence the total volumes to be abstracted, as measured via dewatering flow metres, will potentially be higher than the volumes indicated in the numerical model predictions.

Based on current and previous volumes, direct rainfall and surface run-off can increase water abstraction by up to 4 GL/a (depending on size and frequency of rainfall events) and seepage recirculation an estimated 3 GL/a (depending on location and depth of the surrounding pits and level of the waste fines storage facility), with up to 15 GL/year abstracted from the Mesa J hub.

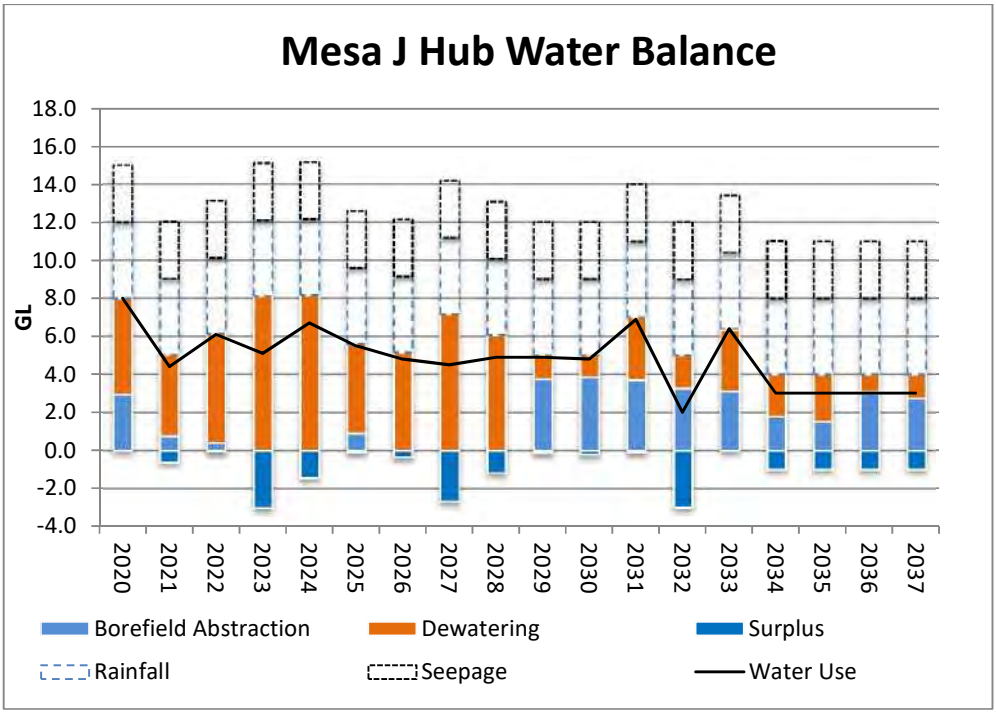

Figure 39: Cumulative Mesa H, J and Borefield groundwater abstraction rates

Table 13: Average Predicted Inflows and Outflows over Life of Mine

Flow Component	Inflow (GL/y)	Outflow (GL/y)
Storage	3.9	3.8
Borefield Pumping	-	1.9
Dewatering	-	3.9
Rainfall Recharge	0.6	-
Discharge to Dan's Dam	1.3	-
Evapotranspiration	-	2.1
Groundwater Inflow / Outflow	0.8	0.8
Stream Leakage	7.5	1.6
TOTAL	**14.1**	**14.1**

7.4 Surplus Discharge

Surplus water from mine pit dewatering to access the BWT resources is proposed to be discharged from the existing licensed discharge point in the Jimmawuarrada Creek. This water management option has been determined to be the most appropriate method of surplus site water management, mostly required during and directly post wet season for surface water management purposes. This option was selected on the basis of its potential to provide supplementary water along zones that will potentially have the biggest drawdown along the Jimmawurrada Creek. These locations are also supported by the ongoing monitoring of the current discharge currently indicating no discernible environmental impact.

The Proponent developed a model to estimate the extent of impact of surplus water discharge along the Jimmawuarrada Creek (Appendix C). Table 14 shows the estimated extent of the discharge footprint along the Robe River adopting six discharge rates scenarios.

Table 14: Estimated discharge extent from discharge location for various discharge rates

Discharge Rate	Maximum Distance Travelled (km)
5 ML/d	3.5
10 ML/d	5.2
15 ML/d	5.2
20 ML/d	5.9
25 ML/d	9.3
30 ML/d	11.8

Based on BWT mine schedule for Mesa H and J, it is predicted that between 2021 and 2030 the totality of the dewatering volumes will be used for ore processing and an increase abstraction from the SCB will be required to meet site water demand. Surplus discharge is only expected during this period for the management of direct rainfall and surface run-off. Between 2030 and 2037, BWT mining will progress more consistently and surplus discharge may occur more often in order to maintain the site water reservoir at a manageable level.

7.5 Prediction Uncertainty

While a reasonable calibration to steady state and time-varying conditions has been achieved for the groundwater flow model, there remains inherent uncertainty in the parameters and setups adopted to describe the hydrogeological system with consequent risks in the prediction of dewatering impacts owing, mostly, to the absence of historical monitoring data for calibration.

To assess the potential impact of these uncertainties, uncertainty predictions have been conducted on the base case model dewatering prediction. Details of the uncertainty runs, focusing mainly on the potential impacts on the Robe River pools, are outlined in Table 15.

Normally, uncertainty analysis is limited to varying input parameters within reasonable limits which are not necessarily supported by the model calibration. However as part of this investigation the uncertainty analysis also included combinations of parameters to assess what conditions might be required to produce dewatering impacts that would trigger necessary mitigation measures to maintain surface water pools along the Robe River. The uncertainty runs were grouped as:

- Conceptual Model Uncertainties: These runs were designed to investigate the impact that hydrogeological changes, that are not supported by the current conceptualisation or the

model calibration, may have on predicted drawdown impacts on surface water pools along the Robe River. These include Runs 8, 10, 11 and 12.

- Climatic Uncertainties: These runs were designed to assess what hydrological conditions might be required to produce worst case drawdown impacts on surface water pools along the Robe River. These include Runs 2, 3, 4, 6 and 9.
- Extreme /Stress Uncertainties: These runs included extreme changes in the model set or operating conditions to assess the drawdown impact on surface water pools along the Robe River. These included Runs 1, 5, 7 and 13.

Table 15: Summary of Uncertainty Runs

Run	Description	Type of Uncertainty
1	Natural inflows to the Robe River and Jimmawurrada Creek not simulated (set to zero)	Stress
2	Natural inflows to the Robe River and Jimmawurrada Creek reduced by 50%	Climate
3	Natural inflows to the Robe River reduced by 50%. Inflows to the Jimmawurrada Creek not simulated (set to zero)	Climate
4	Natural inflows to the Robe River not simulated. Inflows to the Jimmawurrada Creek reduced by 50%	Climate
5	Steady state rainfall recharge and stream flows. Impact associated with CWS not included.	Stress
6	Rainfall recharge reduced by 50% everywhere	Climate
7	Rainfall recharge reduced by 50% everywhere and discharge to Dan's Dam not simulated (set to zero)	Stress
8	General head inflow boundary associated with Robe River not simulated (removed from the model)	Stress
9	Rainfall recharge increased by 50% everywhere. Robe River and Jimmawurrada flows increased by 50%.	Climate
10	Unconfined storage (Sy) of the Robe River alluvium increased by 10% (from 30 to 40%)	Conceptual
11	Hydraulic conductivity of the outcropping Brockman Formation increased to 5 m/d	Conceptual
12	Outflow from the Wittenoom Formation included (General Head Boundary included across the northern model boundary at 115 mAHD)	Conceptual
13	No dewatering from Mesa H and J. All water demand supplied from proposed borefield	Stress

Uncertainty Runs 1, 4 and 8 are predicted to result in the greatest increase in predicted drawdown across the modelled catchment. The total drawdown at tracking points for these three Uncertainty Runs is at least double the total drawdown predicted for the other Uncertainty Runs (and the Base Cases). The next greatest impact on drawdown is predicted by Uncertainty Run 12, however it is less than half of the total drawdown predicted for Uncertainty Runs 1, 4 and 8. Overall however, Uncertainty Runs 1, 2, 3, 4, 6, 7, 8 and 12 predict more drawdown at tracking points compared to the Base Cases.

Uncertainty Runs 5, 9, 10, 11 and 13 all predict less combined drawdown at tracking points than the Bases Cases. As would be expected, Uncertainty Runs 5 and 13 predict less drawdown at

tracking points along the Robe River due to the inclusion of constant recharge and stream flow and moving all pumping to the water supply borefield.

Considering the predicted drawdown at TP7 (along the Jimmawurrada Creek, east of the Southern Cutback borefield), Uncertainty Runs 1 and 3, are predicted to result in the greatest increase in predicted drawdown. As would be expected, simulating all water demand drawn from the borefield (Uncertainty Run 13) predicted the next greatest impact on predicted drawdown at TP7 as TP7 is closest to the water supply borefield; as would be expected, this Uncertainty Run reduced the predicted drawdown at all other tracking points.

A reduction of 50% of the natural inflow in Jimmawurrada Creek (Uncertainty run 2), increased predicted drawdown by ~3m, however, the same uncertainty run showed no significant increase in the drawdown along the Robe River, with max drawdown remaining less than 1m.

Section 8 - Assessment of Potential Impacts

8.1 Groundwater Levels

Predicted drawdown by 2037 (end of mining at Mesa H) is reflected in groundwater level contours provided in Figure 41. Maximum drawdown at the end of mining at Mesa H (end of 2037) is predicted in the immediate area of Pits 4 and 5 at Mesa H, with predicted drawdowns of around 25 m. As dewatering at Mesa J finishes at the end of 2029, borefield pumping is required to meet the projected water demand and drawdown of 15 m is predicted in the borefield area at the end of mining.

Figure 40 40 and Figure 41 shows a visual representation of the zones of maximum drawdown predicted along the Robe River and the Jimmawurrada Creek by Dec 2030 and 2037, respectively.

The drawdown along the Jimmawurrada Creek is predicted to lower the water level up to 9 m by 2030 mostly caused by Mesa J BWT mining, with the water table ranging between approximately 140 and 165 mRL along the zones of drawdown in Figure 41.

However, the drawdown will reduce to 2.3m by 2037 (Figure 42) due to the end of BWT mining at Mesa J and overall reduction in groundwater abstraction from Southern Cutback Borefield from 2034 to 2037 with the water table ranging between approximately 145 and 165 mRL.

The maximum rate of drawdown along the creek is predicted to happen between 2027 and 2030 with a drawdown rate of approximately 2.5 m/year. However, drawdown and aquifer recovery rates of 2m/year will happen frequently depending on duration of dry season and frequency of rainfall events (Figure 42). Between 2023 and 2036 the average rate of drawdown during this entire period is predicted to be approximately 0.2 m/year.

Due to the fact only intermittent / ephemeral pools (no permanent or semi-permanent pools), have been identified along the 12 km section of Jimmawurrada Creek nearest to Mesa J, the predicted drawdown will not have a direct impact to these intermittent pools; these pools are surface water driven - formed immediately after rainfall / streamflow events, and are preserved only for a short period of time until they naturally disappear due to infiltration and evaporation. The intermittent pools are disconnected from the alluvium aquifer due the depth to water along the creek.

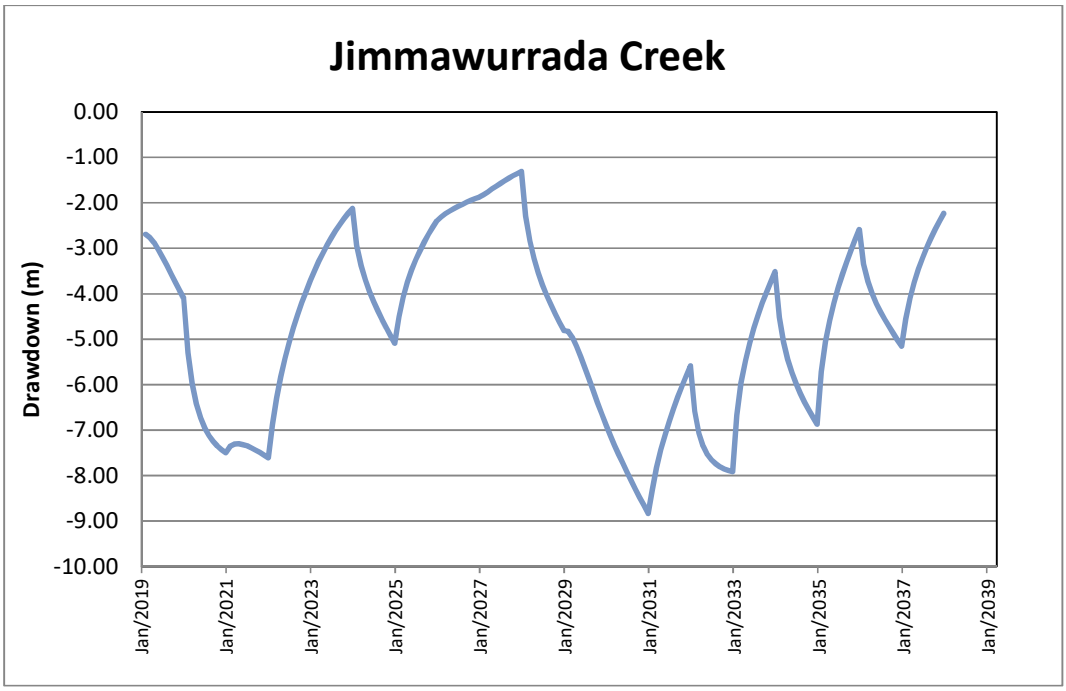

Figure 42: Groundwater drawdown to the east of the southern cutback borefield

Although long term monitoring data in the immediate area of the surface water pools or in Robe River alluvium are not available, monitoring records from the nearby bores close to the river suggest seasonal variation of groundwater levels approximately 3m (Figure 43), this natural fluctuation of the water table in the Robe River alluvium is consistent to what has been observed in the lower Robe River (DoW, 2010).

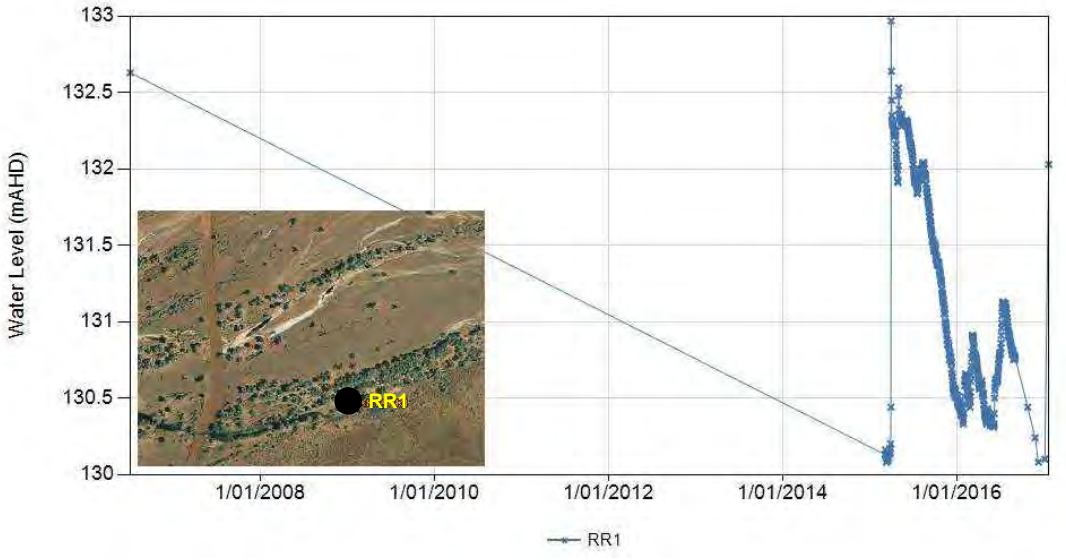

Figure 43: RR1 Hydrograph

There are five main areas where the proposed mining area would be adjacent to the surface water pools and phreatophytic vegetation that could use the groundwater (model tracking points are indicated in Figure 44):

- Tracking point TP2, at the confluence of Robe River and Jimmawurrada Creek, where dewatering at Mesa J and borefield pumping could potentially create extensive drawdown in the Jimmawurrada Creek alluvium extending to the north towards the Robe River. Maximum predicted drawdown at TP2 is 0.26 m.
- Tracking points TP11, 12, 13 and 14 (between Jimmawurrada and West Creek) adjacent to Mesa J mining areas. Maximum predicted drawdown in this area is 0.44 m at TP14.
- Tracking points TP25 and 26, adjacent to the outflow boundary associated with the Wittenoom aquifer. This area is not only in direct hydraulic connection with the orebody aquifers via TPB but is also underlain by high k Wittenoom aquifer. Maximum predicted drawdown in this area is up to 0.68 m at TP25.
- Tracking points TP22, 23 and 24, in the Robe River alluvium west of TP25. This area is in direct hydraulic connection with the CID aquifer via bounded by fresh Brockman Formation. Maximum predicted drawdown in this area is 0.28 m at TP23.
- Tracking point TP7 is located near the Jimmawurrada Creek in the vicinity of the proposed water supply borefield. Maximum predicted drawdown at TP7 is 8.81 m.

In summary, the potential impacts of mining and dewatering at Mesa J and Mesa H on the surface water pools along the Robe River are predicted to be localised, temporary in duration and relatively small, and fall within the natural fluctuation of the Robe River water level (2-3 m). Permanent and semi-permanent pools with more than 0.5 m depth should not be severely impacted, however shallower semi-permanent or seasonal pools, immediately to the north of Mesa H, could potentially seasonally dry out during periods of low rainfall or periods of drought.

The drawdown along the Jimmawurrada Creek is predicted to lower the water table up to 9 m by 2030. This drawdown is caused mostly by the SCB water supply abstraction (bores slotted against the CID and Basement aquifers) and by the Mesa J dewatering scheduled to be finalised by 2029, but also partially attributed to the CWS, which will lower the water table ~10m by 2037 along the inflow boundary of the Mesa H model. However, with the end of dewatering at Mesa J and natural rebound of the water level during wet season, the drawdown at the end of life of mine (Dec 2037) is expected to be between 1 and 5 m along a 11 Km section of Jimmawurrada Creek, and up to 7m from that point due to the overlap with the Coastal Water Supply drawdown cone of depression.

As indicated in Figure 22, extended dry period and lack of cyclonic events simulated by a 50% reduction of natural recharge could further lower the water table along the Jimmawurrada Creek, with a low seasonal level predicted to drop to a maximum depth of 18 m bgl east of SCB (cross section 1).

8.2 Other Users

The Pannawonica town borefield is up gradient from the mine site and impact to the local aquifer and associated borefield is not expected.

The CWS borefield is not expected to impact on or be impacted (yield reduction) by Mesa H and Mesa J dewatering and water supply abstraction, however, groundwater trigger levels set for the CWS in the respective GWOS, along the Jimmawuarrada Creek, could potentially be impacted due to cumulative localized lowering of the water table.

8.3 The Environment

The environmental systems identified which are likely to be sensitive to changes in the hydrogeological regime at Mesa J and H (as identified in DoW 2010) include:

- Riverine ecosystems – particularly semi-permanent and permanent pools
- Riparian ecosystems – particularly phreatophytic vegetation
- Aquifer ecosystems – particularly stygofauna assemblages

8.3.1 Riverine Ecosystems

The Riverine habitat is considered to be of high importance to fauna species providing a range of ecological values to a wide suite of species. A number of semi-permanent to permanent pools have been recorded within the locality (Figure 16). These pools are considered to provide significant fauna habitat due to the refuge they provide to fish, amphibians and water fowl together with foraging habitat for terrestrial fauna (including conservation significant fauna – Northern Quoll, Pilbara Olive Python, Ghost Bats and Pilbara Leaf-nosed Bats during dry times and the vegetation assemblages that they support.

Permanent and semi-permanent pools on the Robe River support “River Pool Ecosystem” type groundwater dependant ecosystems (GDE’s). These ecosystems rely on consistent surface expressions of groundwater, and are often characterised by a specific assemblage of phreatophytes, macrophytes, mesic shrubs and ephemeral taxa. The pools are typically fringed by vegetation association EcMaCv dominated by *M. argentea* and *E. camaldulensis* var. *refulgens*. (Astron 2016). These vegetation associations are consistent with the vegetation that typically occurs along minor and major channels within the River land system.

Vegetation association EcMaCv is considered to represent groundwater dependant vegetation due to the dominant species being *M. argentea* (obligate phreatophyte) and therefore likely to be sensitive to changes in water depth and availability.

Results of the groundwater modelling indicate that the groundwater drawdown from mine pit dewatering at Mesa H may potentially result in a minor change to the water levels in the pools of

the Robe River of <1m. Whilst this may result in changes to the depth and lateral extent of the pools, potential drawdown impacts on riparian vegetation (particularly the woodland community) are predicted to be localised, temporary in duration, relatively small, and within the natural fluctuation range of the Robe river water levels (measured to be in the order of 2-3 m).

8.3.2 Riparian ecosystems

The riparian ecosystems within the Robe Valley are dominated by mixed woodlands of Cajeput (*Melaleuca argentea*), River Red Gum (*Eucalyptus camaldulensis*) and Coolibah (*Eucalyptus victrix*). Major disturbances to vegetation associated with river beds and pools have resulted from variation in the pattern and volume of rainfall. The local topography, and resultant force of floodwaters can uproot young to semi-mature vegetation and other vegetation may die from being submerged under floodwaters for extended periods. Qualitative assessments of riparian vegetation have shown significant physical uprooting evident in both riparian and floodplain vegetation. These changes were a direct result of the high flows and widespread flooding associated with high flow events.

Robe River

The Robe River riverine habitat is dominated by moderately-dense to dense mixed woodlands to open forests of Cajeput (*Melaleuca argentea*), River Red Gum (*Eucalyptus camaldulensis*) and Coolibah (*Eucalyptus victrix*). The open understorey of tall shrubs is dominated by *Petalostylis labicheoides* and *Acacia trachycarpa* with scattered *Sesbania formosa* and *Gossypium robinsonii* over sedges and mixed herbs. Filamentous green algae are common in the waterways, together with emergent macrophytes, such as *Typha domingensis*, *Potamogeton* and *Vallisneria* species, and fringing rushes such as *Schoenoplectus* sp. and *Eleocharis* sp. (Rio Tinto 2017).

Similar to the pools of the Robe River, results of the groundwater modelling indicate that the groundwater drawdown from mine pit dewatering may potentially result in a minor change to the water levels of <1m and thus potential drawdown impacts on riparian vegetation (particularly the woodland community) are within the natural fluctuation range of the Robe river water levels. Therefore, impacts to phreatophytic vegetation in the Robe River are predicted to be negligible.

Jimmawurrada Creek

Jimmawurrada Creek supports moderate-risk facultative phreatophytic vegetation (i.e. species that utilise groundwater for a portion of their water requirements). The dominant phreatophytic species recorded from Jimmawurrada Creek are *Eucalyptus camaldulensis* subsp. *refulgens* and *Eucalyptus victrix* (RTIO 2017). The pre-mining depth to groundwater along Jimmawurrada Creek, throughout the modelled zone of drawdown, has historically occurred around 4-12 mbgl. This spectrum of depth to groundwater represents both a depth where groundwater is likely to have been accessible to root systems, but unlikely to contribute a significant proportion of phreatophytic Environmental Water Requirements (EWR), and the potential outer limits of depth from which mature facultative phreatophytes might successfully supplement their EWR with groundwater.

The groundwater drawdown predicted is unlikely to be represent a significant proportion of EWR and this is supported by the general absence of such species (i.e Melaleuca's) on Jimmawurrada creek. For phreatophytes occurring on Jimmawurrada Creek, the likely reliance on access to groundwater is inferred to be more closely linked to surface and stored soil water availability.

The phreatophytic species (particularly *E. camaldulensis*) along Jimmawurrada Creek are, therefore, unlikely to be wholly dependent on groundwater access. Experience in other parts of the Pilbara shows that *E. victrix* in woodland/open woodland communities (as present along Jimmawurrada Creek) are less likely to be significantly impacted by the predicted drawdown. The key potential impact to phreatophytic vegetation may, therefore be more general changes in the vigour and canopy stature/reach of *E. camaldulensis* subsp. *refulgens* populations along sections of Jimmawurrada Creek.

An approximately 12 Km section of Jimmawurrada Creek is expected to be inside the estimated cumulative drawdown cone of depression. The maximum modelled drawdown of up to 9m (equating to ~14mbgl) over a 6.5km stretch) is likely to alter the water table beyond the reach of most phreatophytic vegetation root systems, and therefore likely to result in drought stress impacts, particularly during extended dry periods. Impacts to overstorey vegetation, especially *E. camaldulensis* subsp. *refulgens* populations are likely to be in the order of a 15-50% canopy decline and 5-15% increased mortality, particularly on the southern channel and terrace zones away from the direct/indirect influence of surface water and discharge. Understorey changes are also likely; mainly in the form of reduced abundance of mesic understorey species. However, overstorey changes are likely to be more discrete, with overstory species gradually reducing canopy cover to match the reduced water availability.

Some intermittent pools appear during high rainfall events, however no permanent or semi-permanent pools have been identified within in this section of Jimmawurrada creekline.

Monitoring

An aquatic ecosystems monitoring program (undertaken by Stremtec) has been in place since 1991 in order to detect any mining related impacts from drawdown and discharge at Mesa J and includes monitoring of aquatic fauna, channel/pool morphology, riparian/bank condition, weeds, water flows and water quality. To date, there have been no detectable changes in the aquatic ecology of the Robe River that could be attributed to mining operations alone (Streamtec 2017). Additional aquatic fauna sampling baseline data has also been collected seasonally since 2017, providing a detailed, quantitative, and systematic analysis of aquatic fauna assemblages and water chemistry, prior to the development of Mesa H, which will support the proposed updated environmental monitoring and management program.

In addition to the existing monitoring program, riparian vegetation transects have been established in 2016 across discharge and reference sites to capture floristic data, population structure, vegetation and crown condition of phreatophytic species. Worldview Lansat imagery has also been acquired to enable vegetation condition to be assessed on a catchment scale. Leaf-water potential measurements are also undertaken as part of the analysis to understand tree-water usage and

stress. Ongoing data capture and analysis will enable vegetation changes to be assessed over time and compared to pre-Mesa H development.

8.3.3 Aquifer ecosystems

The primary habitat for stygofauna in the locality is considered to be the alluvial aquifers and the CID aquifer, the latter underlies the alluvial aquifer along Jimmawurrada Creek. The Southern Cutback Borefield and modelled cumulative groundwater drawdown cone of depression falls within the Priority Ecological Community (Priority 1) *Stygofauna Community of the Bungaroo Aquifer.*

Three stygofauna of conservation significance have been recorded within the cumulative drawdown impact area within two of the main aquifer systems:

- CID aquifer (Mesa H pit area) :
    - Amphipoda species: *Nedsia hurlberti* and *Nedsia sculptilis*, both of which are Schedule 3 species. More sampling and molecular work is being undertaken to gain a better understanding of the local distribution of this species.
- Alluvial aquifers:
    - Nine records of the Commonwealth listed subterranean fauna: Blind Cave Eel (*Ophisternon candidum)* (Vulnerable; Schedule 3) has been recorded in within the alluvial aquifers associated with Bungaroo Creek, Jimmawurrada Creek, and the Robe River and currently represent the only inland Pilbara records of this species.

The Blind Cave Eel records comprise both physical samples and environmental DNA (eDNA) samples, both upstream and downstream of the modelled extent of groundwater drawdown, and have been recorded within the hyporheic zone of the Robe River (Biota 2018, WRM 2019).

The modelled groundwater drawdown is predicted to result in a temporal and localised loss of stygofauna habitat, which has the ability to be recover during rainfall – recharge events. Habitat parameters including groundwater levels and groundwater and surface water quality will be monitored as part of the broader catchment environmental and hydrogeological monitoring program.

8.4 The Aquifer

Once mining is complete and dewatering ceases, groundwater levels in the Mesa J and Mesa H mining areas will recover until a balance is reached between groundwater inflows and groundwater outflows. In the event that pit voids are infilled with waste / waste fines storage facility, groundwater levels will eventually recover to pre-development levels. Aquifer recovery in the pit areas (i.e. the CID aquifer) is expected to take up to 50-60 years to recover to pre-mining level.

The large majority of the drawdown along the Robe River and Jimmawurrada Creek is expected to recover 90% of the drawdown after the first or second significant rainfall events The drawdown in

the Yeera Bluff permanent pool area is estimated to take the longest to recover, with the last 20cm of drawdown taking up to 40 years to recover (Figure 45). Details of the mine closure modelling are outlined below:

- Initial conditions for the prediction were taken from the end of dewatering (December 2037);
- The model was run for a period of 190 years (January 2038 to December 2137);
- The model predictions were run using annual time increments (stress periods);
- Infilling of all mine voids is completed prior to any groundwater recovery;
- The hydraulic conductivity of the infill material will be similar to the material of the original formations excavated during mining;
- The mined out void will be infilled to a level above the pre-development groundwater table and the final land form will be designed such that there will be no increase or decrease in recharge to the infilled mine void;
- The ET setup is identical to that used for the predictions. No ET was included for the infilled void because water levels in the infilled pits are not expected to exceed the top of the infill for extended periods of time;
- Recharge rates as a percentage of annual rainfall as well as stream flows are identical to those used for the model predictions. Annual rainfall and stream flow data from the prediction period is repeated to simulate variable annual recharge and flows for the closure predictions;
- The prediction does not include any further pumping, dewatering or discharge from any other area in the modelled catchment or impacts associated with the Coastal Water Supply Project; and
- All other model parameters were set consistent with the steady state model.

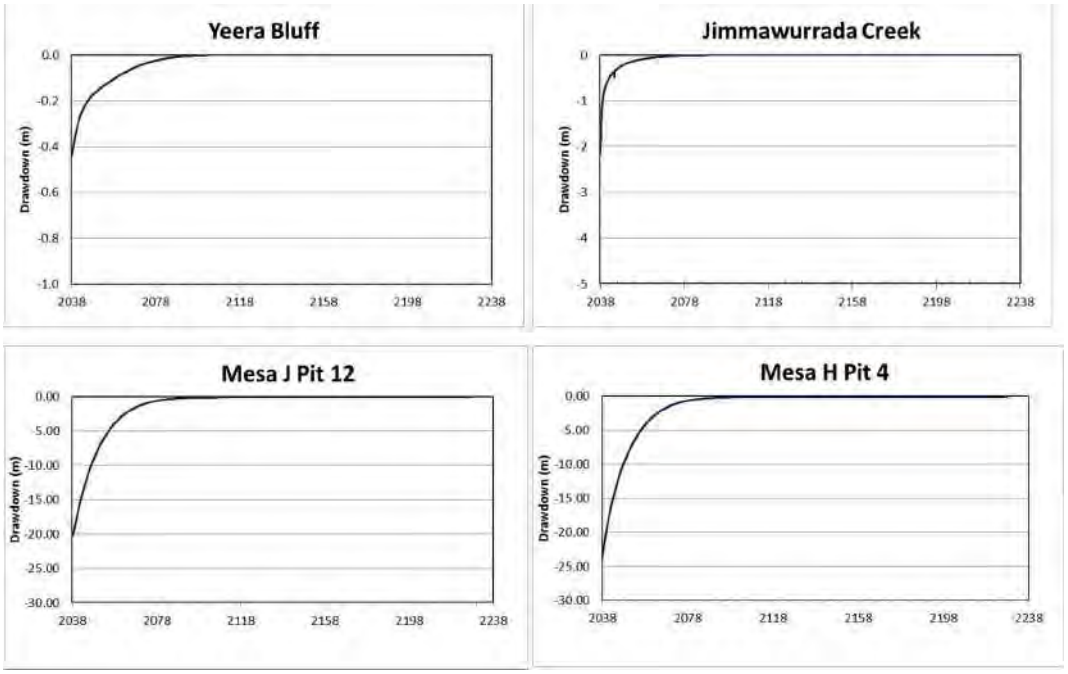

Figure 45: Predicted water level post closure

Section 9 - Site Water Balance

Water respects no boundaries, and drought and floods are events beyond our direct control. Rio Tinto's role in water management is one of stewardship, not ownership, and therefore our operating philosophy is based on the following concepts:

- efficient use of water;
- implementation of the reduce, re-use, recycle concepts;
- avoid or minimise contamination of clean streams and catchments; and
- recognise and protect downstream beneficial uses (for both surface and groundwater).

Implementing these concepts requires considerable planning, based on a clear understanding of the project and the hydrological, geochemical and processing regimes in which it operates.

The hydrologic cycle is the primary model for the input and output water management elements in any site development. These elements include:

- Rainfall: an estimated sum of areas of operational pits times a twice a year 150mm event occurring over a 1-5 day period.
- Evaporation: an estimated sum of areas of the waste fines storage facility, the water reservoir and sumps times the average yearly pan evaporation.
- Dewatering and groundwater abstraction: extracted from the groundwater numerical model.
- Seepage: based on observed volumes seeping through pit walls close to operational waste fines storage facility and Dan's Dam.
- Discharge: excess volume that can't be managed / used on site and will be discharged in the Jimmawurrada Creek.

Site water demand has been defined as:

- Wet Plant processing: estimated based on current site water demand and secondary screening plant design and mine schedule.
- Non-processing infrastructure: based on current site water demand.
- Dust suppression: estimated as 17 litres per ton of moved material based on mine schedule.

Table 16 presents the estimated water demand for Scenario 1 (thickener plant) and Scenario 2 (without thickener plant) used to estimate water demand for the model prediction.

Section 10 - Groundwater Monitoring

The Proponent's aim is to ensure that the environmental requirements for water quality and sustainability are met. This includes ensuring that water quality does not deteriorate below its current state during mining and post-closure. Potential impacts are currently assessed through the existing groundwater monitoring program at Mesa J and will be expanded to include the Mesa H estimated cone of depression. Based on the site water balance, current combined Mesa J and Mesa H groundwater abstraction (~ 12 GL/year) is expected to be maintained to meet site demand during LoM.

Ongoing monitoring of phreatophytic vegetation, aquatic fauna and pool water quality along the Robe River and Jimmawurrada Creek will continue to be undertaken according to the Mesa J Environmental Management Plan. To manage the potential risk to the environmental values, triggers (biological and water related) will be defined before Mesa H dewatering commences.

Based on the current monitoring schedule for Mesa J, outlined in the current approved site GWOS, Table 17 outlines the preliminary proposed monitoring schedule. Monitoring data is reviewed and evaluated for its validity prior to entry into the licensee's central database (EnviroSys) in readiness for reporting requirements. All data collected through the monitoring programme is included within the externally reported Annual and Triennial Aquifer Reviews.

Monitoring bores will be installed up gradient and down gradient from the planned tailings storage facilities to monitor potential changes in the water quality due to seepage and manage any potential impacts to local receptors in the Robe River.

Table 17: Current Monitoring Schedule

Bore Type	Frequency	Parameter
Production Bores	Monthly	Abstraction volume
	Monthly	Water level
	Monthly	EC, pH, Temperature
	Annually	Field Chemistry (EC, pH, temp, TSS, Colour, Turbidity, Total hardness) Major Ions (CO_3, HCO_3, Ca, Na, K, Mg, SO_4, Si, F, Fe, Al, Cl) Dissolved metals (Ag, As, B, Ba, Cd, Co, Cr, Cu, Hg, Mn, Mo, Ni, Pb, Sb, Se, Sn, U, Zn); Nutrients (Total P, Total N, NO_2, NO_3, NH_4) Microbiological (Thermotolerant Coliforms, *E.coli, Naegleria*)
Monitoring Bores*	Quarterly	Water level

Bore Type	Frequency	Parameter
Sumps	Monthly	Water level
Pools	Monthly	Water level
	Annually	Field Chemistry (EC, pH, temp, TSS, Colour, Turbidity, Total hardness) Major Ions (CO_3, HCO_3, Ca, Na, K, Mg, SO_4, Si, F, Fe, Al, Cl) Dissolved metals (Ag, As, B, Ba, Cd, Co, Cr, Cu, Hg, Mn, Mo, Ni, Pb, Sb, Se, Sn, U, Zn); Nutrients (Total P, Total N, NO_2, NO_3, NH_4) Microbiological (Thermotolerant Coliforms, *E.coli, Naegleria*)
Discharge	Quarterly	Field Chemistry (EC, pH, temp, TSS, Colour, Turbidity, Total hardness) Major Ions (CO_3, HCO_3, Ca, Na, K, Mg, SO_4, Si, F, Fe, Al, Cl) Dissolved metals (Ag, As, B, Ba, Cd, Co, Cr, Cu, Hg, Mn, Mo, Ni, Pb, Sb, Se, Sn, U, Zn); Nutrients (Total P, Total N, NO_2, NO_3, NH_4) Microbiological (Thermotolerant Coliforms, *E.coli, Naegleria*)

Section 11 - Management Approach / Conclusions

The Proponent has a defined Water Strategy that guides water management within the group. This strategy requires an integrated approach to water management that promotes, maintains or improves water quality, minimises fresh water use and maximises reuse and recycling. The water abstracted from the Mesa J hub will be used for mining operations, including irrigation of ore to increase moisture content, potable supply, dust suppression and wet processing.

The inclusion of the thickener to the wet plant at Mesa J will have a significant reduction in the drawdown along the Jimmawurrada Creek, reducing from a predicted 18 m to 9 m maximum drawdown. Although supplemental discharge to the creek is not viable due to the lack of an alternative suitable / sustainable aquifer in the region, the reconfiguration of the existing Mesa J discharge system to a single discharge point approximately 2 Km up-gradient of the SCB will off-set some of the drawdown along the creek through the natural seepage of surplus discharge.

A maintenance schedule will be implemented to ensure water infrastructure is operating optimally. Maintenance personnel will visually check the condition of the pipelines and infrastructure associated with transporting water from the borefield for potential leaks and ruptures.

Monitoring bores will be commissioned with data loggers for continuous monitoring of the water level. Selected bores will have monitoring devices that will also read conductivity and salinity changes over time.

All the production bores will be commissioned with automated telemetry systems to optimise water abstraction and manage drawdown throughout the borefield. The groundwater numerical model will be revised yearly based on transient data viability during LoM.

Ongoing data monitoring and collection will be used to develop a baseline criteria for the water levels in the aquifers, Robe River and Jimmawurrada Creek and used to support the development of water level triggers which will be used for the design and implementation of an impact mitigation strategy. The monitoring data will be integrated with the environmental monitoring and management plan focussed on groundwater dependant ecosystems (riparian vegetation, aquatic fauna and stygofauna).

The water level in the pools, when feasible, will be monitored by automated telemetry systems that will be used to trigger supplemental discharge to specific locations along the Robe River, aiming to mitigate any impact that may be adversely affecting the water levels in the pools. Based on the results of a 30 days discharge trial carried out in the Robe River and the analysis of the Mesa J discharge to the West Creek between 2016 and 2017, supplemental discharge to the pools could be used to reduce the drawdown along the Robe River pools, although the discharge points would need to be located at or immediately adjacent to pools to be protected, hence only a few and selected pools could be protected and this solution will require consultation with the traditional owners due to visual impact of this strategy.

Based on regular monitoring of the pools and water levels, if / when the drawdown in the Yeera Bluff is 0.5 m or more than the average natural variance of pre-defined control points (e.g. Medawandy, monitoring bores in the alluvium) Rio Tinto will cease mining Pit 7 below the water table, until a streamflow event recharges the pool and the water levels have reached a steady state without showing any sign of adverse ecological / cultural impact. Figure 46 shows the drawdown effect of mining Pit 7 BWT to the Yeera Bluff permanent pool.

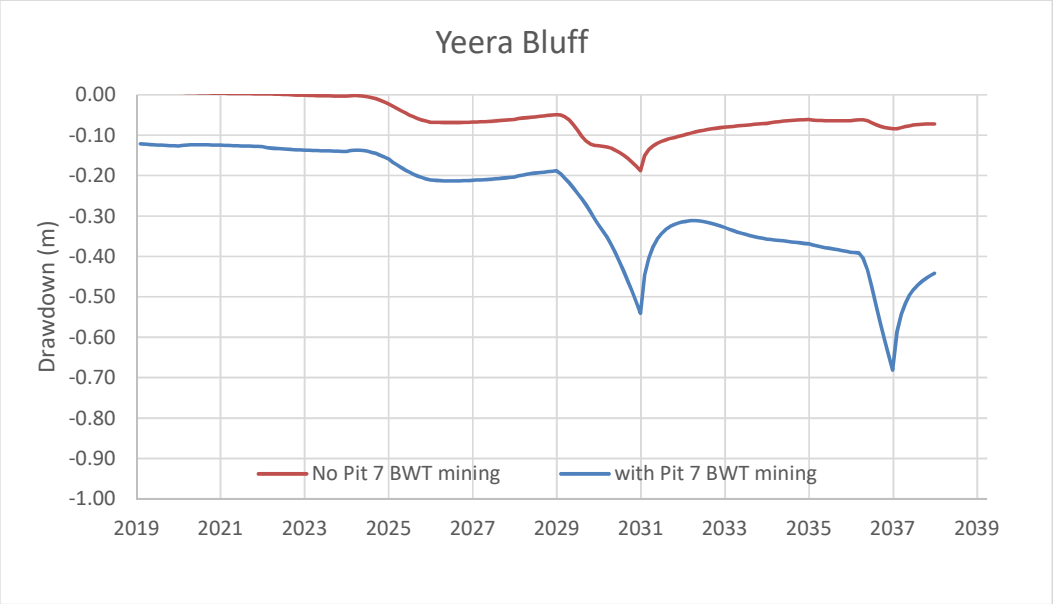

Figure 46: Drawdown caused by Pit 7 BWT to the Yeera bluff permanent pool

The uncertainty run 2 (natural inflows to the Robe River and Jimmawurrada Creek reduced by 50%) was predicted as an appropriate scenario based on climate change, an additional reduction of 2 m as maximum seasonal variation is applied as the worst case scenario. In the worst case scenario, the water table along sections of the Jimmawurrada Creek, east of Mesa J and Southern Cutback, could be lowered down to 18m bgl.

Based on maximum observed alluvium thickness (Figure 22) ranging between 28 and 40m along the channel thalweg, 44% to 64% of saturated alluvium will be preserved below the water table serving as a continuous habitat to the Blind Cave Eel along the Jimmawurrada Creek. Table 18 shows the estimated volume of saturated alluvium in the Jimmawurrada Creek within the numerical model domain for the central case, uncertainty run # 2 and worst case scenarios.

Table 18: Estimated volume of Jimmawurrada Aquifer alluvium preserved by 2030.

Date	Saturated Volume in m^3	% remaining saturated alluvium
Pre-mining	176,900,000	100%
Current	116,650,000	66%
2030 (base case)	113,710,000	64%
2030 (uncertainty run #2)	91,162,000	52%
2030 (uncertainty run #2 + lowest seasonal variation) – worst case scenario	77,526,000	44%

A network of monitoring bores will be installed along the section of the Jimmawurrada Creek that is predicted to be impacted by groundwater abstraction from the SCB and CWS. This network will be used to monitor the water level and trigger mitigation actions (e.g change in the abstraction regime, drill of bores farther away from the creek, direct environmental discharge, aquifer reinjection) during LoM.

Executive Summary

This report outlines the hydrogeological drilling and test pumping results completed at Mesa H deposit and surroundings. The purpose of the Mesa H field investigation was primarily to close conceptual uncertainties and increase the hydrogeological understanding of the deposit and surrounding regional aquifers, to support the Mesa H Feasibility Study (FS). Key objectives of this investigation included:

- Assessing the hydraulic connection between the CID Aquifer, regional basement aquifers and Robe River Alluvial Aquifer in key locations where hydrogeological information was previously uncertain;
- Robe River pool mitigation strategy trial through long term test pumping and discharge management along the Robe River within the Mesa H project area;
- Clarify hydraulic boundary at Yeera bluff and aquifer throughflow continuity in the outer reaches of the Mesa H project area and Robe River vicinity;
- Test the aquifer south of the Mesa H deposit for water supply requirements; and
- Investigate water supply sources for the Mesa H provisory construction camp.

As part of the investigation the following works and installations were completed:

- 5 production bores
- 14 monitoring bores (1 nested monitoring bore)
- 1 monitoring bore for environmental sampling
- 2 Vibrating Wire Piezometers (VWPs) grouting and instrument installations
- Short term test pumping of 4 production bores (24 hour Constant Rate Test (CRT))
- 30 day CRT test pumping of 1 production bore

Section 1 - Introduction

The Mesa H deposit is the subject of a Feasibility Study (FS) from May 2017 to April 2018. Hydrogeological drilling and test pumping works were undertaken at Mesa H during 2017 as part of the FS investigations. The Mesa H deposit is located adjacent to the Mesa J iron ore mining operation, approximately 17 km southeast of the Pannawonica Township and 110 km southwest of Karratha in the Pilbara region of Western Australia.

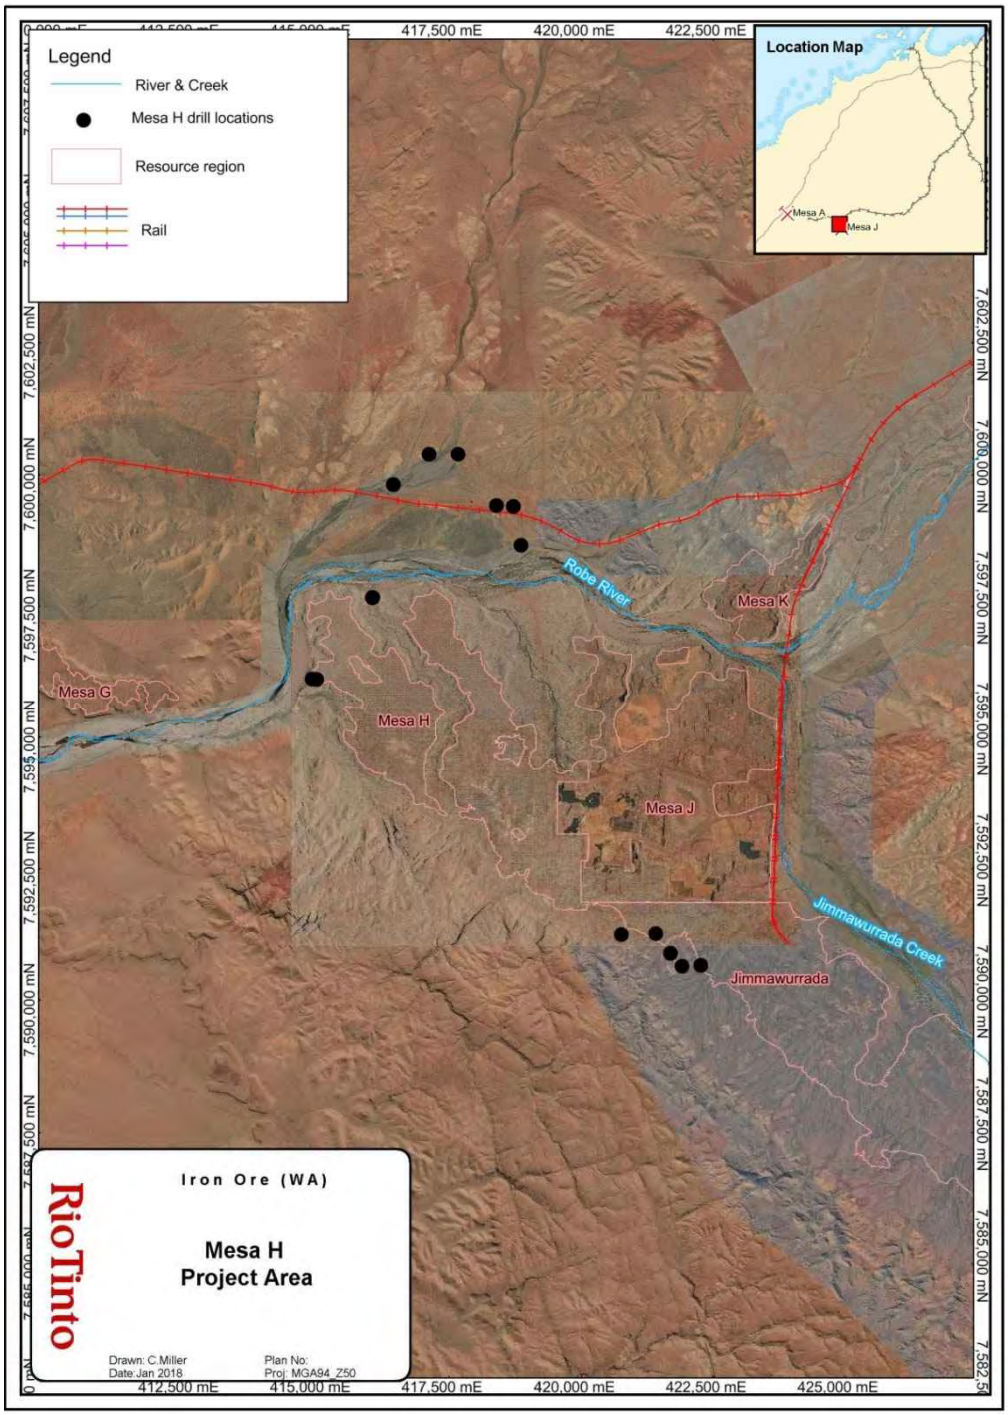

Figure 1 Mesa H project area

1.1 Programme description

The original program scope of works (RTIO-PDE-0152031) comprised of drilling and construction of monitoring bores, production bores and vibrating wire piezometer (VWP) at Mesa H. however due to ground conditions and findings during drilling, changes to the scope have been made during the program. Figure 2 shows the final location of all the installed bores. Test pumping was completed to better understand the aquifer parameters and hydrogeochemical sampling of bore locations was completed for hydro-chemical modelling to support the groundwater potential supply to the Mesa H To address hydrogeological risks identified during early stages of the FS, this program was designed to:

- Assess the hydrogeological characteristics of the basement close to the Yeera Bluff pool;
- Assess the basement continuity north of the Robe River,
- Test the aquifer south of the Mesa H deposit for water supply requirements.
- Perform a discharge trial to support the design of an impact mitigation strategy for the local pools.
- Investigate water supply sources for the Mesa H construction camp

The works included the following:

- 5 production bores and 15 monitoring bores installed at the Mesa H project area
- 2 VWPs installed within the Mesa H project area project area
- 1 Nested piezometer installed within the Mesa H project area
- Complete pumping testing of production bores to assess bore capacities, ascertain aquifer parameters and identify any applicable flow boundaries.
- 30 day discharge trial to assess the hydrogeological characteristics of the basement close to the Yeera Bluff pool;
- Collection of water samples from selected locations to support hydro-chemical modelling.

1.2 Approvals

Before earthworks and drilling commenced, the following Approvals Requests (AR) and 26D Licenses were obtained.

Approvals Requests (ARs)

- AR-16-14020 - Mesa H FS Hydrogeological Program (Heritage Areas)
- AR-16-14023 - Mesa H FS Hydro Drilling (Off Mining Lease)
- AR-16-14024 - Mesa H FS Hydro Drilling
- AR-17-14272 - Mesa H Robe River Discharge Trial
- AR-17-14444 -Water Supply Mesa H Construction Camp

26D Licenses

- CAW183351(1)
- CAW183352(1)

Section 2 - Mesa H Project Setting

Mesa H is a channel iron deposit (**CID**) deposit that forms part of a sinuous chain of mesas which define the palaeochannel of the Robe River and its associated tributaries. The deposit contains high grade and low grade mineralisation, with a combined Mineral Resource of 207 Mt at 54.3% Fe. Approximately 34% of the reported resource occurred below the pre-mining water table, however due to the lowering of the water table caused by dewatering activities at the adjacent Mesa J operation, the reported resource at Mesa H is approximately 13% below the present-day water table.

The project site is located downstream from the confluence of the Robe River and Jimmawurrada Creek. Along the river are permanent and semi-permanent pools which support environmental sensitive ecosystems and are of cultural significance in the area. Due to the close proximity of Mesa H to Robe River and a number of significant surface water pools, this investigations objective is focused on understanding potential impacts that future dewatering activities at Mesa H may have on these areas.

2.1 Geology and Hydrogeology

Geological units and hydro-stratigraphic components in the Mesa H area are well understood. Areas where hydrogeological conceptual uncertainties were identified during the PFS were targeted in this investigation to clarify modelling scenarios based on the understating of geological units in the area.

2.1.1 Mesa H Conceptualisation

Key areas where conceptual uncertainties for the Mesa H FS included the Yeera Bluff location (MB17MEH0011 and MB17MEH0012) where limited drilling and hydrogeological investigations could clarify a groundwater throughflow boundary between CID aquifer and the Robe River Alluvial aquifer which supports what is considered a permanent surface water pool (KM-RR16) directly west of the Mesa H deposit. As such, drilling and bore development suggests the basement geology (unmineralised BIF) in this area causes a groundwater throughflow boundary. Further evidence of this groundwater boundary is suggested by very low airlift yields which shortly after commencing bore development became dry. Water samples were not collected as a result and a production bore to test hydrogeological parameters and hydraulic connectivity between CID and basement were deemed unnecessary.

The uncertainty of basement aquifer continuity in the north of the Mesa H was addressed by drilling at several locations including MB17MEH0007 - MB17MEH0010, MB17MEH0013, MB17MEH00014 in this program and an additional location MB17MEK0001 (RTIO-PDE-0156788) to determine the regional Wittenoom Aquifer throughflow direction north the Robe River. The results are reflected as water level contours shown in Figure 3. Additional information on geological units in the north area can be found in the borehole logs in Appendix A.

Geological and hydrostratigraphic unit uncertainties remain in areas where drilling requests could not be approved or where rig mobilisation was deemed unsafe. These areas are the Robe River alluvial and Jimmawurrada Creek locations.

2.1.2 Water supply

Areas drilled in for the purpose of water supply exploration and construction camp water supply had found varying results and success. In similar geological units, variations in hydrostratigraphic properties were found. As a result, drilling and test pumping was unable to clarify the suitability of the locations for water supply. For example exploration bores in the Southern Cutback (SCB) area of Mesa H (Otherwise known as Jimmawurrada deposit) encountered thick sequences of black, lignitic shale (McRae Shale) overlayed by a thick sequence of clay. While it was found to be largely impermeable, fractured and interbedded zones of chert layers had higher permeability allowing for yields during drilling. Where lost circulation occurred, the yields were at its highest however it is not known how extensive these fractures and cavities are in the area. A large fracture and lost circulation zone was intersected only at one drill pad location MB17MEH0004 and WB17MEH0005. Bore locations which did not encounter lost circulation in the SCB area were dry (MB17MEH0001 and MB17MEH0003) and or yielding very low or had issues developing due to the amount of fines in the sample (MB17MEH0002, MB17MEH0005 and MB17MEH0006). These bore locations were not recommended for production bore construction.

Bores in the north of the Mesa H close to the rail line (MB17MEH0013 & 14) had varying degrees of success for water supply potential for the Mesa H construction camp. The monitoring bores and production bores encountered similar geology with varying degrees of fracturing and weathering profiles within the alluvium and Wittenoom Formation. This suggests that continuous water supply may be at risk due to varying yield performance between the two production bores drilled here (WB17MEH0002 and WB17MEH0004).

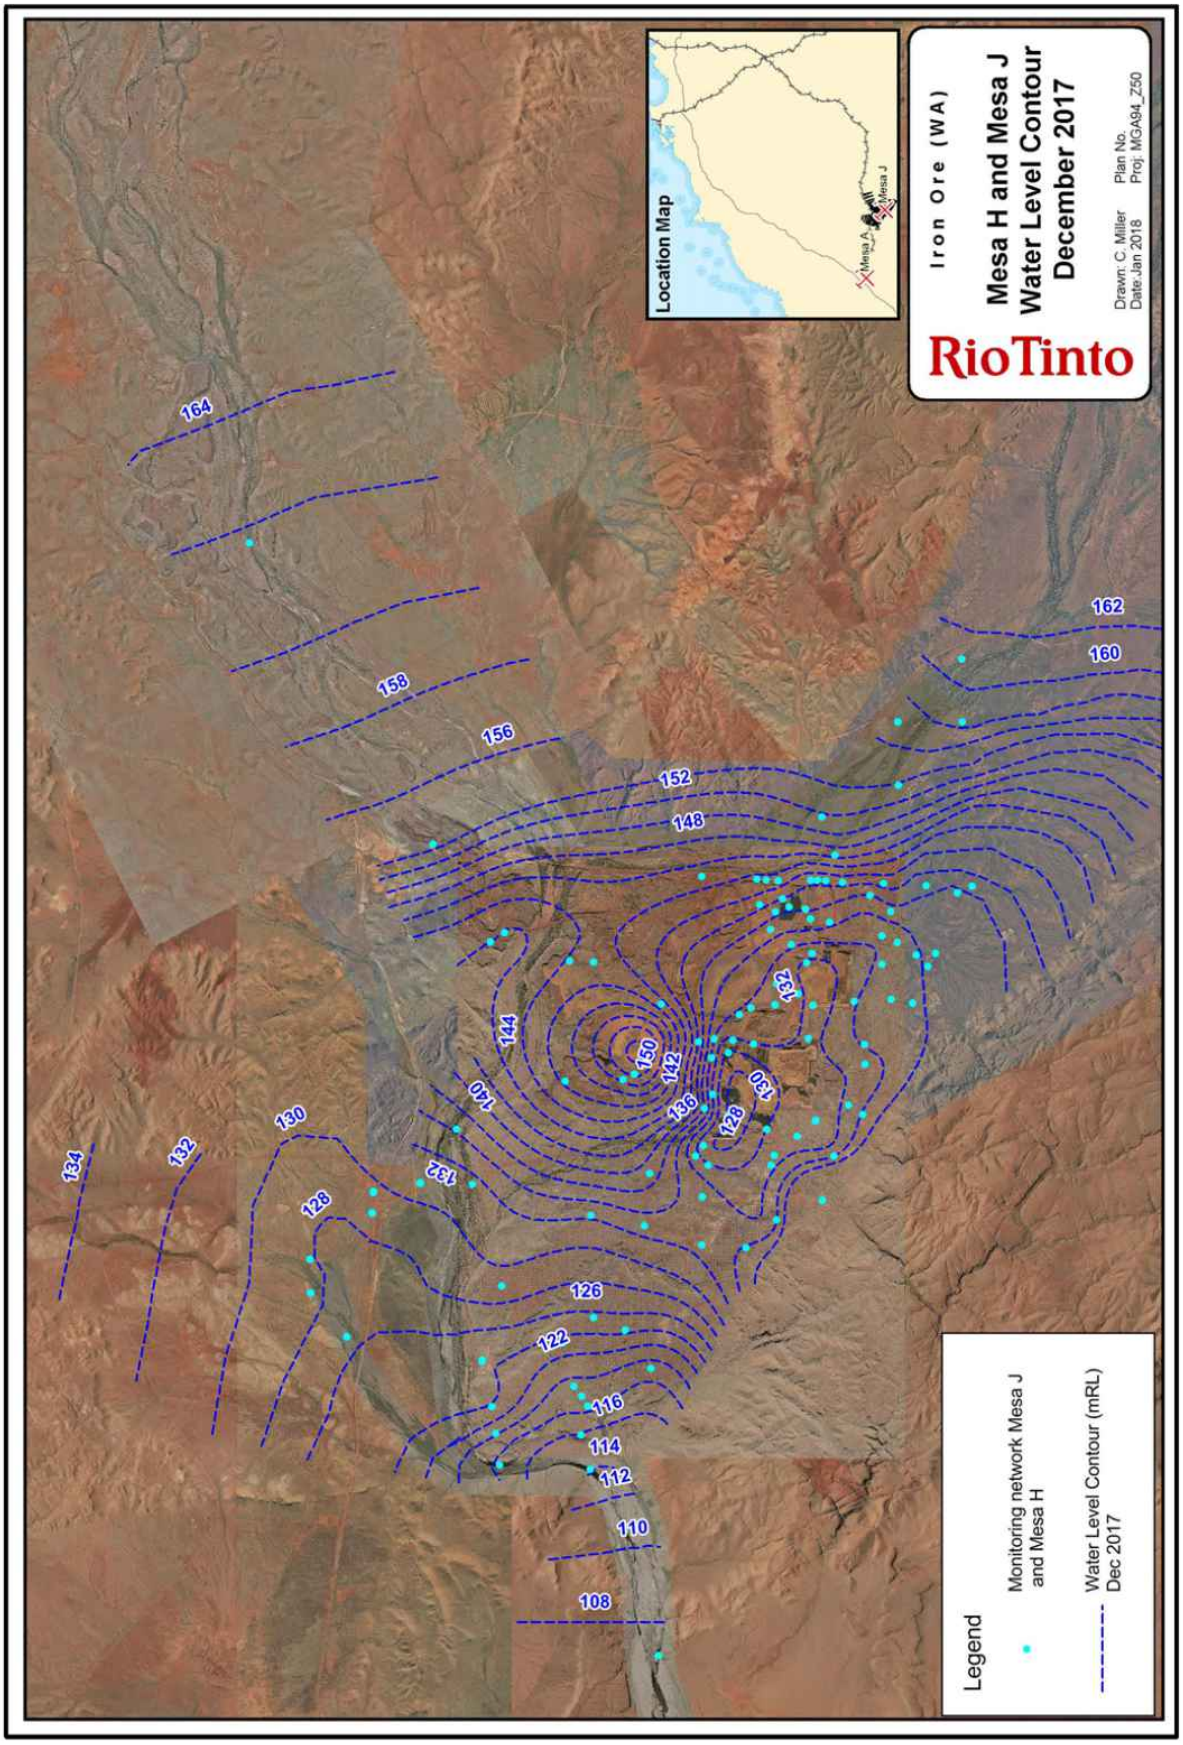

Figure 4 Groundwater level RL post drilling at Mesa C

Section 3 - Drilling Program

3.1 Drilling

Bunbury Drilling Pty Ltd (BDC), were commissioned to carry out the 2017 Mesa H Hydrogeological Drilling Program. A combination of Mud Rotary and Conventional Air Hammer drilling techniques were employed by BDC to ensure successful and timely completion of the project. Where it was deemed necessary, a combination of both techniques were used on the same hole, where mud rotary was used to seal the upper less stable sections, while the rest of the hole was completed using the quicker conventional air drilling technique. Post drilling and construction geophysical surveys were also completed on all production Bores between October 2017 and December 2017 by Kinetic. Installation of VWPs was carried out Foraco Fluid Potential

Drilling, Test Pumping and Geophysical surveys were managed by the Rio Tinto Water Resource Evaluation and Services group (WRE&S). During the field campaign, project logistics and safety oversight was provided by Project Field Coordinators, whilst Technical hydrogeological supervision was provided by Feld Hydrogeologists.

3.2 Mesa H Bore Construction

Bore construction was completed by BDC as per Scope of Works (SoW). Headworks for all bores were completed in accordance with the Rio Tinto Design Specification for Water and Monitoring Bore Headworks (RTIO-PDE-0089729). Complete details of all bore locations, drilling and construction and hydrogeological information collected during drilling and construction activities is provided in Tables 1, 2, 3, and 4 respectively. A summary of construction details for each bore type are below:

Production Bores:

- 12” threaded steel casing stick-up 150mm above the top of the plinth;
- Lockable steel lid with handle;
- Concrete plinth measuring 1 m^2 by 300 mm high (100 mm set below natural ground level).

Monitoring bores (includes dual nested monitoring bores)

- 50mm PVC Class 18 casing, fitted with a PVC cap
- Steel casing stick-up 500 mm above the top of the plinth;
- Lockable steel lid with handle;
- Concrete plinth measuring 1 m^2 by 300 mm high (100 mm set below natural ground level).
- Dual nested monitoring bores were constructed with bentonite seal to separate deep and shallow formations between slotted sections of PVC within the parent hole.
- All bores were gravel packed with graded gravel 3.2 - 6.4 mm in size, except the 3mm aperture monitoring bore which used 6.4-10mm graded gravel.

Vibrating Wire Piezometer (VWPs)

Grouting and instrumentation of VWPs was carried out by Foraco Fluid Potential in November 2017. Table 3 summarises the VWP installation details including depths and formations. All VWPs were sleeved using 50mm PVC by BDC. The multiple sensors were installed post drilling and sleeving activities and grouted up to the surface. A Quattro logger and tripod standard headworks were installed for downloading VWP data. Sensors recording frequency was set to record every 6 hours.

3.3 Geophysics

Gamma and Gyro geophysical surveys were conducted by BDC using the Driller Operated Gamma and Gyro Survey (DOGGS) tools provided by Reflex. Post drilling and construction, geophysical surveys were completed on all production bores in casing. Production bore geophysical surveys were carried out by Kinetic as outlined in the Scope of Works. The geophysics survey reports are presented in Appendix C.

3.4 Water quality

Water quality samples were collected after the end of airlifting activities for all monitoring and production bores. VWP locations were not developed and were not sampled. Any bores not sampled during the program were dry after a short period of airlifting. Sampled were tested for the hydro-geochemical parameters as per the Scope of Works. Hydro-geochemical analysis was completed by ALS environment Laboratory. Certificate of analysis are presented in Appendix D.

3.5 Summary of Field Program Learnings

While the field campaign was executed safely and successfully, a key number of learnings can be taken away from the program. Detailed below are some of the key learnings from Mesa H.

Mesa H Key Learnings

- MB17MEH0012 was planned as a nested piezo but was only constructed as a single piezo due to surfacing casing going to 40m and hence sealing off the CID unit Also, the CID is largely unsaturated. This was due to a large cavity encountered the adjacent monitoring bore.
- MB17MEH0011 was not drilled to planned depth of 110m due to a large cavity between 28 and 62 mbgl and 100% circulation loss. As this location is on the edge of the cliff, it can be assumed this cavity may have external lateral extents to the cliff face. Drilling further away from the cliff face showed there was no cavity there.
- MB17MEH0015 was installed as a 3mm 50mm PVC aperture and course gravel (6.4-10mm) to enable stygofauna surveys. Consequently, airlift had to be abandoned due to excessive silt and due to fear of clogging up the hole. Large aperture bores will allow elevated silt inflow during airlift, especially along the creek bed.
- WB17MEH0005 produced significantly more water than anticipated and was airlifted at 36 L/s. Despite the presence of black shale in the water, the bore was able so sufficiently clean up.

- HM17MEH0003 (17MEH_VW01) encountered significant fallback to37 mbgl from the drilled depth of 110m. It fell back to approximately the top of the clay sequence. The PVC casing was installed to depth using hollow rods. The PVC stayed open for the subsequent installation of the VWP and grouting.
- HM17MEH0001 (17MEH_VW01) and a number of other holes were drilled 16m shorter as basement which was fresh crystalline dolomite was encountered earlier than expected. Other basement contacts included Marra Mamba BIFs and shales.
- Significant clay bands of up to 12m thick were encountered at Mesa H. However these did not pose hole stability issues during mud drilling. Holes stayed open and there were no installation issues.
- Monitoring Bore MB17MEH0011 encountered significant circulation loss (29-62 mbgl), yet it took significantly less gravel than expected given the cavity. This indicates that most lost circulation at Warramboo is more likely a result of fractures and smaller voids, rather than “large cavities”.
- Drilling exploratory monitoring bores with mud limited ability to accurately measure yields and hence make it difficult to pick the best locations for production bores.
- A few locations where dual nested bores were planned have been changed to single installation due to lithology and lack of saturated aquifer thickness. This highlights geological uncertainties within Mesa H.
- Slow penetration rates in fresh basement rocks, especially dolomite. Penetration rates were as low as 2.5m/hr.
- Although the area was classified as fibrous likely, there were no fibrous materials intercepted.
- The use of threaded casing was successfully trailed at Mesa H.
- Deep water crossings and steep terrain posed significant hazards but were managed as per existing procedures and no safety incidents were reported.
- Exploratory monitoring holes/targets for production bores need to be drilled with CH or RC to accurately measure yields and select the best possible target for PBs
- PB bores installations, need to install slots well below water table to stop air getting into the hole and reduce turbulence during test pumping.
- Threaded casing was trialled successful
- Drilling in the pit posed challenges due to operational constraints. Time was lost due to waiting for escorts into and out of the pit.
- Incorporate terrain and discharge management plan into sump designs for potentially high yielding areas.

Section 4 - Test Pumping

4.1 Test Pumping Plan and Methods

Test pumping was conducted by McArthur Drilling and Test Pumping (MDP). The program consisted of a step rate test (SRT) and constant rate test (CRT) for 5 production bores within Mesa H in November 2017. All 5 production bores had 12" diameters. Figure 5 show the location of the production bores tested.

Test pumping objectives consisted of:

- Observe local drawdown in groundwater levels resulting from test pumping to further understand aquifer parameters to support Mesa J / H aquifer water supply capacity in the Southern Cutback borefield area; and
- Access aquifer parameters and bore hydraulics to support the Mesa H construction provisory camp water supply.

To measure water levels within the production bore, two dip tubes attached to the rising main in the pumping bore were utilised. Water levels in monitoring bores were measured with a combination of manual dipping and automated data loggers.

Test pumping involved the following:

- A calibration test to ensure all equipment was functional and to provide an indication of possible flow rates.
- Step drawdown rate test (SRT): Consisting of 5 x 60 or 100 minute tests with increasing yield rates to provide data for bore efficiency assessment and to determine an appropriate pumping rate for the constant rate test.
- Constant rate test (CRT): Consisting of a 24 hour test to provide data for estimation of aquifer properties. WB17MEH0001 had a 30 day test.
- Water sampling after one hour of pumping during the CRT for water quality analysis.
- At CRT cessation, water levels in the production bore were monitored until water level recovery reached 90% of the pre CRT water level.

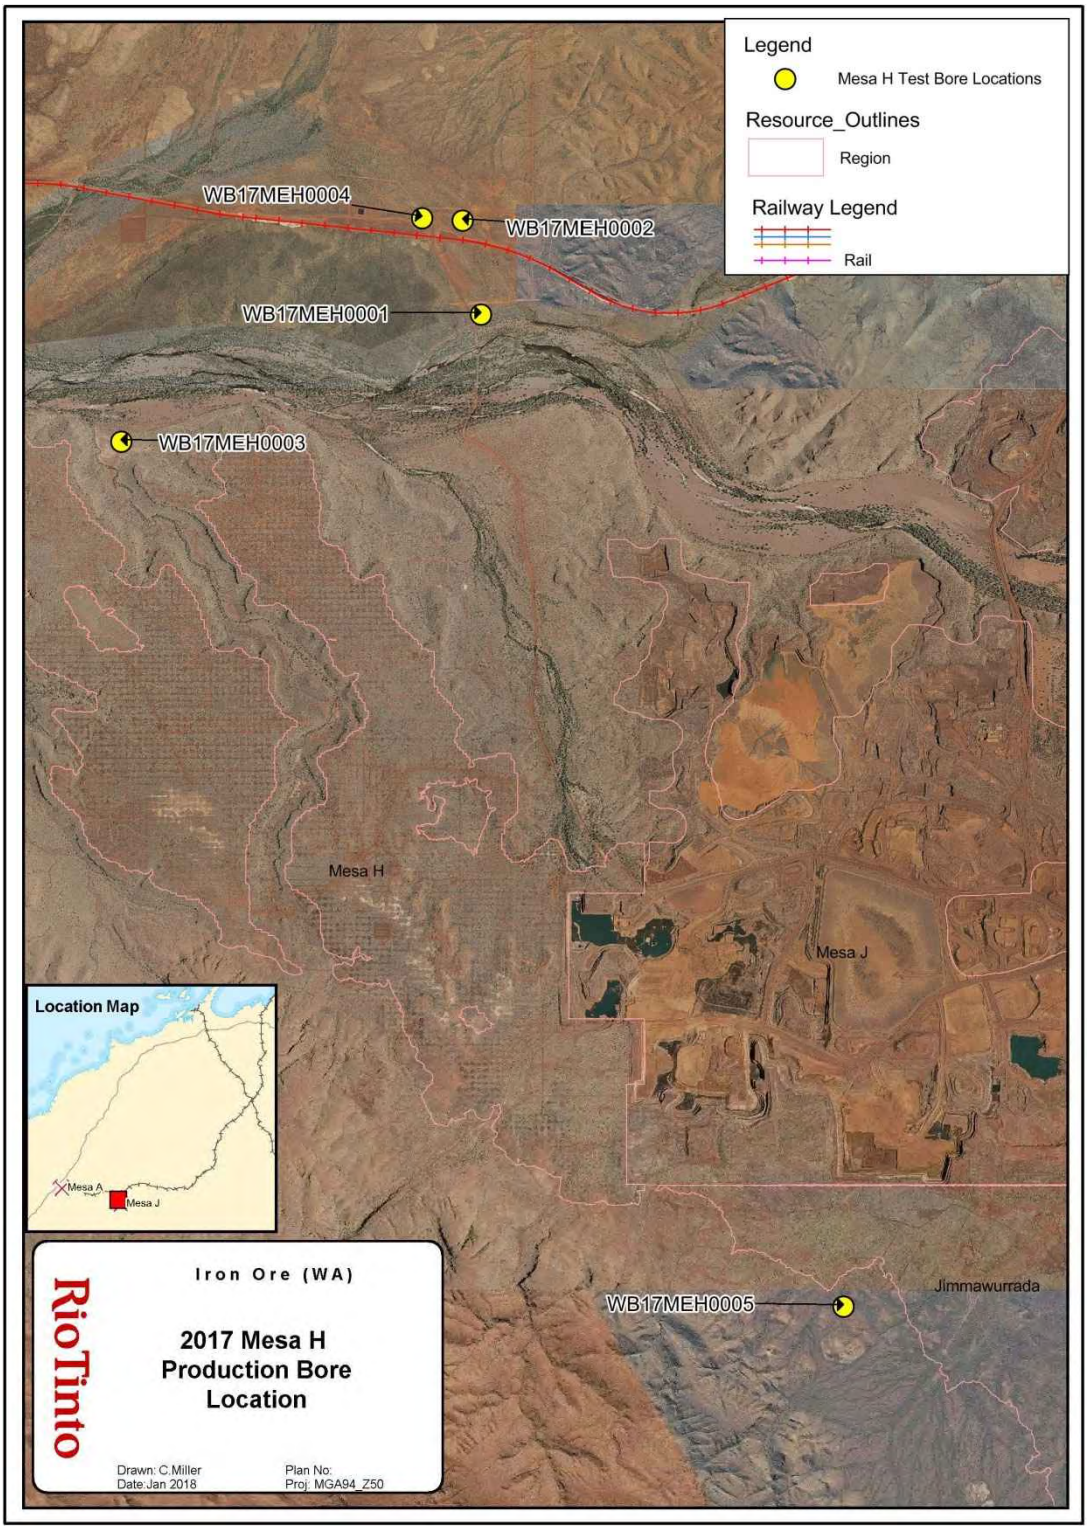

Figure 5: Mesa H production test bore locations

4.1 Aquifer Test Summary

The Hantush-Bierschenk analysis was used to analyse the step rate test data to determine the apparent well efficiency. The step test pumping rates were used to determine the pumping rate for the constant rate test.

The Constant Rate test drawdown results presented a combination of unconfined and semi-confined (leaky) aquifer response. In order to analyse the drawdown response and obtain aquifer paramentes the Moench (unconfined) and the Hantush-Jacob (leaky) solutions were chosen to match the curves.

A review of the test pumping results indicates the following:

- All bores presented a relatively low well loss ranging between $1x10^{-4}$ and $2x10^{-7}$.
- Hydraulic conductivity of the Alluvium ranges between 10.54 and 71.49 m/day.
- Hydraulic conductivity and storage coefficient of Dolomite was 44.9 m/day $6.39E^{-5}$.
- Hydraulic conductivity and storage coefficient of fractured BIF was 568 m/day $6.203E^{-5}$.
- No bores were screened exclusively within CID and therefore CID hydraulic conductivity and storage coefficient can't be estimated.
- WB15MEH0005 displayed accelerated drawdown towards the later portion of the test that indicates a boundary response most likely due to outcropping unmineralised Brockman Formation in the south.

A 30 days CRT test was carried out for WB17MEH0001 to access boundary conditions and for the purpose of a discharge trial to support drawdown mitigation strategies of the Robe River Pools. Although the bore was showing signs of development during the initial stages of the test (at 18 L/s and reduced later to 16 L/s); results indicates:

- hydraulic conductivity of ~70 m/day with a max drawdown lesser than 3m after 30 days, and an associated specific yield of 33%;
- A boundary response was displayed in MB17MEH0007 after 30000 minutes that resulted in an sharp drop in the water level as can be observed in Figure 6.

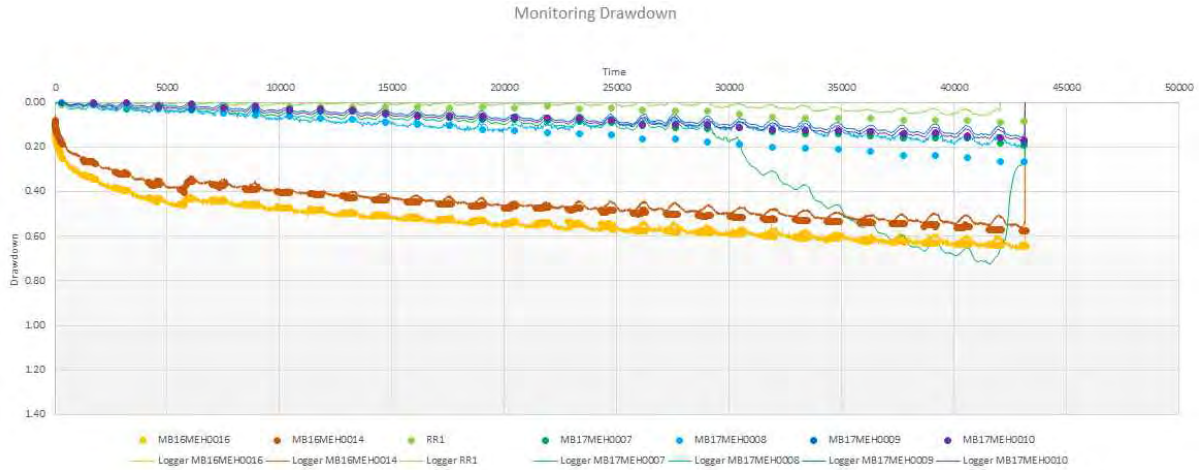

Figure 6: WB17MEH0001 CRT drawdown curves

Table 4 and Table 5 shows the summary of the step drawn-down test and constant rate test results. CRT drawdown curves and analysis using AQTSOLVE is presented in Appendix B.

Section 5 - Conclusions and Recommendations

The 2017 Mesa H hydrogeological program was executed within the approved budget and without incident. A combination of drilling techniques was successfully used to complete drilling activities including Air hammer and mud rotary methods. Through drilling and test pumping an increased understanding of the Mesa H Conceptualisation has been achieved. Conceptual gaps identified in the PFS in 2016 have been addressed with positive conceptualisation outcomes regarding areas of significant cultural and environmental value. Drilling and test pumping will be used to update and refine the Mesa H Conceptual and numerical model as part of the Mesa H FS requirements.

Water supply exploration had varying success for identifying potential future production supply locations. This is largely due to varying presence of fractured and weathered geology profiles which influenced yields in locations of similar geology. This variance and discontinuity in the geology will make it difficult to target future supply locations to meet water supply requirements.

The Robe River discharge trial confirmed an inferred aquifer boundary to the north of the Robe River, and will be valuable to assess hydraulic and engineering designs for the Robe River pools impact and associated mitigation strategy.

Bore Completion Details

HM17MEH0001

PROJECT: MESA H
LOCATION: Mesa H
DATE COMMENCED: 18/08/2017
DATE COMPLETED: 19/08/2017

DRILLING COMPANY: BDC
DRILLER: Luke Wallace
DRILLING METHOD: Mud Drilling
HYDROGEOLOGIST: Y. Alaak

GRID NAME: MGA94_50
EASTING: 416034.012
NORTHING: 7597714.217
ELEVATION: 132.378 mRL TOC

Well Notes: Collar Mud Rotary 0-1m using 12 1/4" drill bit, collar installed 8" steel casing 0-3m. Mud drilling 0-44m using 8 1/2" drill bit.

Depth mbgl	Geology	Lithology	Lithological Description	Gamma 0-100cps	Field Notes	Construction Details
0–15	Alluvium		ALLUVIUM: Alluvials composed of rounded to sun-rounded gravels with sand and clay infills. trace tragments of cherts, shales and pisolites present			50mm Blank PVC (0-3 mbgl)
15–35	CID		TPM: Moderately weathered red clayey and yellow orcherous goethite with.40% vitreous goethite, red brown sand and silts, angular to sub angular		SWL = 19 mbgl	VW17MEH0001 (15 mbgl)
15–35	CID		TPB: Weathered tertiary orcherous goethite and vitrous goethite, yellow, brown and white plastic clays with pislotic clasts of goethite. Increasing plasticity towards end of interval. clay content @ 20-30%			50mm Slotted PVC (3-39 mbgl)
35–40	Whitnoom Dolomite		DOLOMITE: Fresh chrystaline dolomite. light to dark blue, angular to sub-angular, hard to very hard hard. weathered zone at 40-42 mbgl			VW17MEH0002 (37 mbgl)
40						VW17MEJ0003 (40 mbgl)

Bore Completion Details HM17MEH0002

PROJECT: MESA H	**DRILLING COMPANY:** BDC	**GRID NAME:** MGA94_50
LOCATION: Mesa H	**DRILLER:** Joe Mason	**EASTING:** 421409.959
DATE COMMENCED: 20/08/2017	**DRILLING METHOD:** ROTARY HAMMER - AIR	**NORTHING:** 7591295.997
DATE COMPLETED: 22/08/2017	**HYDROGEOLOGIST:** YUOT ALAAK	**ELEVATION:** 174.158 mRL

Well Notes: Mud Rotary Collar 0-18m using 12 1/2" drill bit and installed 10" casing 0-17m. Mud drilled with 8 1/2" drill bit 18 - 80m (EOH). Deep piezometer MB17MEH0002, Shallow piezometer MB17MEH0003

Depth mbgl	Geology	Lithology	Lithological Description	Gamma 0-300cps	Field Notes	Construction Details
0	CID		CID: Weathered vitrous geothite and red clays. weathered pisloites. CID largely unsaturated			Bentonite (0 - 0.5 mbgl)
5						
10						8" Blank Steel (0-17 mbgl)
15						
20						
25						
30						50mm Blank PVC (0-36, 0-61 mbgl)
35	Clay		CLAY: Highly weathered white tertiary clays, resembling calcrete. Unsaturated and highly powdery. Highly plastic when saturated.		SWL Deep - (38.18 mbgl) SWL Shallow - (39.84 mbgl)	
40						50mm Slotted PVC (36 - 48 mbgl)
45					Deep Piezo Final Airlift - Yield - 0.25 L/s pH - 8.4 EC - 964 uS/cm Temp - 30.5 0C	End Cap (48 mbgl)
50						Bentonite Seal (48-52 mbgl)
55	Whitnoom Formation (Paraburdoo Dolomite)		WITTENOOM DOLOMITE: Fresh cyrstalline dolomite, sub-angular to angular, slightly fractured horizon from 60-65 but no significant increase in yields. evidence of contamination from overlaying CID in the chips. Very slow penetration through competent dolomite		FWS = 53 mbgl	
60					Field Chem (@60 mbgl EC=1021, pH=8.2, Temp = 32.8)	
65						
70					Field Chem (@66 mbgl EC=1118, pH=8.6, Temp = 32.8)	50mm Slotted PVC (61-79 mbgl)
75					Field Chem (@72 mbgl EC=1098, pH=8.2, Temp = 32.8)	End Cap (79 mbgl)
80						Fallback (79 - 80 mbgl))

ELEVATION: 175.681

Mud rotary with 12 1/4" drill bit 0-18m for 8" Collar, Air hammer 6 1/2" drill bit from 18-90m (EOH)

Depth mbgl	Geology	Lithology	Lithological Description	Gamma 0-200cps	Field Notes	Construction Details
0	Alluvium		ALLUVIUM: Mixed unconsolidated clasts of GOV pisolith, Chert, BIF, red brown ferrugenous silts/ sands			
10	CID		CID: Vitreous goethite pisoliths			8" Blank Steel (0-18 mbgl)
20						50mm Blank PVC (0-51.5 mbgl)
25			CLAY: Yellow, soft clay and shale, highly weathered, swelling clay, slight-moderate plasticity			Gravel (3.2-6.4mm) (0 - 32mbgl)
30					FWS = 30 mbgl	
35			SHALE: Dark blue grey shale (95%), minor interbedded dolomite and cherty BIF		SWL = 33.88 mbgl Final Airlift - Yield - 1 L/s pH - 8.2 EC - 982 uS/cm Temp - 29.2 0C	Bentonite (32 - 34 mbgl)
40						
45	Wittenoom Formation (Bee Gorge Member)					
50					Yields during drilling up to 5L/s from 50mbgl	
55			WITTENOOM DOLOMITE: Dark grey blue Shale (~70%) interbedded with dark grey/blue dolomite, white/grey cherty BIF and partially mineralised BIF- Hard-medium hematite fractures- dark brown-grey.			
60						50mm Slotted PVC (51.5-87.5 mbgl)
65					Fast penetration rates throughout ~5 rods/hr	Gravel (3.2-6.4mm) (34 - 87.5 mbgl)
70						
75						
80						
85						End Cap (87.5 mbgl)
90			LOST CIRCULATION: 100% lost circulation- Cavities/ Fractures. No air / water or sample return			Fallback (87.5 - 90 mbgl)

Mesa H 2016 Pre-Feasibility Study Hydrogeological Drilling Program Completion Report

May 2016

EXECUTIVE SUMMARY

This report presents drilling and construction details for works completed as part of the Mesa H Pre-Feasibility Study (PFS).The works were carried out by Bunbury Drilling, Ranger Drilling and McArthur Drilling and Test Pumping between the 8th of February and the 25th of March 2016.

Four production bores were drilled using mud rotary drilling techniques and constructed with 12" blank and slotted steel casing. The production bores were subsequently test pumped including a step test, a constant rate test and a recovery test.

A total of three nested monitoring bores and twelve single monitoring bores were constructed. All monitoring bores were cased with 50 mm blank and slotted Class 18 PVC. The nested monitoring bores and one of the monitoring bores were drilled using the air-hammer method, with all remaining monitoring bores drilled using reverse circulation (RC). All holes were logged by a supervising Hydrogeologist and a downhole geophysical survey was conducted on each bore. Water samples were collected from each production bore at the completion of the test pumping and submitted for laboratory chemical analysis.

Drilling results helped define the extent of the Robe Pisolite (CID) underneath the Robe River alluvium, identify the Paraburdoo Member and the Bee Gorge Member of the Wittenoom Formation as local aquifers and at the same time classify the unmineralised BIF (whenever underlying the CID) as an aquitard.

The basal CID has horizontal continuity throughout the deposit, with an average thickness of 20 metres and continuing underneath the Robe River alluvium (Robe River Aquifer) to the north and potentially works as a partial boundary limiting the hydraulic connection between the CID and Wittenoom aquifer.

The Robe River aquifer has a saturated thickness of approximately 20 meters consisting of highly permeable and low storage quaternary sediments with a shallow water table. Drawdown response during the long term test pumping suggests potential hydraulic connection between this aquifer and the CID aquifer.

This work aimed to support the development of a conceptual model to predict the dewatering requirements and impacts of future dewatering activities, particularly in relation to the pools and riparian vegetation associated with the Robe River.

SECTION 1 - INTRODUCTION

1.1 PROGRAM DESCRIPTION

Hydrogeological drilling works were required at Mesa H in 2016 as part of the Pre-Feasibility Study (PFS) for the development of the proposed mine. Approximately 13% of the orebody occurs below the current water table (already depressed due to dewatering activities at the nearby Mesa J mine). As such, work is required to determine the likely dewatering requirements and impacts of future dewatering activities, particularly in relation to the pools and riparian vegetation associated with the Robe River.

The original program scope comprised:

- Drilling, installation and testing of four production bores to enable advancement of the conceptual hydrogeological model;
- Drilling and installation of ten single monitoring bores and six nested monitoring bores (comprising one shallow and one deep installation) across the site;
- Test pumping of all installed production bores including step drawdown test, constant rate test and recovery; and
- Groundwater sampling of all installed production bores.

Before earth works and drilling commenced Approvals Requests (AR-15-13678A and AR-15-13678B) were authorised to carry out the work, as part of this process a 26D license (CAW182227) was obtained to install four production bores during the drilling program.

3.1 DRILLING CONTRACTS

Bunbury Drilling Pty Ltd (BDC) and Ranger Drilling Pty Ltd (Ranger) were commissioned to carry out the 2016 Mesa H PFS Hydrogeological Drilling Program. Drilling was managed by the Rio Tinto Water Resource Evaluation and Services group (WRE&S). The program was undertaken between February and March 2016.

3.3 DRILLING AND CONSTRUCTION

Single well monitoring bores were drilled using reverse circulation (RC) drilling methods, nested monitoring bores were drilled using air-hammer and production bores were drilled using mud rotary techniques. Production bores were constructed with 12” blank steel and slotted steel casing.

Monitoring bores were constructed using blank and slotted 50mm Class 18 PVC casing with bentonite seals placed to isolate the deep and shallow installations. All bores were gravel packed using graded 3.2 - 6.4 mm gravel with headworks completed as per the Rio Tinto Design Specification for Water and Monitoring Bore Headworks (RTIO-PDE-0089729), as follows:

- Production bores:
    - 12” steel casing stick-up above the top of the plinth;
    - Lockable steel lid with handle;
    - Stick up and lid painted white;
    - Concrete plinth measuring 1 m^2 by 300 mm high (100 mm set below natural ground level).
- Monitoring bores:
    - Steel casing stick-up 500 mm above the top of the plinth;
    - PVC stick-up 350 mm above the top of the plinth and fitted with a PVC cap;
    - Lockable steel lid with handle;
    - Concrete plinth measuring 1 m^2 by 300 mm high (100 mm set below natural ground level).

Bore details are provided in Tables 1 (locations), 2 (construction details) and 3 (water levels/airlift yields), and Figure 1 shows the bore locations in relation to the Order of Magnitude (OoM) pit design (mesa_h_opt2_pit_rev4_mga). Bore logs and individual bore completion reports are presented in Appendices A and B respectively.

3.4 GEOPHYSICS

Surtron Technologies (Australia) PTY Ltd (Surtron) was commissioned to carry out the downhole geophysics, including: gamma, gyro and density.

Geophysical survey results are provided in Appendix C with gamma survey results also presented on the bore logs in appendix **A COMPOSITE BORE LOGS** A.

3.5 PROGRAM LEARNINGS

Overall, the program was completed successfully, on time, within the budget and with no injury, however there were some minor difficulties encountered which should be considered for future drilling, including:

- Varying degrees of lost circulation occurred in several drill holes within the CID, resulting in significant mud loss on occasion. In one instance, complete circulation loss was experienced in both the production bore (WB16MEH0002) and the adjacent monitoring bore (MB16MEH0012). Attempts were made to grout up the mud loss zone during drilling of WB16MEH0002 as it was above the water table, however, this was unsuccessful and the remainder of the hole was drilled blind;
- Several of the monitoring bores could not be developed due to inadequate yield and likely low submergence;
- Difficulties were encountered during construction of nested piezometer MB15MEH0005/006. The bore was initially drilled with air, however, a swelling clay zone restricted the installation of casing. As a result, the driller sourced some RC rods to enable casing to be run in-rod. The bore was successfully constructed;
- One production bore could not be properly developed due to inadequate yield and minimal submergence. Attempts were made to flush water down the annulus and inside the casing to break down the mud, however, the flow did not increase as the mud was cleared out.

SECTION 3 - TEST PUMPING

4.1 TEST PUMPING PLAN AND METHODS

Test pumping of the production bores was conducted in March 2016. The objective of the test pumping was to provide information on bore efficiency and yield, and to assess aquifer properties and test groundwater flow boundaries.

The test pumping was carried out by McArthur Drilling and Test Pumping (MDP). Two dip tubes attached to the rising main in the pumping bore was utilised to record water levels during the test. Water levels in monitoring bores were measured using a combination of manual dipping and automated level loggers (data loggers).

Test pumping comprised the following:

- A calibration test to ensure all equipment was functional and to provide an indication of possible flow rates;
- Step drawdown rate test (SRT): Five steps (60 minute duration) of increasing discharge rate to provide data for bore efficiency assessment and to determine an appropriate pumping rate for the constant rate test.
- Constant rate test (CRT): Pumping at a constant discharge rate for periods between 1 and 7 days to provide data for estimation of aquifer properties.
- Water sampling after one hour of pumping during the CRT for water quality analysis.
- Throughout the CRT, a logger with attached flow cell was used to record physiochemical parameters including; dissolved oxygen (DO), electrical conductivity (EC), oxygen reduction potential (ORP) and pH of the discharge water for WB16MEH002 and WB16MEH004.
- At the end of the CRT, recovering water levels in the production bore were monitored until recovery inside the bore reached at least 90% of the original water level.

4.3 STEP TEST ANALYSIS

The Hantush-Bierschenk analysis was used to analyse the step rate test data to determine the apparent well efficiency (see Appendix D). The data was also used to determine the pumping rates for the constant rate tests. A summary of the completed SRT is provided in **Table 4.**

Table 4: Summary of completed test pumps

Bore ID	Number of Steps	Step Duration (minutes)	Discharge Rates (L/s)	Bore Apparent Well Loss	Bore Equation
WB16MEH0001	5	60	5, 8, 11, 15, 18	$4.2E^{-06}$	Sw= 0.0056Q + 4e-6Q2
WB16MEH0002	4	60	1.5, 2, 2.5, 3	$1.66E^{-04}$	Sw= 0.0082Q + 1e-4Q2
WB16MEH0003	Bore could not be tested due to yield lower than 1.5 L/s				
WB16MEH0004	3	60	1.5, 2.5, 3.5	$3.4E^{-05}$	Sw= 0.015Q + 8e-5Q2

4.4 CONSTANT RATE AND RECOVERY TEST ANALYSIS

WB16MEH0001

WB16MEH0001 was constructed with slots over both the CID and Paraburdoo Member, and was pumped at 18 L/s, drawing the water level down a total of 20.67 m in 72 hours. WB16MEH0001 is located directly west of Mesa J Pit 11 Sump, a large source of water (Figure 2); in order to represent this water source in the pumping test analysis, a constant head boundary was entered.

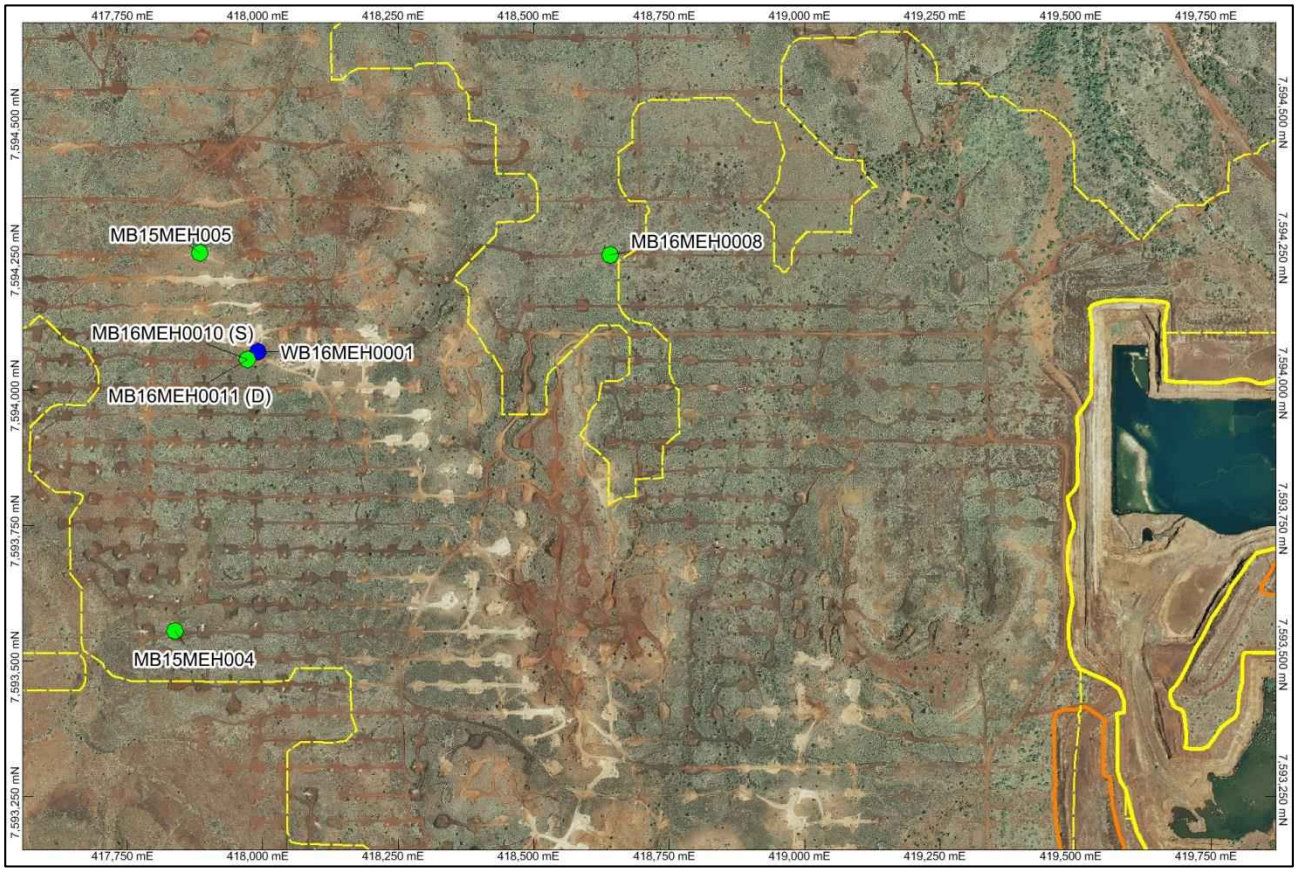

Figure 2: WB16MEH0001 CRT observation bores

The Newman-Witherspoon (1969) solution for a leaky, two aquifer system was fitted to the drawdown data for WB16MEH0001, producing a transmissivity (T) value of 61.8 m^2/day, a hydraulic conductivity (K) of 1.6 m/day and storage coefficient (S) of $8E^{-3}$ (Figure 3).

The closest adjacent bore was nested (HM16MEH0003), with a shallow piezometer (MB16MEH0010) slotted over the CID and a deep piezometer (MB16MEH0011) slotted over the Paraburdoo Member dolomite. The water level prior to pumping was similar in both the shallow (42.19 m) and deep (42.24 m) piezometers. However, MB16MEH0011 showed a much greater response to pumping, with 5.54 m of drawdown, compared to only 0.685 m of drawdown in the shallow bore MB16MEH0010.

The Cooley-Case (1973) solution for a leaky aquifer overlain by a water table aquitard was used to attempt to fit a curve to the drawdown data for MB16MEH0010 (Figure 4) producing a T of 323.30 m^2/day,

corresponding K of 20.21 m/day and S of 7.3E^{-4}. The Hantush-Jacob (1955) / Hantush (1964) solution for unsteady flow in a leaky aquifer was used to fit a curve to the drawdown data for MB16MEH0011, producing a T of 63.16 m^2/day, and corresponding K of 5.26 m/day and S of 3.3E^{-4} (Figure 5).

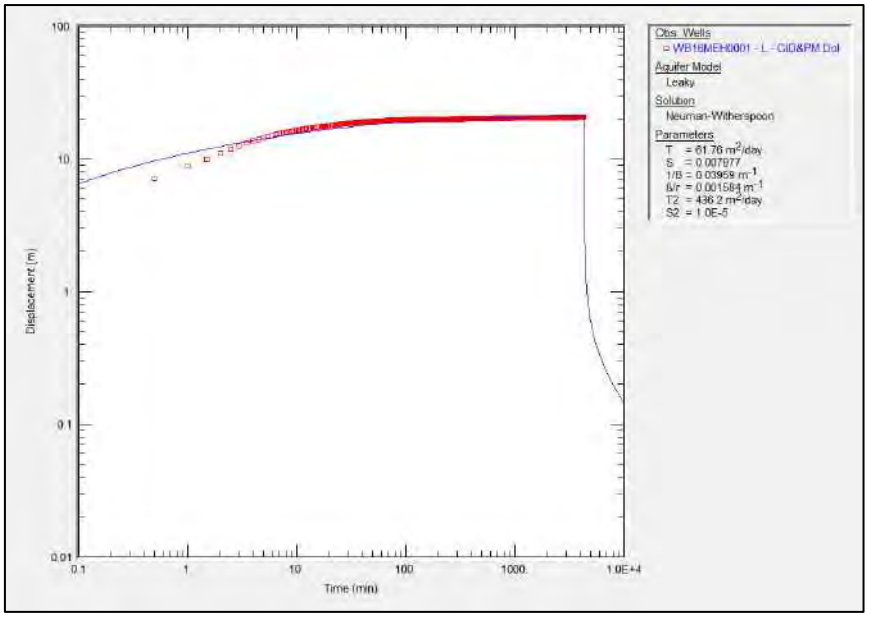

Figure 3: WB16MEH0001 CRT drawdown data with Neuman-Witherspoon solution

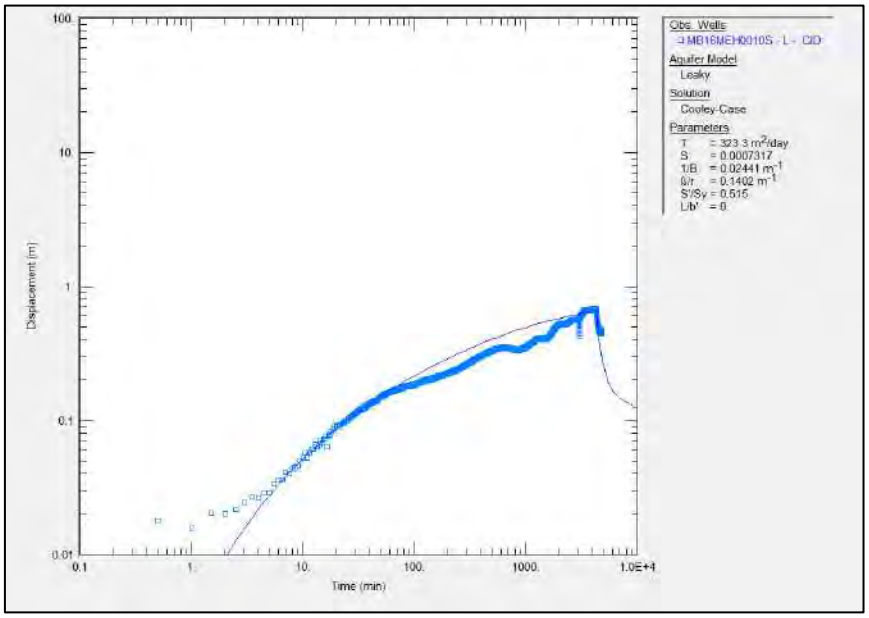

Figure 4: MB16MEH0010 CRT drawdown data with Cooley-Case solution

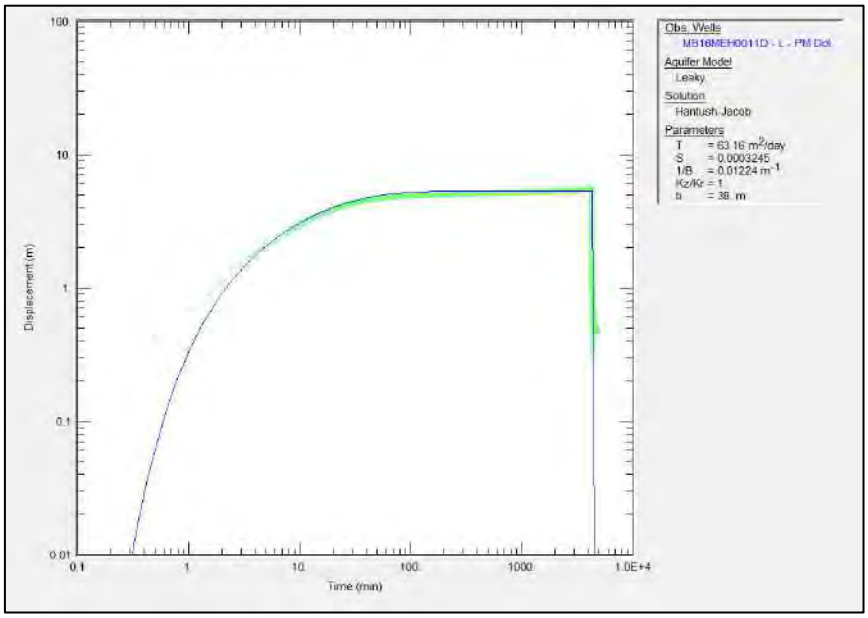

Figure 5: MB16MEH0011 CRT drawdown data with Hantush-Jacob solution

WB16MEH0002

WB16MEH0002 was slotted over the CID and pumped at a rate of 2.5 L/s, with a final drawdown of 11.05 m after 24 hours. WB16MEH0002 is located directly south of Mesa J Pit 11 Sump, a large source of water (Figure 6); in order to represent this water source in the pumping test analysis, a constant head boundary was entered. The drawdown data observed in WB16MEH0002 could not be analysed due to the lack of early data points with the steady state reached very early in the test (Figure 7).

The closest adjacent bore was MB16MEH0012, slotted over the CID and had a final drawdown of 1.41 m. The Hantush-Jacob (1955) / Hantush (1964) solution for unsteady flow in a leaky aquifer was used to fit the drawdown data for MB16MEH0012, producing a T of 19.5 m^2/day, and corresponding K of 1.5 m/day and S of $1.4E^{-4}$ (Figure 8).

Dissolved Oxygen (DO) and pH were stable during the CRT at respectively 1.6mg/L and 7.7. The electrical conductivity (EC) increased from 800 µS/cm to 860 µS/cm during the CRT , then declining to 780 µS/cm during the recovery test (Figure 9), this change in the EC is possibly associated with the increased contribution from a slightly more saline deeper aquifer as the test progresses.

Figure 6: WB16MEH0002 CRT observation bores

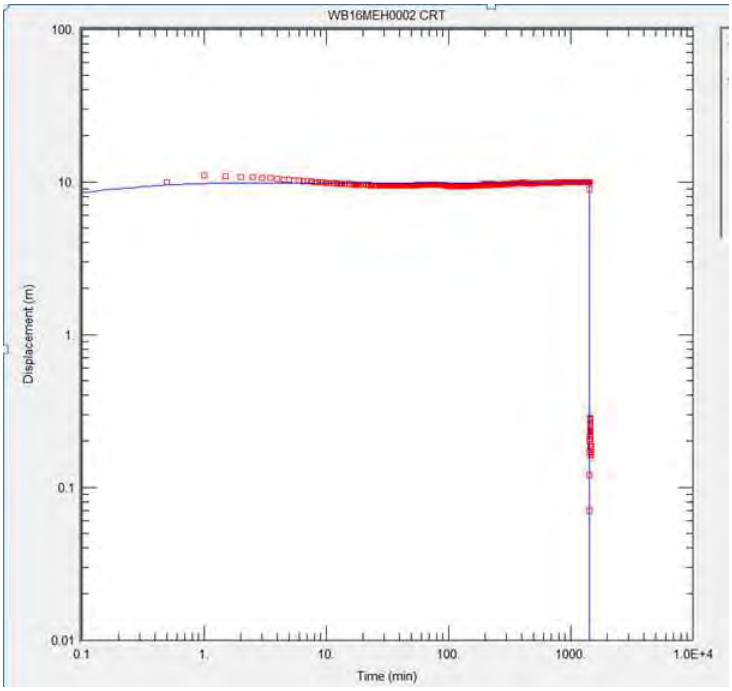

Figure 7: WB16MEH0002 CRT drawdown

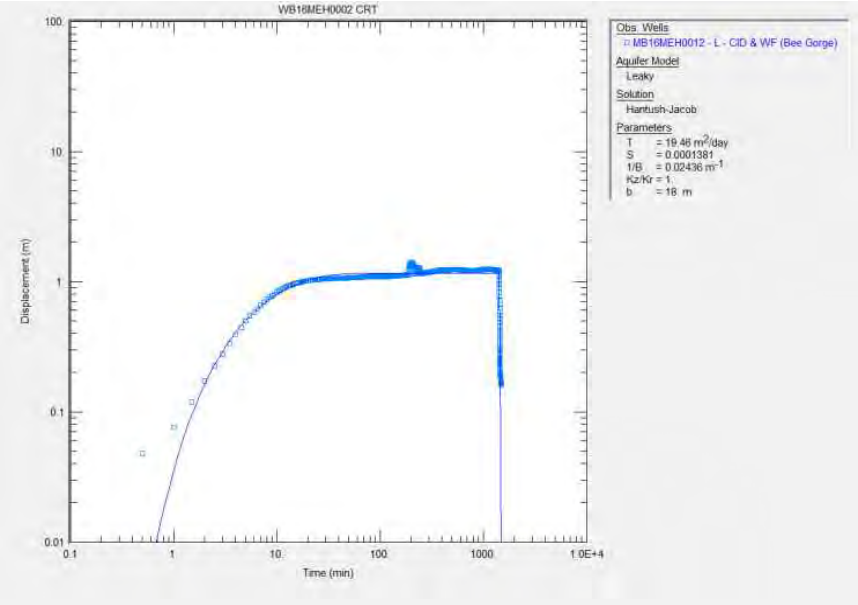

Figure 8: MB16MEH0012 CRT drawdown data with Hantush-Jacob solution

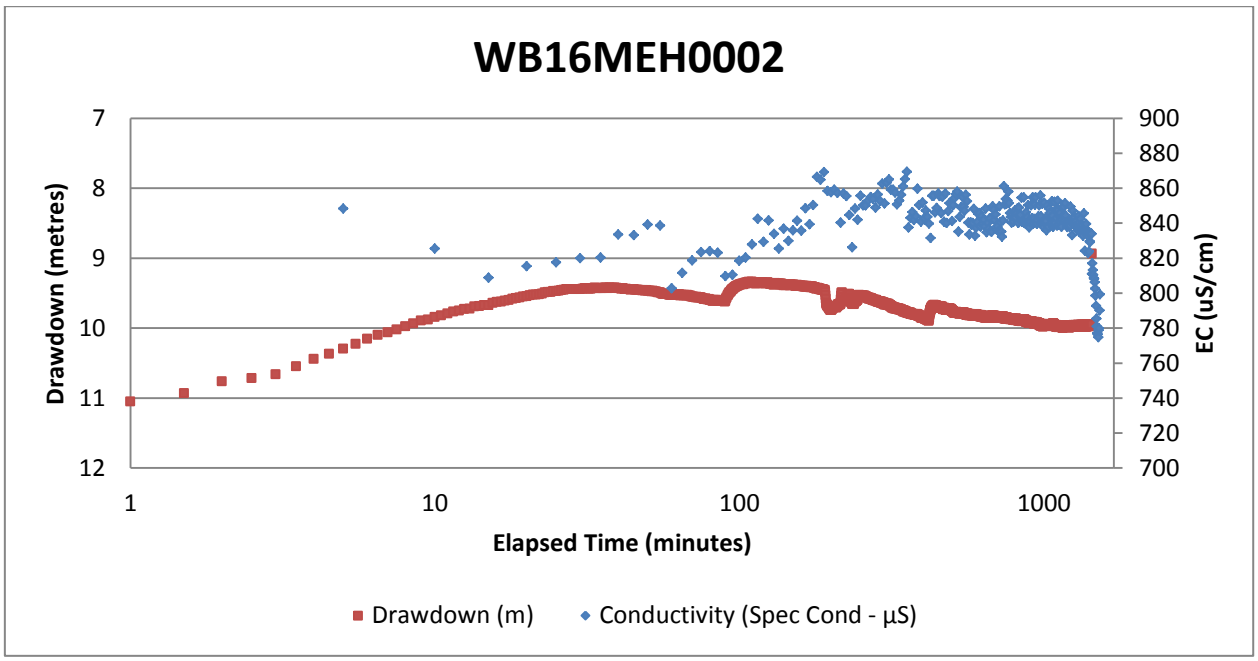

Figure 9: WB16MEH0002 drawdown and EC response during pumping test

WB16MEH0004

WB16MEH0004 was slotted over both the CID and Paraburdoo Member and pumped at 3.5 L/s for 2 days before the rate was lowered to 2.5 L/s for the remaining 8 days of the test. The water level was drawn down a total of 17.40 m over the 10 day period. WB16MEH0004 is in the northeast section of the proposed Mesa H mining area and approximately 1 km to the east of Yeera Bluff, one of the Robe River Pools (Figure 10); in order to represent this water source in the pumping test analysis, a constant head boundary was entered.

There is a dual nested monitoring bore close to the production bore, with the shallow piezometer MB16MEH0004 slotted over the CID and the deep piezometer, MB16MEH0005, slotted over the Paraburdoo Member. MB16MEH0005 showed a greater response to pumping, with 2.40 m of drawdown, compared to MB16MEH0004 with 1.20 m of drawdown.

The Newman-Witherspoon (1969) solution for a leaky, two aquifer system was fitted to the drawdown data for WB16MEH0004, producing a low T value of 10.23 m^2/day, a corresponding K of 0.43 m/day and S of $8.6E^{-6}$ (

Figure 11).

The Moench (Case 1) (1985) solution, for a leaky confined aquifer, was used fit a curve to the drawdown data for MB16MEH0004, calculating a T of 51.07 m^2/day, a corresponding K of 3.65 m/day and S of $2.7E^{-3}$ (Figure 12). The Neuman-Witherspoon (1969) solution was used to fit a curve to the drawdown data for MB16MEH0005, producing a T of 23.34 m^2/day, a corresponding K of 0.73 m/day and S of $1.8E^{-4}$ (Figure 13).

DO increased from 1 mg/L at 10 minutes, then to 2 mg/L at 650 minutes, and remained at this level until 2,880 minutes when the flow rate was decreased, and the DO declined to 1.75 mg/L until 6,000 minutes, where it levelled out for the duration of the test.

EC dropped from 940 µS/cm to 800 µS/cm at 720 minutes where it stabilised until the rate was changed, then rose to 860 µS/cm with the drawdown recovery of 7 metres in the bore until 4,000 minutes, where it started decreasing again to 800 µS/cm, and stabilising at this reading until 7,000 minutes, where the EC began to slowly increase to 850 µS/cm at the end of the test (Figure 14). ORP increased to 50 mV over the first 1,500 minutes, and then plateaued until dropping to 0 mV at 2,890 minutes, when the flow rate was dropped, with ORP increasing exponentially to 184 mV at 4,200 minutes, then at a slower rate to 231 mV until 5,700 minutes, where there was a slight decrease to 229 mV. For the rest of the test, the ORP continued to increase slowly, reaching a maximum of 248 mV by 11,410 minutes (Figure 15). Further analysis of ORP and EC change over time during the CRT test are not conclusive.

4.5 AQUIFER TESTING SUMMARY

A review of the pumping test results suggests the following:

- Hydraulic conductivity and storage coefficient of the CID ranges between 1.2 and 20.2 m/day and $2.6E^{-3}$ and $4.2E^{-6}$ respectively.
- Hydraulic conductivity of the Paraburdoo Member dolomite ranges between 0.7 and 5.3 m/day with a storage coefficient of approximately $2E^{-4}$.
- The bulk average hydraulic conductivity of the CID and Wittenoom aquifer has been calculated as 2.5 m/day with a storage coefficient of 5.5 E^{-3}.
- Basal CID works as a partial boundary to the vertical flow between the CID and the Wittenoom Formation aquifers observed by the difference in drawdown between the shallow and deep monitoring bores associated with the WB16MEH001 and WB16MEH004 test;
- The Robe Alluvium aquifer seems to be in hydraulic connection with the CID aquifer as suggested by the WB16MEH0004 drawdown, EC and ORP analysis.

SECTION 4 - WATER QUALITY ANALYSIS

Water quality parameters (pH, electrical conductivity (EC) and temperature) were measured on site at the end of air development with a TSP WP-81 water quality meter. Field water quality results are presented in Table 6.

Table 6 Field Water Quality

Bore ID	Peg ID	pH	EC (µS/cm)	Temp (°C)
Monitoring Bores				
MB16MEH0001	16MEH_M16	No yield achieved		
MB16MEH0002	16MEH_M08	8.04	683	32.7

WB16MEH0004	16MEH_P04	8.66	677	31.7
Pools				
Yeera Bluff	Yeera Bluff	7.12	1350	28.5

Five samples were collected from the production bores at the beginning of each test (WB16MEH0004 also had a sample collected at the end of the test) and sent to the laboratory for analysis. The full hydrochemical

analysis results are provided in Appendix E.appendix **C SURTRON GEOPHYSICS RESULTS**

Sample WB16MEH0003 returned a significant number of anomalous and conflicting results which suggests that due to very low yield (lesser then 1L/s) the bore could not be properly developed after construction.

The results of the remaining four samples reflect the hydraulic interconnection between the CID and the Wittenoom aquifers. All the analysed parameters returned with values within the Australian Drinking Water Guidelines (2011), including:

- pH between 7.1 – 7.75
- Total Dissolved Solids between 497 – 663 mg/L
- Total Alkalinity as CaCO3 between 160 – 194 mg/L
- Sulphate as SO_4 between 24 – 38 mg/L
- Chloride between 60 – 76 mg/L
- Total Nitrate between 0.54 – 0.86 mg/L

SECTION 5 - PROGRAM FINDINGS

The PFS Hydrogeological Drilling Program at Mesa H enabled the improvement of several conceptual aspects of the hydrogeological system of the deposit. Below is a list of key findings:

- The Paraburdoo Member and the Bee Gorge Member of the Wittenoom Formation are a local aquifer with an approximate thickness of 25 metres associated with the weathered zone;
- The production bore installed outside the OoM pit shell (WB16MEH0003) and slotted across the CID and the Wittenoom Formation could not be tested or developed properly due to very low yield (<1L/s), suggesting the weathering zone of the Wittenoom Fm. is potentially associated with the mineralisation of the CID, and where the mineralisation is absent, the weathering of this stratigraphic unit is less pronounced.
- The unmineralised BIF when underlying the CID is an aquiclude, hence presenting no permeability;
- The groundwater table sits at the CID and flows from southeast to northwest ranging between 132 and 118 mRL, with a hydraulic gradient of 0.002 along the deposit area. The interpreted water table contour map is presented on Appendix F.
- The basal CID, consisting mostly of a clayish pisolite (waste) has horizontal continuity throughout the deposit, with an average thickness of 20 metres and continues underneath the Robe River alluvium towards Mesa I to the north; its hydraulic properties could not be tested but test pumping analysis suggests it works as a partial boundary reducing, but not removing, the hydraulic connection between aquifers;
- The Robe River alluvium has a thickness of approximately 20-25 meters consisting of highly permeable and low storage quaternary sediments with a shallow water table (2-10 mbgl). The long term test pumping carried out on WB16MEH0004 suggests the hydraulic connection between this aquifer and the CID aquifer;
- Test pumping results indicate an average transmissivity of 160 m^2/day, with an associated K of 2.5 m/day and storage coefficient of $5.5E^{-3}$;
- Water samples collected from the production bores suggest the hydraulic interconnection between the CID and the Wittenoom aquifers.

SECTION 6 - MEASURE OF SUCCESS

As described in the original scope, the success of the project was measured against the following drivers:

HSE:

- All drilling and clearances were contained within approved AR;

- Program was completed with one single incident: heat stress; the patient notified his supervisor immediately upon feeling unwell and was transported to the medic who advised some rest in a cool place;
- The single incident was reported and acted upon within minimal time.

Technical drivers:

- Installation and testing of 4 production bores;
- Installation of 18 monitoring bores;
- Water sampling of selected bores;

Project management drivers:

- Completion of the program free of incidents;
- Completion of the program within the schedule duration;
- Completion of the program within budget;
- Provision of accurate drilling and test pumping data;
- Maintained / enhanced relationship with site Study Manager;
- Enhanced conceptual model for dewatering planning and understanding risks of mining related impacts to groundwater levels in the Rights Reserve in support of Mesa H PFS.

EXECUTIVE SUMMARY

Background

The Mesa H Project is an iron ore mining operation located immediately west and adjacent to the existing Mesa J mine, approximately 17 km south-east of the Pannawonica township.

The Mesa H deposit is proposed to be mined over approximately 18 years, beginning in early 2020 and finishing in 2037.

The objective of this groundwater modelling study is to assess the dewatering rates necessary to facilitate dry mining conditions at Mesa H and Mesa J, as well as impacts of dewatering and water supply abstraction (including cumulative impact of the Coastal Water Supply project at Bungaroo Valley) on regional groundwater levels and surface water pools along the Robe River and Jimmawurrada Creek.

Groundwater Modelling

The original Aquaterra 2006 groundwater model (RTIO-PDE-0153689) has been updated to include the current hydrogeological conceptualisation for the Mesa J and Mesa H orebodies. This is based on the results of the recently completed drilling and testing investigations (RTIO-PDE-0156803) and monitoring data. The model has been calibrated to available historical data from January 1990 to December 2016.

The overall model confidence level classification (as per the National Water Commission 2012 guide, Table 2-1) is Class 2. The model meets most criteria for Class 3, other than the absence of sufficient monitoring data in areas along the Robe River and Jimmawurrada Creek and associated surface water pools.

The model was used to predict dewatering rates, water supply pumping requirements and groundwater drawdown impacts for the Life of Mine (LoM) schedule 221211 option 112 for the Robe Valley deposits. Two dewatering scenarios have been simulated. Case 1 assumed no water return from Tailings Storage Facilities (TSFs) due to the commissioning of a thickener plant and Case 2 assumed water return from TSFs ranging between 30% and 50% of discharged tailings. A maximum drawdown of 40 m (Case 2) at the end of mining at Mesa H (end of 2037), is predicted to occur in the immediate borefield area.

Potential groundwater drawdown impacts of dewatering and water supply pumping on the surface water pools along the Robe River are predicted to be temporary in duration and relatively small compared to drawdown predicted in the Mesa H and J mine areas and the water supply borefield. Drawdowns of more than 1 m are not predicted to extend into the Robe River alluvium.

Maximum predicted drawdown along the Jimmawurrada Creek is predicted close to the water supply borefield. Maximum drawdowns are predicted to occur in 2030, 2032 and 2034. Case 1 results predict 9 m of drawdown at tracking point TP7 in 2030. Case 2 results predicts maximum drawdowns of 18 m (2030 and

2032) and 16 m (2034) at TP7 as a larger water demand in included in Case 2 and requires more pumping from the water supply borefield.

Uncertainty Runs, which included the reduction of Robe River and Jimmawurrada Creek flows (including reduced base flow to the river alluvium) resulted in the greatest increase in predicted groundwater drawdown along the Robe River and Jimmawurrada Creek.

To increase confidence in model predictions it is recommended that the model should be periodically reviewed and updated based on the results of ongoing investigations along the Robe River and in the Mesa H and Mesa J mining areas and calibrated against the latest monitoring data sets.

Model Reliability

Long term monitoring data that includes periods of significant aquifer stress (i.e. pumping resulting in groundwater level drawdown) is limited to Mesa H and does not extend along the Robe River and Jimmawurrada Creek. Therefore, there is a significant degree of uncertainty in the model calibration due to the non-uniqueness of the numerical solution (particularly adopted hydraulic connection between the aquifers) that potentially impacts confidence in predictive reliability of outputs.

To help improve model prediction reliability the following are recommended:

- Additional monitoring is required along the Robe River near the surface water pools to collect groundwater data associated with the Robe River alluvial aquifer.

- Once additional drilling and monitoring data becomes available, the model should be revised to include the revised conceptual understanding and if required recalibrated. At this time, it is also recommended that groundwater predictions, that include the latest mine plan are completed.

1. INTRODUCTION

1.1 Background

Mesa H is a channel iron deposit (CID) that forms part of a sinuous chain of mesas (from Mesa A to Mesa N) which define the palaeochannel of the Robe River and its associated tributaries. Mesa H is located immediately west and adjacent to the existing Mesa J mine, downstream from the confluence of the Robe River and the Jimmawurrada Creek, approximately 17 km south-east of the Pannawonica township (Figure 1).

The majority of the orebody occurred below the pre-mining water table, however due to the lowering of the water table in response to dewatering at Mesa J, parts of the Mesa H mine is above the present-day water table (i.e. Pit 9) or partially dewatered.

The local catchment is defined by three major aquifers:

- The basement aquifer comprising the weathered Paraburdoo and Bee Gorge Members of the Wittenoom Formation and weathered Marra Mamba BIF, hereafter referred to as the Wittenoom Aquifer.
- The Channel Iron Deposit aquifer, hereafter referred to as the CID Aquifer, which overlies the Wittenoom Aquifer.
- The Robe River alluvium aquifer, which occurs with the shallow alluvium adjacent to the Robe River and associated tributaries.

The Robe River regional catchment covers an area of approximately 7,500 km^2. Major watercourses occurring within the catchment include the Robe River and the Jimmawurrada, Bungaroo and Mungarathoona Creeks.

The Robe River is an ephemeral river, which carries significant underflow in its alluvial bed. This subsurface flow maintains permanent pools in the river channel, and these pools play an important role in the river ecosystem, supporting a diverse range of aquatic fauna and acts as refuges during periods of drought. Several pools in the Robe River to the north and north-west of the Mesa H deposit have significant environmental and heritage values and dewatering of the deposit could potentially impact some of these pools.

The numerical groundwater model for the catchment (the model) has been developed utilising existing information on the mine area and regional hydrogeology and the outcomes of existing pit area specific dewatering models.

1.2 Scope

The scope of the current modelling work was to:

- Update the regional groundwater model to include the current hydrogeological understanding of the orebody aquifers (Mesa J and Mesa

H) and the regional aquifer system.

- Calibrate the model to available groundwater levels in the Mesa J and Mesa H mining areas and along the Robe River and its tributaries.
- Use the groundwater model to predict:
  - The range of dewatering requirements for Mesa J and Mesa H over the life of mine.
  - The range of potential drawdown associated with groundwater abstraction (i.e. dewatering and water supply) on surface water pools along the Robe River and Jimmawurrada Creek.
  - Groundwater level recovery along the Robe River and Jimmawurrada Creek and in mining area(s) once mining is completed.

2. CONCEPTUAL HYDROGEOLOGICAL MODEL

The regional setting and regional hydrology have been well documented in the Mesa H H3 hydrogeological level assessment (RTIO-PDE-0155970), and the 2017 Mesa H FS Hydrogeological Drilling Bore Completion Report (RTIO-PDE-0156803) and are not detailed as part of this report. Figures 2 and 3 summarise the geological and hydrogeological setting, with the cross-sections (Figure 3) showing the influence of the conceptual hydrogeology on dewatering requirements.

2.1 Pre-mining Water Balance

Groundwater throughflow is estimated to be 1,600 ML/yr based on a 3.5 km cross section of the valley south of Mesa H / J, a saturated profile of 60 m, a hydraulic conductivity of 7 m/d and a hydraulic gradient of 0.004 (RTIO-PDE-0155970). The throughflow derived in previous studies in the Bungaroo Valley up gradient from Mesa H / J, was between 1,800 and 3,800 ML/yr.

To meet water demand for the wet process plant at Mesa J, RTIO has, in the past, harvested surface run-off from the Mesa H central catchment and pumped this into the Pit 11 at Mesa J.

A summary of the estimated water balance inflows and outflows is presented in Table 2.1.

Table 2.1: Conceptual Water Balance Summary

Inflow	ML/yr	Outflow	ML/yr
Throughflow	1,600	Throughflow	1,600
Rainfall recharge	20	Evaporation	1,600
Seepage	500	Abstraction (Environmental Discharge)	7,000 (3,000)
Loss of storage (drawdown)*	8,080		
Total	**10,200**	**Total**	**10,200**

3. GROUNDWATER MODEL SETUP

A groundwater model was developed in 2002 to predict inflows to the open pit workings for the proposed Mesa J mine (Aquaterra 2002a). This model was sequentially updated and upgraded by Aquaterra in 2003, 2004 and 2006.

The core of the current numerical groundwater model is the latest conceptual hydrogeological model developed by RTIO. The current model also includes the results and setups of the previous groundwater models (namely the Aquaterra 2006 model: RTIO-PDE-0153689).

The numerical groundwater flow modelling package Modflow-Surfact (Version 4.0, Hydrogeologic Inc. 1996) was used to develop the model operating under the Groundwater Vistas graphical user interface (Version 7.17 Build 15, Rumbaugh and Rumbaugh 1996–2017). The Modflow-Surfact numerical code was chosen to allow simulation of shallow water tables, reduction of water levels in the mining area and subsequent groundwater recovery.

3.1 Model Grid and Extent

The rectangular dimensions of the modelled area are ~20 km (SE–NW) by ~10 km (SW–NE). The extent, boundary conditions and general features of the model are shown in Figure 4. The model grid comprises seven layers, 391 rows and 193 columns, resulting in 266,026 active model cells. The model grid was rotated 45 degrees counter clockwise from the MGA Zone 50 grid, which aligns it with the groundwater inflow and outflow boundaries, including bounding rivers and the project mining area.

Coordinates of the four corners of the model domain are detailed in Table 3.1. The model grid has uniform spatial resolution of 50 m by 50 m throughout the model domain.

Table 3.1: Model Domain

	Easting (m)*	**Northing (m)***
Top Right	418,033	7,603,938
Top Left	411,208	7,597,117
Bottom Left	425,033	7,583,294
Bottom Right	431,855	7,590,116

*MGA94 Zone50

The hydrogeology of the Mesa H and J areas are represented by seven model layers as illustrated in Figures 5 to 10.

The model utilises flat layers of variable thickness. The thicknesses of the remaining layers are summarised in Table 3.2.

Table 3.2: Layer Setup

Layer	Layer Top (mAHD)	Layer Bottom (mAHD)	Layer Thickness (m)
Layer 1	160 - 180	140	20
Layer 2	140	130	10
Layer 3	130	120	10
Layer 4	120	110	10
Layer 5	110	100	10
Layer 6	100	80	20
Layer 7	80	60	20

3.2 Groundwater Inflow and Outflow

3.2.1 Model Boundaries

Model boundary conditions are shown in Figure 4. The model is bounded in the north, east and west by basement outcrops, represented by no flow boundaries. The Stream Package (STR1 package) of Modflow-Surfact was used to represent the Robe River and its tributaries (Jimmawurrada Creek and West Creek) within the model domain. The STR1 package allows water to flow into (or out of) the model and from (or to) the underlying aquifer at designated stream cells. Flows into or out of a stream cell are controlled by the difference between the groundwater elevation beneath the stream cell and either:

- the difference between the elevation of the bottom of the streambed and the calculated stream stage (option 1), or
- the calculated stream stage (option 2)

and a conductance or calibration term that accounts for stream bed properties (permeability, thickness and width). This is illustrated schematically in Figure 11.

The STR1 package also allows stream flow (river or creek flow) to be included as a designated stream input within the stream package, maintaining a balance between inflows and outflows at each stream cell, with any excess flow routed to the next downstream cell. This feature also assumes that any excess water at the last modelled stream cell is effectively lost from the groundwater system as outflow. The streambed elevations were assigned consistent with RTIO topographic data. The option to compute a stream stage was used and stream stages (Hs) were calculated by the model as shown in Figure 11. Stream width (50 m), streambed conductance (100 m^2/d), roughness (0.045) and slope (0.00245) were set consistent with the RTIO 2016 model.

The stream package approximates field conditions, which may involve complex patterns of saturated and unsaturated material beneath a modelled stream and the underlying aquifer. One of the limitations of the STR1 package becomes important when water levels in the aquifer fall well below the base of the modelled stream. When this occurs, seepage from the stream ceases to depend on head in the aquifer and is driven by the difference between the calculated

head in the stream and the stream bed elevation (option 1 above). This process does not take into account unsaturated flow processes between the base of the stream and the underlying aquifer water levels. However, if the water level in the aquifer is above the bottom of the streambed, flow from the stream is proportional to the head difference between the stream and the underlying aquifer (option 2 above).

The Robe River also carries a significant underflow in its alluvial bed. This subsurface inflow and outflow are simulated using the General Head Boundary (GHB) package in Modflow-Surfact. Underflow boundaries are assigned to the Robe River Valley at the north west model boundary and the eastern model boundary (refer Figure 4). These boundaries were assigned elevations of 114 mAHD and 149 mAHD (respectively) and a conductance of 100 m^2/d.

In the south, the groundwater inflow from the Bungaroo Valley is also represented by a General Head Boundary (assigned an elevation of 172 mAHD and a conductance of 100 m^2/d).

Inflow to the Robe River was based on recorded flows at Ngalooin Pool Station (station #707004), located approximately 18 km upstream from the Mesa J mine site. Due to a lack of gauging stations along the Jimmawurrada Creek, it was assumed that each time the Robe River was flowing, there was also surface water flow in Jimmawurrada Creek. The Jimmawurrada Creek catchment was estimated to be five times smaller than the Robe River catchment and therefore 20% of the recorded Robe River flow was applied to the Jimmawurrada Creek stream input. No natural flow was assigned to the West Creek as its main function in the model was to accommodate surface water discharge from mining at Mesa J.

3.2.2 Rainfall Recharge and Evapotranspiration

Recharge to the groundwater system is assumed to occur via rainfall recharge over the model domain (Figure 12). It was specified as a percentage of the recorded annual rainfall, distributed as follows:

- 0% to BIF outcrop
- 15% to Robe River alluvium
- 2% to Jimmawurrada Creek alluvium
- 1% to CID outcrops.

A mixture of Hardcapped / Hydrated Pisolite (HTP), Tertiary Pisolite TPM (mixed clay and pisolite) and hard Pisolite TPH overlies the CID Aquifer. Hydraulic properties have not yet been defined for these units, however, due to the impermeable nature of these units they are expected to function as a partial barrier to vertical flow, preventing rainfall recharge to the underlying aquifers (CID and TPB). These units were not included in the current model as they are above the pre-development water table and, due to their physical characteristics recharge to the CID aquifer is very low.

Evapotranspiration occurs from the shallow water table within the Robe River and the Jimmawurrada Creek where surface pools and vegetation occur. Elsewhere,

the water table is generally more than 10 m below the surface and losses from the water table to the atmosphere are negligible.

Evaporation from phreatophytic vegetation and from the shallow or near surface water table is modelled using the Evapotranspiration Package (EVT) in Modflow-Surfact. Modflow-Surfact uses a depth dependent relationship to calculate evapotranspiration (EVT) such that if aquifer water levels rise to, or above, a specified evapotranspiration surface, EVT occurs at the maximum specified rate. If the aquifer water level falls to below the specified ET surface, the EVT rate decreases linearly to zero until the water level falls to below an elevation equal to the ET surface minus a set extinction depth. The ET surface was set consistent with topographic data with an extinction depth of 5 m, consistent with type of vegetation along the Robe River and recorded groundwater levels. The EVT relationship is illustrated schematically in Figure 13.

The distribution of evapotranspiration included in the model is shown in Figure 14. Evaporation, measured as pan evaporation is 3,400 mm/yr (BOM, 2008). The EVT rate (70% of recorded pan evaporation) was set consistent with the RTIO conceptual model.

4. GROUNDWATER MODEL CALIBRATION

4.1 Steady State Calibration

The steady state calibration provides:

- A distribution of groundwater levels that reflects the groundwater system prior to any development.
- Initial conditions for the transient calibration.
- Quantification of the groundwater flow through the model domain, under average recharge conditions prior to any development.

The focus of the steady state calibration was to calibrate the model to interpreted pre-development groundwater levels and flows across the catchment. However, the time variant monitoring data covering the period 1990 to 2016 indicates a seasonal trend in water levels, in the order of several meters resulting from the wet and dry season recharge and stream flow patterns. Thus, the groundwater conditions within the catchment are not readily described by an average or steady state set of water level conditions. To accommodate this, a set of initial conditions was generated using average values for groundwater recharge and assigned stream flows for the Robe River and Jimmawurrada Creek which were then used as initial conditions for the transient calibration model. This process involved running the steady state and transient models, and fine-tuning model parameters until a set of conditions were generated that closely matched the start of the calibration period and the pre-development water balance.

Modelling has been completed using a conservative approach with respect to the data limitations and with conservative assumptions made in many instances where actual data is unavailable.

The modelled steady state groundwater level contours are presented in Figure 15. The steady state water balance is presented in Table 4.1.

Table 4.1: Steady State Modelled Water Balance

Flow Component	Inflow (ML/yr)	Outflow (ML/yr)
Groundwater Inflow / Outflow	1,250	295
Evapotranspiration	-	3,265
Recharge	735	-
Stream Leakage	4,600	3,025
Total	**6,585**	**6,585**

A comparison between the modelled steady state water balance and estimated pre-mining water balance is presented in Table 4.2.

Table 4.2: Numerical vs Analytical Water Balance

Flow Component	RTIO Water Balance (ML/yr)	Numerical Model (ML/yr)
Inflow from the Bungaroo Valley	~1,500	Inflow from the GHB = 800 Inflow from the Jimmawurrada Creek = 700 TOTAL = 1,500
Robe River underflow (inflow from the upstream)	>900	Inflow from the GHB = 430 Inflow from the stream leakage = 420 TOTAL = 850
Robe River underflow (outflow to the downstream)	>900	Outflow through the GHB = 290 Inflow from the stream leakage = 330 TOTAL = 630
Robe River flow (inflow from the upstream)	-	43,860
Jimmawurrada Creek flow (inflow from the upstream)	-	8,770
Robe River flow (outflow to the downstream)	-	51,100

As presented in Table 4.2 above, inflow to the model from the Bungaroo Valley and outflow from the model through the Wittenoom aquifer are well matched by the model.

4.2 Transient Model Calibration

The model calibration includes annual time increments from 1990 to 2016 and includes:

- Mesa J mine dewatering to date.
- Historical mine water supply pumping in the area.
- Discharge to Dan's Dam (Mesa J's water reservoir), Jimmawurrada Creek and West Creek.

Transient model performance was tested by comparing predicted and observed groundwater levels over the period 1990 to 2016. It is noted that data are not available for all monitoring locations for the entire calibration period. There are 37 monitoring bores with long term monitoring records and 33 bores with short term monitoring records (both regional bores and Mesa J mine monitoring bores). All of these bores were used in the calibration dataset. The locations of these bores are shown in Figure 16.

Rainfall recharge was applied annually based on the rainfall data records, recorded at Yarraloola Station (station #005032) and the rainfall rates outlined in Section 3.2.2. While the Yarraloola Station provides long term monitoring records, the record is incomplete from 1999 to 2016. To provide a complete and representative rainfall record for the Mesa H site, gridded rainfall data (BOM 2009) was used for the period 1999 to 2016.

Evapotranspiration was assigned a constant value of 0.0065 m/d or 70% of measured average pan evaporation of 3,400 mm/yr.

Discharge to Dan's Dam was simulated using the Recharge (RCH) package of Modflow-Surfact and assigned at 60% of the recorded dam discharge to account for evaporative losses.

During mining at Mesa J, surplus dewatering was historically discharged at two locations (Jimmawurrada Creek and West Creek). These locations are included in the model as shown in Figure 17. Discharge to the creeks is applied as stream inflows at designated locations based on the recorded discharge.

Inflow assigned to the Robe River and Jimmawurrada Creek and excess water discharge to Jimmawurrada and West Creek is presented in Table 4.3. Robe River inflows were assigned as stream inflow based on the recorded Robe River flow at Ngalooin Pool Station. Flow records were available from 1977 until 1999. From 1999 onwards, historical flow data from 1977 to 1993 was used to provide flow estimates for the period 2000 to 2016. As the model was run in annual increments, short term peak flows that occurred in 2006 and 2010 are not included.

Table 4.3: Average Annual Surface Water Flow (ML/yr)

Year	Robe River	Jimmawurrada Creek	Discharge to Jimmawurrada Creek	Discharge to West Creek
1990	4,326	865	0	0
1991	0	0	0	0
1992	50	10	0	0
1993	194,900	38,980	0	0
1994	21,610	4,322	0	0
1995	254,600	50,920	0	0
1996	10,140	2,028	0	0
1997	126,300	25,260	0	0
1998	266	53	0	0
1999	76,880	15,376	0	0

Year	Robe River	Jimmawurrada Creek	Discharge to Jimmawurrada Creek	Discharge to West Creek
2000	1,394	279	0	0
2001	16,410	3,282	0	0
2002	18,990	3,798	0	0
2003	52,020	10,404	0	0
2004	36,470	7,294	0	0
2005	9,099	1,820	0	0
2006	1,195	239	0	0
2007	49,250	9,850	0	602
2008	41,430	8,286	0	1,862
2009	2,850	570	594	1,997

2011	18,240	3,648	2,513	10,184
2012	27,530	5,506	4	1,022
2013	4,326	865	0	1
2014	0	0	84	1
2015	50	10	2,006	2,248
2016	194,900	38,980	1,511	176

Abstraction from the Mesa J borefield was simulated using the Fracture Well (FWL4) package in Modflow-Surfact. Individual bore pumping rates were assigned based on historical abstraction records.

Dewatering at Mesa J was simulated using the Drain (DRN) package in Modflow-Surfact. It is noted that historical pit progressions for Mesa J were not available at the time of this study. Drain elevations were set based on the interpolated historical data. Drain conductance was set sufficiently high (1,000 m^2/d) such that the only resistance to groundwater inflow was provided by the surrounding aquifer rather than the assigned drain cell properties (i.e. drain bed conductance).

4.2.1 Calibration Performance

Calibration hydrographs are presented in Figures A1 to A21. The locations of monitoring bores used for model calibration are shown in Figure 16. Measured groundwater levels and trends are generally well matched by the model. In the immediate vicinity of the Mesa J mine, the decreasing water level trend associated with dewatering is well replicated by the model. The impact of ongoing dewatering and water supply pumping is well matched at MB12MEJ001, MB13MEJ005 and MB13MEJ007 (Figure A1), MB15MEH001 and JWO06 (Figure A2), JWO08, JWO09 and JW011 (Figure A3), JWO16 and JWO18 (Figure A4) and JW020 (Figure A5).

Groundwater levels are over predicted by 5 m at MB15MEH009 (Figure A2), and JW019 (Figure A4) and JW020 (Figure A5), however the decreasing water level trend is replicated by the model at these locations.

Measured groundwater levels are very well matched by the model in the immediate borefield area at DWB01 and DWB02 (Figure A5), DWB03, DWB04 and DWB06 (Figure A6) and DWB07, DWB08 and DWB09 (Figure A7). There is still some uncertainty as to the geology and structural features in this area (the deep, fractured and weathered aquifers which existing and proposed water supply bores draw from). It is suspected that there may also be another groundwater flow path associated with one of the fault splays or even another inflow feature to the east or west that could influence groundwater behaviour in the borefield area.

Further to the south (south of Mesa J) towards the Bungaroo Valley, measured groundwater levels at JWO21 and JWO23 (Figure A8) are well matched by the model. Some of the measured seasonal water level trends are not replicated by the model, however, this is because the current model set up does not include measured surface water flows in Jimmawurrada Creek that originate further upstream.

Further to the north (north of Mesa J) towards the Robe River, measured groundwater levels at JWO17 (Figure A8) and JWO13 (Figure A11) along the Jimmawurrada Creek are well matched by the model.

Long term monitoring records in the Mesa H area and along the Robe River are not available. The model performance in these areas was compared to the monitoring records from 33 recently installed monitoring bores (Figures A12 to A21, bore locations shown in Figure 16). There is a generally good match to the measured groundwater levels at these bores especially at locations closest to the Robe River (RR1 and VW16MEH013, Figure A19, MB15MEH014, Figure A20, MB15MEH013 and MB16MEH009, Figure A21), and to the north of the Robe River (MB16MEH014, Figure A20).

4.2.2 Aquifer Parameters

Figures 5 to 10 show the distribution of hydrogeological units for the calibrated model. The aquifer parameters adopted for the calibrated model are summarised in Table 4.4. Assigned aquifer parameters are consistent with the conceptual model, available hydraulic testing data, previous groundwater models, published data and similar hydrogeological environments.

Table 4.4: Calibrated Aquifer Parameters

Formation	Kh (m/d)	Kv (m/d)	Specific Yield (%)	Confined Storage
Robe River Alluvium	100	50	30	0.0001

The predicted groundwater balance is presented in Table 4.5. The water balance shows that inflows from upstream (Robe River and Jimmawurrada Creek flows) dominate the inputs to the modelled catchment. Besides replenishing the surface water pools along its path, the Robe River and Jimmawurrada Creek flow that recharges the underlying aquifer also feeds partially dewatered aquifers. Inflow from the Robe River and Jimmawurrada Creek into the model (modelled aquifers) is almost 50% of the overall water balance. Dewatering and borefield pumping combined provide the greatest outputs (almost 50% of the overall water balance).

Table 4.5: Modelled Water Balance (January 1990 to December 2016 Average)

Flow Component	Inflow (ML/y)	Outflow (ML/y)
Storage	3,515	900
Borefield Pumping		1,170
Dewatering		4,640
Rainfall Recharge	695	
Discharge to Dan's Dam	510	
Evapotranspiration		2,880
Groundwater Inflow / Outflow	1,430	290
Stream Leakage	5,900	2,170
Total	**12,050**	**12,050**

5. MODEL PREDICTIONS

Approach

The calibrated model was used to predict:

- The dewatering requirements for the Mesa J and Mesa H mines.
- The volume of abstraction required from the water supply borefield in addition to dewatering from Mesa J and Mesa H to meet the project water demand.
- The mine dewatering, water supply borefield abstraction and closure impacts on surface water pools along the Robe River and Jimmawurrada Creek.

Model predictions were based on the current mine plan provided by RTIO (Case 221211 option 112 – RO5_J0.5_A0.5_RV_Report Template_PFS_ 20170111.xlsx) and included:

- Mesa J – Pits 3, 5, 6, 7, 8, 9, 11, 12, 14 and 15.
- Mesa H – Pits 1 to 8 (Pit 9 is above the water table and does not require dewatering).

5.1 Dewatering Model Configuration

The mine schedules adopted for Mesa J and Mesa H dewatering predictions are summarised in Tables 5.1 and 5.2:

Table 5.1: Mesa J Mine Plan

End of Year	Pit 3	Pit 5	Pit 6	Pit 7	Pit 8	Pit 9	Pit 11	Pit 12	Pit 14	Pit 15
2019	146		182	**138**	**126**	158				**142**

The predictions were completed as outlined below:

- Initial groundwater level/flow conditions were derived from the end of the transient calibration (December 2016).
- The prediction period starts in January 2019.
- The model was run for a period of 19 years (January 2019 to December 2037).
- The model predictions were run using annual time increments (stress periods).
- Steady state evapotranspiration rates were used in the prediction model.
- As outlined in the model setup section, Robe River flow records exist until 1999. For the 19 year prediction period, the last 19 years of recorded Robe River flows were used (from 1981 to 1999). Similarly, the rainfall recharge data from the period 1981 to 1999 was used in the prediction models.
- Dewatering at Mesa J and Mesa H was simulated using the Drain Package (DRN) in Modflow-Surfact. Drain elevations and extents were set consistent with the proposed mine plan. Drain bed conductance was set consistent with the calibrated model (i.e. 1,000 m^2/d). When mining and dewatering of individual pits was complete, as shown in Tables 5.1 and 5.2, drain cells were switched off and in pit water levels could recover. Details of infilled

pits included in dewatering and closure predictions are discussed in Section 6.1.

- Discharge to Dan's Dam was applied using the Recharge Package (RCH) in Modflow-Surfact at the average recorded discharge rate from the calibration period.

- Surface water excess discharge to Jimmawurrada Creek and West Creek was not included.

- The water level impact of the Coastal Water Supply borefield was included in model predictions based on the results of a separate groundwater modelling study undertaken by RTIO. Drawdown impacts from the CWS were included in the prediction model by reducing the head assigned to the southern inflow boundary (General Head Boundary, refer Figure 4) consistent with the predicted drawdown impact. The RTIO model for the CWS predicts that 6 m of drawdown will extend north toward the southern model boundary after five years, with 8 m of drawdown at this boundary after 10 years, 9 m of drawdown at this boundary after 15 years and 11 m of drawdown at this boundary after 30 years of water supply pumping. The GHB elevation was lowered linearly over the prediction period consistent with these estimates of drawdown (i.e. reduced from the value assigned in model calibration of 172 mAHD).

- Two projected water supply demands were included as follow:

    - **Case 1**: No water return from TSFs due to the commissioning of a thickener plant.

    - **Case 2**: Water return from TSFs ranging between 30% and 50% of discharged tailings;

The projected water demand for Cases 1 and 2 are presented in Table 5.3 below:

Table 5.3: Projected Water Supply Demand (ML/yr)

Year	Case 1	Case 2
2020	5,000	7,000
2021	5,000	7,000
2022	5,000	7,000
2023	5,000	7,000
2024	5,000	9,000
2025	5,000	9,000
2026	5,000	9,000
2027	5,000	9,000
2028	5,000	9,000
2029	5,000	9,000
2030	5,000	9,000
2031	5,000	9,000

Year	Case 1	Case 2
2032	5,000	9,000
2033	5,000	9,000
2034	4,000	7,000
2035	4,000	7,000
2036	4,000	7,000
2037	4,000	7,000

- Water supply pumping was simulated using the Fracture Well Package (FWL4) in Modflow-Surfact. The volume of abstraction required was calculated as the difference between the projected water demand and the predicted total dewatering. The pumping rates required were calculated using an iterative process and the prediction model was re-run until the assigned borefield pumping and predicted dewatering satisfied the water demands outlined in Table 5.3.

- Seven existing and nine nominal bores were used to simulate water supply pumping when required. Bore locations are shown in Figure 18 and Table 5.4 below:

Table 5.4: Water Supply Bore Location

Bore ID	Easting (m)*	Northing (m)*	Status
DWB18	423,608	7,591,732	Existing bore
DWB15	423,601	7,592,032	Existing bore
DWB20	423,370	7,591,593	Existing bore
WB13MEJ001	423,542	7,589,975	Existing bore
WB13MEJ002	423,443	7,590,213	Existing bore

Nominal_2	425,287	7,589,421	Nominal future bore
Nominal_3	425,325	7,590,128	Nominal future bore
Nominal_4	424,413	7,590,694	Nominal future bore
Nominal_5	424,268	7,591,335	Nominal future bore

* MGA94 Zone 50

Prediction runs have been completed using a conservative approach (i.e. reduced inflow from the southern model boundary, no surface water discharge to creeks when dewatering exceeds water supply requirements, and no seepage from the TSFs) to allow prediction of maximum potential groundwater drawdown throughout the modelled catchment.

5.2 Results

5.2.1 Mesa J Water Levels and Dewatering

Predicted water levels across the Mesa J and Mesa H mine areas are shown in Figures B1 to B9. Modelled observation locations are shown in Figure 18. Predicted water levels closely follow the mining schedule as drains are used to simulate dewatering (i.e. no advanced dewatering using bores is included in model predictions).

Predicted dewatering at Mesa J is presented in Figure B10. For Case 1, dewatering at Mesa J is predicted to peak at 8,100 ML/yr in 2023 (from dewatering at Pits 6, 12 and 15), with another peak of up to 7,170 ML/yr predicted in 2027 (from dewatering at Pits 7, 12, 14 and 15). For Case 2, dewatering at Mesa J is predicted to peak at 8,085 ML/yr in 2023 (similar to Case 1), with another peak of up to 6,140 ML/yr in 2027. The lower water supply requirement for Case 1 is predicted to result in higher dewatering requirements for Case 1 compared to Case 2. Water supply requirements are discussed in the sections below.

Mining at Mesa J ends in December 2029. Drain cells used to simulate dewatering at Mesa J were not included from January 2030 onwards and water levels could recover, assuming mined out voids were infilled to above the pre-mining water table. Predicted water levels in Mesa J are predicted to increase from 2030 to 2037 (Figures B5 to B9).

5.2.2 Mesa H Water Levels and Dewatering

Predicted water levels for Mesa H are shown in Figures B1 to B4. Dewatering at Mesa H is shown in Figure B10 and, is predicted to be similar for both Case 1 and 2, with dewatering for Case 1 predicted to be marginally higher than Case 2 after 2031, due to the greater water supply requirement and borefield pumping included in Case 2.

For Cases 1 and 2, dewatering rates are predicted to reach a maximum of 2,900 ML/yr in 2033, from dewatering at Pit 2. Dewatering is predicted to decrease to 2,500 ML/yr by 2035. After 2035 dewatering is predicted to decrease to 940 ML/y in 2036 and increase to 1,300 ML/yr in 2037.

5.2.3 Borefield Pumping

The model predicts that pumping from the proposed borefield will be required to supplement the predicted dewatering to meet the water demand for both cases (Figure B10). Maximum predicted pumping from the water supply borefield is predicted in 2030 for Case 1 (3,850 ML/yr) reducing to 1,500 ML/yr in 2035, with a further increase to 3,000 ML/yr by 2037. For Case 2, maximum water supply pumping is predicted in 2030 (7,800 ML/yr) reducing to 4,700 ML/yr in 2035 with a further increase to 6,000 ML/yr in 2036 and 2037.

Total pumping (dewatering and water supply pumping) and the required water demand for Cases 1 and 2 are shown in Figure B10, with dewatering and borefield pumping equalling or exceeding the water demand over the life of the mine.

5.3 Drawdown

Contours of predicted drawdown at the end of mining at Mesa J (December 2029) and at end of mining at Mesa H (December 2037) are presented in Figures 19 and 20 for Case 1 and in Figures 21 and 22 for Case 2. These drawdown contours were derived by subtracting the predicted water levels from the dewatering models (Case 1 and Case 2 models), at the end of 2029 and 2037, from predicted water levels at the corresponding times for the No-Development Case. The No-Development Case is simulated for the same duration as the Case 1 and 2 predictions and includes the undisturbed groundwater regime (i.e. with the same stream flows and groundwater recharge as Cases 1 and 2 and without dewatering, water supply pumping, impacts of the CWS or excess water discharge).

5.3.1 Case 1

For Case 1 (Figure 19), maximum drawdown at the end of mining at Mesa J (the end of 2029) is predicted to occur at Pits 11 and 12 which are the deepest two pits at Mesa J (up to 39 m of drawdown), and in the immediate borefield area (10 to 20 m of drawdown). Predicted drawdown to the north-west and north results from ongoing dewatering at Mesa J and dewatering at Mesa H Pits 6, 7 and 8. To the north-west, towards Mesa H, 1 m of drawdown is predicted to extend 6 km north-west of Mesa J Pit 11 and north of Mesa H Pit 9 by the end of 2029. Drawdown of 1 m is not predicted to reach the Robe River by the end of 2029.

By 2037, (Figure 20) a maximum predicted drawdown of 29 m is predicted at Pits 4 and 5 of Mesa H. As dewatering at Mesa J finishes at the end of 2029, borefield pumping is required to meet the projected water demand and drawdown of 15 m is predicted in the borefield area at the end of mining (December 2037).

5.2.2 Case 2

Similar to Case 1, maximum drawdown at the end of mining at Mesa J (end of 2029) is predicted to occur at Pits 11 and 12 which are the deepest two pits at Mesa J (up to 39 m of drawdown, Figure 21). Similar drawdown to Case 1 is also predicted to extend north of Mesa J Pit 9 (drawdown of 1 m) and to the north west of Mesa J. The requirement for pumping from the water supply borefield is predicted to result in drawdown of up to 27 m in the borefield area. Drawdown of up to 5 m is predicted to the south-east of Mesa J towards the Bungaroo Valley, as a result of water supply pumping from the water supply borefield and the CWS, as well as dewatering at Mesa J. Drawdown of 1 m is not predicted to reach the Robe River by the end of 2029.

At the end of mining, in 2037, to the north and north west, the drawdown predicted for Case 2 is similar to the drawdown predicted for Case 1 (i.e. 1 m of drawdown does not reach the Robe River). The increased water demand for Case 2 requires additional pumping from the borefield, resulting in increased drawdown in the borefield area by 2037 (when compared to Case 1). Maximum drawdown of 40 m is predicted in the immediate borefield area. By 2037, drawdown of 10 m is predicted to extend south of the proposed borefield, with

drawdown of up to 5 m predicted towards the Bungaroo Valley (i.e. more than that predicted for Case 1).

5.2.3 Drawdown at Tracking Points

Long term monitoring data in the immediate area of the surface water pools or in the Robe River alluvium are not available. However, monitoring records from nearby bores, located close to the Robe River show a seasonal variation in groundwater levels of around 2 m. Predicted drawdown of 1 m is considered a reasonable drawdown trigger to assess environmental impact in the Robe River because:

- The estimated seasonal groundwater fluctuation is greater than 2 m.
- Groundwater recharge near the Robe River is primarily due to surface water infiltration after storm events, and
- Monitoring indicates that groundwater levels are generally below the bed elevations along the Robe River. A groundwater level drawdown of 1 m is considered to be small compared to the rooting depth of potentially groundwater dependent vegetation.

The location of tracking points, at five locations across the modelled catchment are shown in Figures 19 to 22. At these locations the proposed mining may be adjacent to the surface water pools and potentially groundwater dependent vegetation. These tracking points are used to assess the potential impacts of dewatering and water supply pumping at Mesa J and Mesa H on the surface water pools along the Robe River.

Predicted drawdown at tracking points along the Robe River over the life of the mine are presented in Figures 23 to 25. This drawdown is calculated by subtracting predicted water levels at each tracking point for the No Development Case (described in Section 5.3 above) from predicted water levels for Cases 1 and 2. Predicted drawdown hydrographs show maximum predicted drawdown at all tracking points to be temporary and less than 1 m.

The maximum predicted drawdown at tracking points at the five key areas across the model domain are discussed below:

- Tracking point TP2 is located at the confluence of the Robe River and the Jimmawurrada Creek. At this location dewatering from Mesa J and the water supply borefield pumping may result in drawdown in the Jimmawurrada Creek alluvium extending to the north towards the Robe River. Maximum predicted drawdown at TP2 is 0.26 m for Cases 1 and 2 (Figure 23).
- Tracking points TP11, 12, 13 and 14 are located in the section of the Robe River between the Jimmawurrada and West Creeks, adjacent to the Mesa J mining areas. The maximum predicted drawdown in this area is 0.45 m at TP14 for Case 2 (Figure 24).
- Tracking points TP25 and 26 are located along the Robe River, west of the

West Creek confluence. This area is not only in direct hydraulic connection with the orebody aquifers via the TPB but is also underlain by high permeability associated with the (weathered) Wittenoom aquifer. Maximum predicted drawdown in this area is up to 0.68 m at TP25 for Cases 1 and 2 (Figure 25).

- Tracking points TP22, 23 and 24 are located in the Robe River alluvium, downstream or west of TP25 and TP26. Maximum predicted drawdown in this area is 0.28 m at TP23 (Figure 24).

- Tracking point TP7 is located along the Jimmawurrada Creek near the proposed water supply borefield. Maximum predicted drawdown at TP7 is 8.81 m in Case 1 and 17.42 m in Case 2 (Figure 25). The greater drawdown predicted in Case 2 results from the higher water demand and increased pumping requirement from the water supply borefield.

5.3 Water Balance

The model predicted water balance (average inflows and outflows over the life of mine) is presented in Table 5.5. Consistent with the calibrated model, the sources of inflow are depletion of aquifer storage (by dewatering and borefield pumping), and aquifer recharge from stream leakage (from the Robe River and Jimmawurrada Creek). The major outflow components are pumping from the water supply borefield and mine dewatering.

In the model calibration (steady state and transient) and the No Development prediction models, the southern model boundary associated with the Bungaroo Valley is an inflow boundary. The reduction in elevation at this model boundary included in model predictions to account for impact of the CWS reverses the groundwater flow direction across the model boundary from 2021 onwards. This boundary functions as a groundwater outflow boundary, with groundwater flow and some of the stream leakage from the Jimmawurrada Creek predicted to flow to the south, toward the CWS rather than downstream towards the Robe River. This assumption provides further conservatism to predictions of groundwater drawdown at tracking points along the Robe River.

Table 5.5: Average Predicted Inflows and Outflows over Life of Mine: Base Case Predictions

Flow Component	**Inflow (ML/yr) – Case 1** **Inflow (ML/yr) – Case 2**	**Outflow (ML/yr) – Case 1** **Outflow (ML/yr) – Case 2**
Storage	3,930 **5,020**	3,770 **2,890**

6. CLOSURE MODELLING

6.1 Setup

Once mining is complete and dewatering and water supply pumping ceases, groundwater levels at Mesa J and Mesa H and the water supply borefield area will recover until a balance is reached between groundwater inflows and groundwater outflows. As all pit voids are planned to be infilled with waste / tailings to above the pre-mining water table, groundwater levels will eventually recover to pre-development levels. The Case 1 and Case 2 dewatering models were used to predict the groundwater response, once mining is complete.

To assess the potential impact of key parameters adopted for the closure runs (namely rainfall recharge and stream flows) two closure scenarios were simulated, as outlined below:

Closure Scenario 1 – Variable Recharge Case

- Initial conditions from the end of Case 1 and 2 dewatering and water supply predictions (December 2037).
- Case 1 and 2 models were run for a period of 190 years (January 2038 to December 2137).
- The model predictions were run using annual time increments (stress periods).
- Infilling of all mine voids was completed prior to any groundwater recovery. Some of this infilling is assumed to have occurred as mining was completed at pits at Mesa J (in 2029) and at some pits at Mesa H before 2037.
- The hydraulic conductivity of the infill material will be the same as the material of the original formations excavated during mining.
- The mined out voids will be infilled to a level above the pre-development groundwater table and the final land form will be designed such that there will be no increase or decrease in recharge to the infilled mine voids.
- The ET setup is identical to that used for the predictions. No ET was included for the infilled pits.
- Recharge rates, as a percentage of annual rainfall, and stream flows are identical to those used for the model predictions. Annual rainfall and stream flow data from the prediction period is repeated to simulate variable annual recharge and flows for the closure predictions.
- The predictions do not include any further pumping, dewatering or discharge from any other area in the modelled catchment or impacts associated with the CWS.

- All other model parameters were set consistent with the steady state model.

Closure Scenario 2 – Steady State Recharge Case

The same conditions as Closure Scenario 1, except for the following:

- Average annual rainfall and stream flow conditions were included in the closure model.

6.2 Results

The predicted recovery of groundwater levels at tracking points along the Robe River and for the mined out and infilled areas of Mesa J and Mesa H are shown in Figures C1 to C8 (Case 1) and Figures C9 to C16 (Case 2) (in pit observation locations and tracking point locations are shown in Figure 18). The approach for calculating drawdown at tracking points is the same as that adopted for the Case 1 and 2 dewatering and water supply predictions (outlined in Section 5.3). No Development models were also run for the closure period (January 2038 to December 2137), assuming undisturbed aquifer conditions from 2038 onwards, and the same recharge and stream flow conditions as Closure Scenarios 1 and 2.

Predicted groundwater recovery at tracking points along the Robe River for Cases 1 and 2 are shown in Figures C1 to C3 and C9 to C11 for both variable and steady state recharge and stream flow. For all predictions, groundwater levels are predicted to have recovered within 50 to 60 years after the end of mining and water supply pumping. As would be expected, for the steady state recharge cases, the predicted groundwater recovery does not show annual variations in predicted water levels. Annual variations in recharge and streamflow are predicted to result in a similar overall groundwater recovery trend, with some increases in drawdown before complete recovery is achieved. Despite these early increases in predicted drawdown, the same equilibrium and recovered water levels are predicted at all locations for both recharge cases.

Predicted groundwater recovery at TP7 located along the Jimmawurrada Creek, near the proposed water supply borefield, is presented in Figures C3 and C11. Water levels at TP7 are predicted to have recovered after 20 years or 30 to 40 years earlier than water levels at other tracking points in the catchment. The location of TP7, closer to the Bungaroo Valley (southern inflow boundary) and the water supply borefield area is associated with a much more rapid predicted recovery of water levels compared to the rest of the modelled catchment. Groundwater recovery for Case 1 is also predicted ten years earlier than Case 2 due to the reduced water supply pumping requirement of Case 1.

Predicted groundwater recovery at Mesa J and Mesa H is shown in Figures C4 to C8 and C12 to C16 (locations across Mesa J and Mesa H are shown in Figure 18). The rate of groundwater recovery across the mining areas is related to re-establishment of natural, pre-mining, throughflow across the model domain which

is largely controlled by inflow from the Bungaroo Valley and inflows from the Robe River and the Jimmawurrada Creek. During closure predictions, water supply pumping associated with the CWS in the Bungaroo Valley was assumed to be complete resulting in pre-development groundwater conditions and inflows at the southern model boundary associated with the Bungaroo Valley. During closure predictions, the model predicts resumption of groundwater inflow from the south-east (Bungaroo Valley) to the north/north-west with subsequent recovery of water levels in the borefield area. Areas of maximum drawdown are then predicted further to the north as shown in Mesa J - Pit 15 (Figure C8). Further drawdown propagation to the north (north of the Mesa J mine towards the Robe River) is limited by the low permeability basement outcrops north of the Mesa J mine.

Across the Mesa J and Mesa H mine areas, groundwater levels are predicted to recover to predevelopment levels. The results suggest that groundwater recovery to predevelopment levels is predicted to occur within 50 to 60 years after closure.

7. UNCERTAINTY ANALYSES

7.1 Prediction Uncertainty Approach

While a reasonable calibration to steady state and time-varying conditions has been achieved for the groundwater flow model, there remains inherent uncertainty in the parameters and model setup adopted to describe the hydrogeological system with consequent risks in the prediction of dewatering impacts, owing to the absence of historical monitoring data for calibration.

To assess the potential impact of these uncertainties, Uncertainty Predictions have been conducted on both of the Base Case prediction models (Case 1 and Case 2 models). Details of the Uncertainty Runs, are outlined in Table 7.1.

Table 7.1: Summary of Uncertainty Runs

Run	Description	Type of Uncertainty
1	Natural inflows to the Robe River and Jimmawurrada Creek not simulated (set to zero)	Stress
2	Natural inflows to the Robe River and Jimmawurrada Creek reduced by 50%	Climate
3	Natural inflows to the Robe River reduced by 50%. Inflows to the Jimmawurrada Creek not simulated (set to zero)	Climate
4	Natural inflows to the Robe River not simulated. Inflows to the Jimmawurrada Creek reduced by 50%	Climate
5	Steady state rainfall recharge and stream flows. Impact associated with CWS not included.	Stress
6	Rainfall recharge reduced by 50% everywhere	Climate
7	Rainfall recharge reduced by 50% everywhere and discharge to Dan's Dam not simulated (set to zero)	Stress
8	General head inflow boundary associated with Robe River not simulated (removed from the model)	Conceptual
9	Rainfall recharge increased by 50% everywhere. Robe River and Jimmawurrada flows increased by 50%.	Climate
10	Unconfined storage (Sy) of the Robe River alluvium increased by 10% (from 30 to 40%)	Conceptual
11	Hydraulic conductivity of the outcropping Brockman Formation increased to 5 m/d	Conceptual
12	Outflow from the Wittenoom Formation included (General Head Boundary included across the northern model boundary at 115 mAHD)	Conceptual
13	No dewatering from Mesa H and J. All water demand supplied from proposed borefield	Stress

Normally, uncertainty analysis is limited to varying input parameters within reasonable limits which are not necessarily supported by the model calibration. However, as part of this investigation the uncertainty analysis also included combinations of parameters to assess what conditions might be required to produce dewatering impacts that would trigger mitigation measures to maintain surface water pools along the Robe River.

The uncertainty runs are grouped into three categories:

- **Conceptual Model Uncertainties**: These runs were designed to investigate the impact that hydrogeological changes, that are not supported

by the current conceptualisation or the model calibration, may have on predicted drawdown impacts on surface water pools along the Robe River. These include Runs 8, 10, 11 and 12.

- **Climatic Uncertainties**: These runs were designed to assess what hydrological conditions might be required to produce worst case drawdown impacts on surface water pools along the Robe River. These include Runs 2, 3, 4, 6 and 9.

- **Extreme /Stress Uncertainties**: These runs included extreme changes in the model set or operating conditions to assess the drawdown impact on surface water pools along the Robe River. These included Runs 1, 5, 7 and 13.

For some of the Uncertainty Runs, the steady state and transient model calibrations and the No Development Cases were also re-run with the corresponding changes. None of the steady state or transient models were recalibrated, nor were Uncertainty Run dewatering and water supply predictions re-optimised as part of the current study.

7.2 Results

Predicted drawdown at tracking points for the Base Case Runs (Cases 1 and 2) and Uncertainty Runs 1 to 13 are grouped by Conceptual, Climatic and Extreme / Stress Uncertainty as outlined in Table 7.1 (Case 1, Figures D1 to D9 and Case 2, Figures D10 to D18). Drawdown is calculated by subtracting predicted water levels at each tracking point for the No Development Case (as outlined in Section 5.3) from the corresponding Uncertainty Run. The maximum predicted drawdowns at each tracking point for all Uncertainty Runs are summarised in Table 7.2 (Case 1) and 7.3 (Case 2).

The ranking of the impact of uncertainty on predicted drawdown impacts has been assessed by comparing the sum of the maximum predicted drawdowns at all tracking points for each Uncertainty Run, excluding TP7. The maximum drawdown at TP7, located near the water supply borefield is much larger than the other tracking point maximum predicted drawdowns throughout the catchment. As a result, its inclusion skews the ranking system. Total predicted drawdowns for all Uncertainty Runs (and Base Cases), excluding TP7, are summarised in Table 7.4 and ranked in order from greatest to least impact on total predicted drawdown. Predicted drawdown at TP7 is discussed separately in the sections below.

*BC – Base Case,

Uncertainty Runs 1 (no stream flows), 4 (inflows to the Robe River not simulated and inflows to the Jimmawurrada Creek reduced by 50%) and 8 (Robe River inflow boundary not simulated) are predicted to result in the greatest increase in predicted drawdown across the modelled catchment (ranked 1st, 2nd and 3rd for both Case 1 and 2 Base Cases). The total drawdown at tracking points for these three Uncertainty Runs is at least double the total drawdown predicted for the

other Uncertainty Runs (and the Base Cases). The next greatest impact on drawdown is predicted by Uncertainty Run 12 (outflow to the Wittenoom Formation included), however it is less than half of the total drawdown predicted for Uncertainty Runs ranked 1st to 3rd.

Overall however, Uncertainty Runs 1, 2, 3, 4, 6, 7, 8 and 12 predict more drawdown at tracking points compared to the Case 1 and 2 Base Cases. Very small differences in total maximum predicted drawdown are predicted for Uncertainty Runs ranked from 5th to 8th with the same maximum total drawdown predicted for the 8th ranked Uncertainty Run for Case 1 and 2 (Run 2, natural inflows to the Robe River and Jimmawurrada Creek reduced by 50%). There are some minor differences in the rankings for Cases 1 and 2 (Uncertainty Runs 3 and 7 are ranked differently for Cases 1 and 2).

Uncertainty Runs 5, 9, 10, 11 and 13 all predict less combined drawdown at tracking points than the Case 1 and 2 Bases Cases. For these runs, the ranking of impact on drawdown is the same for Case 1 and 2 Base Cases apart from slightly different rankings for Uncertainty Runs 9 and 10. As would be expected, Uncertainty Runs 5 and 13 predict less drawdown at tracking points along the Robe River due to the inclusion of constant recharge and stream flow and moving all pumping to the water supply borefield.

Considering the predicted drawdown at TP7, Uncertainty Runs 1 and 3 (Run 1, natural inflows to the Robe River and Jimmawurrada Creek set to zero and Run 3, natural inflows to the Robe River reduced by 50% and inflows to the Jimmawurrada Creek set to zero), are predicted to result in the greatest increase in predicted drawdown at TP7 as it is located along the Jimmawurrada Creek. At other tracking points, Uncertainty Run 3 is not predicted to have a significant impact on predicted drawdown as the simulated inflow from the Robe River boundary is still sufficient to mitigate predicted drawdown along the Robe River. As would be expected, simulating all water demand drawn from the borefield (Uncertainty Run 13) predicted the next greatest impact on predicted drawdown at TP7 (Figures D9 and D16) as TP7 is closest to the water supply borefield. As would be expected, this Uncertainty Run reduced the predicted drawdown at all other tracking points.

Table 7.4 Ranking of Uncertainty Runs

Ranking	Case 1 Uncertainty Runs	Total Maximum Drawdown (m) (without TP7)	Case 2 Uncertainty Runs	Total Maximum Drawdown (m) (without TP7)
1	1 Natural inflows to the Robe River and Jimmawurrada Creek set to zero	**15.52**	1 Natural inflows to the Robe River and Jimmawurrada Creek not set to zero	**15.56**
2	4 Natural inflows to the Robe River not simulated. Inflows to the Jimmawurrada Creek reduced by 50%	**10.99**	4 Natural inflows to the Robe River not simulated. Inflows to the Jimmawurrada Creek reduced by 50%	**11.00**
3	8 General head inflow boundary associated with Robe River not simulated (removed from the model)	**8.16**	8 General head inflow boundary associated with Robe River not simulated (removed from the model)	**8.15**

8. MODEL CONFIDENCE LEVEL CLASSIFICATION

The classification of the current model is based on "Australian groundwater modelling guidelines – Waterlines Report Series No. 82 June 2012". It is derived from a semi-quantitative assessment of the available data on which the model is based (for both conceptualisation and calibration), the manner in which the model is calibrated and how the predictions are formulated.

The current model is considered to provide a Class 2 confidence level according to the proposed model classification due to lack of long-term monitoring data along the Robe River which was the key focus of this modelling study.

Factors that restrict the current model to Class 2 confidence level are:

- Data: Groundwater levels were available throughout the model domain, but they do not provide adequate coverage along the Robe River.
- Calibration: As a result of lack of data along the Robe River, long-term trends were not available in all parts of model domain.

The current model is considered to meet some of the requirements of a Class 3 confidence level in terms of model predictions and key indicators, as follows:

- Predictions
  - The length of dewatering, water supply and closure prediction models is not excessive compared to the length of the calibration period.
  - Temporal discretisation used in the predictive model is consistent with the transient calibration.
  - The level and type of stresses included in the predictive model are within the range of those used in the transient calibration.
- Key Indicators
  - The model dewatering prediction time frame is less than the duration of the transient calibration and the closure prediction time frame (up to 60 years taken for groundwater recovery) is less than three times the length of the calibration (27 years).
  - Stresses are no more than two times greater than those included in calibration.
  - Temporal discretisation in the prediction model is the same as that used in calibration.
  - The mass balance closure error is less than 0.5% of the total.
  - The model parameters are consistent with the conceptualisation.
  - Appropriate computational methods were used along with appropriate spatial discretisation.
  - The model has been reviewed and deemed fit for purpose by an experienced, independent hydrogeologist with modelling experience.

9. SUMMARY

The Mesa H regional groundwater flow model includes the current regional hydrogeological understanding of the Mesa J and Mesa H mining areas. The model has been calibrated to pre-development (steady state) and transient conditions using available data, including:

- Measured groundwater levels across the catchment.
- Ongoing dewatering at the Mesa J mine.
- Long term water supply pumping from the Mesa J bores.
- Long term surface water discharge to Jimmawurrada and West Creek.

There are no long term monitoring data covering periods of significant aquifer stress (i.e. pumping and resulting groundwater level drawdown) available for the Robe River, Jimmawurrada Creek or Mesa H deposits. As such, the calibration data are not sufficient to provide a robust transient calibration in those areas. Therefore, there still remains a degree of uncertainty in the model parameterisation (in particular regional hydraulic connection) and predictive reliability. To account for this, modelling has been completed using a conservative approach with respect to the data limitations and with conservative assumptions made in many instances (namely Robe River flows) where actual data is unavailable. Uncertainty analysis was undertaken to address areas of climatic, conceptual and operational /aquifer stress uncertainty.

The calibrated model was used to predict required dewatering rates, water supply requirements and drawdown impacts for a nominal mine plan for the Mesa H and Mesa J mines, over an 19 year period (January 2019 to December 2037) for two total water demands (up to 5,000 ML/yr for Case 1 and up to 9,000 ML/yr for Case 2).

Average predicted dewatering or sump pumping required to maintain groundwater levels below the projected base of mining over the period January 2020 to December 2037 is ~4,000 ML/yr. Abstraction from the water supply borefield is predicted to be required to supplement the shortfalls in predicted dewatering and maintain projected water demands (for both Case 1 and Case 2 water demands of up to 5,000 and 9,000 ML/yr).

The drawdown from dewatering across the mining areas (assuming the current mine plans) is not predicted to extend a significant distance and create a significant impact on surface water pools along the Robe River to the north, north-east or north-west of the Mesa H and Mesa J mine areas. By 2037 dewatering/drawdown impacts are estimated to be less than 1 m at tracking points along the Robe River.

Results of the Uncertainty Runs suggest that predicted groundwater levels at surface water pools along the Robe River are controlled by the leakage from surface water flows and underflow in its alluvial bed. Model predictions were most sensitive to changes in the amount of inflow or underflow associated with the

Robe River. Results suggest that if the Robe River inflows or underflows are significantly reduced, groundwater levels in surface water pools may be reduced.

The groundwater model was also used to predict the time taken for groundwater recovery (post closure) for Cases 1 and 2 for steady state and historical recharge and streamflow conditions. Prediction results suggest that groundwater levels, within all mine voids (infilled to above the pre-mining water table), would recover to final or equilibrium water levels, similar to pre-development levels, after some 50 to 60 years for both recharge cases.

The current model is considered to provide a Class 2 confidence level according to the Australian Groundwater Modelling Guidelines, due to lack of long-term monitoring data along the Robe River (the key focus of this modelling study). However, the model meets the criteria for Class 3 confidence level in all other aspects.

Surplus water discharge extent assessment: Mesa H

Overview

The Mesa H deposit is located approximately 11 km southwest of Pannawonica and adjacent to the Robe JV Mesa J mine, downstream of the confluence of the Robe River and Jimmawurrada Creek (Figure 1). Approximately 40% of the resource is below the current water table (which has been lowered by dewatering at Mesa J). Consequently, approval will be sought to commence mining below water table, which will require dewatering.

Management of water on Rio Tinto sites follows strict environmental and water use standards (refer to Rio Tinto Environmental Standards). These standards align with the "Pilbara Water in Mining Guideline" (DoW, 2009) which identifies options for use and/or release of dewatering discharge:

- Efficient on-site use, including mitigation of any impacts.
- Used for fit for purpose activities (such as processing and dust suppression). The proponent needs to demonstrate that the water is of suitable quality for the end use.
- Transferred to meet other demand including other proponents in the area and public water supply, as approved by the Department. Where it is proposed to use the water for public supply, a drinking water source protection plan should be developed and approved by the Department of Water and the Department of Health.
- Injection back into the aquifer at designated sites determined by the proponent and agreed by the Department.
- Controlled release to the environment where the dewater release is allowed to flow (either through a pipe or overland) into a designated water course or wetland and determined by the proponent and agreed by the Department.

Management of surplus water at Mesa H may include the controlled discharge of surplus water at existing discharge locations at Mesa J, namely Discharge point 5 (Jimmawurrada Creek) or Discharge Point B (Robe River tributary immediately west of Mesa J). Therefore, the objective of this study was to estimate the extent of impact of surplus water discharge along the respective watercourses. The methodology to achieve this objective is outlined below:

- Develop a 2D hydraulic model of the river system downstream of the proposed discharge location.
- Determine the hydraulic characteristics that are not inherently accounted for by the 2D hydraulic model, i.e. saturated hydraulic conductivity of the soils.
- Estimate the maximum possible extent that surplus water discharge will flow under steady-state conditions.
- Investigate multiple steady-state scenarios, namely a continuous discharge rate of 5, 10, 15, 20, 25 and 30 ML/day.

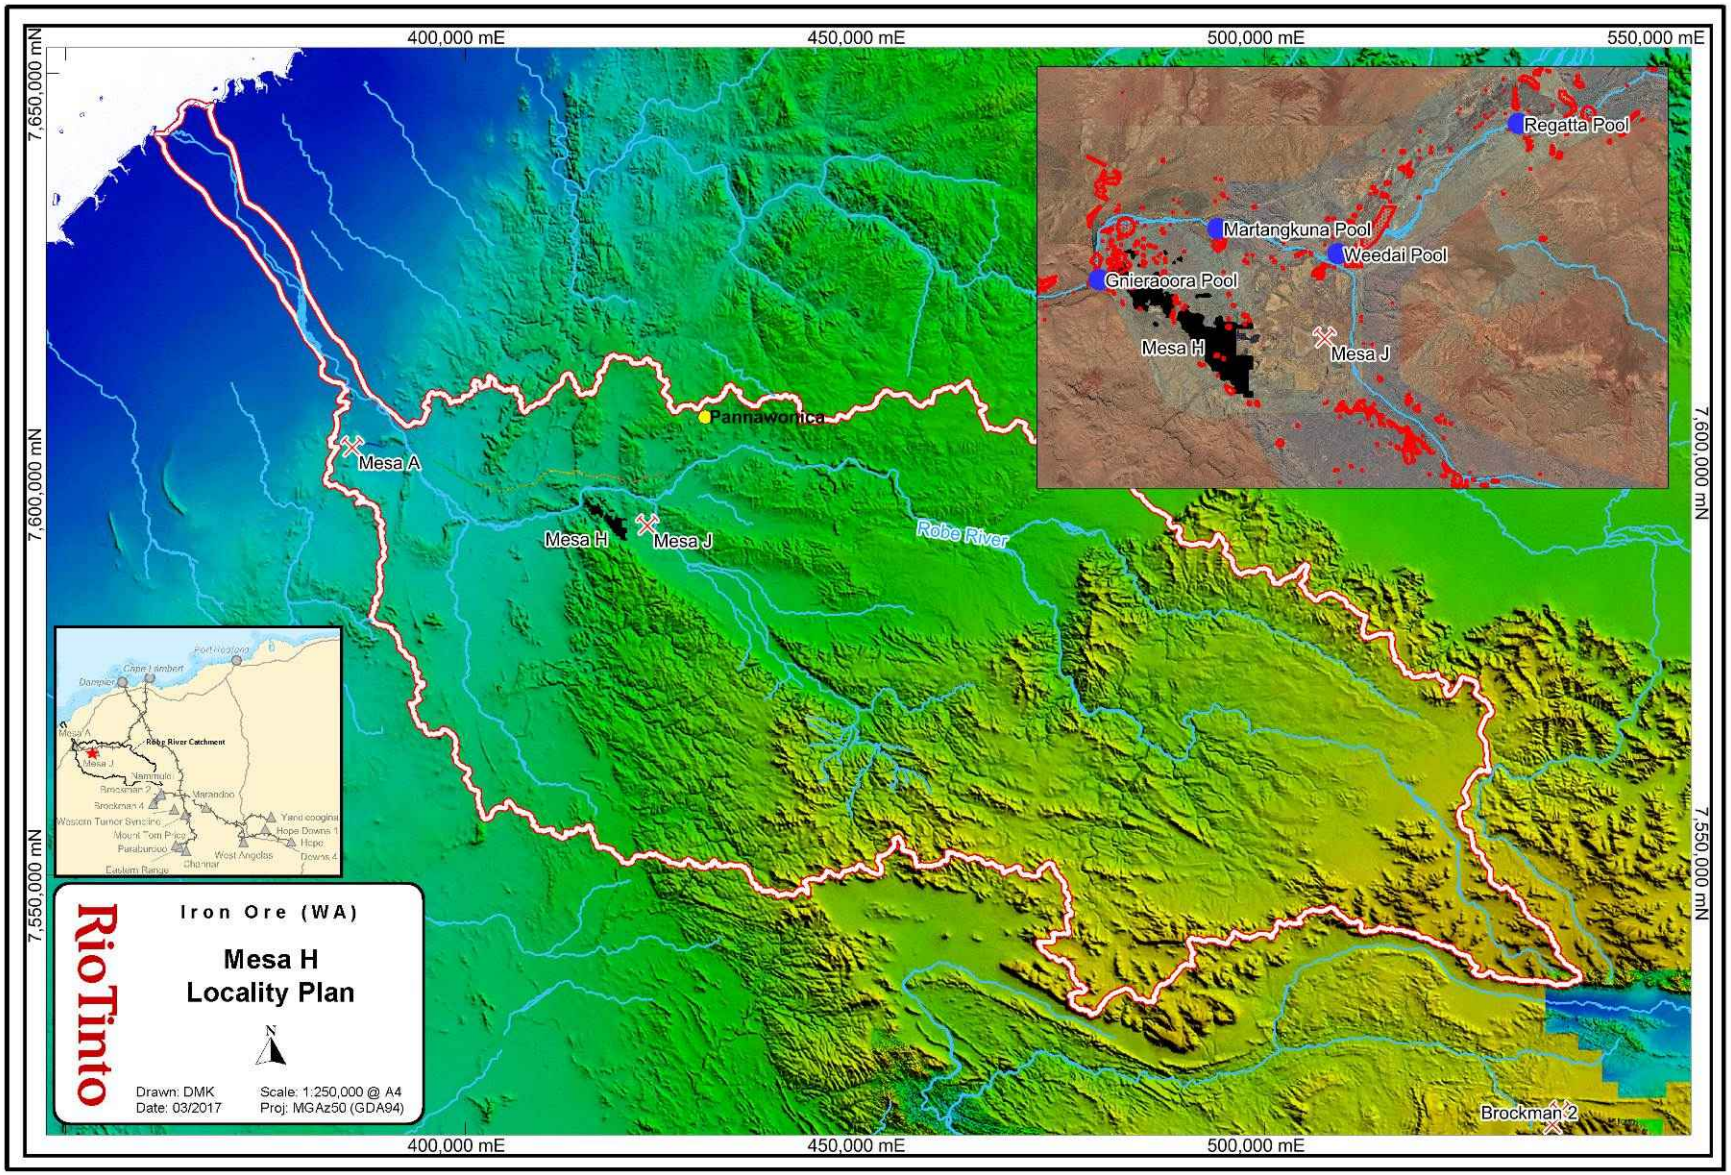

Figure 1: **Mesa H surplus water discharge study location plan**

Modelling Approach

Water flowing in a watercourse is removed from the surface via two mechanisms, namely: evaporation and infiltration. However, these hydrologic processes are inextricably intertwined with the flow characteristics, and hence the hydraulics, of the river system. The braided nature of typical Pilbara watercourses creates a complex hydrodynamic environment where the flow behaviour is essentially 2D in nature, which may be poorly represented using a 1D model.

Recent developments to the **T**wo-dimensional **U**nsteady **Flow** (TUFLOW) model have effectively transformed TUFLOW into a 2D coupled hydrologic-hydraulic modelling system, with the ability to model soil infiltration in both unsaturated and saturated conditions. This makes the TUFLOW model a useful tool for the estimation of surplus water discharge extent.

This section documents the process and assumptions made in developing the 2D hydraulic model for the Mesa H surplus water discharge.

TUFLOW hydraulic model

For this study, TUFLOW's GPU Module was adopted. This is a powerful new solver built into the TUFLOW software, which utilises the substantial parallel computing ability of modern Graphics Processor Units, or GPUs (TUFLOW, 2014). TUFLOW GPU is an explicit solver for the full 2D Shallow Water Equations, including a sub-grid scale eddy viscosity model. The scheme is both volume and momentum conserving. Owing to the power of modern GPUs very large models (>100 million cells) with fine grids can now be run within a sensible timeframe (TUFLOW, 2014). This allowed for a high resolution 1 m DEM, derived from LiDAR, to be used to describe the topography of the river system. This represents a major advantage of this approach. The model configurations are shown in Figure 2.

Manning's roughness coefficient *n*

Surface roughness is defined using the Manning's *n* roughness coefficient. The roughness coefficients adopted for this study were determined according to Chow (1959), which takes into consideration channel irregularities, variation in cross section, obstructions, vegetation density and meandering of the reach. These factors were assessed using aerial photography and confirmed during a site visit. The adopted Manning's *n* roughness coefficient for the Robe River and Jimmawurrada Creek was 0.045, while the Robe River tributary immediately west of Mesa J was assigned a Manning's *n* roughness coefficient of 0.035. These values were applied to all applicable active cells in the model, which was limited to the river/creek channels, as can been seen in Figure 2.

Model inflows

Multiple steady-state scenarios were assessed, namely a continuous discharge of 5, 10, 15, 20, 25 and 30 ML/day.

Model outflows

The maximum discharge extent is achieved when equilibrium is reached between the inflows to and the outflows from the system. Water flowing in a watercourse is removed from the surface through evaporation and/or infiltration.

Evaporation

Annual and monthly potential evaporation rates (A-pan) are available from the Bureau of Meteorology (BoM) website. However, evaporation from open water bodies can be significantly less than A-pan estimates owing to a variety of climatic factors. As such, correction factors are often required to relate A-pan evaporation to evaporation from open water bodies. From Figure 3 it can be seen that evaporation from open water bodies for most of the Pilbara region of Western Australia is between 60-70% of the A-pan evaporation rates.

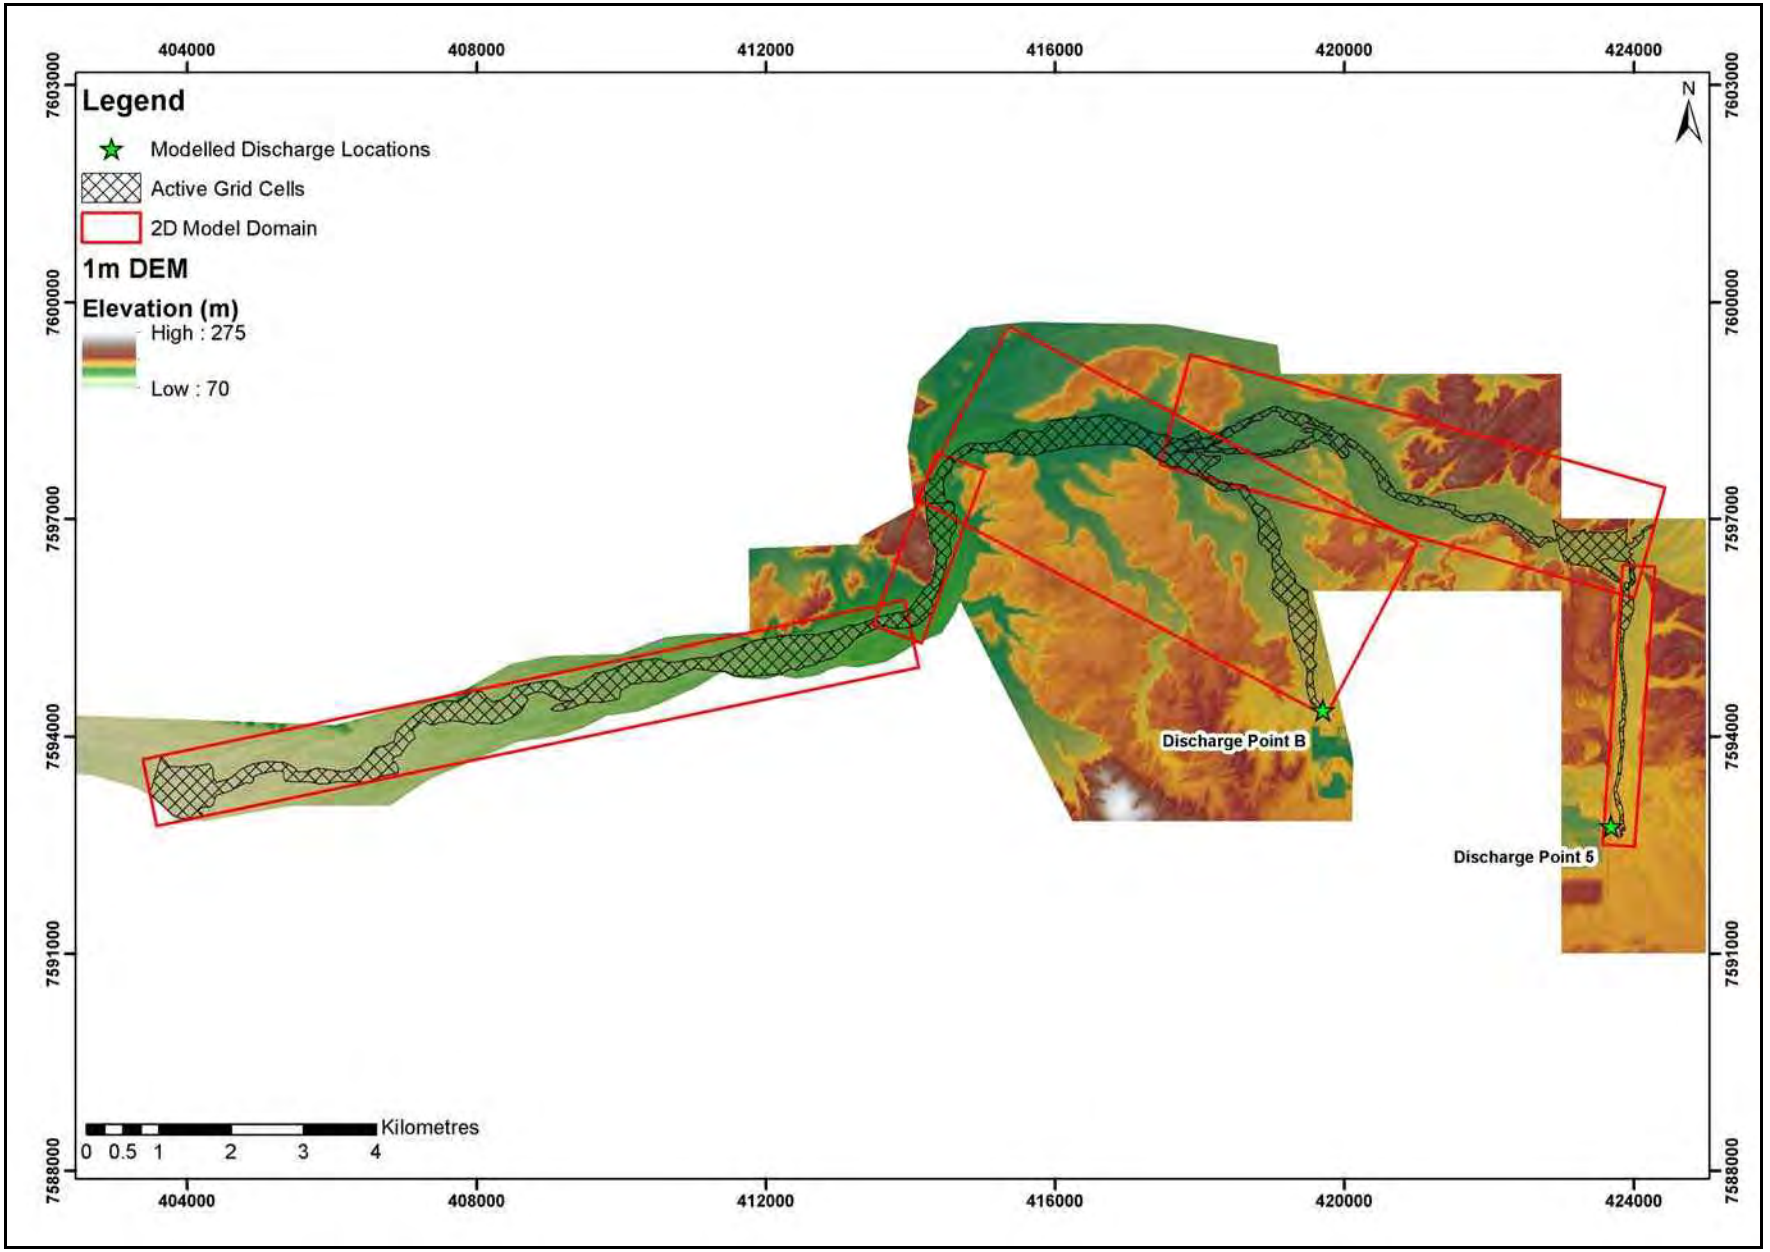

Figure 2: TUFLOW model configuration

From Figure 3, the A-pan evaporation rate for Mesa H was determined to be 3400 mm per year. However, the lowest monthly A-pan evaporation occurs in June (157 mm). This was multiplied by 0.65 (Luke et al., 1987) to relate A-pan to open water body evaporation. Consequently the adopted evaporation rate was 102 mm per month, which translates to an average rate of 0.14 mm/h.

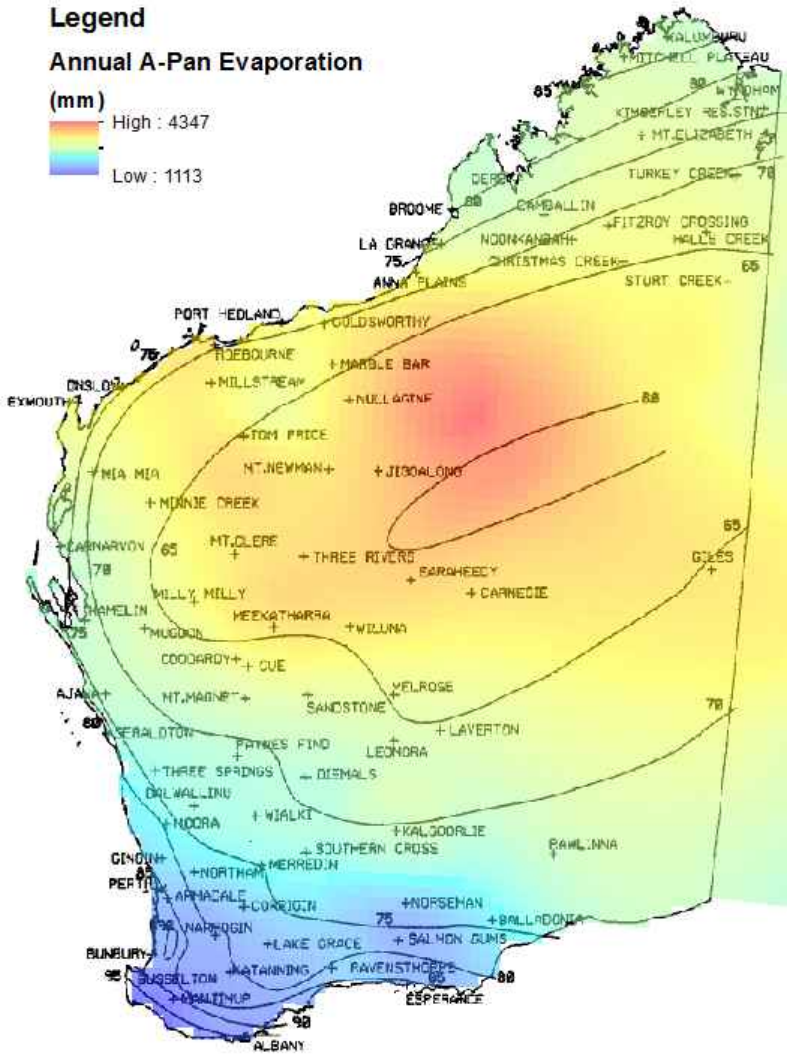

Figure 3: Gridded annual A-pan evaporation and A-pan correction factors (contours) for Western Australia (from BoM and Luke et al., 1987)

Infiltration

The maximum discharge extent is achieved when equilibrium is reached between the inflows to and the outflows from the system. As the soil moisture content increases so the infiltration rate of the soil decreases until the saturated hydraulic conductivity (K_{sat}) of the soil is reached. Consequently, equilibrium between the inflows and outflows, and hence the maximum discharge extent, can only be achieved once the soils have reached saturation. As such, when the aim of the discharge extent modelling is to determine the maximum discharge extent for long-term discharge there is no need to simulate losses in unsaturated conditions, and a continuing loss equal to K_{sat} may be adopted.

Although the Soil Hydrological Properties for Australia (Western and McKenzie, 2006) provides K_{sat} values for the whole of Australia, experience has shown that these values can be up to three orders of magnitude too high, thereby overestimating losses from the system and drastically under estimating the maximum discharge extent. As a result, a texture based approach to estimate K_{sat} in the absence of measured data has been applied. This approach derives a weighted clay content for each Map Unit in the Atlas of Australian Soils (Northcote

et al., 1960-1968), which places the Map Unit into one of six Texture Groups documented by McKenzie et al. (2000), shown in Table 1.

Table 1: Texture groups according to clay content - adapted from McKenzie et al. (2000)

Weighted Clay Content (%)	Texture Group	Texture Grade
0 – 8	Sands	Sand Clayey Sand Loamy Sand
8 – 17.5	Sandy Loams	Sandy Loam Fine Sandy Loam Light Sandy Loam
17.5 – 25	Loams	Loam Loam, Fine Sandy Silt Loam Sandy Clay Loam
25 – 35	Clay Loams	Clay Loam Silty Clay Loam Fine Sandy Clay Loam
35 – 47.5	Light Clays	Sandy Clay Silty Clay Light Clay Light Medium Clay
47.5 – 100	Clays	Medium Clay Heavy Clay

The least permeable texture grade is adopted as the representative texture for each Texture Group, and is therefore considered to be a conservative estimate. The adopted K_{sat} values for each Texture Group are presented in Table 2.

Table 2: Saturated hydraulic conductivities for different texture groups – adapted from Clapp and Hornberger (1978), Cosby et al. (1984) and van Gool et al., (2005)

Texture Group	Adopted K_{sat} (mm/h)
Sands	50.6
Sandy Loams	18.8
Loams	10.1
Clay Loams	6.1
Light Clays	3.7
Clays	3.0

Figure 4 shows that the creeks and rivers downstream of the discharge locations cross four different soil Map Units, namely, B27, Fa13, My1 and Oc66. Using the approach outlined above the Texture Group and K_{sat} for each Map Unit was derived, and is presented in Table 3.

Table 3: Soil Map Units in study area and adopted saturated hydraulic conductivities

Soil Map Unit	Weighted Clay Content of Limiting Soil Horizon (%)	Texture Group	Adopted K_{sat} (mm/h)
B27	30.0	Clay Loams	6.1
Fa13	27.5	Clay Loams	6.1
My1	36.5	Light Clays	3.7
Oc66	44.0	Light Clays	3.7

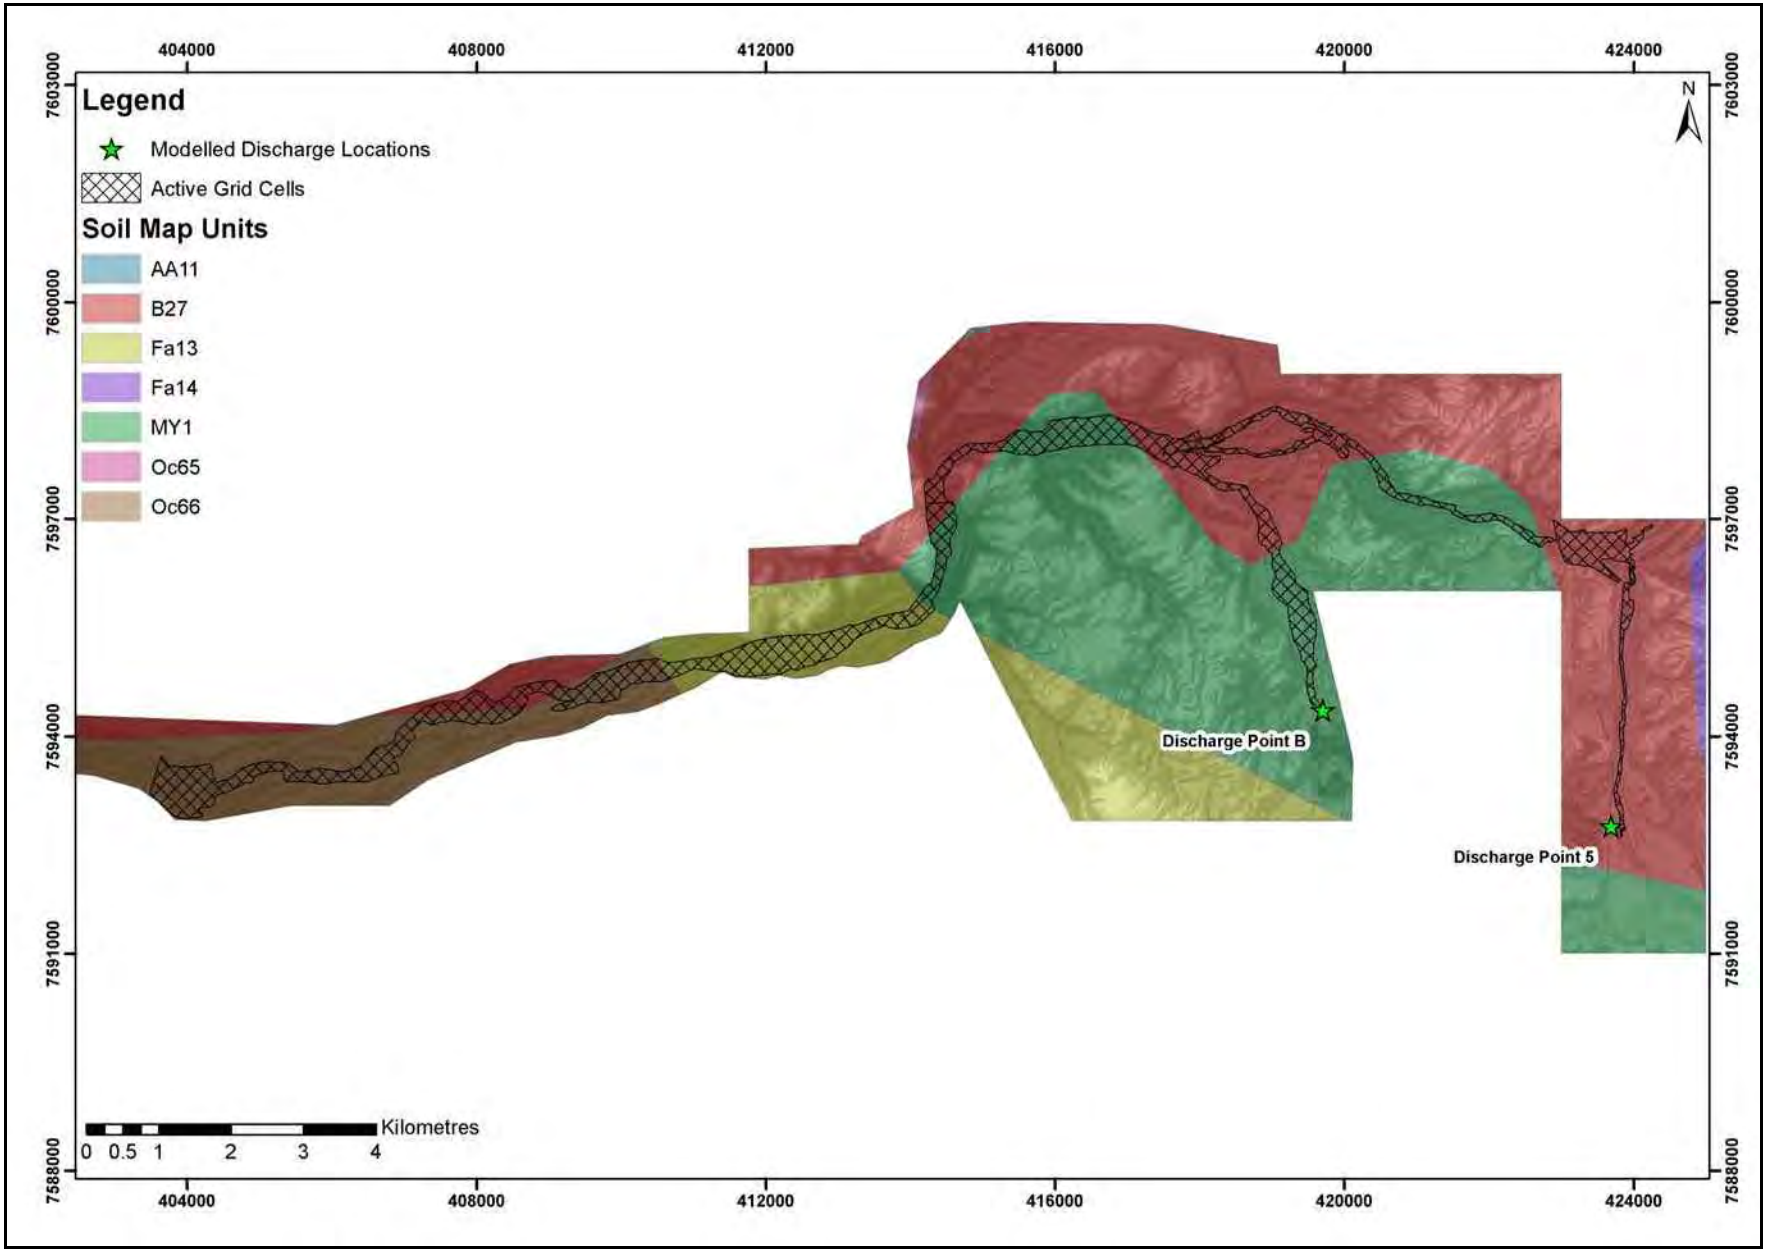

Figure 4: **Soil Map Units intersected by the watercourses downstream of the proposed surplus water discharge locations**

Results

Results for the various discharge modelling scenarios are presented in Table 4 and Figure 5. It is estimated that the surplus water discharge extent will range from 3.5 km to 20 km down gradient of the assumed discharge point depending on the discharge rate and discharge location, before completely infiltrating/evaporating.

Table 4: Estimated discharge extent from discharge location for various discharge rates

Scenario	Distance Travelled (km)	
	Discharge Point 5	Discharge Point B
5 ML/d	3.5	4.7
10 ML/d	5.2	8.8
15 ML/d	5.2	11.8
20 ML/d	5.9	14.4
25 ML/d	9.3	17.2
30 ML/d	11.8	19.9

The braided nature of typical Pilbara watercourses creates a complex hydrodynamic environment where the flow behaviour is essentially 2D in nature. Often braided flows are thought of as a consequence of flooding where flows break out onto poorly defined floodplains. Figure 6 clearly demonstrates that complex bifurcations can also be a characteristic of the low flow regime, and was found in this assessment to be typical in the Robe River, thereby justifying the selection of a 2D hydraulic model.

The surplus water discharge volume would be significantly smaller than the volume generated by the catchment during flood events. Based on model results, discharged water would be contained within the low flow channel/s, hence overtopping of the creek banks in dry conditions is not anticipated.

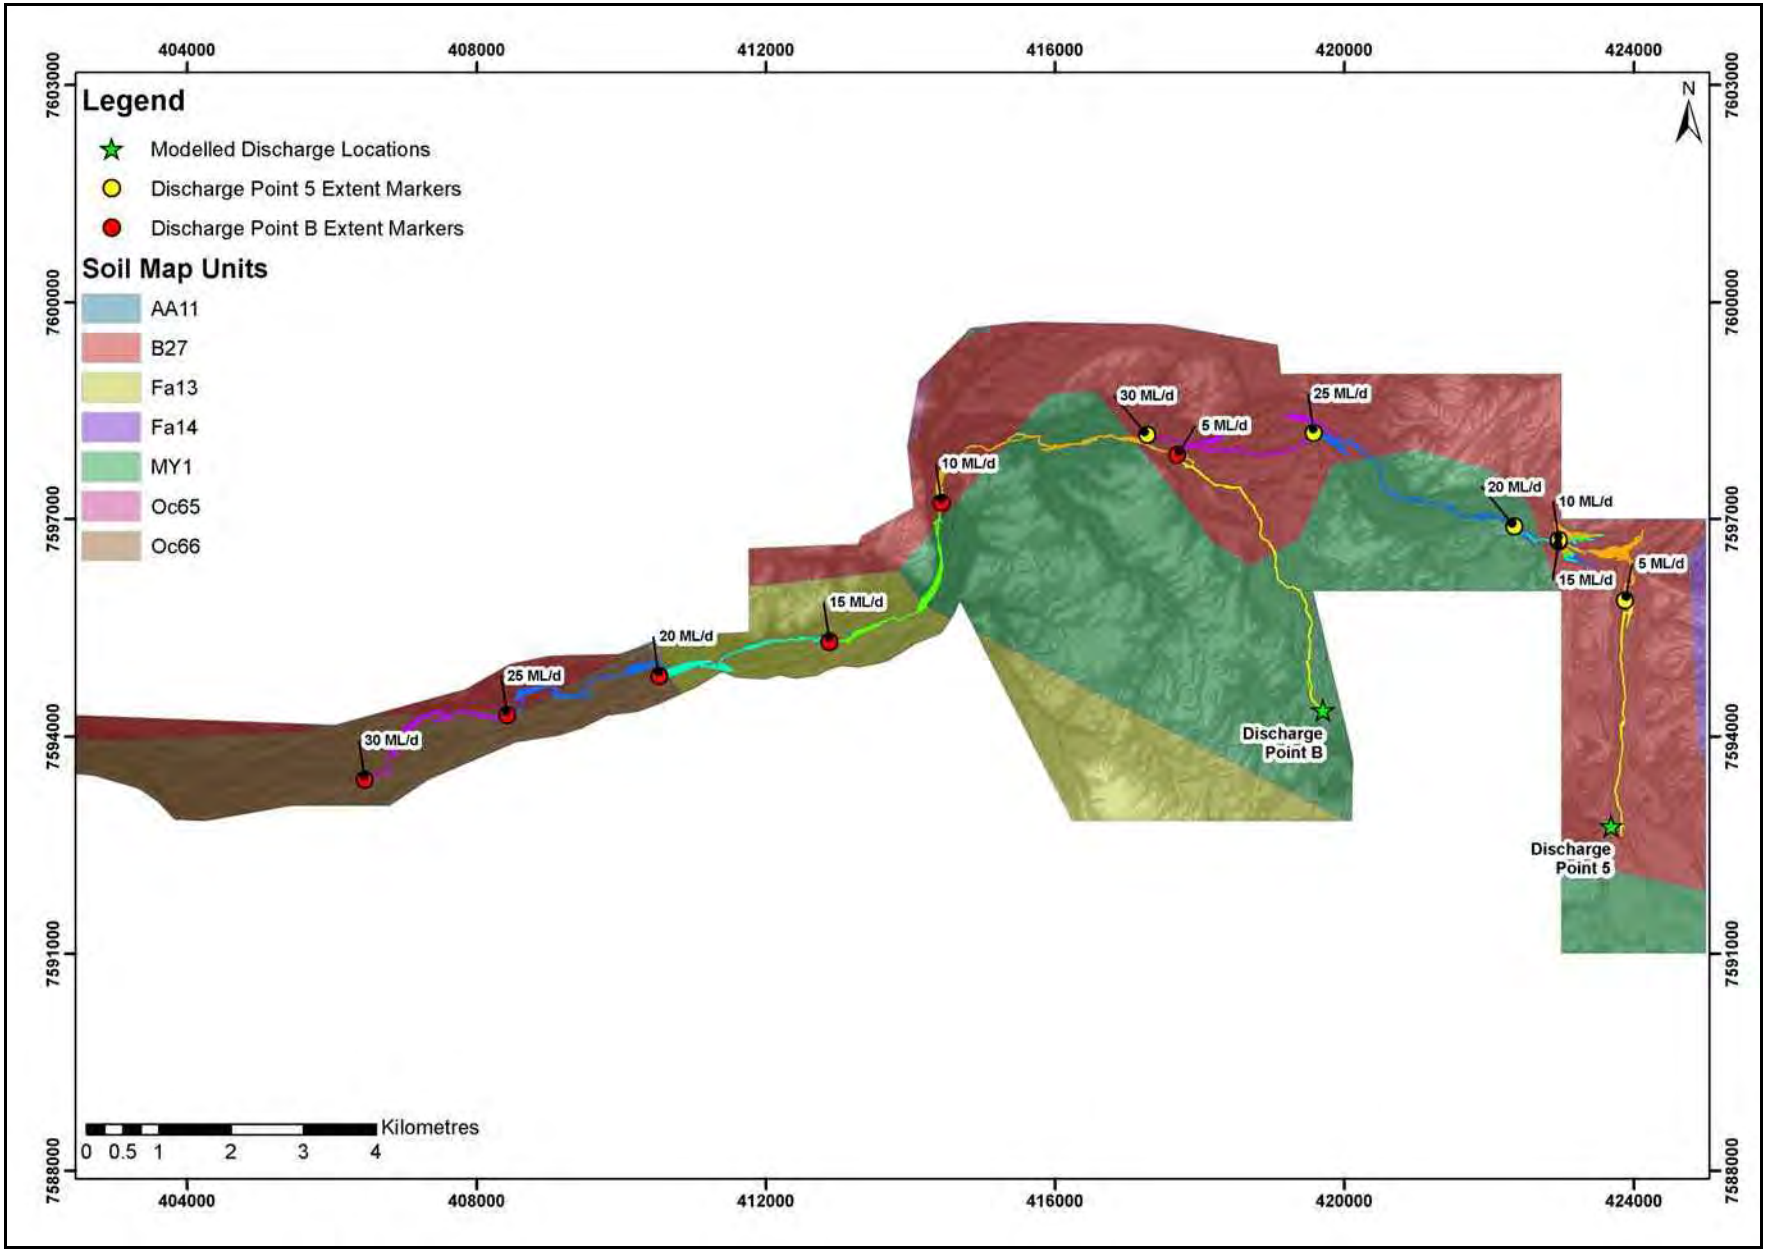

Figure 5: **Modelled maximum discharge extents for various discharge rates**

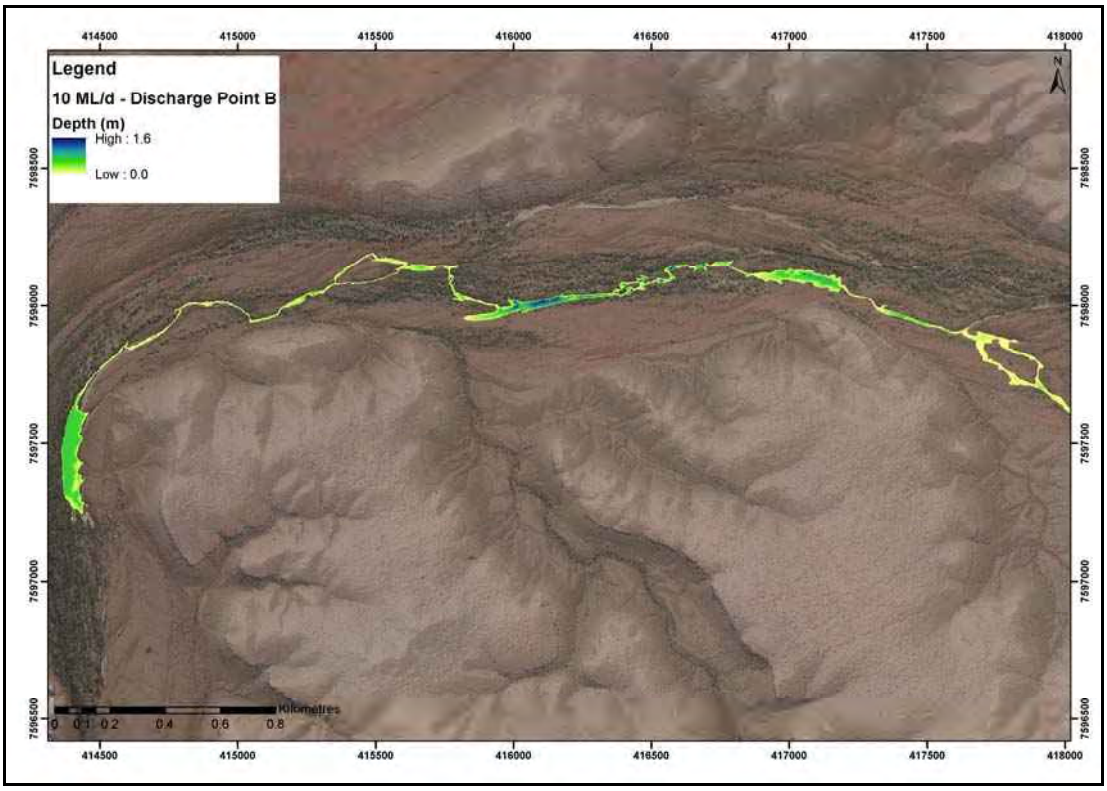

Figure 6: **Complex flow regime of the Robe River modelled in TUFLOW**

Conclusion

A 2D hydraulic model of the Robe River and relevant tributaries has been developed to estimate the extent of future potential surplus water discharge from the proposed Mesa H operations. The key advantage of the approach was the ability to hydraulically simulate the complex hydrodynamic environment while simultaneously accounting for hydrologic processes such as infiltration and evaporation.

The maximum surface water extents from five discharge scenarios were modelled: namely a continuous rate of 5, 10, 15, 20, 25 and 30 ML/day. It is estimated that the surplus water discharge extent will range from 3.5 km to 20 km down gradient of the assumed discharge point depending on the discharge rate and discharge location, before completely infiltrating/evaporating.

The surplus water discharge volume would be significantly smaller than the volume generated by the catchment during flood events. Based on model results, discharged water would be contained within the low flow channel/s, hence overtopping of the creek banks in dry conditions is not anticipated.

APPENDIX D: PEER REVIEW REPORTS

PEER REVIEW: MESA H: H3 HYDROGEOLOGICAL ASSESSMENT

INTRODUCTION

The Robe River Joint Venture (the Proponent) is undertaking studies to support additional mining operations that will sustain production from the Robe Valley. A number of channel iron deposits (CID) resources in the Robe Valley have been considered.

Mesa H is proposed as the next development to sustain the Mesa J hub production and is scheduled to commence Q1 2020 utilising existing Mesa J infrastructure including existing wet processing facilities.

Mining at Mesa H is scheduled to extend over a period of about 18 years. Water levels in much of the Mesa H mine area have been lowered significantly by dewatering activities at the adjacent Mesa J but further dewatering will be required as approximately 13% of the resource lies below the current water-table (BWT). Water supply augmentation for the expanded mining and processing requirements is also planned.

Pre-Feasibility Studies (PFS) have been completed and it is currently anticipated that the works will progress to a Feasibility Study (FS) in 2017/2018 with planned Implementation in 2019. The Proponent is currently planning to submit API/PER approval documents to in Q4 2017 seeking to obtain a Part IV approval by Q4 2018 / Q1 2019.

PROJECT OVERVIEW

Mesa H is located immediately west and adjacent to the existing Mesa J mine, downstream from the confluence of the Robe River and Jimmawurrada Creek.

The deposit is bounded in the north and northwest by the Robe River where riparian vegetation is extensive and a series of pools exist. One of these pools - Yeera Bluff - is a Rights Reserve site of high significance to the traditional owners.

Dewatering at Mesa H, combined with operations at Mesa J, has potential to lower water levels along the drainage courses.

A significant data base and dewatering/water supply experience has been gained over many years at the adjacent Mesa J site, where similar geological conditions exist, but there have been limited investigations at Mesa H prior to 2015.

A detailed PFS investigation was undertaken through 2015-2016 to address hydrogeological risks identified during an earlier Order of Magnitude (OoM) study – specifically, identifying dewatering requirements and assessing potential associated impacts to the Robe River. The 2016 programme comprised drilling, construction and testing of four (4) water bores with 32 associated monitoring bores the results from which were used (in conjunction with Mesa J data) to develop a conceptual hydrogeological model and subsequent groundwater numerical model.

PEER REVIEW

Provisions were made in August 2016 for an independent peer review of the hydrogeological assessments of the Robe Valley projects.

The key objectives of the review were identified as:

- Review and verify the quantity and quality of hydrogeological information considered as part of the assessment is sufficient to satisfy PFS level understanding and to support API/PER approval submissions
- Review and verify the current conceptual hydrogeological models including an assessment of technical robustness, rigour and level of confidence in the interpretations and analyses;
- Review and verify the numerical groundwater model inputs, design, calibrations and outputs and assess in terms of National Water Commission's Australian Groundwater Modelling Guidelines (2012);
- Provide recommendation to address gaps in the conceptualisation and numerical models.

Independent Groundwater Consultants Pty Ltd was commissioned to undertake the review which has been undertaken by Graham Smith, a professional hydrogeologist with 40 years of local and international experience specializing in arid zone hydrogeology with familiarity of the Pilbara and Robe River through site visits, a number of mine development projects and previous Rio Tinto commissions (e.g. member of Expert Panel; 2015 Pre-Feasibility Study for the Bungaroo mine; Peer Reviewer hydrogeological assessments for Warramboo, Mesa C and West Angelas C&D).

The review has involved review of project technical documentation, a site visit and several discussions with technical personnel as the studies have progressed.

This report presents comment on the H3 Assessment Report for Mesa H with primary attention given to data availability, hydrogeological conceptualisation, analysis and assessment methods, groundwater modelling, impact assessments, mitigation measures if/as appropriate, water management planning and proposed future work programmes. The review of the hydrogeological conceptualisations and groundwater models draws on the Australian Groundwater Modelling Guidelines (Barnett et al, 2012).

Key Documents

The primary reference document provided for review was:

- Mesa H: H3 Hydrogeological Level Assessment v4.0 (RTIO, October, 2017).

Supporting documentation included:

- Mesa H: 2016 Pre-Feasibility Study Hydrogeological Drilling Program Completion Report (RTIO, May 2016).
- Mesa H: Groundwater Modelling rev.E (RPS, October, 2017).

Report Overview

The primary report has been well-prepared and is well supported by figures, tables and Appendices providing detail on the bore completions, the numerical model and an assessment of surplus water discharge extent. It includes the following Sections:

Introduction – provides an overview of the deposit (local aquifers, nearby water courses and environmental setting) and the adjacent Mesa J mine where dewatering occurs to facilitate BWT mining and provide process supplies.

Climate and Rainfall – describes climatic conditions, provides annual rainfall data, outlines contributing catchments and provides Robe River annual streamflow data (from upstream Ngalooin Pool and downstream Yarraloola).

Hydrogeology – describes local geology, aquifer occurrence (CID, Wittenoom and Robe River alluvium) well illustrated with cross-sections, hydrographs illustrating water level drawdown resulting from Mesa J dewatering and responses to rainfall, predicted pre-mining and current water level contours, recharge/discharge processes, water balance, an extended section on Robe River hydraulics where an estimate of mean annual flow (50GL/year) is given and contributing factors associated with the occurrence and status of permanent and semi-permanent pools occurring along the drainage are discussed, with supporting hydrographs. This is followed by an overview of flooding within Jimmawurrada Creek and connectivity with upstream Bungaroo palaeochannels.

Four (4) hydrogeological conceptualisations are presented in recognition of stated uncertainties around the characteristics of the Brockman Iron Fm and continuity of the Wittenoom Fm. Constraints associated with the heterogeneity of the local Robe River alluvial aquifer and the paucity of drilling information north of Mesa H and in Jimmawurrada Creek are also identified.

Existing Groundwater Use – describes dewatering (sumps/trenches), abstraction from an external borefield (Southern Cutback Borefield – SCB – that provides process and potable water supplies) and re-cycling at Mesa J, the Pannawonica town supply borefield drawing ~0.7GL/yr since 1981 from the Robe River alluvium (~10km northwest of Mesa H) and the Bungaroo Coastal Water Supply borefield (permitted to supply up to 10GL/yr for the West Pilbara Water Scheme) located upstream ~20km southeast of Mesa H.

Groundwater Investigation – summarises the extensive hydrogeological investigations to support water supply and dewatering at Mesa J since 1987, establishment of 14 monitor bores at Mesa H in 2015 and the 2016 works comprising installation of four (4) test production bores and 18 monitor bores (with reference to bore completion reports given as Appendix A). A summary of pumping tests and results (3 bores in Mesa H and 18 in Mesa J) is provided. Reference is made to RTIO-PDE-0143871 (not sighted) in presentation of Robe Rive alluvial aquifer characteristics as determined from analysis of long-term abstraction from the Pannowonica town supply borefield.

Groundwater Chemistry – presents detail on extensive programme of groundwater (43 bores) and surface water (7 pools) sampling and analysis (since 1993 at Mesa J) with discussion of

major ions, minor ions and isotopic composition to characterise the three main aquifers at the site and assess their potential contribution to the Robe River alluvial aquifer.

Groundwater Flow Model – summarises previous modelling works to predict inflows to Mesa J (initiated in 2002 and subsequently updated in 2003, 2004 and 2006), describes development of a new groundwater model in 2016 that combines both Mesa H and Mesa J (Modflow_Surfact v4.0 with Groundwater Vistas graphical user interface). Reference made to details provided in supporting Appendix B – Groundwater Numerical Model.

Difficulties associated with steady-state calibration and need for a dynamic calibration process are described with resultant good agreement between conceptual and model inflows and outflows.

Transient calibration, using annual time steps, compared predicted and observed groundwater levels through period 1990-2017 (using 37 bores with long-term records and 33 recently installed bores). Calibrated aquifer parameters are tabulated and a water balance presented. Zone budget analyses are described for the confluence of the Robe River and Jimmawurrada Creek and sites of inflow/outflow from the Robe River alluvium.

Model predictions are provided for dewatering of Mesa J and Mesa H and drawdown along the Robe River; these include augmentation of the SCB with an additional 3-5 water supply bores to meet the increased demand of the wet plant (8.7GL/yr) and continued discharge of surplus water along Jimmawurrada Creek the footprint of which as determined from a separate model. Reference made to details provided in supporting Appendix C –Surplus Water Discharge Extent Assessment.

Prediction uncertainty is discussed and eleven (11) additional model runs described for uncertainty analysis.

Assessment of Potential Impacts – using predicted 2037 water level drawdown resulting from dewatering and water supply discusses potential impacts (on water levels, the Robe river and Jimmawurrada Creek environments and the aquifer including predictions on post-mining water level recovery).

Site Water Balance – presents a detailed site water balance for each year through 2019-2037 identifying supply sources to meet demand for wet plant processing, infrastructure and dust-suppression.

Groundwater Monitoring – provides information on current (and planned) monitoring schedule from the approved site Groundwater Operating Strategy. Ongoing monitoring of flora, fauna and pools will continue in accordance with the Mesa J Environmental Management Plan. Risk to the environment with development of Mesa H is cited as high with acknowledgement that formal triggers (biological and water levels) will need definition prior to commencement of dewatering at Mesa H in 2024.

Management Approach/Conclusions – outlines defined Water Strategy, discharge system, maintenance and monitoring.

Key Findings

The key findings reported may be summarized as follows:

Aquifers

Groundwater occurs in three (3) main aquifers – the Robe River alluvials, the CID and the weathered basement (Marra Mamba Iron and Wittenoom Formations). Connectivity between the CID (to be dewatered during mining) and the underlying basement is constrained by the basal pisolites. Regional groundwater throughflow (CID and weathered basement) is estimated to be ~1.6GL/year.

Depth to water along the Robe River channel is shallow (2-5mbgl) and may fluctuate up to 3m annually in response to high rates of recharge and evapotranspiration. Natural groundwater throughflow is estimated to be ~0.8GL/year.

Conceptualisation

Groundwater flow in the CID and basement is from SE to NW following the trend of the CID palaeochannel deposits from upstream Bungaroo valley. The CID and Wittenoom aquifers are bounded by bedrock aquicludes (in the east by fresh Marra Mamba Iron Formation and by the Brockman Iron Formation in the west). Natural recharge is limited to direct inputs from rainfall but this has been locally augmented by leakage from Mesa J reservoirs.

Groundwater throughflow in the streambed alluvials of the Robe River and Jimmawurrada Creek naturally follows the drainage courses and are primarily recharged by infiltration of surface water flows that are generated by major rainfall events (supplemented locally by discharge of surplus water). The two principal drainages coalesce just upstream of Mesa H.

The pools that occur along the Robe River appear to be related to the alluvial aquifer and are groundwater dependent in drought periods.

A number of key uncertainties have been identified all of which may have significant impact on groundwater flow processes and responses to dewatering; these include aquifer characteristics of the Robe River and Jimmawurrada Creek alluvial systems. Four (4) different concepts are presented to accommodate primary uncertainties related to (a) whether the Brockman Iron Formation underlying Yeera Bluff is impermeable and (b) whether flow in the Wittenoom Formation discharges into the overlying Robe River alluvium or continues to the north.

Dewatering

Dewatering at Mesa H will commence 2024/2025 and, for all years, can be affected by in-pit sump pumping. Peak abstraction of 6.5ML/day will occur in 2033; total abstraction during LoM will be 11.3GL. Total abstraction 2019-2037 from the combined Mesa H and Mesa J operations, including water supply, will be 170GL with a peak of 9.5GL/year.

Water Disposal

Surplus water will be discharged to Jimmawurrada Creek at average rate of 2.1GL/year (peak 4.5GL). With potential discharge rates in range 5-30ML/day, the distance travelled by the surface water flow is predicted to be between 3.5km to 11.8km.

Water Demand and Supply

Water demand is dominated by the requirements of the Wet Plant which will require between 8.8 GL/year to 14.2 GL/year (average 11.9GL/year). Total water demand (including evaporative losses from on-site reservoirs) will range from 9.5GL/year to 15.6GL/year (average 13.3GL/year).

Dewatering product, seepage and decant recovery will make a significant contribution to supply but an external source will continue to be required; expansion of the SCB is planned to meet a maximum requirement of 8.5GL/year.

Impacts

Discharge of surplus water from Mesa J operations to Jimmawurrada Creek has likely contributed to maintaining water levels in the alluvial aquifer where no evidence of any impact on the aquatic environment has been found.

Combined dewatering operations at Mesa H and Mesa J will have minimal (<1m) impact on water levels along the Robe River north of the mines.

It is not expected that there will be significant impact to permanent pools in the Robe River (e.g. Yeera Bluff) but shallow semi-permanent and seasonal pools may dry out at a faster rate during prolonged periods when no surface water flows occur. Significant water level drawdowns will occur along a 9km reach of Jimmawurrada Creek as a result of the cumulative, combined impacts of Mesa J dewatering, abstraction from the SCB and the upstream Coastal Water Supply (CWS) borefield operation.

It is not anticipated that there will be any significant impact to riparian vegetation along the Robe River but there will likely be impact on phreatophytic vegetation along a 4-9km reach of Jimmawurrada Creek. Reductions in stygofauna habitats may also occur with lowering of water levels there but this is expected to be localised and minor.

Natural water levels will recover to pre-mining levels after 60 years.

Uncertainties

Inherent uncertainties exist with the parameters adopted to describe the hydrogeological system. Uncertainty analysis has been undertaken to evaluate conceptual model, climate change and numerical model uncertainties; results tend to confirm conceptualization and model behaviour.

Mitigation

The requirement for a mitigation strategy to supplement water to the permanent and semi-permanent pools in Robe River from 2030 (given uncertainties, values and ecosystem sensitivity) is identified. It is envisaged that monitoring of water levels in the Robe River pools and the area predicted to be impacted along Jimmawurrada Creek will be used to develop and trigger mitigation actions Options for mitigation have been identified (eg supplemental discharge, modification of abstraction regime, aquifer reinjection, etc.).

Planned Future Works

Planned works, cited in Scope of Work Mesa H FS Hydrogeology Drilling June 2017 v2.2, seek to address the hydrogeological risks identified in the PFS and include:

- Installation of up to six (6) test bores, eleven (11) monitor bores and two (2) VwP.
- Aquifer testing of all installed bores.
- Discharge trial (up to 30 days) in the Robe River (to support design of an impact mitigation strategy for local pools).
- Investigation of water supply sources for construction camp.

Review Comments

Field Investigations

The PFS investigations have been conducted to a high standard. Drilling, monitor and test production bore construction methods and aquifer testing conform to best-practice, are well documented and provide a sound data set for the Mesa H mine area.

Data Availability

Available rainfall and Robe River streamflow records have been included in the assessment; these demonstrate frequency of major rainfall and flood events. Groundwater levels and quality are well established with an extensive monitor bore network. Whilst there is limited discrete aquifer data, the adopted parameters conform to experience in similar environments and appear reasonable. No test data is provided to support the assumption that the basal pisolites constrain flow between the CID and underlying bedrock aquifers; based on the recorded lithology and thickness, however, this is considered a reasonable assumption. Data to characterize the alluvial aquifers associated with the Robe River near Mesa H and Jimmawurrada Creek near Mesa J are similarly absent. Aquifer parameters deduced from operation of the Pannawonica borefield appear reasonable and provide support for the parameters adopted for the Robe River alluvial aquifer. Uncertainties remain with regard to the alluvial system associated with, and surface water flows within, Jimmawurrada Creek. Notwithstanding the above, the cumulative data set is considered to provide an adequate technical foundation for the conceptualisations and detailed numerical modelling process.

Hydrogeological Conceptualisation

The geological model and characteristics of the primary hydro-stratigraphic units are well-established and provide a sound foundation for hydrogeological assessment. The conceptual model is based on the integration of all available information including background information from previous investigations, extensive experience in water management gained over many years at Mesa J where similar hydrogeological conditions exist, ongoing monitoring at Mesa J and information generated by specific investigations.

The concepts re: pools and alluvial aquifer processes is based on detailed assessment of available water level and water quality data and appear sound.

Uncertainties in conceptualisation have been clearly identified and adequately addressed in the modelling process.

Modelling

The objectives of the modelling are clearly stated and the model set-up honours the documented hydrogeological conceptualisation. Standard modelling packages and techniques have been deployed and what appear to be appropriate boundary conditions established.

Calibrated aquifer parameters are in general conformity with field-derived values; adopted low fresh bedrock values are considered appropriate. Inherent uncertainty exists with storage parameters.

Model predictions accommodate a number of assumptions related to many operational processes. These appear well-considered and further demonstrate a sound site water management plan. The assignment of surface water flows in Jimmawurrada Creek as a proportion of Robe River flows (based on contributing catchment areas) is supported.

Uncertainty analysis has usefully assessed conceptualisation and climate variables. Summary results indicate that drawdowns in the Robe River alluvials in excess of 1m are predicted to only occur in the sustained absence, or large-scale reduction, of flood flows. It is noted, however, that drawdowns of similar magnitude are predicted with modification of the general head inflow boundary associated with the Robe River which warrants further assessment.

The documentation for the modelling effort is of high standard and well-presented. The claimed model confidence level classification – Class 2 – is supported.

Dewatering

The predicted rates/volumes appear reasonable and gain support from the longer-term experience gained in the adjacent Mesa J pits where similar conditions prevail.

Impacts

Potential impacts have been identified and assessed. The dominance of surface water flows in the water balance (or indirect recharge derived therefrom) has, as would be expected, been clearly demonstrated.

The prediction that impacts along the Robe River north of Mesa H and Mesa J will be minor appear sound. Under average annual streamflow conditions and assumption of vertical flow constraints imposed by the basal pisolites underlying the CID aquifer, such impacts are less than natural seasonal variations and consequently considered unlikely to be of such a magnitude to pose any threat to local environmental values. Any water level drawdowns in the alluvials that do result from dewatering operations will, however, be naturally augmented in the absence of flood events. The contention that there will be natural mitigation of minor drawdown impacts along the Robe River by infiltration of surface water flows is supported by hydrographs from monitor bores showing water level responses associated with significant rainfall events (and assumed floods) along the Robe River (at Pannawonica) and Jimmawurrada Creek (near Mesa J) and appears reasonable.

The predicted significant drawdown impacts along a section of Jimmawurrada Creek are as would be anticipated given location near the SCB and predicted groundwater flow reversal resulting from continued operation of the upstream CWS borefield.

Uncertainties

A number of uncertainties have been identified that primarily relate to the aquifer characteristics of various formations, groundwater flow paths and hydraulic connectivity between formations. These should be adequately addressed in the planned, follow-on work programmes with further insight provided by continued monitoring.

Summary

The quantity and quality of hydrogeological information presented is considered sufficient to satisfy PFS-level understanding and to support API/PER approval submissions.

The current conceptual hydrogeological models have been developed on an extensive data set taking due account of local geology, hydrology, hydrogeology and historic site water management and are supported; uncertainties have been identified and will be addressed in follow-on programmes.

The numerical groundwater model honours the hydrogeological conceptualization and is considered fit for purpose meeting key objectives of quantifying required dewatering rates and potential impacts. Design conforms with standard practices and is based on a sound geological model; calibrated parameters are in accordance with field-derived or acceptable values. Information on calibration, predictions and uncertainty runs is well documented. In terms of the National Water Commission's Australian Groundwater Modelling Guidelines (2012), the reported Class 2 level of confidence is supported.

Model predictions indicate that:

- dewatering drawdown impacts along the Robe River will be minor and less than natural water fluctuations. Evidence exists to support contention of natural mitigation through infiltration of surface water flows.

- significant water level drawdowns will occur along a reach of the Jimmawurrada Creek as a result of abstraction from the nearby SCB and upstream CWS.

A requirement for mitigation measures has been identified; options exist and are to be further assessed.

Recommendations

Whilst the proposed work to advance hydrogeological understanding to Feasibility Level and continued monitoring should address the key uncertainties that have been identified, consideration should also be given to:

- Augmentation of the monitoring network with facilities to record flood events along both the Robe River and Jimmawurrada Creek and water levels/quality in any pools therein.

- Further examination of the available data sets with a view to confirming the areal extent, thickness and hydraulic properties of the basal pisolite layer.

- Obtaining discrete hydraulic properties of the key formations.

In addition, as a prelude to future modelling work, a re-assessment of boundary conditions would be prudent and further analysis of zonal water balances to confirm, and improve definition of, expected fluxes between the key formations.

Subject:	Mesa H Groundwater Modelling Review

Dear Milos,

RPS has undertaken a review of recent groundwater modelling for Mesa H completed by AQ2. Mesa H is an iron ore operation located immediately west of the existing Mesa J mine, 17 km south-west of Pannawonica. Mining at Mesa H is proposed from 2020 to 2037.

The following document was reviewed:

AQ2 ref – 182B_006c_FINAL / RTIO ref - RTIO-PDE-0161936 including associated figures and appendices.

The key objectives of the model were to:

- Assess the dewatering rates necessary to facilitate dry mining conditions at Mesa H and Mesa J; and
- Assess the impacts of dewatering and water supply abstraction (including cumulative impact of the Coastal Water Supply project at Bungaroo Valley) on regional groundwater levels and surface water pools along the Robe River and Jimmawurrada Creek.

Modelling Review Focus

It is understood that the model and the modelling report have been through several iterations over a number of years. The Mesa H Groundwater Modelling Report was reviewed by a third party in 2016. Minor changes to the 2016 model were made for this report with the majority of setups and results remaining consistent with the original 2016 model. However, for the purpose of documentation a review has been undertaken as per recommendations in the Australian Groundwater Modelling Guidelines (NWC, 2012). Results are presented in the following tables for (1) Overall Compliance, (2) Planning, (3) Conceptual Model, (4) Design and Construction, (5) Calibration and Sensitivity, (6) Prediction, (7) Uncertainty, (8) Surface Water-Groundwater Interaction.

In addition to the review from a numerical standpoint, we have also made some comment in terms of operational considerations in reference to the key objectives of the modelling exercise.

RPS

Overall Compliance	Yes/No	Comment
1. Are the model objectives and model confidence level classification clearly stated?	Yes	Dewatering requirements and impacts due to dewatering/water supply
2. Are the objectives satisfied?	Yes	
3. Is the conceptual model consistent with objectives and confidence level classification?	Yes	Level 2 confidence level
4. Is the conceptual model based on all available data, presented clearly and reviewed by an appropriate reviewer?	Yes	Conceptual model details within separate report
5. Does the model design conform to best practice?	Yes	
6. Is the model calibration satisfactory?	Yes	No statistics presented, but hydrographs indicate good calibration in most locations
7. Are the calibrated parameter values and estimated fluxes plausible?	Yes	
8. Do the model predictions conform to best practice?	Yes	
9. Is the uncertainty associated with the predictions reported?	Yes	Only for impacts to water levels along rivers
10. Is the model fit for purpose?	Yes	

2. Planning	Yes/No
1.1 Are the project objectives stated?	yes
1.2 Are the model objectives stated?	yes
1.3 Is it clear how the model will contribute to meeting the project objectives?	yes
1.4 Is a groundwater model the best option to address the project and model objectives?	yes
1.5 Is the target model confidence-level classification stated and justified?	yes
1.6 Are the planned limitations and exclusions of the model stated?	yes

RPS

3. Conceptualisation	Yes/No	Comment
2.1 Has a literature review been completed, including examination of prior investigations?	half	Very brief mention of previous AQT/RPS work, RTIO conceptual model. None by others - maybe isn't any.
2.2 Is the aquifer system adequately described?	yes	Separate conceptual report
2.2.1 hydrostratigraphy including aquifer type (porous, fractured rock ...)	yes	
2.2.2 lateral extent, boundaries and significant internal features such as faults and regional folds	yes	Separate conceptual report
2.2.3 aquifer geometry including layer elevations and thicknesses	yes	Separate conceptual report
2.2.4 confined or unconfined flow and the variation of these conditions in space and time?	yes	Separate conceptual report
2.3 Have data on groundwater stresses been collected and analysed?	yes	Separate conceptual report
2.3.1 recharge from rainfall, irrigation, floods, lakes	yes	Separate conceptual report
2.3.2 river or lake stage heights	unknown	
2.3.3 groundwater usage (pumping, returns etc)	yes	Separate conceptual report
2.3.4 evapotranspiration	yes	Separate conceptual report
2.3.5 other?	yes	TSF seepage
2.4 Have groundwater level observations been collected and analysed?	yes	
2.4.1 selection of representative bore hydrographs	no	Not discussed in modelling or conceptual report
2.4.2 comparison of hydrographs	no	Not discussed in modelling or conceptual report
2.4.3 effect of stresses on hydrographs	no	Not discussed in modelling or conceptual report
2.4.4 watertable maps/piezometric surfaces?	yes	Separate conceptual report
2.4.5 If relevant, are density and barometric effects taken into account in the interpretation of	unsure	Not discussed in modelling or conceptual

3. Conceptualisation	Yes/No	Comment
groundwater head and flow data?		report
2.5 Have flow observations been collected and analysed?	yes	Robe River only at Ngalooin Pool
2.5.1 baseflow in rivers	no	Not discussed in modelling or conceptual report
2.5.2 discharge in springs	no	Not discussed in modelling or conceptual report
2.5.3 location of diffuse discharge areas?	no	Not discussed in modelling or conceptual report
2.6 Is the measurement error or data uncertainty reported?	no	Not discussed in modelling or conceptual report
2.6.1 measurement error for directly measured quantities (e.g. piezometric level, concentration, flows)	no	Not discussed in modelling or conceptual report
2.6.2 spatial variability/heterogeneity of parameters	no	Not discussed in modelling or conceptual report
2.6.3 interpolation algorithm(s) and uncertainty of gridded data?	no	Not discussed in modelling or conceptual report
2.7 Have consistent data units and geometric datum been used?	yes	
2.8 Is there a clear description of the conceptual model?	yes	Separate conceptual report
2.8.1 Is there a graphical representation of the conceptual model?	half	Lithology and water table presented, no indication of recharge/discharge/flow directions or changes due to mining
2.8.2 Is the conceptual model based on all available, relevant data?	yes	
2.9 Is the conceptual model consistent with the model objectives and target model confidence level classification?	yes	
2.9.1 Are the relevant processes identified?	yes	Separate conceptual report

3. Conceptualisation	Yes/No	Comment
2.9.2 Is justification provided for omission or simplification of processes?	yes	
2.10 Have alternative conceptual models been investigated?	unsure	

4. Design and Construction	Yes/No	Comment
3.1 Is the design consistent with the conceptual model?	yes	
3.2 Is the choice of numerical method and software appropriate (Table 4-2)?	yes	MODFLOW-Surfact
3.2.1 Are the numerical and discretisation methods appropriate?	yes	
3.2.2 Is the software reputable?	yes	
3.2.3 Is the software included in the archive or are references to the software provided?	yes	
3.3 Are the spatial domain and discretisation appropriate?	yes	
3.3.1 1D/2D/3D	3D	
3.3.2 lateral extent		
3.3.3 layer geometry?	half	Reasonable layer thicknesses, layer elevations could be improved
3.3.4 Is the horizontal discretisation appropriate for the objectives, problem setting, conceptual model and target confidence level classification?	yes	
3.3.5 Is the vertical discretisation appropriate? Are aquitards divided in multiple layers to model time lags of propagation of responses in the vertical direction?	yes	
3.4 Are the temporal domain and discretisation appropriate?	yes	
3.4.1 steady state or transient		Both
3.4.2 stress periods		Annual

4. Design and Construction	Yes/No	Comment
3.4.3 time steps?		Not stated in report (monthly)
3.5 Are the boundary conditions plausible and sufficiently unrestrictive?	yes	
3.5.1 Is the implementation of boundary conditions consistent with the conceptual model?	yes	
3.5.2 Are the boundary conditions chosen to have a minimal impact on key model outcomes? How is this ascertained?	yes	GHB and STR boundary conditions for river flow affect model outcomes (as intended and consistent with conceptual model). No flow at basement outcrop.
3.5.3 Is the calculation of diffuse recharge consistent with model objectives and confidence level?	yes	
3.5.4 Are lateral boundaries time-invariant?	yes	Except where lowered to simulate dewatering by CWS borefield
3.6 Are the initial conditions appropriate?	yes	
3.6.1 Are the initial heads based on interpolation or on groundwater modelling?		Steady state modelling to provide initial heads to transient calibration
3.6.2 Is the effect of initial conditions on key model outcomes assessed?	NA	
3.6.3 How is the initial concentration of solutes obtained (when relevant)?	NA	
3.7 Is the numerical solution of the model adequate?	yes	
3.7.1 Solution method/solver	not stated	Milos old GWV: PCG5, pseudo soil with upstream weighting
3.7.2 Convergence criteria	not stated	Milos old GWV: head change 0.005
3.7.3 Numerical precision	not stated	Mass balance values imply ~0% error

5. Calibration and sensitivity	Yes/No	Comment

5. Calibration and sensitivity	Yes/No	Comment
4.1 Are all available types of observations used for calibration?		
4.1.1 Groundwater head data	yes	
4.1.2 Flux observations	no	Should report obs v mod for dewatering volumes and pumped volumes to date.
4.1.3 Other: environmental tracers, gradients, age, temperature, concentrations etc	no	
4.2 Does the calibration methodology conform to best practice?	yes	
4.2.1 Parameterisation	yes	
4.2.2 Objective function	yes	Comparison of obs v modelled (visual in hydrographs). Assume some statistical measure considered during calibration (e.g. minimising sum of squares, SRMS etc)
4.2.3 Identifiability of parameters	yes	
4.2.4 Which methodology is used for model calibration?	not stated	Assume only manual
4.3 Is a sensitivity of key model outcomes assessed against?	not stated	
4.3.1 parameters	not stated	Intrinsic sensitivity during calibration assumed but not reported
4.3.2 boundary conditions	not stated	Intrinsic sensitivity during calibration assumed but not reported
4.3.3 initial conditions	not stated	Intrinsic sensitivity during calibration assumed but not reported
4.3.4 stresses	not stated	Intrinsic sensitivity during calibration assumed but not reported
4.4 Have the calibration results been adequately reported?	half	Hydrographs, no stats

5. Calibration and sensitivity	Yes/No	Comment
4.4.1 Are there graphs showing modelled and observed hydrographs at an appropriate scale?	yes	Indicate good calibration
4.4.2 Is it clear whether observed or assumed vertical head gradients have been replicated by the model?	no	Multilevel VWP's or nested piezos should be plotted on single chart
4.4.3 Are calibration statistics reported and illustrated in a reasonable manner?	no	Not reported, but likely good based on hydrographs
4.5 Are multiple methods of plotting calibration results used to highlight goodness of fit robustly? Is the model sufficiently calibrated?	no	
4.5.1 spatially	no	Map of residuals to indicate any areas which perform less well
4.5.2 temporally	yes	Hydrographs
4.6 Are the calibrated parameters plausible?	yes	
4.7 Are the water volumes and fluxes in the water balance realistic?	yes	
4.8 has the model been verified?	no	Recommendation for verification and re-calibration was made in report

6. Prediction	Yes/No	Comment
5.1 Are the model predictions designed in a manner that meets the model objectives?	yes	
5.2 Is predictive uncertainty acknowledged and addressed?	yes	Particularly in relation to rivers and mine plan
5.3 Are the assumed climatic stresses appropriate?	yes	
5.4 Is a null scenario defined?	yes	
5.5 Are the scenarios defined in accordance with the model objectives and confidence level classification?	yes	
5.5.1 Are the pumping stresses similar in magnitude to those of the calibrated model? If not, is there	yes	

6. Prediction	Yes/No	Comment
reference to the associated reduction in model confidence?		
5.5.2 Are well losses accounted for when estimating maximum pumping rates per well?	NA	
5.5.3 Is the temporal scale of the predictions commensurate with the calibrated model? If not, is there reference to the associated reduction in model confidence?	yes	
5.5.4 Are the assumed stresses and timescale appropriate for the stated objectives?	yes	
5.6 Do the prediction results meet the stated objectives?	yes	
5.7 Are the components of the predicted mass balance realistic?	yes	
5.7.1 Are the pumping rates assigned in the input files equal to the modelled pumping rates?	unknown	
5.7.2 Does predicted seepage to or from a river exceed measured or expected river flow?	no	
5.7.3 Are there any anomalous boundary fluxes due to superposition of head dependent sinks (e.g. evapotranspiration) on head-dependent boundary cells (Type 1 or 3 boundary conditions)?	no	
5.7.4 Is diffuse recharge from rainfall smaller than rainfall?	yes	
5.7.5 Are model storage changes dominated by anomalous head increases in isolated cells that receive recharge?	unknown	
5.8 Has particle tracking been considered as an alternative to solute transport modelling?	NA	

7. Uncertainty	Yes/No	Comment
6.1 Is some qualitative or quantitative measure of uncertainty associated with the prediction reported together with the prediction?	yes	Ranked by drawdown
6.2 Is the model with minimum prediction-error variance chosen for each prediction?	no	No consideration of impact on calibration results
6.3 Are the sources of uncertainty discussed?	yes	

7. Uncertainty	Yes/No	Comment
6.3.1 measurement of uncertainty of observations and parameters	yes	
6.3.2 structural or model uncertainty	yes	
6.4 Is the approach to estimation of uncertainty described and appropriate?	yes	
6.5 Are there useful depictions of uncertainty?	yes	

8. Surface water–groundwater interaction	Yes/No	Comment
8.1 Is the conceptualisation of surface water–groundwater interaction in accordance with the model objectives?	yes	Noted uncertainty due to limited data
8.2 Is the implementation of surface water–groundwater interaction appropriate?	yes	
8.3 Is the groundwater model coupled with a surface water model?	no	
8.3.1 Is the adopted approach appropriate?	na	
8.3.2 Have appropriate time steps and stress periods been adopted?	na	
8.3.3 Are the interface fluxes consistent between the groundwater and surface water models?	na	

RPS

Guideline Model Review Discussion

The modelling has been undertaken to a high standard and is fit for its intended purpose, being the prediction of dewatering and water supply volumes, and the prediction of impacts to water levels along the Robe River and Jimmawurrada Creek. There are no areas of concern that would have a material effect on the predicted outputs of interest. General comments and minor corrections have been included as tracked changes in the report document.

It is understood that the model has been dramatically simplified in recent years in order to improve run-times. However, considerations for model improvements during future work may include the following:

- Verification of model predictions and re-calibration if required to recent monitoring along the Robe River (as indicated within the report)
- Representation of actual topographic surface as top of model Layer 1.
- Layer bottom elevations more indicative of key lithological horizons shown in conceptual models Figure 3 (assuming geological model for the site is readily available)
- Reduction of stress period length from annual to monthly in order to more accurately represent seasonal fluctuations in both calibration and prediction runs to end of mining. Refine recharge, EVT and stream flow volumes accordingly.
- Inclusion of recorded dewatering volumes from existing mining as a calibration target.
- Characterisation of hydrogeological properties of major faults mentioned in conceptual model for inclusion in the model. Due to the often uncertain nature of faults acting as barriers or conduits (typically both), uncertainty analyses on fault properties may be most appropriate. The conceptual model report notes Yeera Bluff Pool exists as a result of fault structures.
- Application of fill properties/recharge post completion of mining using the TMP package in predictive runs
- Depending on need for water management planning purposes, additional uncertainty analyses with focus on predicted ranges in results of dewatering/water supply volumes and resulting drawdowns may be warranted using standard conductivity/storage parameter perturbation (+/- inclusion of faults as above).

Operational / Planning Considerations

Reviewing the modelling work with regards to the key objectives, and with consideration of the implications of uncertainties for planning and operational management purposes, we make some comments below.

Assessment of Future Dewatering Requirements

In reviewing the model report, it is noted that the calibration and prediction runs focused on the hydrographs and water levels for a verification of calibration confidence. In terms of water balance, the various water balance components within the model seem to be at the lower end of ranges identified in the conceptual hydrogeology report for the area. It may be worth additional enquiry of the calibration model to better understand the modelled abstraction volumes simulated to achieve the drawdowns and cross-check those against the actual dewatering volumes historically. This will enable a greater degree of confidence in the predicted dewatering volumes – as you may gain an appreciation that the model has a tendency to over-predict or under-predict abstraction volumes required to achieve a target water level.

Confidence in the dewatering requirement predictions in terms of volumes will provide greater confidence in the planning and budgeting of required dewatering infrastructure (number of bores, sizing of sump pumps and transfer pipelines, etc).

Assessment of Drawdown Impacts – Particularly on Pools / GDE's

On review of the conceptual hydrogeology report, it is clear that groundwater-fed pools in the proximity of the mining operations are a particular focus – namely Yeera Bluff Pool and Japanese Pool. The modelling exercise was seeking to better understand the potential for dewatering operations to negatively impact upon groundwater levels in proximity to these pools. On that basis, there may be value in exploring a few of the modelling assumptions and key sensitivities to better understand the impact potential. The aspects in question are:

- ***The annual time step / creek recharge application*** – given the seasonality of groundwater levels, especially in the Robe River Alluvium, annual time steps has the potential to mask a drawdown trend in the vicinity of pools that may be more severe within a given year than is currently represented; and
- ***General Head Boundary on Robe River*** – given that the model outcomes were sensitive to this, there may be value in exploring the implications of a seasonal fluctuation on the boundary condition, and/or some piezometer validation to gain confidence in this modelled factor.

In the absence of high confidence in these predictions, there may need to be some consideration given to management approaches that will ensure groundwater levels can be maintained at acceptable limits in proximity to these Pools should operational data indicate unfavourable trends toward these receptors.

It was also noted that the predicted drawdown below the riparian vegetation aligned with Jimmawurrada Creek is significant and sustained, and it could be expected that there is potential for vegetation with a high level of groundwater dependence to be negatively impacted by these local dewatering influences – it is currently not clear if such an impact would be acceptable, or if irrigation measures might be required.

If you have any questions or comments regarding this review, please do not hesitate to get in touch.

Kind regards,

RPS

Subject:	Mesa H Groundwater Modelling Review

Dear Milos,

RPS has undertaken a review of recent groundwater modelling for Mesa H completed by AQ2. Mesa H is an iron ore operation located immediately west of the existing Mesa J mine, 17 km south-west of Pannawonica. Mining at Mesa H is proposed from 2020 to 2037.

The following document was reviewed:

AQ2 ref – 182B_006c_FINAL / RTIO ref - RTIO-PDE-0161936 including associated figures and appendices.

The key objectives of the model were to:

- Assess the dewatering rates necessary to facilitate dry mining conditions at Mesa H and Mesa J; and
- Assess the impacts of dewatering and water supply abstraction (including cumulative impact of the Coastal Water Supply project at Bungaroo Valley) on regional groundwater levels and surface water pools along the Robe River and Jimmawurrada Creek.

Modelling Review Focus

It is understood that the model and the modelling report have been through several iterations over a number of years. The Mesa H Groundwater Modelling Report was reviewed by a third party in 2016. Minor changes to the 2016 model were made for this report with the majority of setups and results remaining consistent with the original 2016 model. However, for the purpose of documentation a review has been undertaken as per recommendations in the Australian Groundwater Modelling Guidelines (NWC, 2012). Results are presented in the following tables for (1) Overall Compliance, (2) Planning, (3) Conceptual Model, (4) Design and Construction, (5) Calibration and Sensitivity, (6) Prediction, (7) Uncertainty, (8) Surface Water-Groundwater Interaction.

In addition to the review from a numerical standpoint, we have also made some comment in terms of operational considerations in reference to the key objectives of the modelling exercise.

Overall Compliance	Yes/No	Comment
1. Are the model objectives and model confidence level classification clearly stated?	Yes	Dewatering requirements and impacts due to dewatering/water supply
2. Are the objectives satisfied?	Yes	
3. Is the conceptual model consistent with objectives and confidence level classification?	Yes	Level 2 confidence level
4. Is the conceptual model based on all available data, presented clearly and reviewed by an appropriate reviewer?	Yes	Conceptual model details within separate report
5. Does the model design conform to best practice?	Yes	
6. Is the model calibration satisfactory?	Yes	No statistics presented, but hydrographs indicate good calibration in most locations
7. Are the calibrated parameter values and estimated fluxes plausible?	Yes	
8. Do the model predictions conform to best practice?	Yes	
9. Is the uncertainty associated with the predictions reported?	Yes	Only for impacts to water levels along rivers
10. Is the model fit for purpose?	Yes	

2. Planning	Yes/No
1.1 Are the project objectives stated?	yes
1.2 Are the model objectives stated?	yes
1.3 Is it clear how the model will contribute to meeting the project objectives?	yes
1.4 Is a groundwater model the best option to address the project and model objectives?	yes
1.5 Is the target model confidence-level classification stated and justified?	yes
1.6 Are the planned limitations and exclusions of the model stated?	yes

RPS

3. Conceptualisation	Yes/No	Comment
2.1 Has a literature review been completed, including examination of prior investigations?	half	Very brief mention of previous AQT/RPS work, RTIO conceptual model. None by others - maybe isn't any.
2.2 Is the aquifer system adequately described?	yes	Separate conceptual report
2.2.1 hydrostratigraphy including aquifer type (porous, fractured rock ...)	yes	
2.2.2 lateral extent, boundaries and significant internal features such as faults and regional folds	yes	Separate conceptual report
2.2.3 aquifer geometry including layer elevations and thicknesses	yes	Separate conceptual report
2.2.4 confined or unconfined flow and the variation of these conditions in space and time?	yes	Separate conceptual report
2.3 Have data on groundwater stresses been collected and analysed?	yes	Separate conceptual report
2.3.1 recharge from rainfall, irrigation, floods, lakes	yes	Separate conceptual report
2.3.2 river or lake stage heights	unknown	
2.3.3 groundwater usage (pumping, returns etc)	yes	Separate conceptual report
2.3.4 evapotranspiration	yes	Separate conceptual report
2.3.5 other?	yes	TSF seepage
2.4 Have groundwater level observations been collected and analysed?	yes	
2.4.1 selection of representative bore hydrographs	no	Not discussed in modelling or conceptual report
2.4.2 comparison of hydrographs	no	Not discussed in modelling or conceptual report
2.4.3 effect of stresses on hydrographs	no	Not discussed in modelling or conceptual report
2.4.4 watertable maps/piezometric surfaces?	yes	Separate conceptual report
2.4.5 If relevant, are density and barometric effects taken into account in the interpretation of	unsure	Not discussed in modelling or conceptual

3. Conceptualisation	Yes/No	Comment
groundwater head and flow data?		report
2.5 Have flow observations been collected and analysed?	yes	Robe River only at Ngalooin Pool
2.5.1 baseflow in rivers	no	Not discussed in modelling or conceptual report
2.5.2 discharge in springs	no	Not discussed in modelling or conceptual report
2.5.3 location of diffuse discharge areas?	no	Not discussed in modelling or conceptual report
2.6 Is the measurement error or data uncertainty reported?	no	Not discussed in modelling or conceptual report
2.6.1 measurement error for directly measured quantities (e.g. piezometric level, concentration, flows)	no	Not discussed in modelling or conceptual report
2.6.2 spatial variability/heterogeneity of parameters	no	Not discussed in modelling or conceptual report
2.6.3 interpolation algorithm(s) and uncertainty of gridded data?	no	Not discussed in modelling or conceptual report
2.7 Have consistent data units and geometric datum been used?	yes	
2.8 Is there a clear description of the conceptual model?	yes	Separate conceptual report
2.8.1 Is there a graphical representation of the conceptual model?	half	Lithology and water table presented, no indication of recharge/discharge/flow directions or changes due to mining
2.8.2 Is the conceptual model based on all available, relevant data?	yes	
2.9 Is the conceptual model consistent with the model objectives and target model confidence level classification?	yes	
2.9.1 Are the relevant processes identified?	yes	Separate conceptual report

3. Conceptualisation	Yes/No	Comment
2.9.2 Is justification provided for omission or simplification of processes?	yes	
2.10 Have alternative conceptual models been investigated?	unsure	

4. Design and Construction	Yes/No	Comment
3.1 Is the design consistent with the conceptual model?	yes	
3.2 Is the choice of numerical method and software appropriate (Table 4-2)?	yes	MODFLOW-Surfact
3.2.1 Are the numerical and discretisation methods appropriate?	yes	
3.2.2 Is the software reputable?	yes	
3.2.3 Is the software included in the archive or are references to the software provided?	yes	
3.3 Are the spatial domain and discretisation appropriate?	yes	
3.3.1 1D/2D/3D	3D	
3.3.2 lateral extent		
3.3.3 layer geometry?	half	Reasonable layer thicknesses, layer elevations could be improved
3.3.4 Is the horizontal discretisation appropriate for the objectives, problem setting, conceptual model and target confidence level classification?	yes	
3.3.5 Is the vertical discretisation appropriate? Are aquitards divided in multiple layers to model time lags of propagation of responses in the vertical direction?	yes	
3.4 Are the temporal domain and discretisation appropriate?	yes	
3.4.1 steady state or transient		Both
3.4.2 stress periods		Annual

4. Design and Construction	Yes/No	Comment
3.4.3 time steps?		Not stated in report (monthly)
3.5 Are the boundary conditions plausible and sufficiently unrestrictive?	yes	
3.5.1 Is the implementation of boundary conditions consistent with the conceptual model?	yes	
3.5.2 Are the boundary conditions chosen to have a minimal impact on key model outcomes? How is this ascertained?	yes	GHB and STR boundary conditions for river flow affect model outcomes (as intended and consistent with conceptual model). No flow at basement outcrop.
3.5.3 Is the calculation of diffuse recharge consistent with model objectives and confidence level?	yes	
3.5.4 Are lateral boundaries time-invariant?	yes	Except where lowered to simulate dewatering by CWS borefield
3.6 Are the initial conditions appropriate?	yes	
3.6.1 Are the initial heads based on interpolation or on groundwater modelling?		Steady state modelling to provide initial heads to transient calibration
3.6.2 Is the effect of initial conditions on key model outcomes assessed?	NA	
3.6.3 How is the initial concentration of solutes obtained (when relevant)?	NA	
3.7 Is the numerical solution of the model adequate?	yes	
3.7.1 Solution method/solver	not stated	Milos old GWV: PCG5, pseudo soil with upstream weighting
3.7.2 Convergence criteria	not stated	Milos old GWV: head change 0.005
3.7.3 Numerical precision	not stated	Mass balance values imply ~0% error

5. Calibration and sensitivity	Yes/No	Comment

5. Calibration and sensitivity	Yes/No	Comment
4.1 Are all available types of observations used for calibration?		
4.1.1 Groundwater head data	yes	
4.1.2 Flux observations	no	Should report obs v mod for dewatering volumes and pumped volumes to date.
4.1.3 Other: environmental tracers, gradients, age, temperature, concentrations etc	no	
4.2 Does the calibration methodology conform to best practice?	yes	
4.2.1 Parameterisation	yes	
4.2.2 Objective function	yes	Comparison of obs v modelled (visual in hydrographs). Assume some statistical measure considered during calibration (e.g. minimising sum of squares, SRMS etc)
4.2.3 Identifiability of parameters	yes	
4.2.4 Which methodology is used for model calibration?	not stated	Assume only manual
4.3 Is a sensitivity of key model outcomes assessed against?	not stated	
4.3.1 parameters	not stated	Intrinsic sensitivity during calibration assumed but not reported
4.3.2 boundary conditions	not stated	Intrinsic sensitivity during calibration assumed but not reported
4.3.3 initial conditions	not stated	Intrinsic sensitivity during calibration assumed but not reported
4.3.4 stresses	not stated	Intrinsic sensitivity during calibration assumed but not reported
4.4 Have the calibration results been adequately reported?	half	Hydrographs, no stats

5. Calibration and sensitivity	Yes/No	Comment
4.4.1 Are there graphs showing modelled and observed hydrographs at an appropriate scale?	yes	Indicate good calibration
4.4.2 Is it clear whether observed or assumed vertical head gradients have been replicated by the model?	no	Multilevel VWP's or nested piezos should be plotted on single chart
4.4.3 Are calibration statistics reported and illustrated in a reasonable manner?	no	Not reported, but likely good based on hydrographs
4.5 Are multiple methods of plotting calibration results used to highlight goodness of fit robustly? Is the model sufficiently calibrated?	no	
4.5.1 spatially	no	Map of residuals to indicate any areas which perform less well
4.5.2 temporally	yes	Hydrographs
4.6 Are the calibrated parameters plausible?	yes	
4.7 Are the water volumes and fluxes in the water balance realistic?	yes	
4.8 has the model been verified?	no	Recommendation for verification and re-calibration was made in report

6. Prediction	Yes/No	Comment
5.1 Are the model predictions designed in a manner that meets the model objectives?	yes	
5.2 Is predictive uncertainty acknowledged and addressed?	yes	Particularly in relation to rivers and mine plan
5.3 Are the assumed climatic stresses appropriate?	yes	
5.4 Is a null scenario defined?	yes	
5.5 Are the scenarios defined in accordance with the model objectives and confidence level classification?	yes	
5.5.1 Are the pumping stresses similar in magnitude to those of the calibrated model? If not, is there	yes	

6. Prediction	Yes/No	Comment
reference to the associated reduction in model confidence?		
5.5.2 Are well losses accounted for when estimating maximum pumping rates per well?	NA	
5.5.3 Is the temporal scale of the predictions commensurate with the calibrated model? If not, is there reference to the associated reduction in model confidence?	yes	
5.5.4 Are the assumed stresses and timescale appropriate for the stated objectives?	yes	
5.6 Do the prediction results meet the stated objectives?	yes	
5.7 Are the components of the predicted mass balance realistic?	yes	
5.7.1 Are the pumping rates assigned in the input files equal to the modelled pumping rates?	unknown	
5.7.2 Does predicted seepage to or from a river exceed measured or expected river flow?	no	
5.7.3 Are there any anomalous boundary fluxes due to superposition of head dependent sinks (e.g. evapotranspiration) on head-dependent boundary cells (Type 1 or 3 boundary conditions)?	no	
5.7.4 Is diffuse recharge from rainfall smaller than rainfall?	yes	
5.7.5 Are model storage changes dominated by anomalous head increases in isolated cells that receive recharge?	unknown	
5.8 Has particle tracking been considered as an alternative to solute transport modelling?	NA	

7. Uncertainty	Yes/No	Comment
6.1 Is some qualitative or quantitative measure of uncertainty associated with the prediction reported together with the prediction?	yes	Ranked by drawdown
6.2 Is the model with minimum prediction-error variance chosen for each prediction?	no	No consideration of impact on calibration results
6.3 Are the sources of uncertainty discussed?	yes	

7. Uncertainty	Yes/No	Comment
6.3.1 measurement of uncertainty of observations and parameters	yes	
6.3.2 structural or model uncertainty	yes	
6.4 Is the approach to estimation of uncertainty described and appropriate?	yes	
6.5 Are there useful depictions of uncertainty?	yes	

8. Surface water–groundwater interaction	Yes/No	Comment
8.1 Is the conceptualisation of surface water–groundwater interaction in accordance with the model objectives?	yes	Noted uncertainty due to limited data
8.2 Is the implementation of surface water–groundwater interaction appropriate?	yes	
8.3 Is the groundwater model coupled with a surface water model?	no	
8.3.1 Is the adopted approach appropriate?	na	
8.3.2 Have appropriate time steps and stress periods been adopted?	na	
8.3.3 Are the interface fluxes consistent between the groundwater and surface water models?	na	

RPS

Guideline Model Review Discussion

The modelling has been undertaken to a high standard and is fit for its intended purpose, being the prediction of dewatering and water supply volumes, and the prediction of impacts to water levels along the Robe River and Jimmawurrada Creek. There are no areas of concern that would have a material effect on the predicted outputs of interest. General comments and minor corrections have been included as tracked changes in the report document.

It is understood that the model has been dramatically simplified in recent years in order to improve run-times. However, considerations for model improvements during future work may include the following:

- Verification of model predictions and re-calibration if required to recent monitoring along the Robe River (as indicated within the report)
- Representation of actual topographic surface as top of model Layer 1.
- Layer bottom elevations more indicative of key lithological horizons shown in conceptual models Figure 3 (assuming geological model for the site is readily available)
- Reduction of stress period length from annual to monthly in order to more accurately represent seasonal fluctuations in both calibration and prediction runs to end of mining. Refine recharge, EVT and stream flow volumes accordingly.
- Inclusion of recorded dewatering volumes from existing mining as a calibration target.
- Characterisation of hydrogeological properties of major faults mentioned in conceptual model for inclusion in the model. Due to the often uncertain nature of faults acting as barriers or conduits (typically both), uncertainty analyses on fault properties may be most appropriate. The conceptual model report notes Yeera Bluff Pool exists as a result of fault structures.
- Application of fill properties/recharge post completion of mining using the TMP package in predictive runs
- Depending on need for water management planning purposes, additional uncertainty analyses with focus on predicted ranges in results of dewatering/water supply volumes and resulting drawdowns may be warranted using standard conductivity/storage parameter perturbation (+/- inclusion of faults as above).

Operational / Planning Considerations

Reviewing the modelling work with regards to the key objectives, and with consideration of the implications of uncertainties for planning and operational management purposes, we make some comments below.

Assessment of Future Dewatering Requirements

In reviewing the model report, it is noted that the calibration and prediction runs focused on the hydrographs and water levels for a verification of calibration confidence. In terms of water balance, the various water balance components within the model seem to be at the lower end of ranges identified in the conceptual hydrogeology report for the area. It may be worth additional enquiry of the calibration model to better understand the modelled abstraction volumes simulated to achieve the drawdowns and cross-check those against the actual dewatering volumes historically. This will enable a greater degree of confidence in the predicted dewatering volumes – as you may gain an appreciation that the model has a tendency to over-predict or under-predict abstraction volumes required to achieve a target water level.

Confidence in the dewatering requirement predictions in terms of volumes will provide greater confidence in the planning and budgeting of required dewatering infrastructure (number of bores, sizing of sump pumps and transfer pipelines, etc).

Assessment of Drawdown Impacts – Particularly on Pools / GDE's

On review of the conceptual hydrogeology report, it is clear that groundwater-fed pools in the proximity of the mining operations are a particular focus – namely Yeera Bluff Pool and Japanese Pool. The modelling exercise was seeking to better understand the potential for dewatering operations to negatively impact upon groundwater levels in proximity to these pools. On that basis, there may be value in exploring a few of the modelling assumptions and key sensitivities to better understand the impact potential. The aspects in question are:

- ***The annual time step / creek recharge application*** – given the seasonality of groundwater levels, especially in the Robe River Alluvium, annual time steps has the potential to mask a drawdown trend in the vicinity of pools that may be more severe within a given year than is currently represented; and
- ***General Head Boundary on Robe River*** – given that the model outcomes were sensitive to this, there may be value in exploring the implications of a seasonal fluctuation on the boundary condition, and/or some piezometer validation to gain confidence in this modelled factor.

In the absence of high confidence in these predictions, there may need to be some consideration given to management approaches that will ensure groundwater levels can be maintained at acceptable limits in proximity to these Pools should operational data indicate unfavourable trends toward these receptors.

It was also noted that the predicted drawdown below the riparian vegetation aligned with Jimmawurrada Creek is significant and sustained, and it could be expected that there is potential for vegetation with a high level of groundwater dependence to be negatively impacted by these local dewatering influences – it is currently not clear if such an impact would be acceptable, or if irrigation measures might be required.

If you have any questions or comments regarding this review, please do not hesitate to get in touch.

Kind regards,

RPS

Executive Summary

Rio Tinto, on behalf of Robe River Mining Co. Pty Ltd (The Proponent), is evaluating the potential development of the Mesa H deposit located adjacent to the Mesa J Operation and approximately 13 kilometres to the south-west of the town of Pannawonica. Astron Environmental Services were commissioned to undertake a two-phase Level 2 vegetation and flora assessment in the Mesa H survey area which is approximately 4,930 hectares in size.

Thirty-eight vegetation associations were described during the survey, none of which represent a Threatened Ecological Community. All but three vegetation associations recorded are well represented beyond the survey area and do not support assemblages of species that are unique, on restricted landforms, or of high conservation significance.

One vegetation association, AprTwTsr, is considered to represent the Priority 3 Priority Ecological Community '*Triodia sp. Robe River assemblages of mesas of the West Pilbara'*. Vegetation representing this Priority Ecological Community accounted for 15.7 hectares and was restricted to the tops, breakaways and gullies of mesa landforms.

Two additional vegetation associations, ChAsppGOrGsppPlSsTeTw and MaEcCv, may be considered locally significant. ChAsppGOrGsppPlSsTeTw was the only vegetation association to contain all three of the recorded Priority flora species. This vegetation was associated with drainage lines throughout the survey area and accounts for approximately 135 hectares (3%) in the survey area. Similar vegetation has been recorded from other regional surveys. Vegetation association MaEcCv, representing approximately 174 hectares (3%), can be considered a groundwater dependent ecosystem as it is characterised by the obligate phreatophyte *Melaleuca argentea* and the facultative phreatophyte *Eucalyptus camaldulensis* var. *refulgens*. MaEcCv fringed permanent and semi-permanent water pools in the survey area and the main flow channels of the Robe River, and as such supported a number of species that were unique to this habitat. Approximately 60% of the Priority 4 species *Rhynchosia bungarensis* P4 occurred in MaEcCv.

Vegetation condition ranged from 'very poor' to 'excellent'. An estimated 67% of the survey area was rated as 'excellent' condition. Approximately 367 hectares (7%) of the survey area was 'disturbed'; disturbed areas generally comprised tracks and rail infrastructure. Weed diversity and abundance was highest in drainage lines and alluvial plains; mesas, hilltops and slopes generally had very low weed abundance. Other disturbances included parts of the ranges being burnt within the past five years and grazing on alluvial plains and in drainage lines.

There were 310 vascular flora species from 53 families and 150 genera recorded in the survey area. The most represented families were Fabaceae, Poaceae and Malvaceae. No Threatened flora were recorded during the survey and based on the results of the desktop assessment no Threatened flora are expected to occur. Three State-listed Priority flora were identified: *Indigofera* sp. Bungaroo Creek (S. van Leeuwen 4301) P3, *Triodia* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 and *Rhynchosia bungarensis* P4. Priority flora records were generally restricted to mesa, drainage line and floodplain habitats.

1 Introduction

1.1 Project Background

Rio Tinto, on behalf of Robe River Mining Co. Pty Ltd (the Proponent), is evaluating the potential development of the Mesa H deposit located adjacent to the Mesa J Operation and approximately 13 km to the south-west of the town of Pannawonica. Key components of the pre-feasibility and feasibility studies being undertaken are the environmental surveys which are required to inform the environmental assessment process for the potential development of the Mesa H deposit. Astron Environmental Services (Astron) has been commissioned to undertake some of these environmental surveys. This report presents the outcome of the Level 2 vegetation and flora assessment of the Mesa H deposit (the survey area). The survey area is approximately 4,930 ha (Figure 1).

1.2 Scope and Objectives

The objective of the assessment was to undertake a two-phase Level 2 assessment of vegetation and flora values through a desktop assessment and field survey. The resultant data has been utilised to produce this report which is intended to support and inform the environmental assessment process in accordance with the requirements of the Environmental Protection Authority (EPA).

The scope of work was to undertake a:

- desktop assessment, including database searches and literature review of available contextual and project related resources
- two-phase vegetation and flora assessment, including:
    - establishment of new quadrats to ensure adequate replication within vegetation associations
    - ground-truthing, verification and refinement of existing vegetation mapping using quadrats, relevés and mapping notes
    - targeted searches for the presence of Threatened and Priority (P) flora, and weeds and vegetation of conservation significance
    - mapping of vegetation condition and disturbance within the survey area
    - generation of a vascular flora species list for the survey area.

This report presents information pertaining to both the Phase 1 and Phase 2 surveys of the vegetation and flora assessment. Table 1 summarises the scope and key limitations. Section 3.5 of this report provides more detail on the limitations of the Phase 1 and Phase 2 surveys.

Table 1: Summary of Astron's vegetation and flora assessment.

Level of survey	Survey area size	Survey timing	Relevant regulatory guidance documents	Key survey limitations
Level 2 two-phase survey	4,930 ha	23 to 30 October 2014 and 24 September to 4 October 2015 (Phase 1). 27 April to 14 May 2016 and 19 to 22 July 2016 (Phase 2).	• Environmental Protection Authority (EPA) Position Statement No. 3 (Environmental Protection Authority 2002) • EPA Guidance Statement No. 51 (Environmental Protection Authority 2004) • EPA & Department of Parks and Wildlife Technical Guide (Environmental Protection Authority and Department of Parks and Wildlife 2015)	• One post-wet season (primary) survey conducted in below-optimal seasonal conditions.

2 Environmental Context

2.1 Physical Environment

2.1.1 Climate

The climate of the Pilbara region of Western Australia is classified as arid tropical with two distinct seasons: a hot, wet summer (October – April) and a mild, dry winter (May – September) (Bureau of Meteorology 2016).

Based on long-term climatic data from the nearest Bureau of Meteorology (BOM) weather station at Pannawonica (Station 5069) (approximately 13 km north-east of the survey area) the mean annual rainfall since 1971 is 403.5 mm (Bureau of Meteorology 2016). The mean maximum daily temperatures range between 28°C and 41°C, and range above 30°C for much of the year (Bureau of Meteorology 2016) (Figure 2).

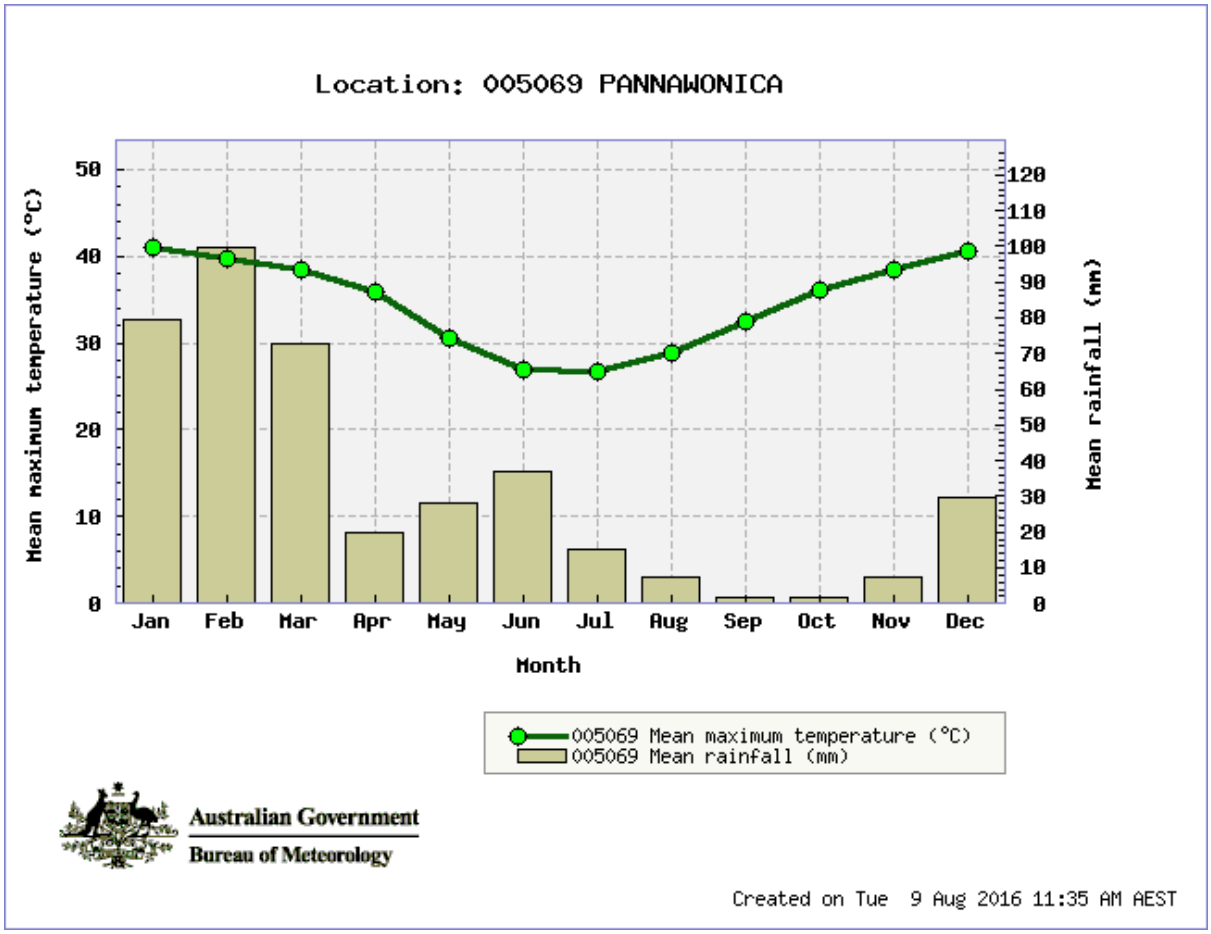

Figure 2: Climate data for Pannawonica (Station 5069). Mean annual rainfall data has been calculated from 1971 – 2016 and mean maximum temperature has been calculated from 1971 – 2005 (Bureau of Meteorology 2016).

2.1.2 Geology and Soils

The survey area occurs on the Hamersley Basin which overlies the Archaean Pilbara Craton and comprises of mafic and felsic volcanics, shale, siltstone, sandstone and conglomerate, as well as dolomite and banded iron formation. The area is extensively deformed with the rocks being folded and faulted (van Vreeswyk et al. 2004). The surface geology of the survey area is comprised of seven

units (Stewart et al. 2008), with Robe Pisolite the most dominant (Table 3). Geological mapping of the survey area and surrounds is presented in Figure A.1 (Appendix A).

Table 2: Geological units of the survey area (Stewart et al. 2008).

Geological name	Label	Area within survey area (ha)
Alluvium 38485: channel and flood plain alluvium; gravel, sand, silt, clay, locally calcreted.	Qa	762.3
Brockman Iron Formation: banded iron-formation, chert, mudstone and siltstone.	Lchk	114.0
Colluvium 38491: colluvium, sheetwash, talus; gravel piedmonts and aprons over and around bedrock; clay-silt-sand with sheet and nodular kankar; alluvial and aeolian sand-silt-gravel in depressions and broad valleys in Canning Basin; local calcrete, reworked laterite.	Qrc	778.2
Marra Mamba Iron Formation: chert, ferruginous chert, jaspilite, banded iron formation, minor shale, siltstone, mudstone.	Achm	635.9
Mount McRae Shale and Mount Sylvia Formation: interbedded shale, chert, banded iron-formation.	Ashm	289.7
Robe Pisolite: pisolitic, oolitic and massive limonite, goethite and hematite deposits containing fossil wood fragments; iron ore.	Czlr	2,261.6
Woongarra Rhyolite: rhyolite, rhyodacite, rhyolitic volcaniclastic breccia and banded iron formation.	Lfhw	88.5

The survey area is mapped as soil landscape zone 285 – Hamersley Plateaux in the Fortescue Province and soil landscape zone 296 – Stuart Plains and Hills Zone of the Ashburton Province (Tille 2006).

The Hamersley Plateaux soil unit is described as hills and dissected plateaux with some stony plains and hardpan wash plains on volcanic and sedimentary rocks. It is comprised predominately of stony soils with red shallow loams and some red-brown non-cracking clays and red loamy earths (Tille 2006). Some drainage habitats occur and these are characterised by sand, gravel, pebbles and stones (van Vreeswyk et al. 2004).

The Stuart Plains and Hills Zone consists of hills and ranges with some floodplains and stony plains on sandstone, shale and conglomerate of the Ashburton Basin. Soils are typically stony with red loamy earth and red shallow loams (Tille 2006).

2.1.3 Surface Water and Hydrology

The Robe River is considered a seasonal watercourse and intersects the northern section of the survey area, flowing in an east-west orientation. A number of permanent pools in the river were observed within the survey area. Numerous creeks and smaller drainage lines stem from the Robe River; drainage lines also occur down the gullies of the surrounding mesas. Springs and pools of the Robe River are listed as 'Wetlands of Subregional Significance' (Kendrick 2001) and are in proximity to the survey area. These wetland ecosystems are distributed from 40 km east of Pannawonica downstream to the North West Coastal Highway. Approximately 998 ha in the south-eastern corner of the survey area is within a Public Drinking Water Source Area: the Bungaroo Water Reserve (Department of Water 2008).

2.2 Biological Environment

2.2.1 Interim Biogeographic Regionalisation of Australia

The Interim Biogeographic Regionalisation for Australia (IBRA version 7) divides the Australian continent into 89 bioregions and 419 subregions (Department of the Environment and Energy 2016a). The IBRA regions represent a landscape-based approach to classifying the land surface, including attributes of climate, geomorphology, landform, lithology, and characteristic flora and fauna. The survey area occurs in the Pilbara Bioregion, of which 5% to 10% is represented in the national reserve system (Department of the Environment and Energy 2016b).

The biodiversity of the 53 subregions recognised in Western Australia was documented as part of a national audit to provide priorities for conservation action (Department of Conservation and Land Management 2002). The survey area occurs within the Hamersley subregions of the Pilbara region. The Hamersley subregion is described in the audit as:

- Hamersley PIL3 – dissected bold plateaux and ranges of flat lying, moderately folded sandstone and quartzite with vegetation described as Mulga low woodland over tussock grasses occurring on fine textured soils in valley floors, with scattered Snappy gum (*Eucalyptus leucophloia*) over *Triodia brizoides* on skeletal soils of the ranges (Kendrick 2001).

2.2.2 Land Systems

Land systems of the Western Australian rangelands have been mapped and described by the Department of Agriculture and Food (DAFWA) outlining the distributions and providing comprehensive descriptions of biophysical resources, including soil and vegetation condition. A total of 102 land systems occur in the Pilbara bioregion covering 181,723 km^2. Six land systems occur in the survey area, with Robe being the most dominant (Table 3). The layout of these land systems within the survey area is shown in Figure A.2 (Appendix A).

Table 3: Distribution of land systems within the survey area and Pilbara bioregion (van Vreeswyk et al. 2004).

Land system	Total area within Pilbara bioregion (ha)	Total area within survey area (ha)	Proportion within survey area (%)
Boolgeeda - stony lower slopes and plains below hill systems supporting hard and soft spinifex grasslands and mulga shrublands.	961,847	559.9	<0.1
McKay - hills, ridges, plateaux remnants and breakaways of meta sedimentary and sedimentary rocks supporting hard spinifex grasslands.	425,967	0.2	<0.1
Newman - rugged jaspilite plateaux, ridges and mountains with hard spinifex.	1,994,339	673.5	<0.1
River - active flood plains, major rivers and banks supporting grassy eucalypt woodlands, tussock grasslands and soft spinifex grasslands.	481,994	816.7	0.2
Robe - low limonite mesas and buttes supporting soft spinifex (and occasionally hard spinifex) grasslands.	128,680	2,758.1	2.1
Urandy - stony plains, alluvial plains and drainage lines supporting shrubby soft spinifex grasslands.	132,039	121.8	<0.1
TOTAL	**4,124,866**	**4,930.2**	-

2.2.3 Pre-European Vegetation

Pre-European vegetation was mapped across the Pilbara region at a scale of 1: 1,000,000 (Beard 1975). The survey area is located in the Stuart Hills and Hamersley Plateau physiographic units of the Fortescue Botanical District (Figure A.3, Appendix A). These physiographic units are described as:

Hamersley: a compact unit defined by the outcropping of jaspilite and dolomite, with some shale, siltstone and volcanics. Vegetation is described as:

- ranges – tree steppe of *Eucalyptus brevifolia* (likely to represent *E. leucophloia*) over *Triodia wiseana* hummock grasslands
- valley plains – mulga (*Acacia aneura* complex) low woodlands, or tussock grasslands on cracking clay soils
- basalt hills – mosaic of mulga low woodland and *Acacia pyrifolia* and *Triodia* species shrub steppe.

Stuart Hills: this unit consists mostly of plains, gently undulating pediplains extending out from Breakaways and residuals capped by Robe pisolites, and stony hills and steeply dissected pediments on fine-grained sandstone, shale and dolomite. Vegetation is described as:

- hills and plains – *T. wiseana* and *Triodia basedowii* hummock grasslands with sparse shrubs, particularly *Acacia bivenosa*
- drainage lines – *Corymbia hamersleyana* and *Corymbia candida* occur occasionally, with *Senna* species and ephemerals
- major rivers – *Eucalyptus camaldulensis* and *Acacia citrinoviridis* along river and mulga low woodland on river flats and tributaries.

Four pre-European vegetation units, 82, 603, 605 and 609 (Shepherd, Beeston, and Hopkins 2002), are associated with the survey area:

> 82: 'Hummock grasslands, low tree steppe; snappy gum over *Triodia wiseana*'
>
> 603: 'Hummock grasslands, sparse shrub steppe; *Acacia bivenosa* over hard spinifex'
>
> 605: 'Hummock grasslands, shrub steppe; *Acacia pachycarpa* and waterwood over soft spinifex'
>
> 609: 'Mosaic: Hummock grasslands, open low tree steppe; bloodwood with sparse kanji shrubs over soft spinifex/Hummock grasslands, open low tree steppe; snappy gum over *Triodia wiseana*'.

Table 4 summarises the current and pre-European extent of these four vegetation units in the Pilbara and the survey area.

Table 4: Extent of pre-European vegetation in the survey area (Government of Western Australia 2014).

Vegetation association	Mapping unit (Beard 1975)	Extent in survey area (ha)	Current extent in Pilbara bioregion (ha)	Pre-European extent (ha)	Proportion of pre-European extent remaining (%)
82	e16Lr t3Hi	2,023.7	2,550,898.98	2,563,583.23	99.51
603	a6Sb t3Hi	534.0	55,764.00	56,726.87	98.30
605	a5,11Sr t1Hi	965.5	114,115.85	114,115.85	100.00
609	e24Lr a2Sp t1Hi /e16Lr t3Hi	1407.0	72,765.18	74,186.11	98.08

2.3 State and Commonwealth Conservation Categories and Management

Commonwealth and State regulatory authorities maintain databases of the locations and conservation status of significant flora, fauna and ecological communities in Western Australia. The *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) provides a legal framework to protect and manage Matters of National Environmental Significance (MNES) including listed flora, fauna and ecological communities. These listed flora, fauna and ecological communities are allocated conservation categories, which are outlined in Tables B.1 to B.6 (Appendix B).

Ecological communities may be subject to processes that threaten to destroy or significantly modify it across much of its range. These communities are identified as Threatened Ecological Communities (TECs) and are listed at both Commonwealth level under the EPBC Act and State level by the Western Australian Minister for Environment (Table B.3, Appendix B). The Department of Parks and Wildlife (Parks and Wildlife) maintains a list of Priority Ecological Communities (PECs), which may also be under threat and are assigned one of four Priority rankings according to the criteria outlined in Table B.4 (Appendix B).

Under Western Australian legislation, all native flora is protected and it is an offence to 'take' protected flora. The *Wildlife Conservation Act 1950* (WC Act) also provides for native plant species to be specially protected when they are under identifiable threat of extinction, are rare, or otherwise in need of special protection (Department of Parks and Wildlife 2015a). Such specially protected flora is considered under the WC Act to be 'declared rare' (Threatened) (Table B.5, Appendix B). In addition, due to the diversity of Western Australia's flora, many species are known from only a few collections or locations, but have not been adequately surveyed. Such flora may be rare or

threatened, but cannot be considered for declaration as Threatened flora until adequate surveys have been undertaken. These flora species are included on a supplementary conservation list managed by Parks and Wildlife called the *Priority Flora List*. Priority flora are categorised according to level of threat and other information and the conservation categories are described in Table B.6 (Appendix B).

2.4 Introduced Flora (Weeds)

Significant weed species are identified at both the state and national level. The Australian Weeds Strategy (Australian Weeds Committee 2012) identifies Weeds of National Significance (WoNS) which have the potential to impact primary industry and/or environmental and social values. The management of weeds in Western Australia is primarily regulated through the *Biosecurity and Agriculture Management Act 2007* (BAM Act). Species listed under this act are allocated one of three declared pest categories which define the required level of management (Department of Agriculture and Food Western Australia 2016). Declared pest categories and listed weed species' priority ratings are presented in Table B.7 (Appendix B).

2.5 Land Use and Tenure

The survey area is located within the Shire of Ashburton. The majority of the survey area is on the Yalleen Station pastoral lease, with 100 ha (< 1% of the survey area) on the Yarraloola Station pastoral lease. The local area is used for pastoralism, mineral exploration and mining activity.

The Millstream-Chichester National Park is the nearest conservation reserve to the survey area, located approximately 79 km to the north-east. The Cane River Conservation Park is located approximately 48 km to the south-west, Murujuga National Park is approximately 120 km north and Karijini National Park is approximately 180 km south-east of the survey area (refer to Figure 1).

3 Methodology

3.1 Desktop Assessment

3.1.1 Database Searches

A search for Environmentally Sensitive Areas (ESAs) in the vicinity of the survey area was conducted using the WA Atlas (Landgate 2015) and Register of the National Estate (RNE) spatial database (Department of the Environment and Energy 2008). Despite all references to the RNE being removed from Commonwealth legislation in 2012, current State regulations (*Environmental Protection (Clearing of Native Vegetation) Regulations 2004*) declare any area registered on the RNE as an ESA (Department of the Environment and Energy 2016c).

In addition, database searches were conducted to identify listed conservation significant ecological communities and flora species within, or in close proximity to, the survey area. Search results are presented in Appendix C and details are summarised in Table 5. Conservation categories for ecological communities and flora are presented in Appendix B. Introduced flora species were compared to the DAFWA list to determine if any have been listed as declared pests (Department of Agriculture and Food Western Australia 2016) and the WoNS list (Australian Weeds Committee 2012). Introduced flora categories are also presented in Appendix B.

Table 5: Database searches requested.

Database name	Date search results received	Search focus	Search area
Protected Matters Search Tool (Department of the Environment and Energy 2016d)	25/07/2016	MNES - flora	40 km radius from an approximate survey area centre point, defined by the coordinates: 21°44’11 S, 116°11’50 E.
Threatened and Priority Ecological Communities database (Department of Parks and Wildlife 2015b)	05/10/2015	Listed Threatened and Priority Ecological Communities	20 km radius surrounding survey area boundary (shapefiles provided).
Threatened and Priority Flora Database (TPFL) (Department of Parks and Wildlife 2015c)	29/09/2015	Threatened and Priority flora	20 km radius surrounding survey area boundary (shapefiles provided).
Threatened and Priority Flora Species List (TP list) (Department of Parks and Wildlife 2015d)			
Western Australian Herbarium flora (Department of Parks and Wildlife 2015e)			
NatureMap (Department of Parks and Wildlife 2016a)	25/07/2016	Terrestrial flora and fauna of conservation significance	40 km radius from an approximate survey area centre point, defined by the coordinates: 21°44’11 S, 116°11’50 E.

3.1.2 Vegetation and Flora

The 30 PECs listed by Parks and Wildlife for the Pilbara region (Department of Parks and Wildlife 2016b) were reviewed to determine if any were analogous with ecological communities recorded in the survey area.

Prior to conducting the field survey, aerial imagery was interpreted to identify potential habitat types. The conservation significant flora species returned from the database searches were then categorised according to the criteria in Table 6 for potential occurrence within the survey area.

Table 6: Pre-survey criteria used to assess the likely presence of conservation significant flora in the survey area.

Likelihood of occurrence	Pre-survey
Likely	Species previously recorded within the survey area or within 10 km of the survey area and suitable habitat appears to be present in the survey area.
Potential	Species previously recorded within 10 km to 20 km of the survey area and/or suitable habitat appears to be present in the survey area.
Unlikely	No suitable habitat appears to be present in the survey area.

Following the field survey, the conservation significant flora species identified during the desktop assessment as having the highest potential to occur within the survey area, yet were not recorded during the current survey, were again assessed to determine their likelihood of occurrence within the survey area. Post-field survey likelihood of occurrence was primarily based on validating the presence (and thorough inspection) of suitable habitats within the survey area, combined with life form, habitat and flowering information for each flora species.

3.1.3 Literature Review

Vegetation and flora surveys which have previously been commissioned by Rio Tinto and that are within the vicinity of the survey area were supplied to Astron for the desktop assessment. The reports reviewed as part of this assessment were:

- Astron Environmental Services 2011, '*Mesa J Tail Track Extension Vegetation, Flora and Fauna Survey*', unpublished report to Rio Tinto
- Astron Environmental Services 2016a, '*Bungaroo Iron Ore Mine and Infrastructure Project Level 2 Vegetation and Flora Assessment*', unpublished report to Rio Tinto
- Astron Environmental Services 2016b, '*Middle Robe and East Deepdale Level 2 Vegetation and Flora Assessment*, unpublished report to Rio Tinto
- Biota Environmental Sciences 2003, '*Mesa J Extension Vegetation, Flora and Fauna Assessment*', unpublished report to Rio Tinto
- Biota Environmental Sciences 2006a, '*A Vegetation and Flora Survey of the Proposed Mesa A Transport Corridor, Warramboo Deposit and Yarraloola Borefield*', unpublished report to Rio Tinto
- Biota Environmental Sciences 2007, '*A Vegetation and Seasonal Flora Survey of the Bungaroo Trial Pit and Transport Corridor to Mesa J, near Pannawonica and Sampling of the Broader Bungaroo Valley*', unpublished report to Rio Tinto
- Biota Environmental Sciences 2011, '*Baseline Flora and Vegetation Assessment of Robe Valley Mesas (Mesas B, C, D, E, F, H and I*', unpublished report to Rio Tinto

- Biota Environmental Sciences 2012, '*Greater Bungaroo Flora and Vegetation Survey*', unpublished report to Rio Tinto
- Rio Tinto 2014, '*Flora Vegetation and Fauna Habitat Assessment at Jimmawurrada*', unpublished report.

The Astron (2011, 2016a), Biota Environmental Sciences (Biota) (2003, 2006a, 2007, 2011, 2012) and Rio Tinto (2014) survey areas overlap part of the current survey area. These reports were most relevant for obtaining contextual information relating to vegetation and flora values recorded within, or in close proximity to, the survey area. Survey area locations for the above listed reports are presented in Figure D.1 (Appendix D). Biota (2007, 2012) are the Phase 2 reports for Biota (2006b, 2009) respectively and contain the final combined Phase 1 and Phase 2 results for those surveys. As such they are not presented separately to avoid duplication and misrepresentation of information.

3.2 Field Survey

Phase 1 surveys were completed 23 to 30 October 2014 and 24 September to 4 October 2015. The two Phase 2 surveys were completed 27 April to 14 May 2016 and 19 to 22 July 2016 (Table 7).

Table 7: Dates and Personnel of Phase 1 and Phase 2 surveys.

Survey	Date	Personnel
Phase 1	23 to 30 October 2014	Janelle Atkinson (Flora permit SL010911 Declared Rare Flora (DRF) 107-1516) Daniel Roocke (Flora permit SL010827; DRF 139-1314) Alice Bott (Flora permit SL011640); DRF 140-1314
	24 September to 4 October 2015	Natalie Cadd (Flora permit SL011621; DRF 170-1415) Dr Kellie McMaster (Flora permit SL011404)
Phase 2	27 April to 14 May 2016	Janelle Atkinson (Flora permit SL011617), DRF 141-1415 Daniel Roocke (Flora permit SL011627), DRF 131-1516 Linda Vaughan (Flora permit SL011631) Dr Kellie McMaster (Flora permit SL011810)
	19 to 22 July 2016	Janelle Atkinson (Flora permit SL011617), DRF 141-1415 Daniel Roocke (Flora permit SL011627), DRF 131-1516

Daily weather observations recorded from Mesa J were used to describe local rainfall and temperatures preceding the surveys (Figure 3). Annual rainfall was 22 mm below the long-term mean prior to the 2014 survey, although more than double the monthly average rainfall was recorded in January, and triple the monthly average rainfall was recorded in May, eight and five months preceding the survey, respectively. Average rainfall was recorded in the six months prior to the 2015 survey, however the annual rainfall total was 67 mm below the long-term mean for the 12 months preceding the survey.

The annual rainfall recorded at Mesa J preceding the first Phase 2 survey in 2016 was 193 mm below the long-term mean of 404 mm at Pannawonica. Rainfall in the 12 weeks preceding the survey was less than half of the long-term mean for the same period, with 56 mm recorded. May, June and July 2016 recorded above average rainfall, with 137 mm (60 mm greater than the long term mean) recorded prior to the second Phase 2 trip. The maximum daily temperatures were lower than the long-term mean, ranging between 25.8°C and 35.4°C (Figure 3)

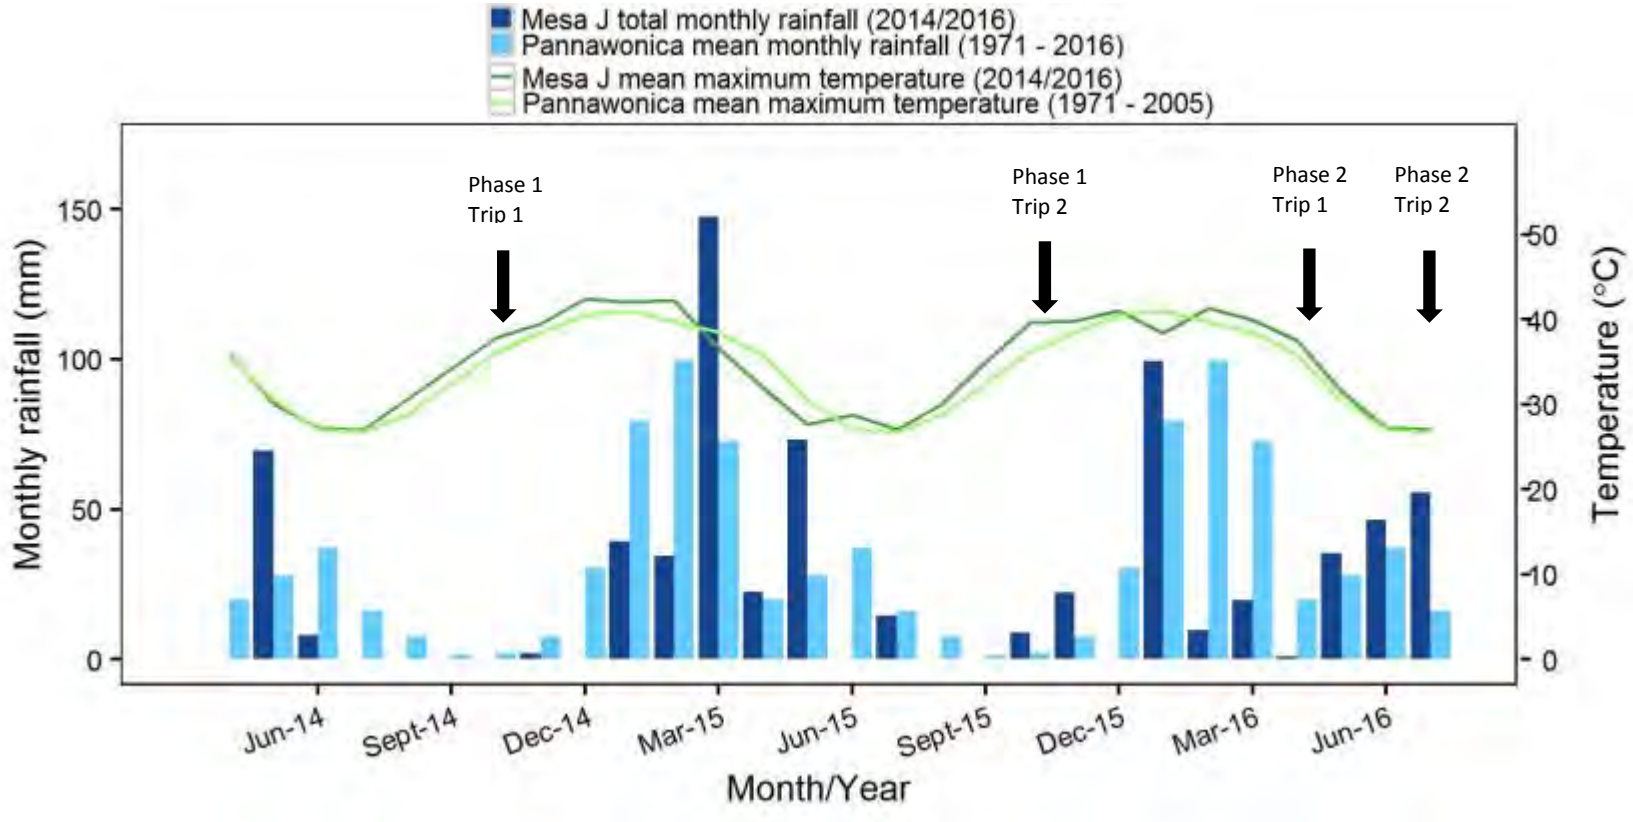

Figure 3: Pannawonica mean monthly rainfall (1971 – 2016) and Mesa J total recorded rainfall (2014 - 2016), and Pannawonica mean monthly maximum temperatures (1971 – 2005) and Mesa J mean monthly maximum temperatures, commencing 12 months preceding the first Phase 1 survey. Black arrows indicates field survey timing. Pannawonica data from Bureau of Meteorology (2016) and Rio Tinto (2016a).

3.2.1 Vegetation and Flora Assessment

The vegetation and flora field survey was undertaken in accordance with the requirements outlined in the EPA and Rio Tinto policy and guidance documents (Environmental Protection Authority 2002, 2004; Rio Tinto Iron Ore 2015).

Information acquired during the desktop assessment assisted in the design of the field survey. Pre-survey planning involved the examination of 1:10,000 scale aerial photography to identify potentially different landforms, habitat and vegetation types. It also involved a review of the flora and vegetation assessment previously completed at Mesa H (Biota Environmental Sciences 2012) to provide context and identify data gaps. Proposed quadrat locations were identified prior to the field survey according to the replicates required to support the previous vegetation mapping (Biota Environmental Sciences 2012).

There were 154 sites, comprising 138 quadrats and 16 relevés, sampled within the survey area. Forty-four quadrats and three relevés installed during the Phase 2 survey had a single season of survey only. Fifteen quadrats which informed a previous survey report (Astron Environmental Services 2016a) were incorporated into the assessment due to overlapping survey areas. Three of these had their second phase of survey during the current assessment. Survey effort is detailed in Table 8. The data from each surveyed site were used for mapping and floristic analysis purposes.

Quadrats were positioned by measuring a square of 50 m x 50 m, in suitable terrain, with the four corners of the quadrat permanently marked with fence droppers. Dimensions of the quadrat were adjusted according to terrain, drainage and landform features, to represent an estimated 2,500 m^2. Data from relevé locations was sampled from an area of approximately 2,500 m^2; in challenging terrain, visual estimation was used to approximate the area.

The following information was collected at each quadrat and relevé:

- Location – coordinates measured using a handheld Global Positioning System (GPS) (Map Grid of Australia 1994 (MGA94), Geocentric Datum of Australia 1994 (GDA94)). One set of coordinates taken from the north-west corner of each unmarked quadrat and relevé.
- Recorder and date – personnel involved in sampling that location and the survey date.
- Species – representative vascular plant species present. The inventory of associated species was more comprehensive for a quadrat location, with each flora species present recorded; at relevés the species most typical of the vegetation unit and represented at that location were recorded. Species that could not be identified in the field were collected for later identification at the Astron herbarium or Western Australian Herbarium (WAHerb).
- Weeds – the coordinates and density of any introduced flora.
- Foliar cover – the percentage cover was estimated for each flora species.
- Vegetation description – vegetation was described according to the Aplin (Aplin 1979) modification of the vegetation classification system of Specht (Specht 1970) (Table E.1, Appendix E) and the National Vegetation Information System, level 5 (Department of the Environment and Energy 2016e). At this level, vegetation is described to 'association' where up to three dominant genera for each of the upper, middle and ground strata are categorised based on dominant growth form, cover and height.
- Vegetation condition – assessed according to the vegetation condition classification adapted from Trudgen (1988) (Table E.2, Appendix E).

- Habitat – a broad description of the surrounding landscape based on landform, topography and soil.
- Photographs – a representative photograph was taken of each quadrat and relevé.
- Disturbances – records of any obvious disturbances such as fire, tracks or grazing.
- Geology – rock type and abundance.
- Soil – including colour and texture.

Quadrat and relevé locations are presented in Figure F.1 (Appendix F).

Table 8: Survey effort for existing and newly installed quadrats and relevés occurring within the survey area.

Author; phase of survey	Number of sites	Name of sites
Two seasons of survey: Astron (current survey)	78 quadrats 14 relevés	MH01, MH02, MH05, MH06, MH07, MH09, MH10, MH11, MH12, MH17, MH18, MH19, MH20, MH21, MH22, MH24, MH25, MH26, MH27, MH28, MH29, MH30, MH31, MH32, MH33, MH34, MH35, MH36, MH37, MH38, MH39, MH40, MH41, MH42, MH43, MH44, MH100, MH101, MH103, MH104, MH105, MH106, MH200, MH203, MH204, MH300, MH301, MH302, MH303, MH305, MH306, MH307, MH308, MH309r, MH310, MH311r, MH312, MH313, MH314, MH315, MH316, MH317, MH318, MH319, MH320, MH321, MH322, MH324, MH325, MH326, MH327, MH328, MH329, MH330, MH331, MH332, MH333r, MH334r, MH335, MH336, MH337r MHJ301r, MHJ302, MHJ303, MHJ304, MHJ305, MHJ306, MHJ309r, MHJr02, MHJr04, MHJr06, MHr200
One season of survey: Astron (current survey)	44 quadrats 3 relevés	MH338, MH339, MH342, MH343, MH344, MH345, MH346, MH348, MH350, MH352, MH353, MH354, MH356, MH357, MH358, MH359, MH360r, MH361, MH363, MH364, MH365, MH368, MH370, MH371, MH373, MH374, MH375r, MH376, MH377, MH392, MH393, MH394, MH395, MH396, MH397, MH398, MH399r, MH400, MH401, MH402, MH403, MH404, MH405, MH406, MH407, MH408, MH409
Two seasons of survey: Astron (current survey) 1 phase and Astron (2016a) 1 phase	3 quadrats	BA209, BA210, BA219
Two seasons of survey: Astron (2016a)	12 quadrats	BA07, BA10, BA18, BA21, BA22, BA32, BA42A, BA111, BAKM15, BADRr05, GBR23, BUN06

3.2.2 Vegetation Description and Mapping

Where appropriate, vegetation was described and mapped to be consistent with the descriptions and mapping previously conducted in and adjacent to the survey area (Biota Environmental Sciences 2006a). Astron adopted these vegetation codes and descriptions, and reconciled vegetation polygon boundaries to maintain consistency with those datasets. The vegetation description for some codes was updated to reflect current nomenclature. Where vegetation was observed to no longer represent previous mapping, vegetation polygon boundaries were adjusted and new vegetation descriptions assigned. Vegetation units were described and mapped using the data collected from

quadrats and relevés, and followed the same convention as that previously used; the vegetation association code is described according to the initials of the dominant flora species defining the community. Mapping notes were also used to mark changes in vegetation throughout the survey area. The details collected at mapping note locations included coordinate, photograph and vegetation description.

3.2.2.1 Vegetation Condition Mapping

Vegetation condition was mapped according to vegetation association boundaries throughout the survey area, using a combination of quadrat and relevé data, opportunistic observations and the mean condition rating for each vegetation association. Vegetation condition was rated at each survey site using the five point Trudgen (1988) scale, and then applied to the whole vegetation association polygon in which it was mapped. A mean condition rating was calculated for each vegetation association using the data collected from survey sites and this was applied to any polygons not already attributed with a rating.

3.2.3 Targeted Flora Survey

Previously recorded conservation significant flora records (Astron Environmental Services 2016a; Biota Environmental Sciences 2003, 2006a, 2007, 2011; Department of Parks and Wildlife 2015c, 2015d, 2015e, 2016a) and associated habitat preference information were used to identify vegetation associations and habitat within the survey area that have the potential to support conservation significant flora. The habitats and vegetation associations considered to have the potential to support conservation significant flora were located within the survey area from 1:10,000 colour aerial imagery and on-ground observations. These areas were then targeted in the field to record the presence or absence of Priority flora. Where conservation significant flora were observed, the area was traversed to record the extent of the population.

Population information for conservation significant flora was captured electronically using ArcPad (Esri) on a handheld device. The information recorded included population size, density, landform, soil and reproductive characteristics.

3.3 Taxonomy and Nomenclature

Plant specimens that were not identified in the field were later identified in Perth by Astron Botanists Johan Hurter, Natalie Cadd, Daniel Roocke and Janelle Atkinson. Each of these botanists has worked extensively in the Pilbara and is very familiar with the flora of the region. The assigned nomenclature is consistent with the current listing of scientific names recognised by the WAHerb and was used for the species list and associated species information collected. Where specimens had inadequate descriptive material to allow confident identification, they were assigned a 'sp.' (species) epithet, indicating that identification could not be confirmed beyond genus level. Data from each quadrat, relevé and mapping note were entered into a customised database.

3.4 Floristic Analysis

A species accumulation curve was created in order to examine the adequacy of survey effort, while a numerical analysis using species presence/absence was conducted to identify statistically significant floristic groups. The species accumulation curve and cluster analysis were completed by Astron Senior Scientist Dr Aaron Gove using R 3.2.1 (R Development Core Team 2015) and PRIMER v6 software (Clarke and Gorley 2006), respectively. Following normal convention, statistically significant clusters were those distinguished by a P-value <0.05.

Cluster analyses were completed to test the relationship between:

- floristic groups and structural vegetation associations within the survey area
- survey area quadrats and relevés and regional quadrats and relevés.

The 154 quadrats and relevés sampled from the survey area were included in the analysis and treated as a single project area. A further 357 sites from appropriate surveys (Astron Environmental Services 2016a, 2016b; Biota Environmental Sciences 2006a, 2007, 2012) were included in a separate analysis in order to provide a regional comparison.

The species lists from all projects were reconciled to provide consistency in nomenclature. Any taxa not confirmed to species level were removed from the analyses. Singletons (species recorded from only one site) were retained. Few rainfall dependent annuals were recorded for three of the field visits. The final Phase 2 survey followed high rainfall and had a much higher diversity of annual and herbaceous species which were not otherwise recorded in the broader survey area. This included *Calotis* species (spp.), *Cheilanthes* spp. and *Dysphania melanocarpa* which were removed from the floristic analysis.

3.5 Limitations

Following completion of the desktop assessment and field survey, a review of any limitations that may affect a complete assessment of the data collected was conducted. The limitations listed in Table 9 are based on those suggested as considerations in Guidance Statement No. 51 (Environmental Protection Authority 2004).

Table 9: Statement of limitations.

Potential limitation	Degree of limitation	Statement regarding potential limitations
(i) Sources of information and availability of contextual information. Is the region well documented?	No limitation	Broad-scale contextual information is available from van Vreeswyk et al. (2004), IBRA (Kendrick 2001; Kendrick and McKenzie 2001) and Beard (1975) mapping. Numerous consultants' reports have been completed within a 50 km radius of the survey area; one of which intersects the Mesa H survey area.
(ii) Scope. The level of survey and detail required to undertake the survey. Was there adequate time to complete the survey to the desired standard?	Minor limitation	Following assessment and gap analysis of the Phase 1 data, and to ensure alignment with the Technical Guide (Environmental Protection Authority and Department of Parks and Wildlife 2015), a further 44 quadrats and 3 relevés were installed and sampled during the Phase 2 survey. These sites had only a single phase of survey. The single phase of survey did not impact on vegetation mapping reliability, nor is it likely to have affected the floristic analysis or interpretation of data significantly. It is possible that additional species may be recorded from these sites if they had a second phase of survey post-rainfall.
(iii) Proportion of flora collected and identified. Was the survey sampling, timing and intensity considered adequate? Was the survey conducted at what was considered	Minor limitation	The Phase 1 field surveys were conducted in October 2014 and September-October 2015. The Phase 2 surveys were conducted in April-May, and June-July 2016. Seasonal conditions for both Phase 1 surveys were considered dry, with below average rainfall in the months preceding. Seasonal conditions for the first

Potential limitation	Degree of limitation	Statement regarding potential limitations
an appropriate time of the year for plant identification? Were any taxonomic groups considered to be under-represented?		Phase 2 survey were also considered poor with below-mean rainfall recorded both 12 weeks and 12 months prior to the survey. Approximately 140 mm of rain was recorded in the 12 weeks prior to the second Phase 2 trip, which resulted in a number of annual and ephemeral species (which had otherwise not been recorded in the survey area) being recorded. Despite the unfavourable seasonal conditions for three trips, the specimens collected from both phases were generally of reasonable quality and with flowering and fruiting material available; few specimens were unable to be confidently identified to species level. Most taxonomic groups expected within the survey area were well represented, and the total floristic richness was considered comparable to other surveys in the area, given the relatively low diversity of landforms. Some species which may be expected to occur post-rainfall, such as *Dysphania* spp., Asteraceae spp. and annual grasses may be considered slightly under-represented. Although the species accumulation curve had reached an asymptote (indicating that sampling had been exhaustive at the time of the surveys), it is possible that additional species may occur post-rainfall.
(iv) Completeness. Is there further work which may be required i.e. was the relevant area fully surveyed?	No limitation	The survey area was considered adequately surveyed to compile a representative list of species, (including Priority and introduced flora species), as well as describe and map vegetation at a level appropriate for possible future management decisions.
(v) Mapping reliability. Were the aerial photographs, satellite images and site maps available considered adequate to fully understand the area surveyed? Was the mapping generated considered to have a high degree of reliability?	No limitation	Colour aerial photography at a scale of 1: 10,000 was used to locate the survey area and to assist in navigation and delineation of vegetation boundaries. The aerial photography was of good resolution and, in general, accurately represented ground conditions.
(vi) Timing. When was the survey conducted in terms of season, rainfall and severe weather events? Was the survey conducted at an appropriate time for access, observation of the optimal suite of species and for identification of flowering and fruiting species?	Minor limitation	The four surveys were conducted at what would normally be considered the optimal time for dry and post-wet season surveys in the Pilbara. The dry season surveys were considered adequate, however during the first post-wet season survey quadrat species richness may have been lower than might be expected. The total floristic richness of the survey area was in line with what may be expected, although a number of the flora species were recorded only from the sites sampled during the second Phase 2 survey.
(vii) Disturbance. Had the survey area been impacted by any disturbance which may have limited the survey, i.e. fire, flood, accidental human intervention?	No limitation	A history of pastoral activity and cattle grazing was evident on the plains, floodplains and drainage lines. A thin area of the ranges (approximately 2% to 5% of the survey area) had been burnt within five years, however this did not compromise the vegetation mapping for

Potential limitation	Degree of limitation	Statement regarding potential limitations
		these locations. *Triodia* sp. Robe River (M.E. Trudgen et al. 12367) P3 was the only conservation significant species considered likely to occur in these areas and regenerating hummocks were large enough to be able to be identified from other *Triodia* species. None of these disturbances limited the outcomes of this survey.
(viii) Intensity. In retrospect, was the intensity considered to be adequate?	No limitation	The intensity of the survey was considered adequate to compile a representative species list, map the vegetation of the survey area to association level with adequate quadrat replication and conduct targeted surveys for Priority flora in potential habitat.
(ix) Resources. Were the appropriate tools and materials available to complete the task effectively?	No limitation	Resources were adequate to complete the survey and all appropriate tools and materials required to complete the task were available.
(x) Access. Were there any factors limiting access to the survey area?	No limitation	Much of the survey area was able to be accessed by vehicle; areas that were unable to be reached by vehicle were accessed and traversed by foot.
(xi) Experience. Were personnel undertaking the field survey and plant identification trained and/or experienced in undertaking the required tasks?	No limitation	The botanists responsible for undertaking the field survey have considerable experience in conducting vegetation and flora surveys in the Pilbara. The identification of specimens brought back from the field was conducted by a taxonomist with extensive Pilbara botanical experience.

4 Results

4.1 Desktop Assessment

4.1.1 Vegetation and Flora

No State or Commonwealth listed TECs are known to occur within or adjacent to the survey area (Department of Parks and Wildlife 2015b).

Two PECs: '*Triodia sp. Robe River assemblages of mesas of the West Pilbara*' P3 and '*Four plant assemblages of the Wona Land System*' P1, have been previously recorded within 20 km of the survey area (Department of Parks and Wildlife 2015b) (Figure G.1, Appendix G). Several mapped occurrences of '*Triodia sp. Robe River assemblages of mesas of the West Pilbara*' are located between approximately 16 km and 19 km south-west of the survey area. The '*Four plant assemblages of the Wona Land System*' PEC is mapped as occurring approximately 21 km north-east of the survey area (Department of Parks and Wildlife 2015b).

Vegetation analogous with the '*Triodia sp. Robe River assemblages of mesas of the West Pilbara*' P3 PEC has been identified during previous surveys undertaken adjacent, and within close proximity, to the survey area (Table 10) (Astron Environmental Services 2016b; Biota Environmental Sciences 2011).

The Parks and Wildlife (TPFL) (Department of Parks and Wildlife 2015c) and WAHerb (Department of Parks and Wildlife 2015e) database searches indicated that no species listed as Threatened have been recorded within 20 km of the survey area. The Parks and Wildlife TP List (Department of Parks and Wildlife 2015d), which is searched according to place names rather than coordinates, listed two Threatened species: *Lepidium catapycnon* T and *Thryptomene wittweri* T. However, since receiving the TP List database search results, *L. catapycnon* has been removed from the Threatened flora list in Western Australia and is currently listed as P4 (Western Australian Government 2015). Under the EPBC Act, *L. catapycnon* is still classified as 'Vulnerable', however, the Finalised Priority Assessment List indicates it has been proposed to be assessed for potential deletion (Department of the Environment and Energy 2016). A review of recorded specimens of *T. wittweri* T, held by the WAHerb (Western Australian Herbarium 1998-2016), indicates that the closest occurrence of this species to the survey area is approximately 270 km to the south-east. In addition, this species has not been identified during previous surveys conducted within, or in close proximity to, the survey area (Astron Environmental Services 2011, 2014, 2016a, 2016b; Biota Environmental Sciences 2003, 2006a, 2007, 2011, 2012; Rio Tinto Iron Ore 2014).

Twelve Priority flora species have been previously recorded within 20 km of the survey area (Table H.1, Appendix H) (Department of Parks and Wildlife 2015c, 2015d, 2015e, 2016a). Of these, two are P1, four are P2, six are P3 and two are P4 status. The pre-survey desktop assessment indicated that three of the listed Priority flora species were considered likely to occur within the survey area; a further eleven were considered to have the potential to occur (Table H.1, Appendix H). A result of *Thryptomene wittweri* T was obtained from the TP List database, which is searched using place names, rather than geo-referenced locations. Due to no other database indicating its occurrence within 50 km of the survey area, it was considered unlikely to occur.

4.1.2 Literature Review

Results of the literature review indicate that no TECs have been previously recorded within, or in the vicinity of the survey area. One PEC has been previously recorded in the vicinity of the survey area,

the '*Triodia sp. Robe River assemblages of mesas of the West Pilbara'* (Astron Environmental Services 2016b; Biota Environmental Sciences 2011).

Ten currently listed Priority flora species have been previously recorded within, or in close proximity to, the survey area: *Dicladanthera glabra* P2, *Pentalepis trichodesmoides* subsp. *hispida* P2, *Stylidium weeliwolli* P2, *Eragrostis surreyana* P3, *Gymnanthera cunninghamii* P3, *Indigofera* sp. Bungaroo Creek (S. van Leeuwen 4301) P3, *Triodia* sp. Robe River (M.E. Trudgen et al. 12367) P3, *Livistona alfredii* P4, *Ptilotus mollis* P4 and *Rhynchosia bungarensis* P4 (Table 10) (Astron Environmental Services 2014, 2016a, 2016b; Biota Environmental Sciences 2003, 2006a, 2007, 2011, 2012; Rio Tinto Iron Ore 2014).

Of these species, *T.* sp. Robe River (M.E. Trudgen et al. 12367) P3 and *R. bungarensis* P4, were recorded in the greatest number of surveys (Astron Environmental Services 2014, 2016a, 2016b; Biota Environmental Sciences 2003, 2006a, 2007, 2011, 2012; Rio Tinto Iron Ore 2014) (Table 10).

Specifically within the survey area, two Priority flora species have been previously recorded: *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 and *R. bungarensis* P4 (Astron Environmental Services 2014; Biota Environmental Sciences 2003).

Limitations affecting the results of previous surveys were minimal and are summarised below:

- Biota (2003): the survey was conducted after an extended dry period; vegetation was therefore visibly drought-affected and annual flora were uncommon.
- Biota (2006a) seasonal conditions for the 2005 survey were considered poor (Table 10); although substantial rainfall occurred in the month prior to the field survey, negligible rainfall was recorded for the 10 months prior to the survey.
- Biota (2012): some access constraints were experienced during the July 2009 field survey, due to some areas being inundated with water.
- Biota (2012): large sections of this survey area were noted as having been subject to recent intense fires and, as such, vegetation mapping for these areas was not an exact representation of the vegetation, rather an indicative account of the most common vegetation.
- Astron (2016a): approximately half of the survey area had been burnt within two years prior to the survey; this limited vegetation mapping verification and targeted surveys.
- Astron (2014): seasonal conditions were considered poor (Table 10) with only 9 mm of rain recorded in the four months prior to the survey.
- Astron (2014): up to 15% of the southern side of the survey area had been burnt in the three years preceding the survey and mapping needed to be extrapolated in this area.

4.1.3 Environmentally Sensitive Areas

No ESAs occur within or adjacent to the survey area. The nearest ESAs to the survey area are the Duck Creek Gorge Area, located approximately 78 km south of the survey area (Department of the Environment and Energy 2008). The Millstream Pools are listed in the Directory of Important Wetlands in Australia, and also represent an ESA 78 km east-north-east of the survey area (Department of the Environment 2015). The Millstream-Chichester National Park is located approximately 85 km east-north-east of the survey area (Department of the Environment and Energy 2008; Landgate 2015).

4.2 Field Survey

4.2.1 Vegetation

There were 38 vegetation associations described within the survey area (Table 11). Vegetation association mapping is provided in Figure I.1 (Appendix I) and the data collected from each quadrat, relevé and mapping note is presented in Appendix J.

In addition, three mosaic vegetation associations, AiAaAbTw/ChAtuTw (177.4 ha, 3.6%), AiAaAbTw/AaTeTw/ChAtuTw (47.3 ha, 0.96%) and AaTeTw/ChAtuTw (10.6 ha, 0.2%), occur in the southern end of the survey area. This vegetation included a dense network of drainage lines and plains that occurred at a scale too fine to capture on the mapping. Unvegetated ('disturbed') land accounts for approximately 367 ha (7%).

Table 11: Vegetation associations recorded for the survey area.

Vegetation association code and description	Sites	Vegetation Condition	Total area (ha) and area proportion (%)	Representative photograph
Mesa tops and hilltops and mesa slopes and hillslopes				
AaAbTwTspR *Acacia ancistrocarpa, A. bivenosa* scattered shrubs to open shrubland over *Triodia wiseana* (*T.* sp. Robe River (M.E. Trudgen et al. MET 12367)) open hummock grassland. **Associated species:** *Acacia tumida var. pilbarensis, A. inaequilatera, Dampiera candicans, Goodenia stobbsiana, Grevillea wickhamii, Petalostylis labicheoides* and *Ptilotus calostachyus.*	BA07, MH338, MH344, BADRr05	Excellent	60.5 (1.2%)	 **Plate 1: Vegetation representing AaAbTwTsr – facing north-west from GPS co-ordinate 421964mE and 7591753mN (MGA Zone 50).**

Vegetation association code and description	Sites	Vegetation Condition	Total area (ha) and area proportion (%)	Representative photograph
AacTw *Acacia acradenia* tall shrubland over *Triodia wiseana* hummock grassland. *Grevillea wickhamii* commonly occurs in the upper stratum where this vegetation occurs near the edge of mesas and gullies, and *A. inaequilatera* was a co-dominant species in a number of areas on the top of mesas. **Associated species:** *Acacia bivenosa, A. inaequilatera, A. trachycarpa, A. tumida* var. *pilbarensis, Cassytha capillaris, Eucalyptus leucophloia* subsp. *leucophloia, Grevillea wickhamii, Hakea chordophylla* and *Keraudrenia velutina subsp. elliptica.*	MH01, MH39, MH327, MH345, MH361	Excellent	42.9 (0.9%)	 **Plate 2: Vegetation representing AacTw – facing south-east from GPS co-ordinate 416340mE and 7597314mN (MGA Zone 50).**
AacTwTsr *Acacia acradenia* open shrubland to open heath over *Triodia wiseana* (*T.* sp. Robe River (M.E. Trudgen et al. MET 12367)) hummock grassland. **Associated species:** *Acacia inaequilatera, Gossypium robinsonii, Grevillea wickhamii* and *Triumfetta maconochieana.*	MH02, MH326, MH346	Excellent	4.8 (0.1%)	 **Plate 3: Vegetation representing AacTwTsr – facing south-east from GPS co-ordinate 415179mE and 7597153mN (MGA Zone 50).**

Vegetation association code and description	Sites	Vegetation Condition	Total area (ha) and area proportion (%)	Representative photograph
AbTw *Acacia bivenosa* open shrubland to open heath over *Triodia wiseana* hummock grassland. **Associated species:** *Acacia inaequilatera, A. synchronicia* and *Corymbia hamersleyana.*	BA10, BA210, MH32, MH324, MH325, MHJ303, MHJ304, MH309r	Very good - Excellent	265.5 (5.4%)	 **Plate 4: Vegetation representing AbTw – facing south-east from GPS co-ordinate 414561mE and 7597523mN (MGA Zone 50).**
AiAanTw *Acacia inaequilatera* and *A. ancistrocarpa* scattered tall shrubs to tall open shrubland over *Triodia wiseana* open hummock grassland to hummock grassland. **Associated species:** *Acacia atkinsiana, A. bivenosa, A. ptychophylla, A. trachycarpa, Grevillea wickhamii, Ptilotus calostachyus, P. nobilis* and *Triodia* sp. Robe River (M.E. Trudgen et al. MET 12367). Small stands of *Acacia pruinocarpa* can occasionally be located within this vegetation unit.	MH40, MH308, MH329, MH331, MH311r, MH330, MH343	Excellent	253.0 (5.1)	 **Plate 5: Vegetation representing AiAanTw – facing south-east from GPS co-ordinate 418157mE and 7598886mN (MGA Zone 50).**

Vegetation association code and description	Sites	Vegetation Condition	Total area (ha) and area proportion (%)	Representative photograph
AiAbTw *Acacia inaequilatera* scattered tall shrubs over *A. bivenosa* scattered shrubs over *Triodia wiseana* hummock grassland. The relative density of *A. inaequilatera* and *A. bivenosa* varied throughout this vegetation association, with one species often more dominant than the other. **Associated species:** *Acacia ancistrocarpa, A. acradenia, A. trachycarpa, Gossypium robinsonii, Grevillia pyramidalis subsp. leucadendron, Ptilotus calostachyus, P. nobilis, Senna artemisioides subsp. oligophylla, S. glutinosa subsp. glutinosa, S. notabilis, Sida* sp. Pilbara (A.A. Mitchell PRP 1543) and *Streptoglossa bubakii.*	MH07, MH19, MH319, MH328, MH377, MH334r, MHJr04	Excellent	603.0 (12.2%)	 **Plate 6: Vegetation representing AiAbTw – facing south-east from GPS co-ordinate 415639mE and 7596919mN (MGA Zone 50).**
AiAptTw *Acacia inaequilatera* scattered shrubs to scattered tall shrubs over *A. ptychophylla* scattered low shrubs to low open shrubland over *Triodia wiseana* open hummock grassland. **Associated species:** *Ptilotus astrolasius, P. calostachyus*, *Senna glutinosa* subsp. *glutinosa, S. glutinosa* subsp. *pruinosa* and *Triodia* sp. Robe River (M.E. Trudgen et al. MET 12367).	MH306, MH368, BA42a	Excellent	115.9 (2.4%)	 **Plate 7: Vegetation representing AiAptTw – facing south-east from GPS co-ordinate 419915mE and 7599310mN (MGA Zone 50).**

Vegetation association code and description	Sites	Vegetation Condition	Total area (ha) and area proportion (%)	Representative photograph
AiTwTsr *Acacia inaequilatera* scattered tall shrubs over *Triodia wiseana, T.* sp. Robe River (M.E. Trudgen et al. MET 12367) open hummock to hummock grassland. **Associated species:** A*cacia bivenosa, Cassytha capillaris, Eriachne mucronata, Goodenia stobbsiana, Grevillea pyramidalis, G. wickhamii, Hakea chordophylla, Ptilotus astrolasius* var. *astrolasius, P. calostachyus, Solanum cleistogamum, Trichodesma zeylanicum* and *Triumfetta chaetocarpa.*	MH10, MH11, MH301, MH352	Excellent	82.3 (1.7%)	 **Plate 8: Vegetation representing AiTwTsr – south-east from GPS co-ordinate 418548mE and 7593981mN (MGA Zone 50).**
AprTwTsr *Acacia pruinocarpa* low woodland over *Triodia wiseana, T.* sp. Robe River (M.E. Trudgen et al. MET 12367) open hummock grassland. **Associated species:** *Acacia tumida, Corymbia hamersleyana, Cymbopogon ambiguus, Eremophila fraseri* subsp. *fraseri, Eriachne mucronata, Eucalyptus leucophloia subsp. leucophloia, Grevillea pyramidalis, Jasminum didymum* subsp. *lineare, Mollugo molluginea, Rhyncharrhena linearis, Sarcostemma viminale, Senna stricta* and *Tephrosia uniovulata.*	MH12, MH42, MH103, MH101, MH105, MHJ309r	Very good - Excellent	15.7 (0.3)	 **Plate 9: Vegetation representing AprTwTsr – facing south-east from GPS co-ordinate 418228mE and 7594335mN (MGA Zone 50).**

Vegetation association code and description	Sites	Vegetation Condition	Total area (ha) and area proportion (%)	Representative photograph
AptTw *Acacia ptychophylla* low open shrubland over *Triodia wiseana* open hummock grassland. **Associated species:** *Acacia ancistrocarpa, A. inaequilatera, A. synchronicia, A. trachycarpa, Bulbostylis barbata, Dampiera candicans, Eriachne mucronata, Grevillea wickhamii, Hakea chordophylla, Indigofera monophylla* and *Triumfetta appendiculata.*	MH33, MH34, MH106, MH300, MH371	Excellent	71.7 (1.5%)	 **Plate 10: Vegetation representing AptTw – facing south-east from GPS co-ordinate 418720mE and 7595616mN (MGA Zone 50).**
AtuTwTsr *Acacia tumida* var. *pilbarensis* tall shrubland over *Triodia wiseana, T.* sp. Robe River (M.E. Trudgen et al. MET 12367) open hummock grassland. **Associated species:** *Acacia inaequilatera, Corymbia hamersleyana, Duperreya commixta, Eriachne mucronata, Gossypium robinsonii, Grevillea wickhamii* and *Petalostylis labicheoides.*	MH18, MH27, MH28, MH29, MH104	Very good - Excellent	29.0 (0.6%)	 **Plate 11: Vegetation representing AtuTwTsr – facing south-east from GPS co-ordinate 417922mE and 7595431mN (MGA Zone 50).**

Vegetation association code and description	Sites	Vegetation Condition	Total area (ha) and area proportion (%)	Representative photograph
ChAiAbTw *Corymbia hamersleyana* scattered low trees over *Acacia inaequilatera* scattered tall shrubs over *A. bivenosa* scattered shrubs over *Triodia wiseana* hummock grassland. This vegetation association was also recorded on plains habitat. **Associated species:** *Acacia synchronicia, Gossypium robinsonii, Ptilotus astrolasius, Senna glutinosa* subsp. *glutinosa, Stylobasium spathulatum* and *Trichodesma zeylanicum.*	MH09, MH22, MH26, MH305, MHJ301r, MH374	Very good - Excellent	800.7 (16.2%)	 **Plate 12: Vegetation representing ChAiAbTw – facing south-east from GPS co-ordinate 417168mE and 7594275mN (MGA Zone 50).**
ElAiAbTw *Eucalyptus leucophloia* subsp. *leucophloia* scattered low trees over *Acacia inaequilatera* scattered tall shrubs over *A. bivenosa* scattered shrubs to open shrubland over *Triodia wiseana* hummock grassland. **Associated species:** *Acacia acradenia, A. synchronicia, Corymbia hamersleyana, Cymbopogon ambiguus, Hakea chordophylla* and *Senna glutinosa* subsp. *glutinosa.*	MH31, GBR23, MH342, MH359	Excellent	56.7 (1.2%)	 **Plate 13: Vegetation representing ElAiAbTw – facing south-east from GPS co-ordinate 418236mE and 7598271mN (MGA Zone 50).**

4.2.1.1 Vegetation Condition

Vegetation in the survey area ranged from 'very poor' to 'excellent' (Trudgen 1988) condition (Table 12; Figure K.1, Appendix K). Vegetation of the slopes and crests of the low hills was generally of high quality ('excellent' condition), with almost no weeds present nor signs of grazing. Vegetation of the plains and drainage lines typically occurred on deeper soils and weed species such as **Argemone ochroleuca* subsp. *ochroleuca* (Mexican Poppy) and **Cenchrus* spp. (Buffel and Birdwood Grasses) were a typical component of this vegetation. Grazing from cattle was also evident in these habitats. The density of weed species, in particular **Cenchrus* spp. and **A. ochroleuca* subsp. *ochroleuca,* varied considerably between season and grazing pressure (Plate 38 and Plate 39).

Plate 38: Weed cover in Jimmawarruda Creek in dry conditions and post-grazing.

Plate 39: Weed cover in Jimmawarruda Creek following rainfall.

An extensive network of drill lines, drill pads and tracks exists within the survey area. Rail lines occur in the northern and south-eastern parts of the survey area. Together this 'disturbed' vegetation accounts for approximately 367 ha (7 %) in the survey area. A number of colonising annual species were observed regenerating on some of these tracks, but most remained cleared of vegetation.

Table 12: Vegetation condition recorded for the survey area, based on the Trudgen (1988) scale.

Vegetation condition	Total mapped area within the survey area (ha)	Proportion of the survey area (%)
Excellent	3309.6	67
Very Good	657.2	13
Good	500.9	10
Poor	93.6	2
Very Poor	1.6	<1
Disturbed	367.3	7

4.2.1.2 Conservation Significance of Vegetation

No TECs were recorded in the survey area.

Vegetation representing the PEC '*Triodia sp. Robe River assemblages of mesas of the West Pilbara*' was recorded at the northern extent of the survey area in association with a mesa landform, where *Acacia pruinocarpa* occurred in conjunction with *T.* sp. Robe River (M.E. Trudgen et al. MET 12367)

P3 (Plate 40). This vegetation, mapped as AprTwTsr, covered an area of approximately 15.7 ha, representing 0.3% of the survey area. The abundance of *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) varied across the delineated polygons for this vegetation unit. For example, the areas containing quadrats MH101 and MH105 have been mapped as AprTwTsr due to *Acacia pruinocarpa* and *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) co-existing, even though *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) was not a dominant species at those particular sites.

A number of permanent and semi-permanent pools occurred within the flow channels of the Robe River, inside the survey area. These areas supported an assemblage of species unique from other habitats and generally supported a high diversity of flora species. These pools occurred within vegetation association MaEcCv which covered 147.4 ha, representing 3% of the survey area, and distributed in the northern and western parts of the survey area (Plate 41).

Plate 40: Vegetation representing the *Triodia* sp. Robe River PEC.

Plate 41: Vegetation dominated by *Melaleuca argentea* and *Eucalyptus camaldulensis* subsp. *refulgens* surrounding a water pool in the Robe River.

Three species which may be considered indicator species for Groundwater Dependent Ecosystems (GDE) were recorded within the rivers and larger creeks of the survey area. *Melaleuca argentea* and *Eucalyptus camaldulensis* subsp. *refulgens* are the dominant upper stratum species of MaEcCv, and *E. camaldulensis* subsp. *refulgens* and *Eucalyptus victrix* are the dominant upper stratum species of EcEvAtrApyPlTw. The vegetation mapped as EcEvAtrApyPlTw covered approximately 311 ha, and represents 6.3% of the survey area. *Melaleuca argentea* is considered an obligate phreatophyte and therefore highly dependent on groundwater, while *E. camaldulensis* subsp. *refulgens* and *E. victrix* are facultative phreatophytes and use groundwater opportunistically during periods of drought or some life stages.

The remaining vegetation associations recorded in the survey area are considered typical of what may be expected on similar landforms in the broader Hamersley subregion.

4.2.1.3 Floristic Groups

Based on classification analysis, there were 32 significant floristic groups identified within the survey area. Of the 154 sites assessed from the survey area, all except six grouped with other survey sites. These six sites are therefore considered to be statistically distinct at a floristic level Table 13. These sites showed structural and floristic similarities with other quadrats and relevés within the survey area at the vegetation association level. Both survey sites and vegetation associations from similar landforms generally grouped together in the classification analysis. The results of the floristic analysis are presented in Appendix L.

Table 13: Floristic groups identified by one site in the survey area and corresponding vegetation association.

Quadrat/ relevé	Quadrat/relevé description	Structural vegetation association
MH27	*Acacia tumida* var. *pilbarensis* and *Grevillea wickhamii*, tall open scrub over *Petalostylis labicheoides* scattered shrubs over *Triodia wiseana* hummock grassland.	AtuTwTsr
MH302	*Corymbia hamersleyana* scattered low trees over *Stylobasium spathulatum*, *Acacia trachycarpa, A. pyrifolia* tall open shrubland over *Grevillea pyramidalis* subsp. *leucadendron, Abutilon* sp. Dioicum (A.A. Mitchell PRP 1618) scattered shrubs over *Triodia epactia* open hummock grassland and **Cenchrus setiger* scattered tussock grasses.	ChAbTwTe
MH325	*Acacia bivenosa* open shrubland over *Triodia wiseana* hummock grassland.	AbTw
MH350	*Acacia inaequilatera* and *A. ancistrocarpa* tall open shrubland over *A. bivenosa* open shrubland over *Triodia wiseana* hummock grassland.	AiAaAbTw
MH357	*Corymbia hamersleyana* low open woodland over *Petalostylis labicheoides* and *Gossypium robinsonii* tall open shrubland over *Triodia wiseana* and *T. angusta* open hummock grassland.	ChPlAbGOrTw
MH375r	*Triodia wiseana* and *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) open hummock grassland.	Tw

Site MH302 occurs adjacent to a drainage line that has been truncated due to the Mesa J mine, approximately 500 m upstream. Two tracks also occur immediately east, and approximately 300 m south, of the quadrat. Water discharge has been noted to occur in this drainage line, causing short-term inundation and increasing frequency of cattle grazing. The combined effects of these disturbances have increased the floristic diversity of this site compared to other similar sites in the survey area, with a particularly high diversity of weed species.

Sites MH27, MH325, MH350 and MH357 each had at least two or three species that may be considered unusual for the vegetation type and/or landform. For some sites this may have been due to the placement of the quadrats capturing some species from adjacent vegetation types; site MH357, however, had been burnt within an estimated 2 to 5 years and therefore some coloniser species were recorded.

Site MH375r was surveyed during only one phase and had only three species recorded, which is considerably lower than the average floristic diversity for other sites. This is likely to be attributed to its exposed rocky hillslope landform and associated shallow soils.

There were 110 statistically significant clusters identified from the regional analysis, 22 of which consisted of only a single quadrat or relevé (Appendix L). Four significant clusters were represented by a single quadrat or relevé from the survey area. One site, MH302, is statistically significant at both a regional and within-project scale. Three of the single-site clusters were statistically significant at a regional scale, but not at a project scale, indicating that they had a similar assemblage of species to other sites in the survey area (Table 14). The remaining 88 clusters consisted of multiple survey sites.

Table 14: Floristic groups identified by one site in the regional analysis and corresponding vegetation association.

Quadrat	Quadrat description	Structural vegetation association
MH18	*Corymbia hamersleyana* low open woodland over *Acacia tumida* var. *pilbarensis* tall shrubland over *Triodia wiseana* and *T.* sp Robe River (M.E. Trudgen et al. MET 12367) P3 open hummock grassland.	AtuTwTsr
MH203	*Acacia trachycarpa, Petalostylis labicheoides* and *A. bivenosa* tall open scrub.	AtrPl
MH302	*Corymbia hamersleyana* scattered low trees over *Stylobasium spathulatum, Acacia trachycarpa, A. pyrifolia* tall open shrubland over *Grevillea pyramidalis* subsp. *leucadendron, Abutilon* sp. Dioicum (A.A. Mitchell PRP 1618) scattered shrubs over *Triodia epactia* open hummock grassland and **Cenchrus setiger* scattered tussock grasses.	ChAbTwTe
MH315	*Corymbia hamersleyana* scattered low trees over *Acacia bivenosa* and *Gossypium robinsonii* open shrubland over *Triodia wiseana* very open hummock grassland.	ChPlAbGOrTw

Site MH18 occurs in a gully and has a species assemblage that would be considered a mix of typical drainage line flora, combined with *Triodia wiseana* and *T.* sp. Robe River (M.E. Trudgen et al MET 12367) P3 as the dominant species at lower stratum, which are both considered common to hillslopes and the crests of mesas in the region. Site MH315 also occurs in a gully and has *T. wiseana* as the dominant species at the lower stratum. Here, there were some less common species recorded such as *Pimelea ammocharis* and *Heliotropium pachyphyllum*. Five species were recorded in MH203 that were not otherwise recorded in the sparsely vegetated AtrPl association. As previously noted, multiple disturbances at the location of MH302 resulted in higher species diversity causing this site to be identified during floristic analysis.

4.2.2 Flora

There were 310 plant species from 53 families and 150 genera confirmed in the survey area. A further 36 specimen collections were unable to have identification confirmed to species level and therefore may represent additional taxa. A species list and a site by species matrix for the survey area are presented, respectively, in Tables M.1 and M.2 (Appendix M). A combined species list, tabling flora species from both the current and previous surveys reviewed as part of this assessment, is also presented in Table M.3 (Appendix M). The dominant plant family was Fabaceae, with 58 species confirmed, while *Acacia* was the most frequently recorded genus (Table 15). Six taxonomically distinct species have not been previously recorded within or adjacent to the survey area (Table M.3, Appendix M) (Astron Environmental Services 2014; Biota Environmental Sciences 2003, 2006a, 2011; Astron Environmental Services 2016a, 2016b, 2011; Biota Environmental Sciences 2012; Rio Tinto Iron Ore 2014).

Table 15: Families and genera with the greatest number of taxa in the survey area.

Family	Number of taxa
Fabaceae	58
Poaceae	36
Malvaceae	35
Genus	**Number of taxa**
Acacia	21
Ptilotus	12
Senna	10

4.2.2.1 Conservation Significant Flora

No State or Commonwealth listed Threatened flora were recorded, or are likely to occur, within the survey area.

Targeted searches in potential habitat within the survey area identified three state-listed Priority flora species: *I.* sp. Bungaroo Creek (S. van Leeuwen 4301) P3, *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 and *R. bungarensis* P4. Habitat and abundance details for these species are summarised in the below text and Table 16. Detailed location information and abundance data for each recorded occurrence, for both this survey and previous surveys, along with representative photographs of each species, are presented in Tables N.1-N.6 (Appendix N). Conservation significant flora locations, for both this survey and previous surveys, are also mapped in Figure N.1.A (Appendix N).

One population of *I.* sp. Bungaroo Creek (S. van Leeuwen 4301) P3 was recorded from the eastern side of the survey area, from one vegetation association. The 20 *I.* sp. Bungaroo Creek (S. van Leeuwen 4301) P3 individuals were recorded from the floodplain of a tributary of the Robe River. *Indigofera* sp. Bungaroo Creek (S. van Leeuwen 4301) P3 has not been previously observed within the survey area, however has been recorded in surrounding areas, particularly in association with the Bungaroo Valley and Bungaroo Creek, immediately to the south (Astron Environmental Services 2016a).

Triodia sp. Robe River (M.E. Trudgen et al. MET 12367) P3 was observed at several locations associated with the uplands of the survey area, with approximately 68,000 individuals recorded from 24 vegetation associations. Individuals were predominantly recorded along rocky slopes and crests of low hills, occasionally also occurring within rocky drainage gullies. The majority of individuals were recorded from vegetation associations AiAanTw, AiAptTw, AiTwTsR and ChAiAbTw. It was typically recorded in conjunction with *T. wiseana* in the lower stratum of vegetation. *Triodia* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 has previously been recorded within the survey area (Astron Environmental Services 2014; Biota Environmental Sciences 2003).

An estimated 2,500 individuals of *R. bungarensis* P4 were recorded in the survey area, typically occurring in the Robe River. *Rhynchosia bungarensis* P4 was generally recorded from densely shaded vegetation in the river channels, under *E. camaldulensis* subsp. *refulgens* and *M. argentea* woodlands and forests. Although recorded from 15 vegetation associations, approximately 60% of records were associated with MaEcCv and a further 15% from EcEvAtrApyPlTw. *Rhynchosia bungarensis* P4 has previously been recorded within the survey area; and also adjacent to and in close proximity to the survey area (Astron Environmental Services 2016a, 2016b; Biota Environmental Sciences 2003, 2006a, 2007, 2011).

Table 16: Conservation significant flora recorded in the survey area.

Species	Estimated abundance	Habitat	Vegetation association/s
Indigofera sp. Bungaroo Creek (S. van Leeuwen 4301) P3	20	Floodplain of major creek	ChAsppGOrGsppPlSsTeTw
Triodia sp. Robe River (M.E. Trudgen et al. MET 12367) P3	68,000	Crests and upper slopes of mesas, gullies/gorges	AacTw, AacTwTsr, AbTw, AiAaAbTw, AiAanTw, AiAbTw, AiAptTw, AiTwTsr, AprTwTsr, AsAbTwCspp, AsTw, AtuTwTsr, ChAbTwTe,ChAsppGOrGsppPlSsTeTw, ChAiAbTw, ChAtuTe, ChAtuTw, ChPlAbGOrTw, ElAiAbTw, ElAiTwTsr, ElTw, EvAtrTwCspp, TspFcAoTe, Tw

4.2.2.2 Post-survey Likelihood of Occurrence of Conservation Significant Flora

Following the survey, and with greater understanding of the landforms, soils and habitats of the survey area, four priority flora species, *Triodia* sp. Pannawonica (B.M. Anderson & M.D. Barrett BMA 89) P1, *Euphorbia australis* var. *glabra* P2, *S. weeliwolli* P2 and *E. surreyana* P3 are considered to have potential to occur but were not recorded. These species have been previously recorded in close proximity to the survey area and suitable habitat for these species was identified within the survey area. If present, these species may have gone unnoticed due to their small habit and likely absence of flowers at the time of survey. None of these species would be restricted to the survey area if present, as indicated by the voucher records listed with the WAHerb (Western Australian Herbarium 1998-2016). Survey effort, as shown by tracklog traverses within the survey area, is presented in Figure O.1 (Appendix O).

4.2.2.3 Range Extensions

Although there are records in the Pilbara region, three species recorded in the survey area (*Cynanchum pedunculatum, Sauropus crassifolius* and *Senna* sp. Meekatharra (E. Bailey 1-26)) were beyond their normal range of occurrence and are therefore considered outliers. A single specimen of each of these species was observed. *Cynanchum pedunculatum* is a prostrate twining perennial species that was recorded from a floodplain on the eastern side of the survey area, near the Mesa J mine. *Sauropus crassifolius* is a small perennial shrub that was recorded from a steep-sided gully in the southern part of the survey area. *Senna* sp. Meekatharra (E. Bailey 1-26) is a perennial shrub that was recorded from the alluvial plains in the south-eastern part of the survey area.

4.2.2.4 Introduced Flora

Weed diversity in the survey area is considered high with 20 weed species recorded. Habitat and abundance details for these species are summarised in Table 17. All recorded weeds are not listed as declared pests under the BAM Act, or as a WoNS (Australian Weeds Committee 2012). The recorded

locations within the survey area and a description of each weed are presented in Tables N.7 and N.13 (Appendix N).

Table 17: Introduced flora species (weeds) recorded during the survey.

Species	Family	Estimated abundance	Habitat
**Aerva javanica* (Kapok Bush)	Amaranthaceae	2,050	Disturbed, major and minor drainage, plains
**Argemone ochroleuca* subsp. *ochroleuca* (Mexican Poppy)	Papaveraceae	7,000	Disturbed, major and minor drainage
**Bidens bipinnata* (Bipinnate Beggartick)	Asteraceae	600	Major and minor drainage
**Cenchrus ciliaris* (Buffel Grass)	Poaceae	75,200	Disturbed, plains, major and minor drainage
**Cenchrus setiger* (Birdwood Grass)	Poaceae	86,000	Disturbed, major and minor drainage, plains
**Chloris barbata* (Purpletop Chloris)	Poaceae	50	Disturbed, major and minor drainage, plains
**Citrullus colocynthis* (Colocynth)	Cucurbitaceae	65	Disturbed, major and minor drainage, plains
**Cynodon dactylon* (Couch Grass)	Poaceae	260	Major and minor drainage
**Echinochloa colona* (Awnless Barnyard Grass)	Poaceae	5	Major and minor drainage
**Euphorbia hirta* (Asthma Plant)	Euphorbiaceae	800	Major and minor drainage
**Flaveria trinervia* (Speedy Weed)	Asteraceae	140	Disturbed, major and minor drainage, plains
**Lactuca serriola* (Prickly Lettuce)	Asteraceae	40	Major and minor drainage, plains
**Malvastrum americanum* (Spiked Malvastrum)	Malvaceae	920	Disturbed, major and minor drainage, plains
**Ocimum basilicum* (Basil)	Lamiaceae	15	Major and minor drainage
**Passiflora foetida* subsp. *hispida* (Stinking Passion Flower)	Passifloraceae	890	Major and minor drainage
**Phoenix dactylifera* (Date Palm)	Araceae	8	Major and minor drainage
**Rumex vesicarius* (Ruby Dock)	Apocynaceae	640	Disturbed, major and minor drainage, mesa tops and hilltops and mesa slopes and hillslopes, plains
**Setaria verticillata* (Whorled Pigeon Grass)	Poaceae	1,270	Disturbed, major and minor drainage, plains
**Sonchus oleraceus* (Common Sowthistle)	Asteraceae	20	Major and minor drainage
**Tribulus terrestris* (Caltrop)	Zygophyllaceae	50	Major and minor drainage, plains
**Vachellia farnesiana* (Mimosa Bush)	Fabaceae	290	Disturbed, major and minor drainage, plains

5 Discussion

5.1 Overview of Study Area

The survey area is defined by low and broad mesa formations extending from the north-eastern footslopes of the Hamersley Ranges and flanked to the north and west by the Robe River. Low hills and plains surround the uplands and river. The mesas, hills and plains are dominated by open shrublands of *Acacia* species over *Triodia* species (Spinifex) hummock grasslands. The Robe River supports extensive woodlands of *Melaleuca argentea* (Silver Cadjeput) and *Eucalyptus camaldulensis* subsp. *refulgens* (River Red Gum) over sedges in the main channels, and is surrounded by sparely vegetated shingle beds and tall shrublands of *Acacia trachycarpa* and *Petalostylis labicheoides*.

5.2 Vegetation

The vegetation recorded generally represents what would be expected from similar landforms in the broader Hamersley subregion. Thirty-eight vegetation associations and three mosaic vegetation units were mapped within the survey area and 33 statistically significant groups were identified from the floristic analysis. This indicates that the scale of mapping based on visual interpretation was conservative and appropriate for the floristic diversity of the survey area.

There were no Commonwealth or State listed TECs recorded within the survey area. One vegetation association, AprTwTsr, is analogous with the PEC '*Triodia sp. Robe River assemblages of mesas of the West Pilbara*'. This vegetation association was recorded from discrete pockets on the edge of mesa landforms in the survey area. Vegetation association AprTwTsr typically occurred on the rocky tops of mesas adjacent to gullies and breakaways, and was dominated by an open shrub stratum of *Acacia pruinocarpa* over mixed open hummock grassland of *Triodia wiseana* and *Triodia* sp. Robe River (M.E. Trudgen et al. MET 12367) P3. The dominance of these two *Triodia* species varied between occurrences. Vegetation association AprTwTsr represents 15.7 ha (0.3%) within the survey area. The *Triodia* sp. Robe River PEC is listed as Priority 3, 'poorly-known ecological communities'.

One quadrat, MH302, did not group with other quadrats or relevés from within the survey area or other regional surveys in the floristic analysis. The effects of multiple disturbances, such as altered surface hydrology, tracks and grazing, combined with water discharge nearby, has probably contributed to the relatively high floristic diversity at this site. Although a number of additional species were recorded at MH302 relative to other similar quadrats and relevés, it had a similar structural composition to other sites within the survey area, did not occur on an under-represented landform and did not otherwise appear to be of local or regional significance.

Weed diversity and density were likely to have been under-represented on the alluvial plains at the northern side of the survey area at the time of the surveys, due to heavy grazing and poor seasonal conditions. This includes vegetation associations AsTw and AsAbTwCspp which occur on clay soils that are likely to have abundant individuals of *Cenchrus* spp. following rainfall. The survey in Jimmawurrada Creek was completed over two field visits, one pre-rainfall and one post-rainfall. There was a considerable increase in the density and diversity of weed species in Jimmawurrada Creek post-rainfall which had not been observed prior to the rain.

Vegetation condition in undisturbed vegetation in the upland areas, including mesas, ranges and hills, was 'excellent' with generally no weeds or evidence of other types of disturbance. The dominant mesa landform was highly fragmented due to the network of tracks and drill pads. Although a high diversity of weed species occurred in the Robe River, the vegetation structure was generally intact and floristic diversity was as would be expected for a major ephemeral watercourse in the Pilbara.

5.3 Flora

The suite of flora species recorded was considered typical of what may be expected in the area (Beard 1975; Payne et al. 1988) and aligns with what has been previously recorded in surrounding areas (Astron Environmental Services 2014, 2016a, 2016b; Biota Environmental Sciences 2003, 2006a, 2007, 2011, 2012; Rio Tinto Iron Ore 2014). Despite rainfall being below the long-term average for three of the four surveys, the floristic diversity was considered reasonably high. It is likely however, that many of the annuals and herbaceous species that were noted would have been more widespread throughout suitable habitats in better seasonal conditions. Specimens generally had adequate material to allow confident identification, however a number of samples collected during the first Phase 2 survey were of poor quality and were unable to be identified to species level.

Areas considered 'likely' or 'potential' habitat for Threatened or Priority flora were targeted and searched. Opportunistic searches were also conducted in a proportion of all other landform and vegetation types observed whilst traversing the survey area. Three Priority flora species were recorded within the survey area: *I.* sp. Bungaroo Creek (S. van Leeuwen 4301) P3, *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 and *R. bungarensis* P4. Priority flora records were distributed throughout the survey area, but were concentrated around the edges of mesas and throughout the Robe River.

Indigofera sp. Bungaroo Creek (S. van Leeuwen 4301) P3 was recorded on floodplains at one location in the south-eastern part of the survey area. This species has not been previously recorded within the survey area but has been recorded from similar habitats adjacent to the survey area (Astron Environmental Services 2016a, 2016b; Biota Environmental Sciences 2012). There are 37 records of *I.* sp. Bungaroo Creek (S. van Leeuwen 4301) P3 listed at the WAHerb, with a range of approximately 215 km (Western Australian Herbarium 1998-2016). Nearly 17,000 *I.* sp. Bungaroo Creek (S. van Leeuwen 4301) P3 individuals from 2,119 locations are listed on the Rio Tinto database. These span from Mesa A in the west, to Tom Price in the east, with a range of approximately 225 km (Rio Tinto Iron Ore 2016b). The locations in the survey area may represent the northern extent of this species.

Populations of *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 were recorded in association with mesas, low hills and ranges, particularly favouring rocky ledges and breakaways in these habitats. This species has been previously recorded within and adjacent to the survey area (Astron Environmental Services 2016a, 2016b; Biota Environmental Sciences 2003, 2007, 2011, 2012; Rio Tinto Iron Ore 2014). Thirty-eight records of *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 are listed at the WAHerb, with a known range of approximately 175 km (Western Australian Herbarium 1998-2016). Rio Tinto holds 3,443 records consisting of more than 238,000 *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 individuals, with a geographical distribution spanning from Mesa A in the west to Mettawandy, a range of approximately 150 km (Rio Tinto Iron Ore 2016b).

Rhynchosia bungarensis P4 was recorded in locations along the Robe River. This species has previously been recorded from within the survey area (Biota Environmental Sciences 2006a, 2007). Seventy records of *R. bungarensis* P4 are listed at the WAHerb, with a known range of approximately 545 km (Western Australian Herbarium 1998-2016). The Rio Tinto database lists 10,865 individuals from 1,134 locations, distributed between Mesa A in the west, to Yandicoogina, with a range of approximately 360 km (Rio Tinto Iron Ore 2016b).

Four Priority flora species not found in the survey area are considered to have potential to occur: *T.* sp. Pannawonica (B.M. Anderson & M.D. Barrett BMA 89) P1, *E. australis* var. *glabra* P2, *S. weeliwolli* P2 and *E. surreyana* P3. Seasonal conditions were not ideal for locating any of these species.

Triodia sp. Pannawonica (B.M. Anderson & M.D. Barrett BMA 89) P1 is known from only one location, approximately 3 km north-east of the survey area. Due to the dry conditions the *Triodia* spp. were generally not flowering, or had incomplete racemes and spikelets during the surveys. Given the similar appearance of this species to other more common *Triodia* species, it may have been difficult to identify should it occur within the survey area.

Although some *E. australis* were recorded from the survey area, the specimens observed had hairs on the leaf laminae differentiating them from the priority form. Given the small habit (≤10 cm) and often frequent occurrence of *E. australis*, not all individuals were observed and there is potential that *E. australis* var. *glabra* P2 occurred but was not recorded. *Euphorbia australis* var. *glabra* P2 has previously been recorded from Jimmawurrada Creek, but more typically occurs in the vicinity of Tom Price (Western Australian Herbarium 1998-2016).

Stylidium weeliwolli P2 is a delicate annual species that is difficult to observe when not in flower and may not have been present, should it occur, due to the low rainfall prior to the surveys. *Stylidium weeliwolli* P2 has previously been recorded within the survey area, however this location may be erroneous given the unsuitable habitat at the locality.

The small annual tussock grass *E. surreyana* P3 is unlikely to occur during dry conditions and would be difficult to observe post-rainfall if occurring among a grass-dominated lower stratum (such as *Cenchrus* spp. tussock grassland). *Eragrostis surreyana* has previously been recorded in Jimmawurrada Creek (Western Australian Herbarium 1998-2016), which runs through the eastern side of the survey area.

Three species recorded in the survey area were beyond their normal range of distribution, and are considered species of interest. *Cynanchum pedunculatum* typically occurs further east, around Tom Price, or in the northern Kimberley region. *Sauropus crassifolius* has records from the southern Pilbara, as well as the Cape Range, Gascoyne, Murchison, Yalgoo and Geraldton sandplains regions. Records of *S.* sp. Meekatharra (E. Bailey 1-26) extend from the Tom Price area, to the Gascoyne, Cape Range, Murchison and Yalgoo regions (Western Australian Herbarium 1998-2016).

Weed diversity was relatively high in the survey area, with 20 species recorded. The majority of records were from drainage line habitats, with few weeds recorded from mesas or hill habitats. One weed species, **Ocimum basilicum* (Basil) is an unusual record for the area. The nearest previous record on Florabase is the junction of the Pannawonica Road and North West Coastal Highway; the other seven records are from the Broome and Derby areas (Western Australian Herbarium 1998-2016). **Bidens bipinnata* (Bipinnate Beggartick), **Lactuca serriola* (Prickly Lettuce), **O. basilicum* (Basil), **Phoenix dactylifera* (Date Palm), and **Tribulus terrestris* (Caltrop) are new records for the survey area. All other species have been previously recorded within the survey area (Astron Environmental Services 2011, 2016a; Biota Environmental Sciences 2003, 2006a, 2007, 2011, 2012; Rio Tinto Iron Ore 2014).

5.4 Contextual Analysis

Three vegetation associations recorded within the survey area are considered to be of local significance because of uniqueness, restricted occurrence and strong association with Priority flora.

Vegetation association AprTwTsr is likely to represent the '*Triodia sp. Robe River assemblages of mesas of the West Pilbara*' PEC. Floristically and structurally similar vegetation has previously been recorded in the broader area (Astron Environmental Services 2016b; Biota Environmental Sciences 2006a, 2007). Although similar vegetation was recorded during the 2014 to 2016 surveys, the PEC

had not been described during the 2006 and 2007 surveys and therefore the landforms may not consistently conform to the mesas characteristic of the PEC.

One vegetation association, ChAsppGOrGsppPlSsTeTw, has locations with each of the three recorded Priority flora species within it. This vegetation was associated with creeks throughout the survey area and is characterised by *C. hamersleyana* over a dense tall shrub layer of *Acacia, Gossypium* and *Grevillea* species, and *P. labicheoides* and *Stylobasium spathulatum,* over *Triodia epactia* and *T. wiseana*. A total of 20 *I.* sp. Bungaroo Creek P3, 114 *T.* sp. Robe River (M.E. Trudgen et al. MET 12367) P3 and six *R. bungarensis* P4 were recorded from ChAsppGOrGsppPlSsTeTw. This vegetation association accounted for 135.3 ha (2.3%) in the survey area and condition ranged from 'good' to 'excellent' (Trudgen 1988). Similar vegetation has been recorded from other regional surveys (Astron Environmental Services 2011, 2016a, 2016b; Biota Environmental Sciences 2003, 2011). Vegetation described for 'drainage floors and channels' landforms of the Robe land system is considered similar at a broad scale (van Vreeswyk et al. 2004).

A number of permanent and semi-permanent pools occur in the main flow channels of the Robe River, both within and adjacent to the survey area. These pools are typically fringed by vegetation association MaEcCv, characterised by *M. argentea* and *E. camaldulensis* var. *refulgens* in the upper stratum. Springs and pools of the Robe River are listed as 'Wetlands of Subregional Significance', and include the springs and pools occurring from 40 km east of Pannawonica, downstream to the North West Coastal Highway. These significant wetlands are described as 'running spring ecosystems with large deep permanent pools and consist of seasonal and irregular rivers and streams, and freshwater springs, oases and rock pools' (Kendrick 2001). The flora species that occur in MaEcCv are generally habitat restricted to damp and humid conditions and many therefore do not occur beyond this landform and vegetation. Approximately 60% of the *R. bungarensis* P4 individuals recorded in the survey area were observed in MaEcCv.

Vegetation association MaEcCv is also considered to be a GDE due to the dominant presence of *M. argentea* and *E. camaldulensis* var. *refulgens*. Instances of juvenile stands were observed in open shingle beds within the Robe River. Juvenile stands comprising purely of saplings are not necessarily GDE. This vegetation occurs both upstream and downstream of the survey area throughout the Robe River. *Melaleuca argentea* and *E. camaldulensis* var. *refulgens* may be sensitive to changes in groundwater availability and depth. Similar vegetation has been recorded in the broader area (Astron Environmental Services 2016b; Biota Environmental Sciences 2011), and the vegetation is typical of what is described for the minor and major channels within the River land system. The River land system accounts for 2.3% of the Pilbara and the river channels constitute 20% of this area (van Vreeswyk et al. 2004). Condition of this vegetation ranged from 'very good' to 'excellent' (Trudgen 1988) within the survey area, with weeds and grazing being the most common impacts.

The remaining 35 vegetation associations recorded within the survey area are considered to be well represented beyond the survey area and do not support assemblages of species that are unique, on restricted landforms, or of high conservation significance.

Appendix B: Conservation Categories for Flora, Fauna and Ecological Communities, and Categories for Introduced Flora

This page has been left blank intentionally.

Table B.1: Categories and definitions for EPBC Act listed flora and fauna species listed under the *Environment Protection and Biodiversity Conservation Act 1999*.

Conservation category	Definition
Extinct	Taxa with no reasonable doubt that the last member of the species has died.
Extinct in the wild	Taxa known to survive only in cultivation, in captivity or as a naturalized population well outside its past range; or it has not been recorded in its known and/or expected habitat, at appropriated seasons, anywhere in its past range, despite exhaustive surveys over a time frame appropriate to its life cycle and form.
Critically endangered (CR)	Taxa facing an extremely high risk of extinction in the wild in the immediate future, as determined in accordance with the prescribed criteria.
Endangered (E)	Taxa are not critically endangered; and are facing a very high risk of extinction in the wild in the near future, as determined in accordance with the prescribed criteria.
Vulnerable (V)	Taxa are not critically endangered or endangered; and are facing a high risk of extinction in the wild in the medium-term future, as determined in accordance with the prescribed criteria.
Conservation dependent (CD)	Taxa are the focus of a specific conservation program the cessation of which would result in the species becoming vulnerable, endangered or critically endangered; or the following subparagraphs are satisfied: i) the taxa is a species of fish; ii) the taxa is the focus of a management plan that provides management actions necessary to stop the decline of, and support the recovery of, the taxa so that its chances of long term survival in nature are maximized; iii) the management plan is in force under a law of the Commonwealth or of a State or Territory; iv) Cessation of the management plan would adversely affect the conservation status of the taxa Fish includes all taxa of bony fish, sharks, rays, crustaceans, molluscs and other marine organisms, but does not include marine mammals/reptiles.

Three categories exist for listing threatened ecological communities under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

Table B.2: Definitions and criteria for threatened ecological communities listed under the *Environment Protection and Biodiversity Conservation Act 1999*.

Categories of ecological communities	
Critically endangered	If, at that time, it is facing an extremely high risk of extinction in the wild in the immediate future, as determined in accordance with the prescribed criteria.
Endangered	If, at that time, it is not critically endangered and is facing a very high risk of extinction in the wild in the near future, as determined in accordance with the prescribed criteria.
Vulnerable	If, at that time, it is not critically endangered or endangered, and is facing a high risk of extinction in the wild in the medium-term future, as determined in accordance with the prescribed criteria.

Table B.3: Categories of threatened ecological communities (Department of Parks and Wildlife 2016b).

PD: Presumed Destroyed
An ecological community that has been adequately searched for but for which no representative occurrences have been located. The community has been found to be totally destroyed or so extensively modified throughout its range that no occurrence of it is likely to recover its species composition and/or structure in the foreseeable future. An ecological community will be listed as presumed totally destroyed if there are no recent records of the community being extant **and either** of the following applies (A or B): A) Records within the last 50 years have not been confirmed despite thorough searches of known or likely habitats **or** B) All occurrences recorded within the last 50 years have since been destroyed.
CR : Critically Endangered
An ecological community that has been adequately surveyed and found to have been subject to a major contraction in area and/or that was originally of limited distribution and is facing severe modification or destruction throughout its range in the immediate future, or is already severely degraded throughout its range but capable of being substantially restored or rehabilitated. An ecological community will be listed as **Critically Endangered** when it has been adequately surveyed and is found to be facing an extremely high risk of total destruction in the immediate future. This will be determined on the basis of the best available information, by it meeting **any one or more of** the following criteria (A, B or C): A) The estimated geographic range, and/or total area occupied, and/or number of discrete occurrences since European settlement have been reduced by at least 90% **and either or both** of the following apply (i or ii): i) geographic range, and/or total area occupied and/or number of discrete occurrences are continuing to decline such that total destruction of the community is imminent (within approximately 10 years); ii) modification throughout its range is continuing such that in the immediate future (within approximately 10 years) the community is unlikely to be capable of being substantially rehabilitated. B) Current distribution is limited, **and one or more** of the following apply (i, ii or iii): i) geographic range and/or number of discrete occurrences, and/or area occupied is highly restricted and the community is currently subject to known threatening processes which are likely to result in total destruction throughout its range in the immediate future (within approximately 10 years); ii) there are very few occurrences, each of which is small and/or isolated and extremely vulnerable to known threatening processes; iii) there may be many occurrences but total area is very small and each occurrence is small and/or isolated and extremely vulnerable to known threatening processes. C) The ecological community exists only as highly modified occurrences that may be capable of being rehabilitated if such work begins in the immediate future (within approximately 10 years).

En: Endangered

An ecological community that has been adequately surveyed and found to have been subject to a major contraction in area and/or was originally of limited distribution and is in danger of significant modification throughout its range or severe modification or destruction over most of its range in the near future.

An ecological community will be listed as **Endangered** when it has been adequately surveyed and is not Critically Endangered but is facing a very high risk of total destruction in the near future. This will be determined on the basis of the best available information by it meeting **any one or more** of the following criteria (A, B, or C):

A) The geographic range, and/or total area occupied, and/or number of discrete occurrences have been reduced by at least 70% since European settlement **and either or both** of the following apply (i or ii):

i) the estimated geographic range, and/or total area occupied and/or number of discrete occurrences are continuing to decline such that total destruction of the community is likely in the short term future (within approximately 20 years);

ii) modification throughout its range is continuing such that in the short term future (within approximately 20 years) the community is unlikely to be capable of being substantially restored or rehabilitated.

B) Current distribution is limited, **and one or more** of the following apply (i, ii or iii):

i) geographic range and/or number of discrete occurrences, and/or area occupied is highly restricted and the community is currently subject to known threatening processes which are likely to result in total destruction throughout its range in the short term future (within approximately 20 years);

ii) there are few occurrences, each of which is small and/or isolated and all or most occurrences are very vulnerable to known threatening processes;

iii) there may be many occurrences but total area is small and all or most occurrences are small and/or isolated and very vulnerable to known threatening processes.

C) The ecological community exists only as very modified occurrences that may be capable of being substantially restored or rehabilitated if such work begins in the short-term future (within approximately 20 years).

VU: Vulnerable

An ecological community that has been adequately surveyed and is found to be declining and/or has declined in distribution and/or condition and whose ultimate security has not yet been assured and/or a community that is still widespread but is believed likely to move into a category of higher threat in the near future if threatening processes continue or begin operating throughout its range.

An ecological community will be listed as **Vulnerable** when it has been adequately surveyed and is not Critically Endangered or Endangered but is facing a high risk of total destruction or significant modification in the medium to long-term future. This will be determined on the basis of the best available information by it meeting **any one or more of** the following criteria (A, B or C):

A) The ecological community exists largely as modified occurrences that are likely to be capable of being substantially restored or rehabilitated.

B) The ecological community may already be modified and would be vulnerable to threatening processes, is restricted in area and/or range and/or is only found at a few locations.

C) The ecological community may be still widespread but is believed likely to move into a category of higher threat in the medium to long term future because of existing or impending threatening processes.

Possible threatened ecological communities that do not meet survey criteria or that are not adequately defined are added to the Priority Ecological Community Lists under Priorities 1, 2 and 3. Ecological Communities that are adequately known, and are rare but not threatened or meet criteria for Near Threatened, or that have been recently removed from the threatened list, are placed in Priority 4. These ecological communities require regular monitoring. Conservation Dependent ecological communities are placed in Priority 5.

Table B.4: Definitions and criteria for priority ecological communities (Department of Parks and Wildlife 2016b).

P1: Priority One – Poorly-known ecological communities
Ecological communities that are known from very few occurrences with a very restricted distribution (generally ≤5 occurrences or a total area of ≤ 100ha). Occurrences are believed to be under threat either due to limited extent, or being on lands under immediate threat (e.g. within agricultural or pastoral lands, urban areas, active mineral leases) or for which current threats exist. May include communities with occurrences on protected lands. Communities may be included if they are comparatively well-known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under immediate threat from known threatening processes across their range.
P2: Priority Two – Poorly-Known ecological communities
Communities that are known from few occurrences with a restricted distribution (generally ≤10 occurrences or a total area of ≤200ha). At least some occurrences are not believed to be under immediate threat of destruction or degradation. Communities may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements, and/or are not well defined, and appear to be under threat from known threatening processes.
P3: Priority Three – Poorly-Known ecological communities
(i) Communities that are known from several to many occurrences, a significant number or area of which are not under threat of habitat destruction or degradation or: (ii) communities known from a few widespread occurrences, which are either large or with significant remaining areas of habitat in which other occurrences may occur, much of it not under imminent threat, or; (iii) communities made up of large, and/or widespread occurrences, that may or may not be represented in the reserve system, but are under threat of modification across much of their range from processes such as grazing by domestic and/or feral stock, and inappropriate fire regimes. Communities may be included if they are comparatively well known from several localities but do not meet adequacy of survey requirements and/or are not well defined, and known threatening processes exist that could affect them.
P4: Priority Four
Ecological communities that are adequately known, rare but not threatened or meet criteria for Near Threatened, or that have been recently removed from the threatened list. These communities require regular monitoring. (i) Rare. Ecological communities known from few occurrences that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These communities are usually represented on conservation lands. (ii) Near Threatened. Ecological communities that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable. (iii) Ecological communities that have been removed from the list of threatened communities during the past five years.
P5: Priority Five – Conservation dependent ecological communities
Ecological communities that are not threatened but are subject to a specific conservation program, the cessation of which would result in the community becoming threatened within five years.

Table B.5: Conservation codes for Western Australian flora and fauna under the *Wildlife Conservation Act 1950*.

Code	Conservation category	Definition
S1	Schedule 1 of the Wildlife Conservation (Specially Protected Fauna) Notice and Wildlife Conservation (Rare Flora) Notice under the *Wildlife Conservation Act 1950*.	Taxa that is rare or likely to become extinct, as critically endangered taxa.
S2	Schedule 2 of the Wildlife Conservation (Specially Protected Fauna) Notice and Wildlife Conservation (Rare Flora) Notice under the *Wildlife Conservation Act 1950*.	Taxa that is rare or likely to become extinct, as endangered taxa.
S3	Schedule 3 of the Wildlife Conservation (Specially Protected Fauna) Notice and Wildlife Conservation (Rare Flora) Notice under the *Wildlife Conservation Act 1950*.	Taxa that is rare or likely to become extinct, as vulnerable taxa.
S4	Schedule 4 of the Wildlife Conservation (Specially Protected Fauna) Notice and Wildlife Conservation (Rare Flora) Notice under the *Wildlife Conservation Act 1950*.	Taxa that is presumed to be extinct.
S5	Schedule 5 of the Wildlife Conservation (Specially Protected Fauna) Notice under the *Wildlife Conservation Act 1950*.	Birds that are subject to international agreements relating to the protection of migratory birds.
S6	Schedule 6 of the Wildlife Conservation (Specially Protected Fauna) Notice under the *Wildlife Conservation Act 1950*.	Fauna that are of special conservation need being species dependent on ongoing conservation intervention.
S7	Schedule 7 of the Wildlife Conservation (Specially Protected Fauna) Notice under the *Wildlife Conservation Act 1950*.	Declared to be fauna that is in need of special protection, otherwise than for the reasons mentioned.

Note: Schedules 5, 6, and 7 are only related to conservation significant fauna.

Threatened fauna and flora (Schedule 1) are further ranked by the Department according to their level of threat using IUCN Red List criteria:

- CR: Critically Endangered - considered to be facing an extremely high risk of extinction in the wild.
- EN: Endangered - considered to be facing a very high risk of extinction in the wild.
- VU: Vulnerable - considered to be facing a high risk of extinction in the wild.

Taxa that have not yet been adequately surveyed to be listed under Schedule 1 or 2 are added to the Priority Flora and Priority Fauna Lists under Priorities 1, 2 or 3. These three categories are ranked in order of priority for survey and evaluation of conservation status so that consideration can be given to their declaration as threatened flora or fauna. Taxa that are adequately known, are rare but not threatened, or meet criteria for Near Threatened, or that have been recently removed from the threatened list for other than taxonomic reasons, are placed in Priority 4. These taxa require regular monitoring. Conservation Dependent species are placed in Priority 5.

Table B.6: Priority species under Western Australian *Wildlife Conservation Act 1950*.

P1: Priority One – Poorly known taxa
Taxa that are known from one or a few collections or sight records (generally five or less) which are potentially at risk. All occurrences are either: very small; or on lands not managed for conservation, e.g. agricultural or pastoral lands, urban areas, road and rail reserves, gravel reserves, and active mineral leases; or otherwise under threat of habitat destruction or degradation. Taxa may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements and appear to be under immediate threat from known threatening processes. Such taxa are in urgent need of further survey.
P2: Priority Two – Poorly known taxa
Taxa that are known from one or a few collections (generally five or less), some of which are on lands managed primarily for nature conservation, e.g. national parks, conservation parks, nature reserves, and other lands with secure tenure being managed for conservation. Taxa may be included if they are comparatively well known from one or more localities but do not meet adequacy of survey requirements and appear to be under threat from known threatening processes. Such taxa are in urgent need of further survey.
P3: Priority Three – Poorly known taxa
Taxa that are known from several localities and does not appear under imminent threat, or from few but widespread localities with either large population size or significant remaining areas of apparently suitable habitat, much of it not under imminent threat. Taxa may be included if they are comparatively well known from several localities but do not meet adequacy of survey requirements and known threatening processes exist that could affect them. Such taxa are in urgent need of further survey.
P4: Priority Four: Rare, near threatened and other taxa in need of monitoring
(a) Rare. Taxa that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These taxa are usually represented on conservation lands. (b) Near Threatened. Taxa that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable. (c) Taxa that have been removed from the list of threatened species during the past five years for reasons other than taxonomy.
P5: Priority Five: Conservation dependent taxa
Taxa that are not threatened but are subject to a specific conservation program, the cessation of which would result in the taxa becoming threatened within five years.

The management of introduced flora species in Western Australia is regulated through the *Biosecurity and Agriculture Management Act 2007* (BAM Act). A list of declared pests, including 'pest' plants is provided under the BAM Act, which has been updated to incorporate a number of other Acts that are administered by DAFWA (2016). Declared pests can fall into two categories: one that relates to the prevention of introducing the species or eradicating it; and the other relates to managing the species and whether it can be kept (i.e. for scientific purposes, education or other purpose).

The threat and risk posed to site-specific biodiversity values, influences to rehabilitation success, primary production, infrastructure assets or human health will differ depending on the unique characteristics of each site and the associated land management practice or operation. Therefore site or project specific weed assessments and priorities should be reviewed for each project.

As per introduced flora species, the BAM Act seeks to establish a modern biosecurity regulatory scheme to prevent serious animal pests from entering the State and becoming established, and to minimise the spread and impact of any that are already present within the State. Declared animal pests fall into three categories as Gazetted under the BAM Act (DAFWA 2016). These categories are outlined in Table B.7.

Table B.7: Declared pests categories as gazetted under the *Biosecurity and Agriculture Management Act 2007* (Department of Agriculture and Food 2016).

Category	Description
C1 (Exclusion)	Pests will be assigned to this category if they are not established in Western Australia and control measures are to be taken, including border checks, in order to prevent them entering and establishing in the State.
C2 (Eradication)	Pests will be assigned to this category if they are present in Western Australia in low enough numbers or in sufficiently limited areas that their eradication is still a possibility.
C3 (Management)	Pests will be assigned to this category if they are established in Western Australia but it is feasible, or desirable, to manage them in order to limit their damage. Control measures can prevent a C3 pest from increasing in population size or density or moving from an area in which it is established into an area which currently is free of that pest.

East Perth WA 6004

Attention: Natalie Cadd

Dear Natalie Cadd,

REQUEST FOR THREATENED AND PRIORITY FLORA INFORMATION

I refer to your request of 14 September 2015 for Threatened (Declared Rare) and Priority Flora information in the Pannawonica area. The search was conducted within the area of the coordinates you submitted with an additional 20km buffer.

A search was undertaken for this area of **(1)** the Department's *Threatened (Declared Rare) and Priority Flora* database (for results, see "TPFL" – coordinates are GDA94), **(2)** the *Western Australian Herbarium Specimen* database for Threatened and Priority flora species opportunistically collected in the area of interest (for results, see "WAHERB"- coordinates are GDA94 – see condition number 4 in the attached 'Conditions in Respect of Supply') and **(3)**, the Department's *Threatened and Priority Flora List* [this list is searched using 'place names'. This list, which may also be used as a species target list, contains species that are declared rare (Conservation Code R or X for those presumed to be extinct), poorly known (Conservation Codes 1, 2 or 3), or require monitoring (Conservation Code 4) – for results, *if any*, see "TP List"]. The results are attached electronically to this email.

Attached also are the conditions under which this information has been supplied. Your attention is specifically drawn to the ninth point, which refers to the requirement to undertake field investigations for the accurate determination of Threatened and Priority flora occurrence at a site. *The information supplied should be regarded as an indication only of the Threatened and Priority flora that may be present and may be used as a target list in any surveys undertaken.*

The information provided does not preclude you from obtaining and complying with, where necessary, land clearing approvals from other agencies.

An invoice for $ 300 (plus GST) to supply this information will be forwarded.

It would be appreciated if any populations of Threatened and Priority flora you encounter in the area could be reported to this Department to ensure their ongoing management.

If you require any further details, or wish to discuss Threatened and Priority flora management, please contact Dr Ken Atkins, Manager, Species and Communities Branch, on (08) 9334 0455.

Yours faithfully

Jessica Donaldson

Department of **Parks and Wildlife**

THREATENED AND PRIORITY FLORA INFORMATION

Conditions with Respect to the Supply of Information

- The data supplied may not be provided to any other organisations, nor be used for any purpose other than for the project for which it has been originally provided for; without the prior consent of the Executive Director, Department of Parks and Wildlife.
- Specific locality information for threatened flora is regarded as confidential, and should be treated as such by receiving organisations. Specific locality information for threatened flora may not be used in reports without the written permission of the Executive Director, Department of Parks and Wildlife. Reports may only show generalised locations at a low resolution or, where necessary, show specific locations without identifying species. Species and Communities Branch is to be contacted for guidance on the presentation of threatened flora information.
- The Department of Parks and Wildlife respects the privacy of private landowners who may have threatened and priority flora on their property. Threatened and priority flora locations identified in the data as being on private property should be treated in confidence, and contact with property owners must only be made through the Department of Parks and Wildlife.
- The development of the Perth Herbarium database was not originally intended for electronic mapping (eg. GIS ArcView). The latitude and longitude coordinates for each entry are not verified prior to being data based. It is only in recent times that collections have been submitted with GPS coordinates. Therefore, be aware when using this data in ArcView that some records may not plot to the locality description given with each collection.
- Acknowledgment of the Department of Parks and Wildlife as the source of data is to be made in any published material and cited as Parks and Wildlife (2015) Threatened and Priority Flora Database Search for [search area] accessed on the [date of search]. Prepared by the Species and Communities Branch for [Requesters name and company] for [purpose of search].
- Copies of all such publications are to be forwarded to the Department of Parks and Wildlife, Attention; the Manager, Species and Communities Branch.

Disclaimers with Respect to the Supply of Information

- Receiving organisations should note that while every effort has been made to prevent errors and omissions in the data, they may be present. The Department of Parks and Wildlife accepts no responsibility for this.
- Receiving organisations must also recognise that the database is subject to continual updating and amendment, and such considerations should be taken into account by the user.
- It should be noted that the supplied data does not necessarily represent a comprehensive listing of the threatened flora of the area in question. Its comprehensiveness is dependent on the amount of surveys carried out within a specified area. The receiving organisation should consider engaging a botanist, if required, to undertake a survey of the area under consideration.

ABBREVIATIONS USED IN THE WESTERN AUSTRALIAN HERBARIUM DATABASE

Geocode Method - The method that was used to record the latitude and longitude.

Auto - Indicates that the coordinate data in the record was created automatically (i.e. by software), usually by creating a coordinate from information provided in the Nearest Named Place or Locality textual description fields.

GAP - Acronym for "Generalised Arbitrary Point" as used in HISPID. GAP indicates that the coordinate data was obtained manually from the Nearest Named Place or Locality textual description fields.

GPS - Acronym for "Global Positioning System". GPS indicates that the coordinate data in the record was obtained from a GPS unit by the collector of the specimen.

MAN - Shorthand for manual. MAN indicates that the coordinate data was created by hand using some method not allowed for by one of the other manual Geocode Method values, in particular, TOPO, GAP, or GPS.

TOPO - Shorthand for topographic map. TOPO indicates that the coordinate data was obtained by plotting textual locality details against a topographic map.

None - Indicates that no coordinate data has been supplied by the collector.

Unknown - Indicates that there is no known method for determining the coordinate data. Should be used if the collector provided no indication of how they sampled the specimen's coordinate data.

PREC (Precision) - precision ratings for coordinates.

Precision 1: Absolutely precise (to nearest 100m or nearest second) and must be GPS determined. For example 35°26'42"S 123°40'26"E

Precision 2: Falling within a diameter of 3km (ca 2 minutes) or if no GPS mentioned in collecting notes. (The location must be able to be pinpointed on a 1:250 000 map, a spot locality. For example 35°26'42"S 123°40'26"E

Precision 3: Falling within a diameter of 10km (ca 7 minutes) or for degrees and minutes, where seconds have not been given. For example 35°26'_"S 123°40'_"E

Precision 4: Falling within a diameter of ca 50km (30 minutes). For example 35°26'_"S 123°40'_"E

Precision 5: Where a location is a prescribed large geographical area within a state or only the state is given. Diameter is greater than 50km. For example 35°_'_"S 123°_'_"E

Precision 6: used when localities are New Holland, Eastern Australia or Not given. Fields will be left blank.

Department of Parks and Wildlife

CONSERVATION CODES

For Western Australian Flora and Fauna

T Threatened species

Listed as Specially Protected under the *Wildlife Conservation Act 1950,* published under Schedule 1 of the Wildlife Conservation (Specially Protected Fauna) Notice for Threatened Fauna and Wildlife Conservation (Rare Flora) Notice for Threatened Flora (which may also be referred to as Declared Rare Flora).

- Fauna that is rare or likely to become extinct are declared to be fauna that is in need of special protection
- Flora that are extant and considered likely to become extinct, or rare and therefore in need of special protection, are declared to be rare flora

Species* which have been adequately searched for and are deemed to be, in the wild, either rare, at risk of extinction, or otherwise in need of special protection, and have been gazetted as such.
The assessment of the conservation status of these species is based on their national extent.

X Presumed extinct species

Listed as Specially Protected under the *Wildlife Conservation Act 1950,* published under Schedule 2 of the Wildlife Conservation (Specially Protected Fauna) Notice for Presumed Extinct Fauna and Wildlife Conservation (Rare Flora) Notice for Presumed Extinct Flora (which may also be referred to as Declared Rare Flora).

Species which have been adequately searched for and there is no reasonable doubt that the last individual has died, and have been gazetted as such.

IA Migratory birds protected under an international agreement

Listed as Specially Protected under the *Wildlife Conservation Act 1950,* listed under Schedule 3 of the Wildlife Conservation (Specially Protected Fauna) Notice.

Birds that are subject to an agreement between the government of Australia and the governments of Japan (JAMBA), China (CAMBA) and The Republic of Korea (ROKAMBA), relating to the protection of migratory birds.

S Other specially protected fauna

Listed as Specially Protected under the *Wildlife Conservation Act 1950.* Fauna declared to be in need of special protection, otherwise than for the reasons mentioned for Schedules 1, 2 or 3, are published under Schedule 4 of the Wildlife Conservation (Specially Protected Fauna) Notice.

Threatened Fauna and Flora are ranked according to their level of threat using IUCN Red List categories and criteria. *For example:* Carnaby's Cockatoo (*Calyptorynchus latirostris*) is listed as 'Specially Protected' under the *Wildlife Conservation Act 1950,* published under Schedule 1, and referred to as a 'Threatened' species with a ranking of 'Endangered'.

CR Critically Endangered - considered to be facing an extremely high risk of extinction in the wild.

EN Endangered - considered to be facing a very high risk of extinction in the wild.

VU Vulnerable - considered to be facing a high risk of extinction in the wild.

A list of the current rankings can be downloaded from the Parks and Wildlife Threatened Species and Communities webpage at http://dpaw.wa.gov.au/plants-and-animals/threatened-species-and-communities/

P Priority species

Species that maybe threatened or near threatened but are data deficient, have not yet been adequately surveyed to be listed under the Schedules of the Wildlife Conservation (Specially Protected Fauna) Notice or the Wildlife Conservation (Rare Flora) Notice, are added to the Priority Fauna or Priority Flora Lists under Priorities 1, 2 or 3. These three categories are ranked in order of priority for survey and evaluation of conservation status so that consideration can be given to their declaration as threatened flora or fauna. Species that are adequately known, are rare but not threatened, or meet criteria for near threatened, or that have been recently removed from the threatened list for other than taxonomic reasons, are placed in Priority 4. These species require regular monitoring. Conservation dependent species that are subject to a specific conservation program are placed in Priority 5.

Assessment of Priority codes is based on the Western Australian distribution of the species, unless the distribution in WA is part of a contiguous population extending into adjacent States, as defined by the known spread of locations.

1: Priority One: Poorly-known species

Species that are known from one or a few locations (generally five or less) which are potentially at risk. All occurrences are either: very small; or on lands not managed for conservation, e.g. agricultural or pastoral lands, urban areas, road and rail reserves, gravel reserves and active mineral leases; or otherwise under threat of habitat destruction or degradation. Species may be included if they are comparatively well known from one or more locations but do not meet adequacy of survey requirements and appear to be under immediate threat from known threatening processes. Such species are in urgent need of further survey.

2: Priority Two: Poorly-known species

Species that are known from one or a few locations (generally five or less), some of which are on lands managed primarily for nature conservation, e.g. national parks, conservation parks, nature reserves and other lands with secure tenure being managed for conservation. Species may be included if they are comparatively well known from one or more locations but do not meet adequacy of survey requirements and appear to be under threat from known threatening processes. Such species are in urgent need of further survey.

3: Priority Three: Poorly-known species

Species that are known from several locations, and the species does not appear to be under imminent threat, or from few but widespread locations with either large population size or significant remaining areas of apparently suitable habitat, much of it not under imminent threat. Species may be included if they are comparatively well known from several locations but do not meet adequacy of survey requirements and known threatening processes exist that could affect them. Such species are in need of further survey.

4: Priority Four: Rare, Near Threatened and other species in need of monitoring

(a) Rare. Species that are considered to have been adequately surveyed, or for which sufficient knowledge is available, and that are considered not currently threatened or in need of special protection, but could be if present circumstances change. These species are usually represented on conservation lands.
(b) Near Threatened. Species that are considered to have been adequately surveyed and that do not qualify for Conservation Dependent, but that are close to qualifying for Vulnerable.
(c) Species that have been removed from the list of threatened species during the past five years for reasons other than taxonomy.

5: Priority Five: Conservation Dependent species

Species that are not threatened but are subject to a specific conservation program, the cessation of which would result in the species becoming threatened within five years.

*Species includes all taxa (plural of taxon - a classificatory group of any taxonomic rank, e.g. a family, genus, species or any infraspecific category i.e. subspecies, variety or forma).

DEPARTMENT OF ENVIRONMENT AND CONSERVATION

THREATENED AND PRIORITY ECOLOGICAL COMMUNITIES INFORMATION

CONDITIONS IN RESPECT OF SUPPLY OF INFORMATION

1. All requests for data are to be made in writing to the Director General, Department of Environment and Conservation Attention: Species and Communities Branch

2. The data supplied may not be supplied to other organisations, nor be used for any purpose other than for the project for which they have been provided, without the prior written consent of the data custodian (Val English), Species and Communities Branch.

3. Specific locality information for threatened and priority ecological communities (TECs/PECs) is regarded as confidential, and should be treated as such by receiving organisations. Specific locality information for TECs/PECs may not be used in public reports without the written permission of the Director General, Department of Environment and Conservation. Publicly available reports may only show generalised locations (ie buffer locations). The TEC database manager is to be contacted for guidance on the presentation of TEC/PEC information.

4. Note that the Department of Environment and Conservation respects the privacy of private landowners who may have threatened and priority ecological communities on their property. Locations of TECs/PECs identified in the data as being on private property should be treated in confidence, and contact with property owners made through the Department of Environment and Conservation.

5. Receiving organisations should note that while every effort has been made to prevent errors and omissions in the data provided, they may be present. The Department of Environment and Conservation accepts no responsibility for this.

6. Receiving organisations must also recognise that the Threatened Ecological Communities database is subject to continual updating and amendment, and such considerations should be taken into account by the user.

7. It should be noted that the supplied data do not necessarily represent a comprehensive listing of the threatened and priority ecological communities of the area in question. Its comprehensiveness is dependant on the amount of survey carried out within the specified area. Private property has been relatively little surveyed. The receiving organisation should employ a consultant, if there is any likelihood of the presence of any threatened or priority ecological community, to undertake a survey of the area under consideration.

8. Acknowledgment of the Department of Environment and Conservation as source of the data is to be made in any published material. Copies of all such publications are to be forwarded to the Department of Environment and Conservation, Attention: Manager, Species and Communities Branch.

Threatened and Priority Ecological Community buffers in WA

UNDER NO CIRCUMSTANCES IS THIS DATA TO BE PROVIDED TO ANY THIRD PARTIES, for more details see conditions for the supply of this information.

Citation

Title: Threatened and Priority Ecological Community buffers in WA

Custodian: Department of Environment & Conservation

Description

Abstract: Ecological communities throughout WA that are "Presumed Totally Destroyed", "Critically Endangered", "Endangered", "Vulnerable", "Priority 1-5", "Lower Risk" and "Not evaluated". Communities are based on various life-forms including plants, invertebrates and micro-organisms.

Geographical Bounding Box

North: -14.788854

South: -35.005719

East: 128.870214

West: 113.765525

Data Currency and Status

Beginning Date: 1/1/94

Ending Date: current

Maintenance/Update: As requested

Access

Stored Data Format: ESRI shapefile

Coordinate System: GCS_GDA_1994

Access Constraints:	**Digital data is only available with written permission of the custodian. In addition, some occurrence data eg. location of sites on private land, is password restricted.**

Data Quality

Positional Accuracy:	**Point location data within occurrences usually from GPS fix, usually within 100 metres. Some digitized from hard copy.**
Attribute Accuracy:	**Not documented.**
Logical Consistency:	**Not documented.**
Completeness:	**Information on specific communities was obtained from regional, subregional or specific habitat surveys of floristic communities, invertebrate communities, wetland assemblages and communities of micro-organisms.**

Attributes List:

Name	Description
BDY_ID	Associated boundary polygon unique identifier
OCC_UNIQUE	Unique occurrence identifier
COM_ID	Shortened community name identifier
COM_NAME	Community name
CT_DESC	State listed Category of Threat
S_ID_COUNT	Number of Site IDs within a buffer
FIRST_S_ID	First site identifier
LAST_S_ID	Last site identifier
BUFFER	Buffer radius from site ID or boundary in metres

General Information:

Priority Ecological Communities

- There are 284 known PECs and subtypes , 271 (~95%) of these on the TEC/PEC database
- The location of priority communities is good, but not complete across the state
- There is a formal list of PECs at http://www.dec.wa.gov.au/content/view/849/2017/
- Many PECs are awaiting endorsement as TECs

buffers

- The buffer radius around each occurrence of a TEC or PEC is included to help ensure that developments with potential to impact groundwater or surface water are picked up.
- For wetland TEC or PECs we seek to include an area within the buffer zone that is intended to help protect groundwater and surface water. The area required to protect different types of wetlands from a variety of hydrological impacts will, of course, differ.

- For upland TEC or PECs that are believed not to be groundwater dependent, the buffer area radius encompasses the TEC or PEC site location recorded in the TEC database, and extends at least to the furthest point in the occurrence. This is to ensure that the 'buffer' area encompasses at least the entire TEC or PEC. This means that some linear occurrences may need a larger buffer radius to encompass the entire occurrence.
- Occurrences with a buffer distance of 0 are no longer extant.

Conservation Codes
T - Rare or likely to become extinct
X - Presumed extinct
IA - Protected under international agreement
S - Other specially protected fauna
1 - Priority 1
2 - Priority 2
3 - Priority 3
4 - Priority 4
5 - Priority 5

[1] For NatureMap's purposes, species flagged as endemic are those whose records are wholely contained within the search area. Note that only those records complying with the search criterion are included in the calculation. For example, if you limit records to those from a specific datasource, only records from that datasource are used to determine if a species is restricted to the query area.

Australian Government

Department of the Environment

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected.

Information on the coverage of this report and qualifications on data supporting this report are contained in the caveat at the end of the report.

Information is available about Environment Assessments and the EPBC Act including significance guidelines, forms and application process details.

Report created: 25/07/16 16:03:50

Summary

Matters of National Environmental Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance:	None
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	None
Listed Threatened Ecological Communities:	None
Listed Threatened Species:	8
Listed Migratory Species:	7

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at http://www.environment.gov.au/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Land:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	12
Whales and Other Cetaceans:	None
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Commonwealth Reserves Marine:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have nominated.

State and Territory Reserves:	None
Regional Forest Agreements:	None
Invasive Species:	10
Nationally Important Wetlands:	None
Key Ecological Features (Marine)	None

Details

Matters of National Environmental Significance

Listed Threatened Species		[Resource Information]
Name	Status	Type of Presence
Birds		
Pezoporus occidentalis Night Parrot [59350]	Endangered	Species or species habitat may occur within area
Rostratula australis Australian Painted Snipe [77037]	Endangered	Species or species habitat may occur within area
Mammals		
Dasyurus hallucatus Northern Quoll, Digul [331]	Endangered	Species or species habitat known to occur within area
Macroderma gigas Ghost Bat [174]	Vulnerable	Species or species habitat likely to occur within area
Macrotis lagotis Greater Bilby [282]	Vulnerable	Species or species habitat likely to occur within area
Rhinonicteris aurantia (Pilbara form) Pilbara Leaf-nosed Bat [82790]	Vulnerable	Roosting known to occur within area
Plants		
Lepidium catapycnon Hamersley Lepidium, Hamersley Catapycnon [9397]	Vulnerable	Species or species habitat likely to occur within area
Reptiles		
Liasis olivaceus barroni Olive Python (Pilbara subspecies) [66699]	Vulnerable	Species or species habitat known to occur within area

Listed Migratory Species		[Resource Information]
* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.		
Name	Threatened	Type of Presence
Migratory Marine Birds		
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area
Migratory Terrestrial Species		
Hirundo rustica Barn Swallow [662]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
[Motacilla cinerea](#)		
Grey Wagtail [642]		Species or species habitat may occur within area
[Motacilla flava](#)		
Yellow Wagtail [644]		Species or species habitat may occur within area
Migratory Wetlands Species		
[Charadrius veredus](#)		
Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
[Glareola maldivarum](#)		
Oriental Pratincole [840]		Species or species habitat may occur within area
[Pandion haliaetus](#)		
Osprey [952]		Species or species habitat known to occur within area

Other Matters Protected by the EPBC Act

Listed Marine Species [Resource Information]

* Species is listed under a different scientific name on the EPBC Act - Threatened Species list.

Name	Threatened	Type of Presence
Birds		
[Apus pacificus](#)		
Fork-tailed Swift [678]		Species or species habitat likely to occur within area
[Ardea alba](#)		
Great Egret, White Egret [59541]		Species or species habitat known to occur within area
[Ardea ibis](#)		
Cattle Egret [59542]		Species or species habitat may occur within area
[Charadrius veredus](#)		
Oriental Plover, Oriental Dotterel [882]		Species or species habitat may occur within area
[Glareola maldivarum](#)		
Oriental Pratincole [840]		Species or species habitat may occur within area
[Haliaeetus leucogaster](#)		
White-bellied Sea-Eagle [943]		Species or species habitat likely to occur within area
[Hirundo rustica](#)		
Barn Swallow [662]		Species or species habitat may occur within area
[Merops ornatus](#)		
Rainbow Bee-eater [670]		Species or species habitat may occur within area
[Motacilla cinerea](#)		
Grey Wagtail [642]		Species or species habitat may occur within area
[Motacilla flava](#)		
Yellow Wagtail [644]		Species or species habitat may occur within area

Name	Threatened	Type of Presence
Pandion haliaetus		
Osprey [952]		Species or species habitat known to occur within area
Rostratula benghalensis (sensu lato)		
Painted Snipe [889]	Endangered*	Species or species habitat may occur within area

Extra Information

Invasive Species [Resource Information]

Weeds reported here are the 20 species of national significance (WoNS), along with other introduced plants that are considered by the States and Territories to pose a particularly significant threat to biodiversity. The following feral animals are reported: Goat, Red Fox, Cat, Rabbit, Pig, Water Buffalo and Cane Toad. Maps from Landscape Health Project, National Land and Water Resouces Audit, 2001.

Name	Status	Type of Presence
Birds		
Columba livia		
Rock Pigeon, Rock Dove, Domestic Pigeon [803]		Species or species habitat likely to occur within area
Mammals		
Capra hircus		
Goat [2]		Species or species habitat likely to occur within area
Equus asinus		
Donkey, Ass [4]		Species or species habitat likely to occur within area
Felis catus		
Cat, House Cat, Domestic Cat [19]		Species or species habitat likely to occur within area
Mus musculus		
House Mouse [120]		Species or species habitat likely to occur within area
Oryctolagus cuniculus		
Rabbit, European Rabbit [128]		Species or species habitat likely to occur within area
Vulpes vulpes		
Red Fox, Fox [18]		Species or species habitat likely to occur within area
Plants		
Cenchrus ciliaris		
Buffel-grass, Black Buffel-grass [20213]		Species or species habitat likely to occur within area
Parkinsonia aculeata		
Parkinsonia, Jerusalem Thorn, Jelly Bean Tree, Horse Bean [12301]		Species or species habitat likely to occur within area
Prosopis spp.		
Mesquite, Algaroba [68407]		Species or species

Name	Status	Type of Presence
		habitat likely to occur within area

Caveat

The information presented in this report has been provided by a range of data sources as acknowledged at the end of the report.

This report is designed to assist in identifying the locations of places which may be relevant in determining obligations under the Environment Protection and Biodiversity Conservation Act 1999. It holds mapped locations of World and National Heritage properties, Wetlands of International and National Importance, Commonwealth and State/Territory reserves, listed threatened, migratory and marine species and listed threatened ecological communities. Mapping of Commonwealth land is not complete at this stage. Maps have been collated from a range of sources at various resolutions.

Not all species listed under the EPBC Act have been mapped (see below) and therefore a report is a general guide only. Where available data supports mapping, the type of presence that can be determined from the data is indicated in general terms. People using this information in making a referral may need to consider the qualifications below and may need to seek and consider other information sources.

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

For species where the distributions are well known, maps are digitised from sources such as recovery plans and detailed habitat studies. Where appropriate, core breeding, foraging and roosting areas are indicated under 'type of presence'. For species whose distributions are less well known, point locations are collated from government wildlife authorities, museums, and non-government organisations; bioclimatic distribution models are generated and these validated by experts. In some cases, the distribution maps are based solely on expert knowledge.

Only selected species covered by the following provisions of the EPBC Act have been mapped:

- migratory and
- marine

The following species and ecological communities have not been mapped and do not appear in reports produced from this database:

- threatened species listed as extinct or considered as vagrants
- some species and ecological communities that have only recently been listed
- some terrestrial species that overfly the Commonwealth marine area
- migratory species that are very widespread, vagrant, or only occur in small numbers

The following groups have been mapped, but may not cover the complete distribution of the species:

- non-threatened seabirds which have only been mapped for recorded breeding sites
- seals which have only been mapped for breeding sites near the Australian continent

Such breeding sites may be important for the protection of the Commonwealth Marine environment.

Appendix E: Vegetation Classification and Condition Scales

This page has been left blank intentionally.

Table E.1: Vegetation Classification System (Specht 1970) as modified by Aplin (1979).

Stratum	70-100% cover	30-70% cover	10-30% cover	2-10% cover	<2% cover
Trees > 30 m	Tall closed forest	Tall open Forest	Tall woodland	Tall open woodland	Scattered tall trees
Trees 10-30 m	Closed forest	Open forest	Woodland	Open woodland	Scattered trees
Trees < 10 m	Low closed forest	Low open forest	Low woodland	Low open woodland	Scattered low trees
Shrubs > 2 m	Tall closed scrub	Tall open scrub	Tall shrubland	Tall open shrubland	Scattered tall shrubs
Shrubs 1-2 m	Closed heath	Open heath	Shrubland	Open shrubland	Scattered shrubs
Shrubs < 1 m	Low closed heath	Low open heath	Low shrubland	Low open shrubland	Scattered low shrubs
Hummock grasses	Closed hummock grassland	Hummock grassland	Open hummock grassland	Very open hummock grassland	Scattered hummock grasses
Grasses, sedges, herbs	Closed tussock grassland/ sedgeland/ herbland	Tussock grassland/ sedgeland/ herbland	Open tussock grassland/ sedgeland/ herbland	Very open tussock grassland/ sedgeland/ herbland	Scattered tussock grasses/ sedges/ herbs

Table E.2: Summary of vegetation condition scale, as adapted from Trudgen (1988).

Vegetation condition	Condition description
Excellent	Pristine or nearly so, no obvious signs of damage caused by human activities since European settlement.
Very Good	Some relatively slight signs of damage caused by human activities since European settlement. For example, some signs of damage to tree trunks caused by repeated fire, the presence of some relatively non-aggressive weeds, or occasional vehicle tracks.
Good	More obvious signs of damage caused by human activity since European settlement, including some obvious impact on the vegetation structure such as that caused by low levels of grazing or slightly aggressive weeds.
Poor	Still retains basic vegetation structure or ability to regenerate to it after very obvious impacts of human activities since European settlement, such as grazing, partial clearing, frequent fires or aggressive weeds.
Very Poor	Severely impacted by grazing, very frequent fires, clearing or a combination of these activities. Scope for some regeneration but not to a state approaching good condition without intensive management. Usually with a number of weed species present including very aggressive species.
Completely Degraded	Areas that are completely or almost completely without native species in the structure of their vegetation; i.e. areas that are cleared or 'parkland cleared' with their flora comprising weed or crop species with isolated native trees or shrubs.

Appendix H: Threatened and Priority Flora Species Likelihood of Occurrence within the Survey Area

This page has been left blank intentionally.

Table H.1: Likelihood of occurrence of Threatened and Priority flora recorded within 20 km of the survey area (NatureMap (Department of Parks and Wildlife 2016a), TPFL (Department of Parks and Wildlife 2016c), TP List (Department of Parks and Wildlife 2016d), WAHerb (Department of Parks and Wildlife 2016e)). The TP List database is searched using place names. As a result, many of the records obtained from this database may occur beyond 50 km of the survey area.

Species	Habit and flowering information	Life Form	Habitat	Likelihood of occurrence	
				Pre-survey	Post-survey
Threatened					
Thyrptomene wittwerii	Spreading or rounded shrub, 0.5 m to 1.5 (-2.1) m high. White-cream flowers in April or July or August.	Perennial	Skeletal red stony soils. Breakaways, stony creek beds.	Unlikely	Unlikely
Priority 1					
Bothriochloa decipiens var. *cloncurrensis*	Herbaceous grass, to 1.4 m high.	Perennial	Seasonally damp depression. Stony clay plain.	Potential	Unlikely
Triodia sp. Pannawonica (B.M. Anderson & M.D. Barrett BMA 89)	Hummock grass.	Perennial	Shale	Potential	Potential
Priority 2					
Dicladanthera glabra	Spreading herb or shrub, to 0.6 (-1) m high.	Perennial	Alluvium. Along watercourses, near rock pools.	Potential	Unlikely
Euphorbia australis var. *glabra*	Herb	Annual	Creek banks. Red brown loam, some pebbles.	Potential	Potential
Pentalepis trichodesmoides subsp. *hispida*	Multi-stemmed shrub to 0.8 m high. Flowers July to October.	Perennial	Summits of ridges, cobbled slopes, outcrops, banks of creeks and edges of basalt screes.	Potential	Unlikely
Stylidium weeliwolli	Herb, 0.1 m to 0.25 m high, throat appendages 4, rod-shaped. Pink and red flowers from August to September.	Annual	Gritty sand soil, sandy clay. Edge of watercourses.	Likely	Potential

Species	Habit and flowering information	Life Form	Habitat	Likelihood of occurrence	
				Pre-survey	Post-survey
Priority 3					
Eragrostis surreyana	Grass. Culms erect or decumbent, 5-8 (-13) cm tall. Panicle linear, 9 cm to 13 cm long; 0.5 cm to 1.3 cm wide.	Annual	Soak area. Red-brown sandy clay.	Potential	Potential
Indigofera sp. Bungaroo Creek (S. van Leeuwen 4301)	Shrub or herb 0.2 m to 2 m high. May to July.	Perennial	Drainage lines, creeks in hills or plains. Brown silty loam.	Potential	Recorded
Pleurocarpaea gracilis	Rounded shrub to 0.5 m. June to October.	Perennial	Summit of rounded hill, slopes, skeletal red gritty soil over massive Brockman Iron Formation rock.	Potential	Unlikely
Solanum albostellatum	Low herb or shrub to 0.2 m high. March.	Perennial	Floodplains, slight bedrock outcrops. Red brown silty clay loam. Cracking clay.	Potential	Unlikely
Terminalia supranitifolia	Spreading tangled tree or shrub to 3 m high.	Perennial	Sandy soils or among basalt rocks.	Potential	Unlikely
Triodia sp. Robe River (M.E. Trudgen et al. MET 12367)	Hummock grass. June, July, September.	Perennial	Mesa tops and edges; breakaways; hillsides and hilltops.	Likely	Recorded
Priority 4					
Goodenia nuda	Erect to ascending herb to 0.5 m high. Yellow flowers, April to August.	Short-lived perennial	Alluvial soils over ironstone, floodplains, valleys, watercourses, orange-brown alluvial sand over ironstone.	Potential	Unlikely
Rhynchosia bungarensis	Compact, prostrate shrub, to 0.5 m high. May to November.	Short-lived perennial	Pebbly, shingly coarse sand amongst boulders. Banks of flow line in the mouth of a gully in a valley wall.	Likely	Recorded

Site: MH101
Location: Map 7 on edge of Mesa and gully **Type:** 50x50m Relevé
Date: 2016-05-07 **Described by:** KMc
MGA Zone: 50 **Easting:** 417063 **Northing:** 7594625
Habitat: Hillslope
Soil: Brown silty clay loam
Rock type: Ironstone
Vegetation: *Acacia pruinocarpa* tall open shrubland over *Eremophila fraseri* scattered low shrubs over *Triodia wiseana* very open hummock grassland.
Veg Condition: Excellent
Fire Age: No fire evident

Species List

Name	Cover (%)	Height (m)
Acacia bivenosa	0.5	1.5
Acacia inaequilatera	0.5	3.5
Acacia pruinocarpa	7	3.5
Corchorus lasiocarpus subsp. *parvus*	0.5	0.6
Eremophila fraseri subsp. *fraseri*	1	0.8
Eriachne mucronata	0.5	0.2
Lysiana casuarinae	0.5	2.5

Appendix L: Floristic Analysis

This page has been left blank intentionally.

1 Floristic Analysis

1.1 Sampling Effort

Sampling effort was assessed using a species accumulation curve and modelled estimates of the total species pool. Species accumulation curves are created by randomly sampling an incremental number of samples, and plotting the mean number of species sampled at each sample size. Species estimators are particular statistical models of species accumulation which are employed to estimate the total species pool available. Four different species estimators were compared: Chao 2, Jackknife 1, Jacknife 2, and Bootstrap (Colwell and Coddington 1994). All analysis was performed in R 3.2.1 (R Development Core Team 2015) using the package "Vegan".

1.2 Vegetation Classification

Similarity amongst vegetation quadrats was assessed using a dendogram which was based on Sorensen's index of Similarity. The dendogram was constructed using the UPGMA (Unweighted Pair Group Method with Arithmetic Mean) method, within Primer. Significant clusters of samples were identified using the Simprof test (Clarke, Somerfield, and Gorley 2008). In order to understand the regional context of the current survey, a separate analysis was carried out to include the following surveys: Astron Environmental Services (2016a, 2016b) and Biota Environmental Sciences (2006, 2007, 2012). Owing to the size of the larger dendogram illustrating broader context, it is not displayed here.

1.3 Floristic Community Groups

1.3.1 Sampling Effort

A total of 254 species from the current survey were included in the floristic analysis. Only quadrat and relevé data was included (opportunistic records were excluded) and names not confirmed to species level were removed from the analysis. The species accumulation curve indicates that the total number of species has reached an asymptote, and that sampling has been near-exhaustive (Figure L.1). This is highlighted by the fact that the final 10% increase in sampling effort only led to a 2% increase in species sampled.

The species estimators suggest that there were between 276 and 308 species available in the pool at the time of the surveys. This suggests that between 83% and 92% of the total species pool has been sampled from quadrats and relevés (Table L.1). Including opportunistic observations, 310 species were recorded, indicating that 100% of the potential total species pool available at the time of the surveys was observed. Given the dry conditions for some of the surveys it is possible that the entire species pool may be higher in better seasonal conditions.

Table L.1: Total number of taxa sampled in comparison to estimates of the total species pool based on several models.

Observed		Estimated			
		Chao2	Jackknife 1	Jackknife 2	Bootstrap
Species	254	282.7	296.7	307.8	275.6
Est. % sampled		89.8	85.6	82.5	92.2

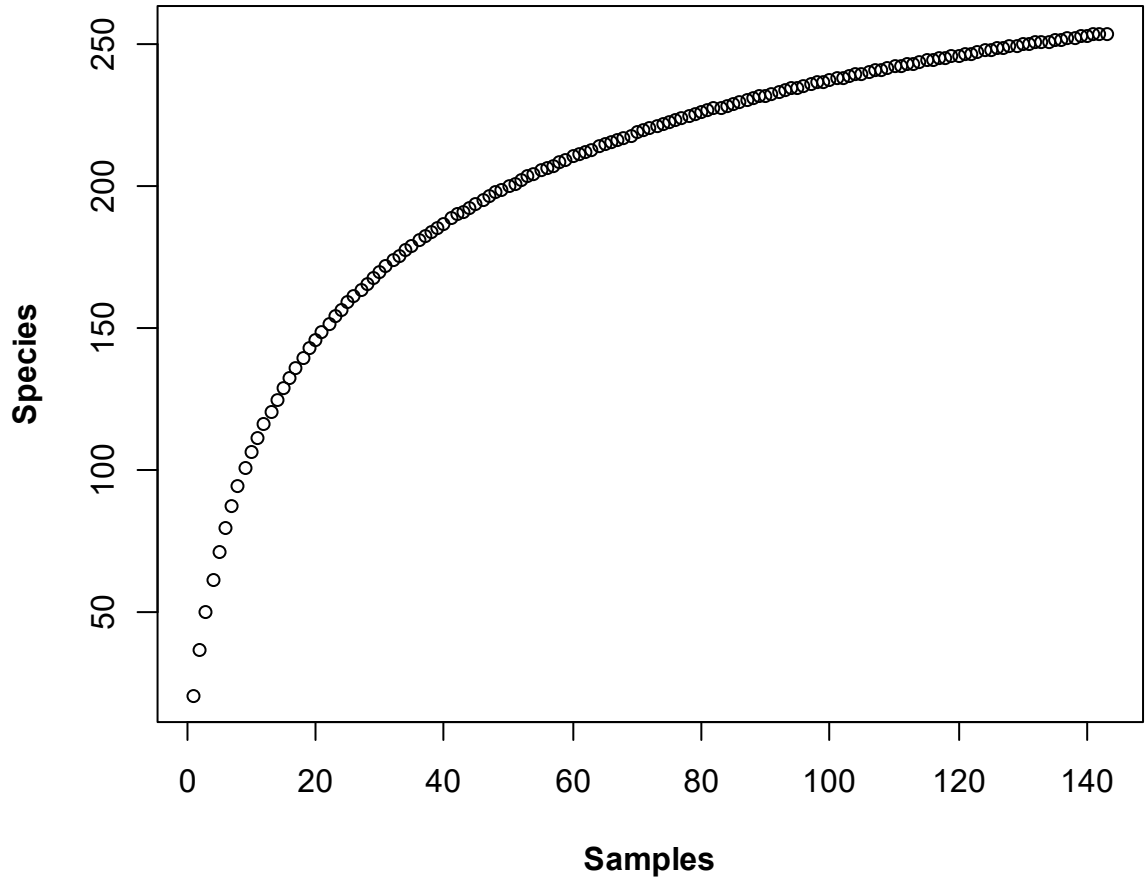

Figure L.1: Species accumulation curve for all Astron quadrats and relevés employed in the 2016 survey.

1.3.2 Vegetation Classification

Dendogram production combined with the Simprof statistical test for the current survey led to the identification of 32 distinct floristic clusters (Figure L2). Of these clusters, six were formed by individual samples from the current survey: MH27, MH302, MH325, MH350, MH357 and MH375r. Clusters showed some pattern of grouping according to the structural vegetation associations, as well as similar landforms.

Analysis of the clusters within a regional context led to identification of 110 significant clusters. Twenty two other significant clusters which were made up only of quadrats/relevés from the current survey were also identified. Of these clusters, four were formed by individual samples from the current survey: MH18, MH203, MH302 and MH315. Most of these clusters aligned with the structural vegetation associations; where they differed it was typically due to structural differences between the survey sites. As nearly half of the significant clusters were from the current survey it indicates that the survey area may be somewhat unique regionally, with vegetation that is floristically different to that in the broader region.

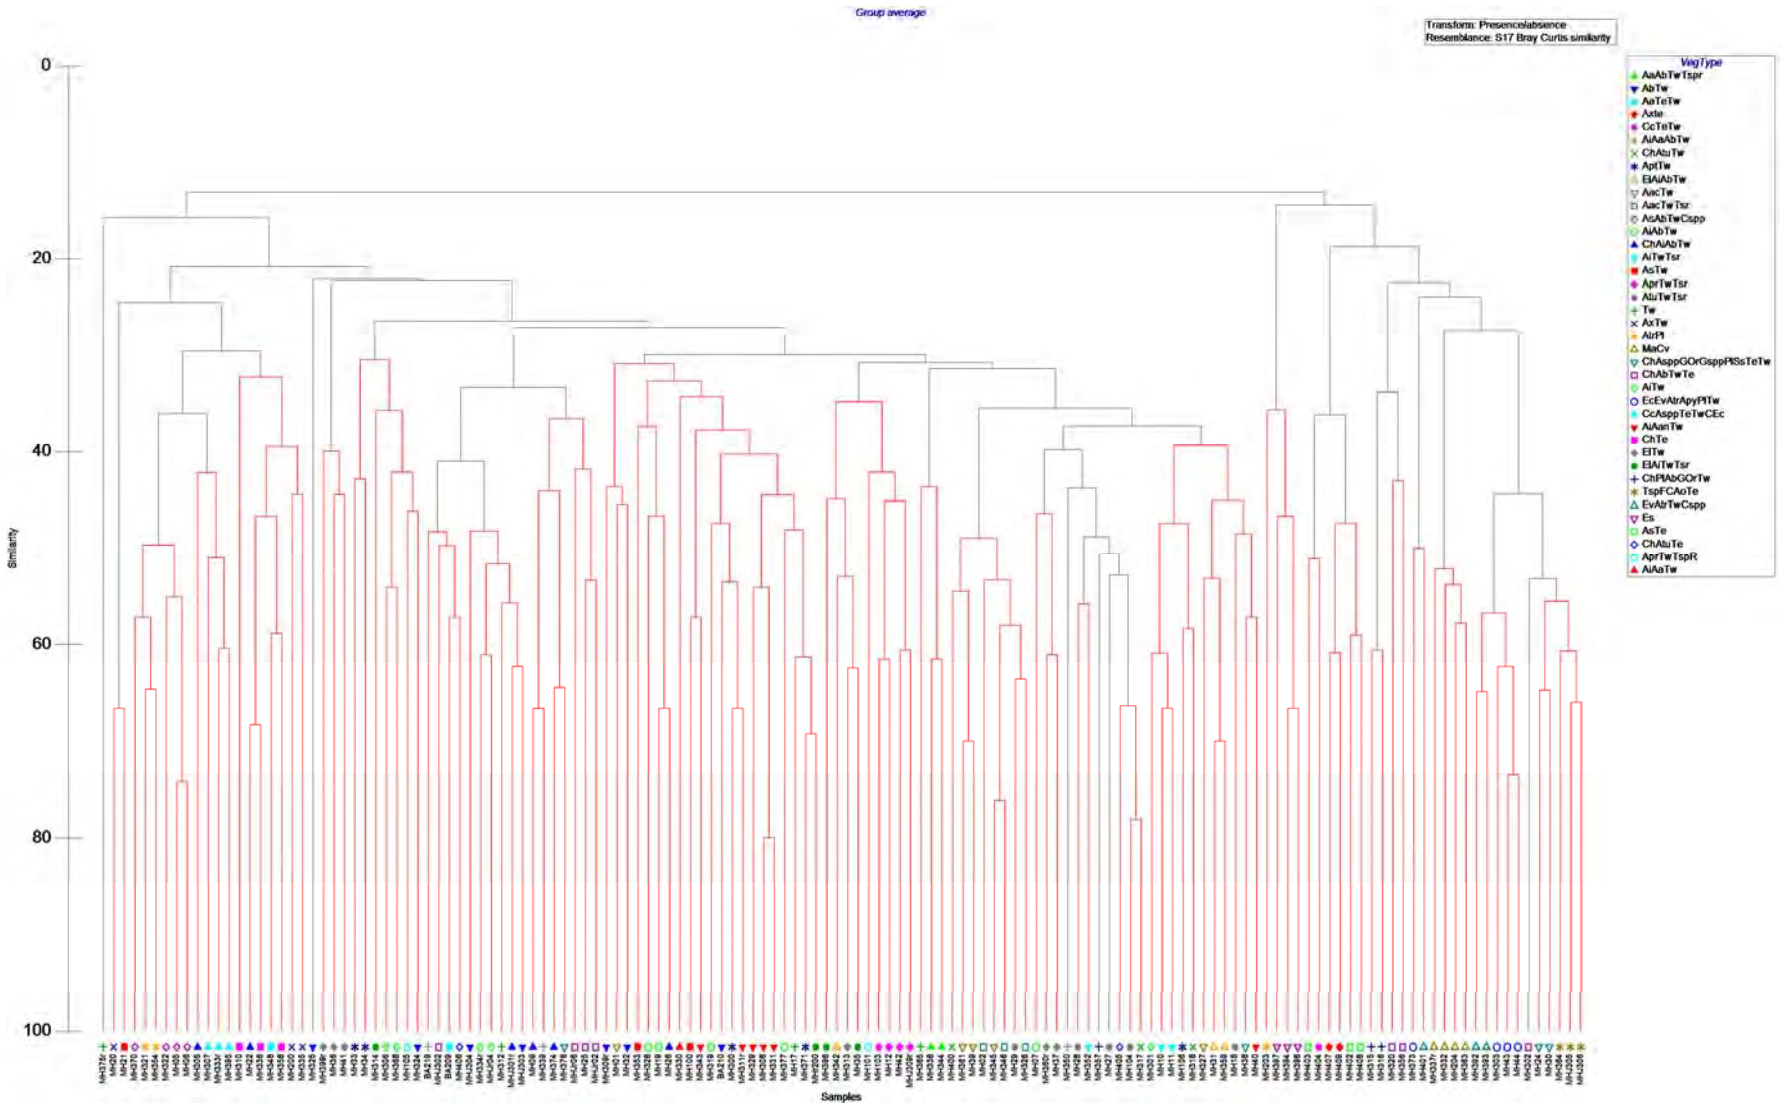

Figure L2: Dendrogram showing relationship between current survey quadrats and relevés according to the degree of shared species (Sorensen's Index). Significant clusters are distinguished by solid black lines.
